3. The AMTO should have a system for monitoring and tracking student progress.

8.5.4.4 **Simulator Devices:** These are devices that replicate real-world situations or scenarios to provide hands-on training to students. For example, a simulator may be used to teach students how to perform a maintenance task on an aircraft. Important points to consider for simulator devices:

1. The simulator should accurately represent the real-world situation or scenario being taught.

2. The simulator should be well-maintained and regularly calibrated.

3. The AMTO should have a system for monitoring and tracking student progress.

8.5.4.5 **Training Videos and Audio Recordings:** These are pre-recorded videos or audio recordings that are used to deliver training material to students. For example, a training video may be used to teach students about safety procedures.

8.5.4.6 Important points to consider for training videos and audio recordings:

1. The video or audio recording should be up-to-date and relevant to the training being provided.

2. The AMTO should have a system for monitoring and tracking student progress.

3. The AMTO should ensure that the video or audio recording is of high quality and easy to understand.

8.5.5 Maintenance Training Material

8.5.5.1 DASR 147.A.120 requires approved maintenance training organisations (AMTOs) to develop and use maintenance training material that is appropriate for the type and level of training being delivered. DASR 66 specifies requirements for both basic and type course training material. Here are some important points to consider for each Basic course training material:

1. The training material used for basic courses must cover a broad range of topics and must be suitable for entry-level students. The following are some important points to consider when developing or using training material for basic courses:

    i. The training material must cover the theoretical and practical aspects of the aircraft, system, or component being taught.

Superseded

ii. The training material must be easy to understand and follow.

iii. The training material must include practical exercises that reinforce theoretical knowledge.

iv. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.

v. The training material must be appropriate for the level of experience and education of the students being trained.

Type Course Training Material

8.5.5.2 The training material used for type courses must cover the specific make and model of the aircraft, system, or component being taught. The following are some important points to consider when developing or using training material for type courses:

1. The training material must cover all relevant aspects of the aircraft, system, or component, including maintenance, inspection, troubleshooting, and repair.
2. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.
3. The training material must be appropriate for the level of experience and education of the students being trained.

8.5.5.3 Some additional important points to consider when developing or using maintenance training material include:

1. The training material must be structured in a logical and organized manner.
2. The training material must be consistent with the relevant regulations and standards.
3. The training material must be presented in a manner that is engaging and interesting for students.
4. The AMTO must have a system for tracking and monitoring the use of training material, including the progress and performance of students.

8.5.5.4 By meeting the requirements of DASR 147.A.120, AMTOs can ensure that they are providing high-quality maintenance training material that is appropriate for the level and type of training being delivered. This can help to ensure that students receive the knowledge and skills they need to perform maintenance tasks safely and effectively.

8.5.6 Examinations

8.5.6.1 DASR 147.A.135 specifies the requirements for conducting examinations for aircraft maintenance training organisations (AMTOs) to ensure that their students have the necessary knowledge and skills to perform their maintenance duties effectively and safely. Here are some key points regarding the examination requirements:

Examination Development

Superseded

8.5.6.2 The AMTO should develop examination questions that are aligned with the training objectives and outcomes. The questions should be designed to test the knowledge and skills that the student has acquired during the training program. The AMTO should also ensure that the examination questions are reviewed and approved by qualified personnel.

Examination Administration

8.5.6.3 The AMTO should have procedures in place for administering examinations. This includes ensuring that students are aware of the examination format, rules and regulations, and any special instructions that apply. The AMTO should also ensure that the examination environment is conducive to learning and that the examination is conducted in a fair and unbiased manner.

Examination Security

8.5.6.4 The AMTO should have procedures in place for ensuring the security of all the question, examinations and databanks. Particular attention should be made to the storage and transportation of the examination between venues and whilst onsite. Care must be taken to ensure the examination questions are secure at all times. Electronic means of storage may be utilised where available, providing that suitable security arrangements are in place.

Examination Grading

8.5.6.5 The AMTO should have procedures in place for grading and evaluating examination results. The grading procedures should be fair, consistent, and transparent, and should be based on established criteria. The AMTO should also ensure that examination results are communicated to students in a timely manner and that students have access to feedback on their performance.

Examination Records

8.5.6.6 The AMTO should maintain records of examination results, including the student's performance and any relevant feedback. These records should be kept in a secure location and retained for a specified period of time in accordance with regulatory requirements (e.g. Annex A to AMC 147.A.125)

Examination Review

8.5.6.7 The AMTO should have procedures in place for reviewing and evaluating examination results to identify any areas where improvements can be made. This includes analysing trends in examination results, identifying areas where students are struggling, and taking corrective actions to improve the effectiveness of the training program.

8.5.6.8 In summary, the examination requirements outlined in DASR 147.A.135 are designed to ensure that the AMTO's training program is effective and that students have the necessary knowledge and skills to perform their maintenance duties safely and effectively. By following these requirements, the AMTO can maintain a high standard of training and contribute to the overall safety of the aviation industry.

8.5.7 Training Procedures and Quality System

8.5.7.1 DASR 147.A.130 requires Aircraft Maintenance Training Organizations (AMTOs) to establish and maintain effective training procedures and a quality system to ensure that their training programs are of a high standard and meet the requirements of all applicable regulations and standards

Superseded

including DASRs. Some important points to be considered when developing or maintaining training procedures and a quality system are:

Training Procedures

8.5.7.2 The training procedures must include a description of the training program, including the objectives, scope, and content of the training. This should include the methods and materials used for training, the sequencing of the training, and the assessments used to measure the effectiveness of the training.

Courseware

8.5.7.3 The AMTO should have a system in place to develop, review, and update courseware, including lesson plans, training manuals, visual aids, and other materials used for training. The courseware should be reviewed and updated regularly to ensure that it remains relevant and effective.

Instructor Qualifications and Training

8.5.7.4 The AMTO should have procedures in place to ensure that their instructors are qualified and competent to deliver the training. This includes requirements for instructor qualifications and training, such as experience in the industry, knowledge of the subject matter, and teaching skills. The AMTO should also have a system in place to regularly assess the performance of their instructors and provide them with feedback / training as necessary.

Assessment Procedures

8.5.7.5 The AMTO should have a system in place to assess the effectiveness of their training, including the use of assessments and evaluations to measure the knowledge and skills of the students. The assessments should be designed to provide a fair and accurate measure of the student's performance, and be reviewed and updated regularly to ensure that they remain valid and reliable.

Quality System

8.5.7.6 The AMTO should have a quality system in place to ensure that their training program meets the requirements of DASRs and any other applicable regulations and standards. This includes procedures for monitoring and evaluating the effectiveness of the training by identifying, correcting and preventing recurrence of any deficiencies and continuously improving the training program.

8.5.7.7 Some additional important points to consider when developing or maintaining training procedures and a quality system include:

1. The AMTO should ensure that all training is conducted in a safe and secure environment, and that appropriate safety procedures are followed at all times.
2. The AMTO should ensure that their training programs are accessible to all students and meet their needs.
3. The AMTO should ensure that all training is conducted in accordance with relevant laws and regulations including those related to privacy and data protection.
4. The AMTO should ensure that all training is conducted in a professional and ethical manner, and that all students are treated fairly and with respect.

Superseded

Quality Policy

8.5.7.8 The AMTO should have a quality policy that outlines the organisation's commitment to quality and its goals for maintaining a high standard of training. The policy should be communicated to all staff and stakeholders, and reviewed and updated regularly.

Quality Objectives

8.5.7.9 The AMTO should establish quality objectives that are measurable and aligned with the goals of the organisation. The objectives should be reviewed and updated regularly, and progress towards meeting the objectives should be monitored.

Document Control

8.5.7.10 The AMTO should have a system in place to manage and control documents related to training procedures and the quality system. This includes procedures for document creation, control, review, approval, distribution and revision.

Record Keeping

8.5.7.11 The AMTO should maintain records related to the training programs and the quality system, including records of student performance, instructor qualifications, audit results, corrective actions taken, and other relevant information.

Records of Students

8.5.7.12 DASR 147.A.125 requires approved maintenance training organisations (AMTOs) to maintain accurate and complete records of their students. These records must include a variety of information to demonstrate that the student has successfully completed the required training and has the necessary knowledge and skills to perform maintenance tasks safely and effectively. Here are some important points to consider when developing or maintaining student records:

1. Student Identification: The record must include the student's full name, date of birth, contact information, and any relevant identification numbers or codes.
2. Training History: The record must include a detailed history of the student's training, including the courses they have completed, the date of completion, and the grade they received. This information should also include any remedial training or retesting that was required.
3. Assessment Records: The record must include documentation of any assessments or examinations the student has completed, including the results and any feedback or comments provided by the examiner.
4. Attendance and Absences: The record must include information on the student's attendance and any absences from training, including the reason for the absence and any make-up training that was required.
5. Certification: The record must include information on any certifications the student has received as a result of their training, including the type of certification, the date it was issued, and any restrictions or limitations.
6. Other Relevant Information: The record should also include any other relevant information about the student, such as their prior education or experience in the field

Superseded

of maintenance, any disciplinary actions taken, or any other notable achievements or accomplishments.

7. Some additional important points to consider when developing or maintaining student records include:

   i. The record must be maintained in a secure and confidential manner to protect the privacy of the student.

   ii. The record must be accurate, complete, and up-to-date at all times.

   iii. The record must be available for review by relevant authorities, such as regulatory agencies or potential employers.

   iv. The AMTO must have a system in place to ensure that student records are regularly reviewed and updated as necessary.

8.5.7.13 By meeting the requirements of DASR 147.A.125, AMTOs can ensure that they are maintaining accurate and complete records of their students, which can help to demonstrate that the students have received the necessary training and are qualified to perform maintenance tasks safely and effectively.

Corrective and Preventive Actions

8.5.7.14 The AMTO should have a system in place to identify and address non-conformities or areas where the procedures and system can be improved. This includes procedures for taking corrective and preventive actions to avoid recurrence including causal or root cause analysis, tracking and monitoring the effectiveness of the actions taken, and documenting the results.

Management Review

8.5.7.15 The AMTO should conduct regular management reviews of the training procedures and quality system to ensure that they are effective and meeting the goals of the organisation. The management review should include a review of audit results, quality objectives, corrective and preventive actions, and other relevant information.

Audit Procedures

8.5.7.16 Auditing is an important part of ensuring that the training procedures and quality system of the AMTO are effective and meeting the requirements of the applicable regulations. Audits should be conducted by an independent auditor, who can be an internal auditor or an external auditor.

Internal Auditing

8.5.7.17 The AMTO should conduct internal audits of their training procedures and quality system on a regular basis to ensure that all aspects of DASR 147 compliance are checked at least once in every 12 months and may be carried out as one complete single exercise or subdivided over a 12-month period in accordance with a scheduled plan. The purpose of internal audits is to identify any non-conformities or areas where the procedures and system can be improved. The results of the internal audits should be documented and corrective actions should be taken to address any non-conformities.

External Auditing

Superseded

8.5.7.19 The AMTO should also undergo external audits by an independent auditor, who is not part of the AMTO organisation. The purpose of external audits is to ensure that the training procedures and quality system of the AMTO are in compliance with the requirements of the regulation. The results of the external audits should be documented, and any corrective and preventive actions that need to be taken should be identified and addressed.

8.5.7.20 By meeting the requirements of DASR 147.A.130, AMTOs can ensure that their training programs are of a high standard and meet the requirements of the regulation, which can help to ensure the safety and effectiveness of maintenance operations in the aviation industry.

8.5.8 Military Aircraft Type Ratings

Introduction

8.5.8.1 Military Aircraft Type Rating Training consists of theory and examination, practical and assessment, plus On-the-Job Training (OJT) – see DASR 66.A.45(c) – for first aircraft in licence category/subcategory. Any subsequent Military Aircraft Type Rating (MATR) within the same category/sub-category require both theory and practical elements but will only require further OJT if stipulated by DASA during the approval of the course.

Note: A minimum of only theory and examination is required for the Category C Military Aircraft Maintenance Licence (MAML) rating (AMC 66.A.45).

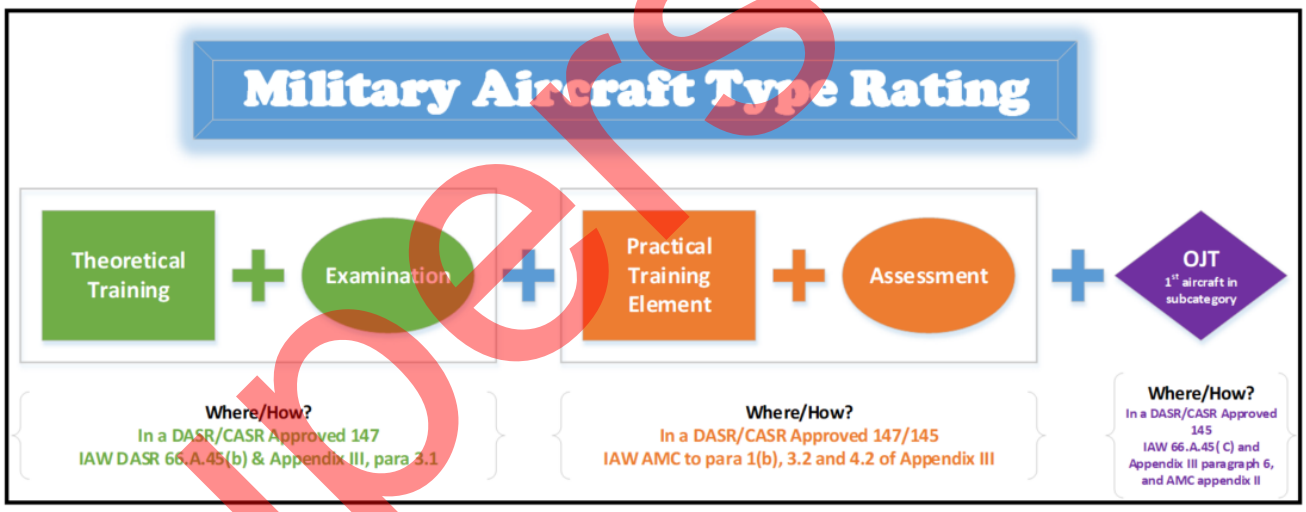

Figure 1: Military Aircraft Type Rating (MATR) - Required Elements

Privileges

8.5.8.2 In order to be entitled to exercise certification privileges for B and C categories on a specific aircraft type, the holder of a MAML shall have their MAML endorsed with the relevant Military Aircraft Type Ratings.

ADF Course Design and Development

Superseded

8.5.8.3 To ensure consistency across all ADF courses, the design and development of courses, including the course curriculum, should follow the System Approach to Defence Learning (SADL) – see SADL Website.

MATR Course – Initial Approval / Change Management

8.5.8.4 In order to facilitate approval by the authority, the following relevant DASR Forms are to be completed and submitted as appropriate:

1. DASR Form 12 - Application for DASR 147 Initial-Changes of Approval. The DASR Form 12 is the official DASA form to apply for a DASR 147 Maintenance Training Organisation approval. This form is considered part of an application pack and should be submitted with the appropriate evidence as detailed within the form to support the application.

2. DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval. The DASR Form 12A is to accompany the DASR Form 12 when the application is for an initial course approval. For an update to an existing approved course, only the completed Form 12A and associated evidence documents are required for submission.

8.5.8.5 As a minimum standard, the following documents must be submitted as evidence for MATR courseware approval:

1. Training Needs Analysis (TNA) or equivalent as accepted by DASA
2. Completed DASR 66 Appendix III MATR Courseware Assessment Matrix
3. MATR Theory Element (Learning Management Plan)
4. MATR Practical Element (Practical Training Logbooks)
5. On-The-Job-Training (OJT) logbook.

DASA Notification Requirements

8.5.8.6 Changes to MATR Courses shall be defined as either a Major or Minor Change.

8.5.8.7 A Major Change is any amendment, alteration or change to a MATR Course that is not accurately categorised as a Minor Change within the relevant Maintenance Training Organisation (MTO) Exposition procedure. A DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval must be submitted and approved prior to any Major Change to a MATR Course.

8.5.8.8 A Minor Change is any amendment, alteration or change to a MATR Course that does not affect the DASR related approval. Minor Changes may be acceptable to DASA without prior approval by the Authority; contingent to endorsement by the relevant MTO QMS that no adverse material effect is posed to safety, quality of training or the knowledge, skills and attitudes of course graduates, course learning outcomes or location.

8.5.8.9 An internally reportable process for approval of Minor Changes to MATR Courseware must be included within the relevant MTO Exposition/Annex; containing either a specific predefined listing of all actions, or defining statement considered by the MTO to fall within the scope of a 'Minor Change'.

8.5.8.10 Subject to the endorsement of the MTO QMS, listed actions could include (but are not limited to):

Superseded

1. Grammatical and typographic changes

2. Changes that incorporate updates from the relevant platform specific technical publications (e.g. updated maintenance procedures, configuration changes etc.)

3. Changes of content (provided the learning outcomes are not affected).

Theoretical Element of the Military Aircraft Type Rating Training

8.5.8.11 The theoretical element of the Type Course shall provide the person with detailed theoretical knowledge of the applicable systems, structure, operations, maintenance, repair, and troubleshooting of the aircraft type according to the approved maintenance data, including:

1. The appropriate use of manuals and approved procedures, including any relevant inspections and limitations;

2. How to perform system, power-plant and component functional checks as specified in the maintenance manual;

3. Related information for the purpose of making decisions in respect of fault diagnosis and rectification within the scope of the maintenance manual;

4. Describing procedures for replacement of components unique to the aircraft.

8.5.8.12 Theory training shall be conducted by an appropriately approved DASA 147 MTO or an organisation recognised by DASA.

8.5.8.13 In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA.

8.5.8.14 Theory training shall have been started and completed within the 3 years preceding the application for a MATR endorsement.

8.5.8.15 The minimum pass mark for the theoretical exam is 75%.

8.5.8.16 The theoretical type training shall describe how the type training is delivered (i.e. classrooms, training equipment, instructors qualifications, TNA etc.) meeting the requirements of DASR 66 and 147, as appropriate.

8.5.8.17 The course content and duration shall be demonstrated by:

1. a detailed curriculum showing the levels for each chapter of the type training, which should be assessed for equivalence to Appendix III to DASR 66 for the relevant certifying staff category; and

2. verifying that both content and duration are justified through a comprehensive TNA (or equivalent as accepted by DASA).

8.5.8.18 Evidence is required for the following elements:

1. the teaching methods and instructional equipment;

2. the material and documentation provided to the student;

3. the qualification of instructors, examiners;

Superseded

4. the documentation and records provided to the student to justify the satisfactory completion of the training course and related assessment.

Note: For further information about these elements, refer to the MTO exposition.

Practical Element of the Military Aircraft Type Rating Training

8.5.8.19 Practical training is a structured training activity that consolidates the knowledge gained during the theoretical phase of type training and as such, may be performed after or integrated within the theory training. Practical training should:

1. Address the different parts of the aircraft and its associated engines, which are representative of the structure, the systems/components installed and the cabin.
2. Include the use of technical manuals, maintenance procedures and the operational interfaces with the aircraft (e.g. FMC, electronic flight bag, etc.)
3. Include common maintenance and ground handling activities.
4. Cover both type specific and generic safety elements of the aircraft's maintenance.
5. Develop the student's competence in performing safe maintenance, prior to the practical assessment.

8.5.8.20 The purpose of practical training is not to include all the maintenance tasks associated with a particular type, but a representative sample of them that will allow the student to acquire the required knowledge, attitude and skills to safely carry out maintenance on that type.

8.5.8.21 The practical element of the MATR Training can be performed concurrently with the OJT element if both are performed on the same military aircraft type and in a real maintenance environment.

8.5.8.22 Practical training may be performed either following or integrated with the theoretical elements however, it should not be performed before theoretical training.

8.5.8.23 Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.24 Table 1 summarises the MATR Training requirements contained in DASR 66.A.45, and Appendix III to DASR 66.

Military Aircraft Type Rating Training requirements		
Aircraft Group	**B1/B2 MAML**	**C MAML**
All military aircraft are considered to be complex motor-powered aircraft	**Military Aircraft Type Rating Training:** Theory + examination Practical + assessment PLUS OJT (for first aircraft in licence category/subcategory. For subsequent Military Aircraft Type Rating within the same category/sub-category, further OJT only if required by DASA)	**Military Aircraft Type Rating Training:** Theory + examination Note: In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA

Table 1: Military Aircraft Type Rating Training requirements

Superseded

8.5.8.25 IAW AMC to Para 3.2 of Appendix III to DASR 66 - "The practical training may include instruction in a classroom or in simulators, but part of the practical training should be conducted in a real maintenance, or manufacturer, environment." It would be acceptable to complete practical training in a classroom or in simulators, if the practical training could be effectively delivered in this environment.

1. Practical training conducted in a real maintenance environment implies practical training on live aircraft or high fidelity maintenance training aids that are representative of the live aircraft. Practical training in a real maintenance environment should always be conducted on the highest fidelity training device reasonably available and include the use of maintenance data and specialist tooling.

2. Practical training should always be conducted in a real maintenance environment, where it is:

    i. the only reasonable method due to the complexity of the task, or

    ii. the only method available to enable familiarity with component location/ identification, or

    iii. the only method available to demonstrate the use of special equipment / tools.

8.5.8.26 Para 3.2 g. of Appendix III to DASR 66 states “The objective of practical training is to gain the required competence in performing safe maintenance, inspections and routine work…”. In the context of practical elements of the military aircraft type training, competence to perform safe maintenance, inspections and routine work does not require the actual performance of the maintenance (e.g. it is acceptable to use a live aircraft as a training aid without physical removal / installation of components). Practical training could be a visit to / walk around of an aircraft in the maintenance environment, identifying specialised tooling / equipment used on the aircraft, process walkthroughs for removal / installations tasks, and scenario based activities for troubleshooting. Practical training should also ensure students are knowledgeable in the use of technical literature, documentation, specialised tooling and test equipment.

8.5.8.27 Selected tasks should consist of a group of representative maintenance tasks drawn from the type training and examination curriculum, at the indicated level and shall cover all the relevant chapters described in the table contained in paragraph 3.2 of Appendix III to DASR 66.

8.5.8.28 The task curriculum must:

1. Be distributed in order to cover all applicable S1000D chapters.

2. Include all of the task categories (LOC, FOT, SGH, R/I, MEL, TS - Refer table 2 below) and may include others deemed appropriate to the type (e.g. ‘INS’pection, ‘ADJ’ustment).

3. Include an appropriate number of tasks in each task category for the aircraft type’s training requirements to be met.

4. Be sufficient to cover at least 50% of the crossed tasks in Appendix III to DASR 66 para 3.2. (Refer to “How should the 50% of tasks required for practical training be selected?” below).

Note: for further information on the S100D Specification refer to the following links on the DASA website. S1000D - International specification for technical publications.

Superseded

8.5.8.29 The duration of the practical training should ensure that the content of training required by paragraph 3.2 of Appendix III to DASR 66 is completed.

8.5.8.30 A record of the tasks completed should be entered into a logbook which should be designed such that each task or group of tasks may be countersigned by the designated assessor. The logbook format and its use should be clearly defined.

8.5.8.31 The practical element (for power-plant and avionics systems, armaments, escape systems and other relevant military-specific systems) of the MATR Training may be subcontracted by the approved DASA 147 organisation under its quality system according to the provisions of DASR 147.A.145(d)3 and the corresponding Guidance Material.

How should the 50% of tasks required for practical training be selected?

8.5.8.32 When selecting the tasks, the usage of a filtering method based on the criteria similar to that described in AMC to paragraph 3.1(d) of Appendix III to DASR 66, point 5f) is recommended.

8.5.8.33 The selection of 50% of tasks cannot be selected according to the glossary only (e.g. LOC, FOT, SGH, R/I, etc.):

1. Paragraph 3.2 of Appendix III to DASR 666 states that 'the tasks selected shall be representative of the aircraft and systems both in complexity and diversity'. In addition, the practical training should particularly address the tasks which cannot be explained by theoretical training only. While relatively simple tasks may be included, other more complex tasks shall also be incorporated and completed as appropriate to the aircraft type.

2. Guidelines on complex / simple tasks (taken from CASA AMC/GM Part 66, V7.4 of December 2024) are as follows:

   i. Complex tasks may have the following attributes:
   - involve several comprehensive steps to perform
   - have multiple decision points in order to complete
   - may use specialised test equipment
   - often requires more than one person to perform
   - have direct impact on flight safety

   ii. Simple tasks may have the following attributes:
   - does not use specialised test equipment
   - can be completed by a single person
   - does not require any in-depth skill/knowledge
   - does not involve decision steps (no troubleshooting)
   - may involve an on-board maintenance system BITE check to determine serviceability

3. How each task is selected (LOC, SGH, etc.), should be based upon the potential gains for the students' competency or its impact on safety. Availability should not be a

Superseded

reason to omit a pertinent task and consideration should be made to include a 'real maintenance environment' to complete an important or critical learning objective.

4. All pertinent sub-tasks, associated with the safe completion of each main task, such as Isolating mechanical/electrical systems, opening/closing CBs, locking flight controls, etc., should be included and the applicable aircraft maintenance manuals used.

5. Regarding the way to read the table in paragraph 3.2, each line aims to cover each of the main systems so that no line relevant to the particular aircraft type should be omitted in the selection. Inside each line applicable to the aircraft type, half or more of the crosses can be selected. From a learning point of view, selecting 2 simple tasks as LOC and SGH would not be "representative", while selecting LOC and TS, for example, would be much more appropriate of the aircraft and systems both in complexity and diversity.

6. The intent of the following tables are to provide a compliance report demonstrating that the practical type training meets the standard required by Appendix III to DASR 666. In particular, the tables shall indicate the percentage of tasks effectively performed against the tasks contained in the Appendix III to DASR 66 which are applicable to the aircraft type.

8.5.8.34 The following tables have been developed as a guide for assessment of MATR practical courseware elements. These tables are included in the MATR courseware assessment which can be found at the following link - DASR 66 Appendix III MATR Courseware Assessment Matrix. This assessment matrix should be completed by the MTO delivering the MATR practical type training in order to enable approval of courseware by the authority.

Percentage by Task Type

Type of task	Number of tasks applicable to the A/C type	Total number of tasks selected	Percentage (%) effectively performed against applicable tasks (should be at least 50% of the applicable tasks)
LOC			
FOT			
SGH			
R/I			
MEL			
TS			

Table 2 – Practical Task Training Requirements (By Task Type)

Superseded

Glossary of the table: LOC: Location; FOT: Functional/Operational Test; SGH: Service and Ground Handling; R/I: Removal/Installation; MEL: Minimum Equipment List; TS: Trouble-Shooting.

Percentage by Chapter

Chapter	Number of Practical Requirements for Each Chapter	Total number of Practical Elements Included Within Courseware	Percentage (%) included against applicable Chapter (should be at least 50% of the applicable practical requiorements within each Chapter)
05 Time limits / maintenance checks			
06 Dimensions/Areas (MTOM, etc.)			
.....			
99 Electronic Warfare			

Table 3 - Practical Task Training Requirements (By Chapter)

Practical Training Logbook

8.5.8.35 A Military Aircraft Type specific Practical Training Logbook (PTL) must be developed by a DASA 147 MTO, completed by the student and a certified true copy retained by the MTO delivering the training. It will record the training activities carried out during the practical training course and the subsequent assessment of trainee competence.

8.5.8.36 The PTL shall list all of the applicable S1000D systems, as specified within Appendix III to DASR 66, Section 3.2.

8.5.8.37 After the practical element of the MATR Training has been completed, an assessment must be performed, which must comply with the following:

1. The assessment shall be performed by designated assessors appropriately qualified (AMC to Appendix III).
2. The assessment shall evaluate the knowledge and demonstrated understanding of the trainee.

8.5.8.38 The PTL should include:

1. Trainee attendance sheet.
2. Course and Instructor’s details.
3. S1000D system number and title.
4. Aircraft Maintenance Manual or work-pack reference for each training task.
5. A list and detailed description of the training tasks.

Superseded

6. Each task must have a method of denoting the training technique (Synthetic, Aircraft registration, Classroom, etc.).

7. Task type (R/I, LOC, SGH etc.).

8. Date of each individual task completion.

9. Instructor signatures or stamps.

10. Spare entries for documenting additional/replacement “ad hoc” training tasks.

Note: Additional/replacement tasks must be of relevance to those they replace, be of benefit to the training objective and only replace planned tasks in exceptional circumstances.

8.5.8.39 EASA provide Practical type training logbook examples for both B1 and B2 PTL that can be used for guidance.

Practical Instructors and Assessors

8.5.8.40 In the majority of cases, the Practical instructor will be the same as that used for the Theory phase of the type training. They are a logical choice, as they possess an in-depth knowledge of the aircraft’s systems and will have developed an understanding of each student’s specific academic requirements.

8.5.8.41 Using the same instructor for both the Theory and Practical phases will often suit the business model of many organisations. In some cases, however, especially where a DASA 147 / DASA 145 affiliation exists, the organisation may choose to utilise experienced MAML holders / technicians, as appropirate, from their own maintenance workforce to deliver the Practical training.

8.5.8.42 These individuals must be given suitable training on the organisational processes involved, particularly the use of the Practical training record. It is recommended that they attended a train the trainer course, whether delivered by an external or internal source, which should specifically target the training techniques required for Practical training and set the organisation’s bench mark for the conduct of this training. They should be familiar with the tools or the techniques used by the training organisation to assess the competence of the practical abilities of trainees (maintenance simulators, mock up and etc.).

8.5.8.43 They should be experienced and show solid judgement regarding the abilities of the assessed trainees, they must have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks IAW current regulation, utilising approved procedures, maintenance practices etc. They should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated to maintain the system.

8.5.8.44 Workforce sourced Instructors will be qualified and managed by the DASA 147 organisation. Refer to DASR 147.A.105 for details.

8.5.8.45 They must be included in the list Instructional staff (point 1.5 of the MTOE) and be subject to the same Instructor records and update training requirements as the directly employed Instructors.

8.5.8.46 Practical assessments may be conducted by either the Practical Instructor or a dedicated assessor, who has undergone a similar training and qualification process to that detailed above.

8.5.8.47 Upon completion of the PTL, it must be reviewed, assessed and approved by the relevant DASA 147 in its entirety.

Superseded

OJT Element of the Military Aircraft Type Rating

8.5.8.48 OJT is required for the initial type rating being sought in each licence category or sub-category:

8.5.8.49 For example; If a B1.1/B2 MAML is endorsed with the P-8A type in the B1.1 category and the MAML holder wishes to add the P-8A in the B2 category, he/she will have to complete B2 related OJT representative of that aircraft and its systems.

8.5.8.50 If the same B1.1 MAML holder adds the B1.3 category to their MAML, and wishes to add their first helicopter type, he/she must complete OJT representative of that first helicopter type. Any subsequent MATR within the same category/sub-category will only require further OJT if stipulated by DASA during the approval of the course.

8.5.8.51 A DASA 145 maintenance organisation appropriately approved for the maintenance of the particular aircraft type can conduct OJT for that type rating:

1. The OJT content shall be approved by DASA (Appendix III to DASR 66, sec. 6) and supported by a detailed curriculum showing its content and recorded within detailed worksheets/logbook;
2. OJT tasks shall be signed off by the student and countersigned by a 'designated supervisor';
3. Final assessment of OJT is mandatory and shall be performed by a 'designated assessor';
4. It can be carried out in an approved DASA 145 maintenance organisation with a Category A rating (maintenance on aircraft) and the procedures for OJT should be included in the exposition (MOE chapter 3.15 "OJT procedure") approved by DASA.
5. Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.52 The OJT should include a sufficient number of tasks that are carried out under 'one to one' supervision (i.e. one supervisor dedicated to one trainee) and should involve actual work task performance on aircraft/components, covering line and/or base maintenance tasks.

8.5.8.53 AMC to Appendix II to DASR 66 contains a list of tasks, from which a representative sample appropriate to the type and licence (sub-) category applied for, should be extracted and approved by the MAA. The OJT should cover at least 50% of this approved extracted list.

8.5.8.54 Up to 50% of the required OJT may be undertaken before the aircraft theoretical MATR Training starts, noting that:

1. the ADF Initial Employment Training (IET) workplace journals are the primary means of meeting the practical requirements for the Defence Registered Training Organisation issuance of selected MEA Unit of Competency;
2. portions of these workplace journals may also be utilised as a means of meeting the requirements of OJT, as long as they are completed in a DASA 145, and on the

Superseded

platform/components which the individual is completing their Type Rating training (Appendix III to DASR 66, para 6).

8.5.8.55 If these journal tasks are not carried out on the aircraft type (or its components) required for their subcategory, then these tasks cannot be constituted as OJT.

8.5.8.56 As a minimum, the OJT procedure should describe the following elements:

1. Content of the OJT: the list of tasks that should be performed during the OJT or a list of generic tasks and the process how to develop a list of particular tasks out of this list of generic tasks,
2. Qualifications of the assessor and supervisors performing the OJT,
3. OJT logbook/worksheets format and content,
4. OJT compliance report format and content,
5. Production planning for the implementation of OJT (how to plan the tasks),
6. Supervision process and the assessment process, what to do if the assessment is not positive,
7. Safe release to service of the aircraft after OJT,
8. OJT Log Book final assessment process and associated forms:
    i. An OJT Logbook assessment is carried out on an OJT Logbook to ensure that all required tasks have been carried out and certified for in accordance with the OJT Logbook assessment procedure.
    ii. MTOE procedure and associated documents should contain a procedure for the final assessment of an OJT Logbook and who it is completed as well as any associated forms needed and who is qualified to carry out such assessment.

Note: AMC to Section 6. of Appendix III to DASR-66 should be used when defining the content of the procedure.

Practical Assessment Vs On the Job Training (OJT) for Military Aircraft Type Ratings

8.5.8.57 The objective of OJT is to gain the required competence and experience in performing safe, effective and efficient maintenance. The practical assessment addresses the practical portion of any type training, whereas the OJT assessment addresses the additional hands-on experience necessary in a true maintenance environment as part of the first type rating in a (sub)category, as illustrated by the table below:

Superseded

Practical Assessment Vs On the Job Training		
	Practical Assessment	**OJT Assessment** ***For the purpose of DASR 66.A.45(c)***
What/Who is assessed	Candidates following practical element of Military Aircraft Type Ratings training.	Completeness of OJT
	Reference: 66.A.45 (a)(b); Appendix III, 4.2.; AMC Appendix III	Reference: 66.A.45 (c); Appendix III, section 6; AMC to Section 6 of Appendix III
Function of assessor:	To perform the final evaluation of the knowledge, skills and attitude of the trainee following the practical element of the type training	To conduct the final assessment of the completed OJT, whereas the candidate's competence is indirectly justified.
	Reference: Appendix III 4.2.; AMC Appendix III	Reference: Appendix III, 6.; AMC to Section 6 of Appendix III 8.
Organisation :	• DASA-147 • Approved maintenance environment (DASR-145, M.A. Subpart F with A rating, manufacturer) under the DASA-147 approval • Defined maintenance environment as described in the direct approved procedure by the competent authority	Always in a maintenance organisation approved under DASA-145 with an aircraft rating.
	Reference: Appendix III 1(b)	Reference: Appendix III 6.; AMC to Section 6 of Appendix III 1.
Objectives:	To evaluate if the candidate has gained the required competence in performing safe maintenance, inspections and routine work according to the aircraft documentation and other relevant instructions and tasks as appropriate for the type of aircraft.	To confirm the completion of the required diversity and quantity of OJT, based on the supervisor(s) reports and feedback. It is sufficient that the completion of individual OJT tasks is confirmed by the direct supervisor(s), without necessary being the direct evaluation of the assessor.
	Reference: Appendix III, 3.2.	Reference: AMC to Section 6 of Appendix III 7. & 8.
Type of assessment:	The assessment may be: • diagnostic (prior to a course), • formative • summative (partial or final evaluation) • performed task-by-task • performed as a group of tasks • partly executed on simulation devices • performed as a final assessment	• Continuous during OJT (confirmed by the direct supervisor) • Summative, as a final evaluation by a designated assessor of the completeness of the OJT (based on the supervisor(s) reports and feedback)
	Reference: AMC to DASR-66 Appendix III 2)	Reference: AMC to Section 6 of Appendix III to DASR-66
Qualification of the assessor:	The assessment shall be performed by designated assessors appropriately qualified. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Guidance about the qualification is given in AMC to DASR-66 Appendix III 3.)	The OJT shall be assessed by appropriately qualified and designated assessors. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Practical DASR 147 MILITARY AIRCRAFT TYPE TRAINING LEVELS VS SERVICE LEARNING LEVELS

Superseded

The following table provides guidance on the correlation between the DASR Military Aircraft Type Training levels (TL), Air Force (MAFET) Learning Levels (LL), Army (ATI 1-3/20), SADL TLs and Navy LLs;

DASR		RAAF			ARA			SADL		RAN
TL	Description	LL	Definition	Description of graduate	LL	Definition	Assessment	TL	Description	
1	Graduate is: • Able to define descriptions and maintenance practices • Identify appropriate manuals and maintenance practices • Define layout of major systems • Define layout and characteristics of power plant • Identify special tooling and testing equipment	1	Training provides background knowledge only. It is familiarising in nature or is an introduction to further training.	The graduate has completed learning that either has no clear links to identified workplace requirements or supports underpinning knowledge, skills or range of variables.	1	**Low** - Unable to perform, little to no experience.	Skill and Knowledge are not assessed, but confirmation of learning may occur during training	1	Trained, but not against a prescribed standard.	Navy do not use Training Levels.
N/A		2	Trained to a level below that required for successful assessment against identified workplace requirements, without further training and/or practice.	The graduate has limited knowledge and has performed components of, but not the complete task, during training.	2	**Basic** - Limited in ability or knowledge, needs significant help from others.	Skill and Knowledge are assessed against a restricted set of performance criteria	2	Partially trained against a prescribed standard.	
2	Graduate is able to: • Understand theoretical fundamentals • Apply knowledge in a practical manner • Recall safety precautions • Describe systems and aircraft handling • Identify locations of principal components • Explain normal functioning of major systems • Perform procedures for servicing • Demonstrate proficiency in interpreting crew reports and reporting systems and determine airworthiness • Demonstrate the use, interpretation and application of appropriate documentation	3	Trained to the level to achieve the identified workplace requirement, but unable to be assessed in the context of the training environment. Subsequent experience and assessment using the prescribed workplace requirements or UoC is needed in the workplace environment.	The graduate is trained and ready for assessment against the identified workplace requirements or UoC. The graduate will be aware of common problems in standard workplace contexts but will likely encounter new situations with limited confidence.	3	**Demonstrable** - Able to perform at basic level, has some experience, needs help from time to time.	Skill and Knowledge are to be formally assessed against a set of defined performance criteria	3	Fully trained and ready for assessment against prescribed standard.	
3	Graduate is able to: • Demonstrate theoretical knowledge of systems, structures and their relationship with other systems. Provide detailed descriptions and interpret results applying corrective action where appropriate • Perform checks as specified in maintenance manuals • Demonstrate use, interpretation and application of appropriate documentation • Correlate information for the purpose of decision making • Describe procedures for replacement of components	4	Trained to the level required to achieve the workplace requirements, without the need for further workplace training or practice. Assessment, using the prescribed workplace requirements or UoC, is completed in training environment.	The graduate is trained and assessed, and can be employed effectively on the job. The graduate will be able to cope with common problems in standard workplace contexts and will encounter new situations with moderate confidence.	4	**Advanced** - Capable and experienced, demonstrated proficiency, able to work independently with little help.	Skill and Knowledge are assured under defined employment conditions	4	Trained and assessed competent against the prescribed standard.	
N/A		5	Training reflects outcomes related to values and/or feelings prescribed for the workplace.	The graduate has chosen a certain course of personal action, as prescribed for the workplace.	5	**Expert** - Fully capable and experienced, sought for help by others, needs no assistance to complete tasks, ability to train and lead others, seen as SME.	Skill and Knowledge are internalised by practice and reflection and expressed as autonomous professionalism	N/A

8.3.4. Acceptance of Aircraft Component

8.1 Introduction

8.1.1 This chapter is intended to provide additional guidance on continuing airworthiness regulations to supplement the DASR (DASP Manual Volume 2). This chapter provides additional guidance on aviation safety outcomes that may incorporate compliance with multiple regulations.

8.1.2 The sub-chapters within this chapter are associated with Continuing Airworthiness Management, Maintenance Organisations, Maintenance Licencing and Maintenance Training Organisations. These sub-chapters will also reference, where appropriate, other chapters and sub-chapters within DASP Manual Volume 3 for common aviation safety elements (e.g. occurrence reporting). Other DASP content relevant to continuing airworthiness will also be referenced where possible.

8.1.3 This chapter will contain information that has historically been communicated via Factsheets, Advisory Circulars (ACs) and Frequently Asked Questions (FAQs). In some instances, these historical methods of communicating guidance will remain – particularly for guidance that has a limited period of applicability or when inclusion in DASP Manual Volume 3 is not an intuitive way to communicate specific information. Use of separate Factsheets, enduring ACs and FAQs will be the exception, with the intent that DASP Manual Volume 3 to be the central repository for continuing airworthiness guidance outside of DASR.

8.1.4 The content in this chapter will evolve as the need for additional guidance is identified, with new content and/or new sub-chapters being added over time to support optimal capability outcomes. Accordingly, DASA welcomes any suggestions for future continuing airworthiness guidance noting that awareness training is available via the DASA website.

8.2 Continuing Airworthiness

8.2.1 Continuing Airworthiness Management

Introduction

8.2.1.1 The following chapters provide additional guidance on DASR M regulations – they cover activities such as Deferment of Defects, Acceptance of Components and Aircraft Maintenance Programs.

8.2.1.2 The Continuing Airworthiness Management Organisation (CAMO) should be principally located within the aircraft's operational organisation, although the majority of DASR M functions may be outsourced/assigned to other organisations or service providers.

8.2.1.3 Continuing airworthiness management regulation is summarised in the requirements of DASR M.A.101 as 'This [DASR M] establishes the measures to be taken to ensure that [continuing] airworthiness is maintained, including maintenance. It also specifies the conditions to be met by organisations involved in such continuing airworthiness management'.

Superseded

8.2.1.4 Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including other chapters of DASP Manual Volume 3.

DASR M - Continuing Airworthiness Management

8.2.1.5 CAMOs are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided. The scope of continuing airworthiness management activities should be in accordance with the Operating Organisation's policy and procedures defined in the Continuing Airworthiness Management Exposition (CAME). The CAME is approved by DASA and sets out the procedures, means and methods of how the CAMO intends to comply with the requirements of DASR M. A list of key management positions will be listed in the CAME. The CAME also includes all functions and privileges required to ensure the aircraft are maintained in an airworthy condition, the issue of Military Airworthiness Review Certificates (MARC), and/or changes to the Aircraft Maintenance Programme (AMP). Additional Information on gaining DASA approval to become a CAMO can be found in Chapter 5.3 Annex H –CAMO.

8.2.1.6 CAMOs are responsible for ensuring that maintenance of aircraft is performed by an organisation approved by DASA or another organisation acceptable to DASA. A maintenance organisation is acceptable to DASA if its services are accessed in accordance with the terms of a recognition certificate.

8.2.1.7 Recognition certificates may enable a CAMO to fulfil the aircraft Certificate of Release to Service (CRS) requirement using a maintenance organisation not approved by DASA. These provisions are applicable where DASA has recognised another airworthiness authority in the area of aircraft maintenance. Chapter 6.5, Recognition of Other Aviation Safety Authorities, provides further guidance on the application of recognition.

8.2.1.8 Recognised systems may include an artefact equivalent to an aircraft CRS; however, maintenance organisations may be prevented from issuing a native artefact against a Defence-registered aircraft by legal or policy constraints. Instead, the CAMO should request an artefact that meets the requirements set out in DASR M.A.801.

Airworthiness Directives

8.2.1.9 Airworthiness Directives (ADs) mandate actions to be performed on an aircraft to restore an acceptable level of safety. Furthermore it is mandatory that CAMOs comply with any AD applicable to its aircraft, guidance on Airworthiness Directives can be found in Section 7.4.3 – Airworthiness Directives.

Data for modifications and repairs

8.2.1.10 DASR M.A.304(d) provides for the consumption of data already approved within a recognised airworthiness framework. A CAMO may consume data for repairs and 'minor' modifications when the data is produced by an organisation accepted by DASA. An organisation is accepted by DASA if its design products are being accessed in accordance with the terms of a recognition certificate and a suitable procedure. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. The suitability assessment will consider, among other things, the effect of the design classification and its compatibility with the ADF Configuration, Role and Environment (CRE). Additional guidance can be found in Section 7.2.4 – Repair Designs.

Superseded

Aircraft continuing airworthiness record system

8.2.1.11 An Authorised Release Certificate is necessary for the release to service of either new or used components. It is a document issued by an entity that has the applicable privilege and attests that a new or used component has been produced or maintained in accordance with the approved design data/standard, modification standard or applicable maintenance data. Additional guidance on tracking status of service life-limited components and other usage data for aircraft structures and propulsion systems can be found in Chapter 6.6.4.

Airworthiness review staff

8.2.1.12 Airworthiness review entails a full documented review of the aircraft records and a physical survey of the aircraft. Airworthiness Review Staff are authorised by the CAMO and accepted by DASA to perform Airworthiness Reviews on aircraft which are listed on the CAMO approval certificate.

8.2.2 Operation of an Aircraft with a known Defect

Introduction

8.2.2.1 This chapter provides direction on what constitutes a Defect, how Defence aircraft can operate with a known defect and who can authorise an aircraft to operate with a known Defect.

Background

8.2.2.2 To meet the demands of operational availability, where it is not reasonably practicable to rectify defects, deferment of defects may be considered. The regulations provide Operators the flexibility to defer defects once assessed. The mechanism used should ensure due consideration is given to the impact to capability and safety. Organisations should ultimately prioritise, to the maximum practicable extent, rectifying defects prior to operating an aircraft.

What Constitutes a Defects?

8.2.2.3 A defect is an imperfection that impairs the structure, composition, or system of a product part or appliance or exceedance of operational limitations in the Instructions for Continuing Airworthiness (ICA).

Defect Management

8.2.2.4 Defects can be identified during operations or during the conduct of maintenance. However, regardless of how a defect is identified the CAMO must ensure that all defects discovered or reported are managed appropriately until rectified by a DASR 145 AMO. Annex A outlines the process for defect deferment.

8.2.2.5 Where a defect cannot be rectified before the next flight due to operational requirements, lack of spares or unavailability of maintenance services the CAMO may IAW a DASA approved procedure described at AMC M.A.301(a)(2) choose to defer the defect until it is reasonably practicable to rectify.

Deferment Options

8.2.2.6 Deferment of MEL/CDL allowable defects can be accomplished by a DASR 145 AMO or Operator in compliance with the relevant aircraft technical log procedures. MEL/CDL allowable defects are subject to acceptance by the aircraft commander.

Superseded

8.2.2.7 Where a MEL/CDL does not exist and there is credible data available, IAW GM M.A.301(a)(2), a determination can be made as to the impact to airworthiness for the aircraft. AMC M.A.301(a)(2) allows the CAMO to defer such a defect IAW a procedure documented in the CAME and approved by the MAA.

8.2.2.8 The procedure must ensure:

1. Airworthiness[1] is maintained, using only credible data, in the defect deferment determination;
    i. Within the context of Airworthiness, 'without significant hazard' is considered to mean that no credible hazard exists that would impact airworthiness.
    ii. A non-credible hazard is a defect that is considered so implausible as to its affect on Airworthiness that it does not need to be accounted for. To manifest into an Issue would require a series of exceptional failures or conditions to happen simultaneously making it impractical to consider for a given operational period.
2. potential hazards arising from the cumulative effect of any combination of defects and restrictions/limitations on the same aircraft are considered as to the impact on airworthiness;
3. deferred defects are documented in the continuing airworthiness record system, including the deferment period and any associated limitations/restrictions as described at M.A.306(a);
4. any conditions, limitations or restrictions are clearly identified and visible to aircrew;
5. monitoring on a continuous basis, defects occurring in flight and defects found during maintenance, highlighting any defects that are repetitive;
    i. Where repetitive defects are identified the CAMO may develop a list of pre-assessed defects that have been documented with consideration to the requirements of the DASA approved procedure. However, the accountability remains on the authorised person approving the defect to ensure the context in which the credible data used to assess the defect and the aircraft condition remains appropriate for the specific pre-assessed defect application.
    ii. In each instance of a pre-assessed defect MTCH engagement should be sought. This will allow consideration of inclusion of the repetitive defect in the relevant platform MEL/CDL or review of existing ICA for possible improvements.
6. Persons who determine whether a defect affects Airworthiness are competent and authorised to defer defects.

8.2.2.9 The procedure should also address how ongoing analysis of the effectiveness of the CAMO's defect control system is carried out.

8.2.2.10 If the defect does not allow the aircraft to remain airworthy the Operator may seek to use the following for ongoing operations:

1. Military Permit to Fly, or

Superseded

2. Command Clearance.

8.2.2.11 Where the CAMO has contracted/tasked the day-to-day control of aircraft technical log deferred defects to another Organisation or the DASR 145 has identified a defect in the course of maintenance that entity may defer that defect IAW M.A.306 (a) subject the following:

1. The defect has been assessed using maintenance data defined in DASR 145.A.45, by appropriately authorised certifying staff IAW DASR 145.A.48 (c), as not a Hazard to flight safety;

   i. Authorised certifying staff may only use maintenance data, as defined through DASR 145.A.45 in making an Endangerment to Flight Safety Assessment (EFSA). The authorised certifying staff may only consider the consequence of failure to determine if a defect hazards flight safety.

   ii. If available maintenance data is insufficient to enable a data driven assessment to identify if the defect either does or does not hazard flight safety the DASR 145 should seek additional maintenance data from the CAMO. If further maintenance data is not available or a definitive assessment cannot be made then the defect is to be processed as if it does hazard flight safety.

   iii. Where a defect does hazard flight safety this does not preclude the CAMO from operating the aircraft. However, the CAMO must establish, for the context of the intended aircraft operation, through the procedure described under 8.2.2.1 that the aircraft remains airworthy with the defect deferred.

2. potential hazards arising from the cumulative effect of any combination of defects and restrictions/limitations has been considered as to the impact on the Flight Safety Assessment; and

3. CAMO has been notified as described under DASR 145.A.48 (c) of the defect and agrees to its deferment.

8.2.2.12 Where a CAMO does not agree to the deferment of a defect they are to task a DASR 145 MO as described under DASR M.A.201(g) to rectify the defect.

Annex:

A. Deferred Defect Management Process – Flowchart

8.2.3 Alternate Artefacts

Introduction

8.2.3.1 This chapter provides additional guidance on acceptance of components – specifically the acceptance of alternate documentation, where components are not supplied with a DASA Form 1 or equivalent recognised document.

8.2.3.2 The introduction of DASRs brought with it a change to the information requirements accompanying components to be consumed on ADF aircraft. DASRs require that components be supplied with a DASA Form 1, or recognised equivalent, that declares the airworthiness of a component.

Superseded

8.2.3.3 This chapter relates to the acceptance of new and used aircraft components, which are listed by the appropriate design organisation as eligible for installation in/on a product and included in the design data approved by the Authority[1]. The term components broadly covers any product (other than complete aircraft), part or appliance that is, or is intended by its manufacturer to be, a part of or used in operating an aircraft in flight, or is installed in or attached to a product. This may include any self-contained part, combination of parts, assembly, subassemblies or units, which perform a distinctive function necessary to the operation of the airframe, engine, or propeller, or may include any other instrument, mechanism, equipment, apparatus, software or accessory, including communications equipment.

8.2.3.4 Although alternate artefacts are consumed by a DASR 145 Approved Maintenance Organisation (AMO), DASA requires the relevant CAMO to seek approval for and manage the ongoing validity of alternate artefacts for their respective platforms. Further detail on alternate artefacts can be found in Chapter 8.3.4 – Acceptance of Aircraft Components

What constitutes an 'alternate artefact' accepted by DASA?

8.2.3.5 DASA may agree that an AMO may consume an alternate artefact other than a DASA Form 1, or recognised equivalent Authorised Release Certificate, that is produced by an organisation accepted by DASA. A CAMO can seek approval of an Alternate Artefact from DASA using DASR Form 155 – Application for Acceptance of Alternate Artefact. AMC to DASR M.A.201(g) and M.A.802(c) provide detail on when an alternate artefact would be acceptable. Chapter 8.3.4 – Acceptance of Aircraft Components provides further detail.

Consumption of United States (US) Department of Defence (DoD) products

8.2.3.6 There has been confusion with consumption of US DoD supplied products where associated documentation, such as DD Form 250, does not meet the requirements of a DASA Form 1 or recognised equivalent. The DASR provide a path for the regulated community to accommodate the consumption of products where the product supplied does not meet the requirements of a DASA Form 1. This is:

1. AMOs and CAMOs comply with DASR 145.A.42 and DASR M.A.201 (g) (e.g. via direct recognition or DASR Form 155 Application for Acceptance of Alternate Artefact).
2. Where (a) above is not reasonably practicable, CAMOs can develop a procedure within their exposition to demonstrate to DASA how these products can be consumed whilst maintaining an equivalent level of protection. DASA will then assess this procedure against the requirements of DASR GR.80(b), and if appropriate, approve the procedure for use.
3. Where (a) is not reasonably practicable, and an equivalent level of protection cannot be ensured (b), CAMOs can develop a procedure within their exposition to demonstrate to DASA how these components will be consumed; accompanied by a demonstration that the resultant risks are appropriately managed by the applicable MAO. DASA will then assess this procedure against the requirements of DASR GR.80(c), and if appropriate, allow the use of the procedure.

8.2.4 Aircraft Maintenance Programme

Introduction

Superseded

8.2.4.1 This chapter provides guidance on Aircraft Maintenance Programmes (AMPs) and Reliability Programmes (RPs).

Aircraft Maintenance Programme (AMP)

8.2.4.2 DASR M.A.302(a) requires that maintenance of each aircraft shall be organised in accordance with an AMP. The AMP encompasses the actual maintenance programme in its entirety. An AMP provides the scheduled maintenance tasks, their associated maintenance procedures and standard maintenance practices that are applied to the maintenance of an aircraft. The RP, which continually reviews the applicability of the AMP to the aircraft and operator, is also considered a part of the AMP.

8.2.4.3 Guidance on the application and approval of AMPs can be found in Chapter 5.3 Annex T – AMP with additional guidance in Chapter 6.6.4 (particularly guidance on how integrity programs can support the development and ongoing validity of the AMP).

Extension of promulgated maintenance interval

8.2.4.4 If a contracted/tasked maintenance organisation advises the CAMO that the maintenance cannot be carried out by the required timeframe and requests an extension of the promulgated maintenance interval, the CAMO when processing the request for an extension, has the following options available:

1. where the packaged/promulgated interval is less than the engineering justified interval, extend the interval up to a maximum of the engineering interval;
2. extend the task interval using the CAMO's indirect approval procedure, if suitably privileged, either once-off or permanently,
3. request DASR 21J design support for the requested interval extension; or
4. utilise the Command Clearance process to operate the aircraft IAW DASR M.A.301(a)(2) .

8.2.4.5 **Extending the Packaged Interval.** Interval flexibility may exist between a maintenance task's packaged/promulgated interval and its engineering/design interval in the AMP. The task may be packaged at a lesser interval maintenance efficiency due to tasks required in the same area or aligning maintenance to be conducted in blocks. If this is the case, and provided the CAMO has the underlying analysis that identifies the engineering interval and the reasons why the task was packaged at a lesser interval, the CAMO may authorise an extension to the packaged interval up to a maximum of the recorded engineering interval.

8.2.4.6 **Extend the AMP Task Interval.** If the AMP task interval has been reached, the CAMO may have sufficient data to extend the AMP task interval either once off, for a defined period, or permanently. To amend the AMP the CAMO must have the privilege from the MAA and sufficient scope as agreed in the indirect approval procedure. Note: where a task's interval has been extended permanently, the task may still be packaged as desired (not exceeding the extended interval).

8.2.4.7 **Request DASR 21J Design Support.** If the two options at para 8.2.4.4a and b above are not applicable, the CAMO may request DASR 21J design support to either extend the interval once off, for a defined period, or permanently.

8.2.4.8 **Utilise the Command Clearance process.** DASR M.A.301(a)(2) contains provisions for the Operating Organisation to deviate from the Initial / Continued / Continuing regulations.

Superseded

8.2.4.9 For servicings with multiple tasks, the decision on extending the interval and the method used will be dependent on the individual circumstances of each task within the servicing. A combination of paragraphs 8.2.4.4a to d may be necessary.

8.2.4.10 Note, that extending a maintenance task beyond its promulgated interval may reduce the preventive effect of the task by increasing the risk of exposure to the failure consequences of the failure mode being addressed. Extension of maintenance could adversely affect the operational capability and/or safety of the aircraft. Also, the percentage by which the interval is extended does not universally reflect the increase in risk in exposure to the failure consequences of the failure mode(s) the task is addressing. The increase in risk with the extension of a task's interval needs to be assessed individually based on the underlying Reliability Centered Maintenance (RCM) analysis that justified the existing interval and the context in which the interval extension is being asked.

8.2.5 Airworthiness Review

Introduction

8.2.5.1 This chapter provides guidance on Airworthiness Reviews (AWRs) to supplement the AMC M.A.710(a)

Airworthiness Review

8.2.5.2 During airworthiness review of an aircraft, the airworthiness review staff must examine continuing airworthiness records for the aircraft and perform a physical survey of the aircraft to determine whether the aircraft continues to comply with the airworthiness requirements as set out in DASR M.A.710(a) and DASR M.A710(b).

8.2.5.3 For many aircraft, the quantity of records that must be examined and the level of examination required will be extensive. It is anticipated that the airworthiness review staff will be assisted by other employees of the CAMO and/or appropriately experienced personnel in this regard. This does not prevent other personnel from assisting to retrieve records, compile information and prepare reports etc. for the examination by the airworthiness review staff. However, it is up to the airworthiness review staff carrying out the airworthiness review to be satisfied with the source, authenticity and accuracy of the information made available to them.

8.2.5.4 The airworthiness review staff are expected to have a level of understanding of the continuing airworthiness records system for the aircraft that allows them to carry out the review without error.

8.2.5.5 **Rectification of defects.** AWR staff shall examine the aircraft's continuing airworthiness record system to determine if any defects need rectification before flight. Defects that require rectification before flight must be rectified before the issue of an airworthiness review certificate.

8.2.5.6 **Deferred defects.** AWR staff shall examine the existing deferred defects as recorded in the aircraft's continuing airworthiness record system to determine whether deferral of rectification has been carried out.

8.2.5.7 **Airworthiness Directives (AD).** AWR staff shall examine the records containing compliance with ADs to determine whether actions required by each AD that applies to the aircraft, product, parts or appliances fitted to the aircraft have been complied with. An examination of documents that substantiate each AD has been complied with should verify that information kept is correct. Examples of documents that may substantiate an AD has been complied with, includes:

Superseded

1. maintenance records for maintenance carried out on the aircraft;

2. copies of authorised release certificates for product, parts or appliances; and

3. log books for products such as engines and propellers.

8.2.5.8 For a product, parts or appliances, the document that substantiates compliance with the AD should relate to the product that is identified in the records by part number and serial number.

8.2.5.9 Where an AD requires compliance with requirements contained in another document such as a service bulletin (SB), a record of compliance with the service bulletin would be acceptable as evidence of compliance with the AD.

8.2.5.10 **Modifications.** AWR staff shall examine the records of modifications kept to determine whether there is a DASR 21 (see DASR M.A.304—Data for modifications and repairs) approval for each design of the modification. For the purpose of this paragraph, a modification includes a repair that involves change to the approved design of the aircraft.

8.2.5.11 **Life Limited Components**. AWR staff should examine the records of life-limited components kept to determine whether part number, serial number, has correctly identified each life-limited part and whether the life limit has been exceeded for any of the parts.

8.2.5.12 In addition, documents that have been used to substantiate remaining life at installation shall be checked to verify that information kept for life-limited components is correct. Examples of such substantiating documents include:

1. maintenance records for installation of the parts;

2. authorised release certificates for the parts; and

3. life limited component history/log card.

8.2.5.13 **Weight and Balance.** AWR staff shall examine the record of the aircraft's weight and balance kept to determine if it is consistent with all the changes made to the weight and balance since the last weighing of the aircraft. All changes made to the weight and balance should be substantiated by documents such as a modification approval and an equipment list for the aircraft.

8.2.5.14 **Aircraft Configuration.** AWR staff shall examine the aircraft's continuing airworthiness records to determine whether the aircraft's configuration as recorded complies with the specification in the military type certificate data sheet (TCDS) for the aircraft, engine and propeller.

8.2.5.15 **Findings.** All findings discovered during an airworthiness review should be documented and managed in accordance with the CAMO's quality management system / safety management system, consistent with requirements of M.A.905.

8.2.6 Master Minimum Equipment List (MMEL) and Minimum Equipment List (MEL)

Introduction

8.2.6.1 This chapter provides guidance on Master Minimum Equipment List (MMEL) and Minimum Equipment List (MEL) development and approval.

Background

Superseded

8.2.6.2 Under certain conditions the required level of safety can be maintained with specific aircraft components being unserviceable, for a limited period of time, until repairs can be made. Many aircraft also have equipment installed that is not required for safe operation under certain operating conditions (e.g. aircraft with multiple VHF radios can operate with single radio if operations do not require the use of the systems associated). Equipment, such as entertainment systems, galley equipment, mission equipment or systems, may have no impact of flight safety.

8.2.6.3 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment, based on the aircraft type certification. An MEL consists of an approved list of the specific unserviceable equipment for a particular aircraft by serial and registration mark, based on the MMEL and the Operator's Configuration, Role and operating Environment (CRE).

8.2.6.4 An MEL can be used as the first step in a defect management process in accordance with procedures developed by the CAMO and approved by the DASA to meet the requirements of DASR M.A.301 (a) 2, for the deferral of defects.

8.2.6.5 Useful background information when developing a MEL can be found in:

1. CASA CAAP 37-1(5) - Minimum Equipment Lists (MEL)
2. EASA Rules for Master Minimum Equipment List (CS-MMEL)

DASA Regulatory Basis

8.2.6.6 DASR GM 21.A.15(a) - Application for a Military Type Certificate may include the MMEL as Operational Suitability Data (OSD) that may be approved as part of Type Certification and form part of the Military Type Certificate (MTC) .

8.2.6.7 DASR M.A.301 Continuing airworthiness tasks, refers to MEL and Configuration Deviation List (CDL) for use in the deferment of defect rectification.

8.2.6.8 DASR AO Gen.05 Management of OIP, ORO.05 Conduct of Flying Operations and ORO.30 Flight Authorisation support discharging flight operations requirements referred to in this chapter.

Configuration Deviation List

8.2.6.9 A Configuration Deviation List (CDL) is a listing of regulator-approved non-structural external parts that may be missing but the aircraft remains airworthy. A CDL provides options to dispatch an aircraft for flight when listed parts may be missing, provided the necessary performance corrections are adhered to (including limits or restrictions if required and specified rectification periods). Refer DASR M.A.301(a)2 and associated AMC/GM.

8.2.6.10 CDLs are part of the certified type for any civil derivative aircraft (certified by the European Aviation Safety Agency (EASA) or the Federal Aviation Administration (FAA)). Within the ADF context, as part of Military Type Certification, the CDLs are presented as part of the Aircraft Flight Manual (AFM) for approval during Type Certification. Usually, they are contained in a standalone section of the AFM. The AFM is approved as part of Military Type Certification (DASR 21 Subpart B) and changes would be approved under (DASR 21 Subpart D).

8.2.6.11 The CDL should not be confused with the Minimum Equipment List (MEL). While the MEL describes the limitations of aircraft operation in case of a system being inoperative or having malfunctioned (e.g. transponder failure), the CDL deals with situations where external parts of an aircraft are missing (e.g. fairings, aerodynamic seals or panels).

Superseded

MMEL

What is a MMEL?

8.2.6.12 A MMEL is a document created specifically to permit the continued operation of an aircraft type (e.g. C-130J-30) with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL does not take into account the operating circumstances of individual operators of that type. The MMEL cannot, in itself, be regarded as providing operational permission. It can, however, be the basis for the development of an individual Operator's MEL.

MMEL Characteristics

8.2.6.13 **Aircraft Type.** MMEL relief for a particular item may be unique to a specific aircraft type. Therefore, MMEL relief for an item for one aircraft type may not be the same as the relief allowed for the same item found in another aircraft type.

8.2.6.14 **Items required by an Airworthiness Directive (AD) are prohibited.** An MMEL will not include items that an AD requires to be operative, unless the AD specifically allows them.

8.2.6.15 **Variable Number of Items Required for Dispatch.** A MMEL may depict a variable number of items required for dispatch based on various makes and models of the same series aircraft. The MMEL must clearly articulate which makes and models each MMEL item is applicable to.

8.2.6.16 **Multiple Versions of the Same Item.** A MMEL may contain multiple versions of particular items (e.g., very high frequency (VHF) communications systems and fire extinguishers) that are installed on different models or series of the aircraft covered by the MMEL. The MMEL must clearly articulate which versions each MMEL item is applicable to.

8.2.6.17 **Repair Categories.** A MMEL will contain a repair category for each item. Each repair category allows for a certain amount of time until repairs must be accomplished.

8.2.6.18 **Prohibited Items.** A MMEL will not include items of the aircraft that are required for basic flight (wings, flaps, rudder, etc.), nor will it include instruments and equipment required for specific operations.

MEL

What is a MEL?

8.2.6.19 A MEL is a document created specifically to manage the continued operation of an aircraft with unserviceable equipment consisting of an approved list of the specific unserviceable equipment for a particular make and model of aircraft by serial/production number and registration mark (e.g. C-130J-30, 5440, A97-440) as applicable. Its use is authorised by accepting the associated application procedures contained in an operator's Continuing Airworthiness Management Exposition (CAME) and/or operations manual, or other appropriately documented procedures.

MEL Transferability

8.2.6.20 An approved MEL for an aircraft is a non-transferable document, i.e. if the MAO of the aircraft changes, then a new approval for the MEL is required even if the aircraft retains the same registration mark.

Superseded

8.2.6.21 If an aircraft moves from one Military Air Operator Certificate (MAOC) holder to another, the new MAOC holder cannot automatically use the approved MEL for the aircraft. The new MAOC holder will be authorised by DASA only if they have acceptable associated application procedures contained in their CAME and/or operations manual and have assessed the operator's CRE.

Use of the MMEL/MEL

MMEL/MEL Considerations for Use

8.2.6.22 The MMEL/MEL is an alleviating document. Its purpose is not to encourage the operation of aircraft with unserviceable equipment. It is never desirable that aircraft continue operations with unserviceable equipment. Such operations are permitted only as a result of careful analysis of each item to ensure that the required level of safety is maintained. A fundamental consideration in permitting the operation of aircraft with unserviceable equipment is that the continued operation of an aircraft in this condition is to be eliminated or otherwise minimised so far as reasonably practicable (SFARP).

Invoking the MEL

8.2.6.23 The Aircraft Captain or appropriately licenced and authorised Military Aircraft Maintenance Licence (MAML) holder invokes the MEL on behalf of the CAMO. It is the decision of the Aircraft Captain to accept the aircraft for flight with unserviceable systems or equipment listed in the MEL. The overriding principle is that, notwithstanding the provision of an approved MEL, a MAML holder should not release an aircraft for flight, and the Aircraft Captain should not accept an aircraft for flight, if it is considered unsafe for a particular flight.

8.2.6.24 A MAO may authorise Aircraft Captains to invoke MEL items through provisions in the Operations Manual. Where an Aircraft Captain is not authorised to invoke a MEL item the Aircraft Captain is to refer to local procedures for actions required to invoke the MEL item.

Developing a MMEL

MMEL Development Options

8.2.6.25 **Existing CAA/MAA MMEL as part of Operational Suitability Data (OSD).** As part of the introduction of a new type to Defence the initial certification package may contain a MMEL that has been developed by the OEM as part of the OEM state of design certification process. This MMEL document can be submitted as OSD, as part of the Australian MTC certification package and be assessed for approval as the DASA approved MMEL. Similarly, for an existing type with no DASA approved MMEL, an existing Civil Aviation Authority (CAA) / Military Aviation Authority (MAA) approved MMEL may be submitted for approval as a change to the type certificate.

8.2.6.26 In both cases above, foreign CAA/MAA approval of a MMEL does not constitute automatic approval under DASRs. DASA issues its own sovereign Military Type Certificates (MTC) for each aircraft type and does not 'accept' foreign civil or military TCs. Therefore, in order for a MMEL to be approved under DASRs it must be approved under the initial issue of, or as a change to, the DASA issued MTC and be included on the DASA issued Type Certificate Data Sheet (TCDS).

8.2.6.27 **MEL submitted in lieu of MMEL.** If the operator has access to an existing, or has developed, a MEL for the type, for which no MMEL exists, the operator may submit the MEL through the Military Type Certificate Holder (MTCH), for assessment as a MMEL. If the MEL is submitted, DASA

Superseded

will consider it a MMEL submission and assess it as such. It may then be used as the basis for acceptance as a MEL.

8.2.6.28 **Development of a new MMEL.** A MTCH may elect to submit a new MMEL to DASA for approval. DASA does not stipulate any specific format and/or contents of a MMEL. However, the Certification Programme must propose an appropriate Certification Basis that the MMEL will comply to, and that may include content and format requirements. Establishing the Certification Basis early and following the associated format will avoid delays in assessment and approval of the MMEL.

8.2.6.29 **Suitable Certification Specifications.** The Certification Programme should be submitted to DASA, proposing a Certification Basis for the MMEL. The following two certification specifications will likely be suitable for development of MMELs:

1. EASA CS-MMEL. CS-MMEL is the Certification Specification (CS) mandated by EASA for MMEL development and is likely to provide an acceptable basis for MMEL approval for Defence aircraft.

2. FAA FOEB process. FAA policy for MMEL approval is through the Flight Operational Evaluation Board process. MMEL document templates, guidance on specific systems, general format requirements, and guidance on justification requirements are available on the FAA FSIMS website. (Reference ICAO Manual – MMEL/MEL5 and Flight Standards Information Management System).

8.2.6.30 Alternate Certification Bases may be proposed in the Certification Programme but will require further justification.

MMEL development process

8.2.6.31 As the MMEL forms part of the Military Type Certificate, any MMEL change is to be classified IAW the guidance in DASR 21.A.91. On initial issue of the MMEL or identification of a MMEL change as Major, the Major Change to Type Certificate process as per DASR 21 subpart D applies. Minor changes to MMELs are to be processed IAW DASR 21.A.95. This process is depicted at Appendix 2.

8.2.6.32 **MMEL Change Classification Criteria.** The following guidance for classification of MMEL changes elaborates upon the generic classification advice in GM to DASR 21.A.91.

8.2.6.33 Conditions requiring classification of a MMEL change as Major:

1. Where the change requires an adjustment of the MMEL certification basis;
2. Where the applicant proposes changes to the Means of Compliance (MoC) with the requirements for the MMEL certification basis (i.e. MMEL safety assessment methodology);
3. Where the extent of substantiation data and the degree to which the substantiation data has to be assessed and evaluated is considerable, in particular but not only when:
    i. The substantiation data involving review of failure conditions that are classified as hazardous or catastrophic has to be evaluated;
    ii. The assessment of the failure effects (including next worst failure/event effects) on crew workload and the applicable crew procedures has to be evaluated; or

Superseded

iii. The capability of the aircraft to perform types of operation (e.g. Defence Long Range Operations (DLRO), Instrument Flight Rules (IFR)) under MMEL is extended.

8.2.6.34 Conditions where the MMEL change can be considered Minor:

1. Modifications to an item/s when:

   i. The change is only to the applicability of an item for configuration management purposes;

   ii. The change is the removal of an item;

   iii. The change is an increase in the number of items required for dispatch; and

   iv. The change is a reduction in the rectification interval of an item.

2. Addition of a new item when:

   i. It is considered as non-safety related IAW FAA MEL Requirements for 14 CFR Parts 91 Subpart K (Part 91K), 121, 125, 125 LODA, 129, and 135 Operations CS-MMEL GM2 MMEL.110; or

   ii. It is indicated as eligible for minor change classification in FAA MEL Requirements for 14 CFR Parts 91 Subpart K (Part 91K), 121, 125, 125 LODA, 129, and 135 Operations, GM1 CS MMEL.145.

8.2.6.35 **Justification and development of supporting data.** Items must be justified for inclusion in the MMEL against the agreed certification basis. Any risk associated with inclusion of items is to be eliminated or minimised to the level inherent in the applicable design standards. Alternate methodologies for justification of changes must be presented to the Authority during the Certification Programme agreement (CP) process.

8.2.6.36 If the conditions and limitations applied against a MMEL item are assessed as insufficient to fully eliminate the associated risk, or an Equivalent Safety argument cannot be made that the risk meets the level of safety inherent in the applicable design standards in the aircraft Type Certification Basis (TCB), the MMEL item is NOT to be included in the MMEL.

8.2.6.37 Operational endorsement should be sought from the MAO (e.g. Hazard Tracking Authority or Standards Officer (STANDO) for any operational conditions or limitations identified against MMEL items. The MTCH in developing the MMEL considers the operational conditions/limitations of the aircraft against the type certification. The MMEL operational procedures are not specific to an individual Operator's Configuration Role and operating Environment (CRE).

8.2.6.38 **Relief from Development of Compliance Demonstration Evidence.** Relief from the requirement to develop compliance demonstration evidence can be sought on an item by item basis for MMELs. The requirements for leveraging prior certification from another CAA/MAA as per AMC to DASR 21.A.20 still apply when relief is applied in this manner.

MMEL approval process

8.2.6.39 Initial Type Certification

1. The applicant for initial DASA MTC would submit the MMEL as part of the application package.

Superseded

8.2.6.40 MMEL for an aircraft with an existing DASA MTC

1. An MTCH submitting a MMEL for DASA approval must do so in accordance with the Change to Type Design process as described in DASR 21

2. Refer to Appendix 2: for the process flow to seek DASA approval of a MMEL.

Developing a MEL

Developing a MEL using an existing/relevant MMEL

8.2.6.41 DASA do not stipulate any specific format and/or contents of a MEL. Using an international recognised format could avoid delays in assessing the MEL. In the development of an MEL, DASA recommends that the MEL be developed in accordance with international standards as referenced in the Certification Programme from the MMEL (detailed above).

8.2.6.42 The MEL should be developed from the latest issue of the applicable MMEL on an item-by-item basis and keeping in view the relevant regulatory requirements.

8.2.6.43 If an operator chooses to add items that are not found in the MMEL (due to its particular type of operation) an assessment of those items must be carried out. This assessment is required to ensure that these items do not affect the design standards or safe operation of the aircraft and are not in conflict with the flight manual and any DASR requirements. Refer to the International standards as referenced in the Certification Programme from the MMEL for guidance on how to assess the criteria for these items.

8.2.6.44 In general, a MEL should be as, or more, restrictive than the applicable MMEL for the type of aircraft. If a certain item(s) of the applicant's MEL is less restrictive than the applicable MMEL, DASA will require an extensive qualitative and/or quantitative analysis to substantiate the proposed departure from the MMEL.

MEL Development with no MMEL

8.2.6.45 If a platform has no MMEL or MEL available from the manufacturer or other CAA/MAA and the operator wants to utilise the flexibility that a MEL affords, the Operator may choose to engage the MTCH to develop a MMEL from previously available deferment options.

8.2.6.46 The MMEL should be developed in accordance with the guidance provided earlier in this chapter.

8.2.6.47 Once the MMEL is approved by DASA the operator can seek approval of the MMEL for use as an MEL from DASA.

MEL approval process

8.2.6.48 An Operator submitting a MEL for approval must provide DASA with:

1. A minute of application from the CAMO requesting approval of the MEL;

2. Digital access to a copy of the proposed MEL;

3. All OIP created for use of the MEL; and

Superseded

4. If the MEL has no associated DASA approved MMEL, the MEL must be submitted for approval as a MMEL.

8.2.6.49 A MEL may cover more than one aircraft of the same type. However, all differences in the equipment/systems installed, if any, should be clearly identified by the aircraft registration mark.

8.2.6.50 Refer to Appendix 1: for the DASA process flow of MMEL/MEL approval.

Application for amendment to the MEL

8.2.6.51 Amendments to MELs are either mandatory or voluntary, depending upon the particular circumstances. Mandatory amendment of a MEL is required either:

1. When the applicable MMEL is amended so as to become more restrictive; or
2. When required by DASA in light of in-service experience.

8.2.6.52 Voluntary amendment of a MEL may be carried out when either:

1. The MMEL is amended so as to become less restrictive; or
2. As required by the operator, provided the proposed change is no less restrictive than the MMEL; or
3. Regulatory changes occur.

8.2.6.53 An application for amendment to an approved MEL, together with appropriate substantiation, should be forwarded to DASA.

MMEL/MEL Development Considerations

Operations and maintenance procedures

8.2.6.54 The objective of operations ((O)) and maintenance ((M)) procedures is to provide everyone using the document with clear and concise directions on how they are to proceed in case of unserviceability. The (O) and (M) procedures form part of the approved MEL.

8.2.6.55 **(O) Procedures:** Where the (O) symbol appears in the MMEL, an operations procedure must be developed that provides clear direction to the flight crew. These procedures may be included in the MEL. Where they are not included in the MEL, they must be available to the aircrew in another document that is always available to the aircrew (i.e. an operations manual or in an approved electronic form). In these cases, the MEL shall refer to a section of the appropriate document(s).

8.2.6.56 **(M) Procedures:** The MMEL may identify items that require a maintenance procedure. If this is the case, the operator must ensure that relevant (M) procedures have been developed for the MEL. These procedures must provide clear direction to the maintenance personnel.

Procedures for the use and guidance of flight crews and maintenance personnel

8.2.6.57 The operator must establish procedures for the use and guidance of flight crews and maintenance personnel, in relation to the MEL. These procedures must agree with those in the operator's CAME, Aircraft Maintenance Program (AMP), operations manual, and other operating documents. These procedures should include, but are not limited to, procedures for:

1. Deferring rectification action or invoking MEL item(s) for unserviceable equipment;

Superseded

2. Placarding requirements as per the MEL;

3. Ensuring that a dispatched aircraft with an invoked MEL item(s) complies with the limits and conditions of the MEL;

4. Ensuring that existing deferred defects / MPTF / Command Clearances do not impact invoking of MEL provisions;

5. Controlling categorised repair intervals; and

6. The training of organisations personnel who are responsible for compliance with MEL procedures.

8.2.6.58 Procedures for invoking MEL items are normally contained in the operator's CAME, operations manual or an alternative document. Prior to issuing a MEL approval, DASA will ensure that the MEL references these procedures in the CAME, operations manual or similar document, if not already included in the MEL. If no procedures for the invoking of MEL items exist within the operator's organisation, then DASA will, in addition to vetting the MEL, require amendment to the CAME/MOE and/or operations manual.

8.2.6.59 A placarding procedure should be established and set out in the CAME/MOE and operations manual or, at least, within the approved MEL document.

8.2.6.60 When invoking a MEL item, the person responsible must:

1. Identify, in the aircraft technical log or appropriate document/maintenance information system, that this action has occurred;

2. Identify the item with its MEL number; and

3. Ensure that an unserviceable label is placed in an appropriate location (where applicable).

8.2.6.61 A procedure documenting the above requirement in the appropriate operator's documentation is acceptable for compliance purposes.

Repair intervals

8.2.6.62 Each item of a MEL must be repaired within the specified repair interval. These intervals are set to limit the maximum time an aircraft may fly with an unserviceable item(s) of equipment, and are designated Category 'A, B, C or D'. The definition of repair intervals should align with the selected certification basis for the MMEL as defined at para 8.2.6.29.

8.2.6.63 The operator must establish procedures whereby the maintenance support periodically reviews the deferred items. This is done to ensure that any accumulation of deferred items neither conflict each other nor present an unacceptable increase in crew workload. Notwithstanding the categorisation of item repair intervals, it should be the aim of each MEL document holder to ensure that unserviceable items are repaired as quickly as possible.

Repair interval extension

8.2.6.64 Each operator's MEL management program needs to contain procedures for controlling extensions to item repair intervals. Procedures must include the limitations of each extension and the method by which the operator approves an extension.

Superseded

MEL training program

Training Requirement

8.2.6.65 The operator should as part of the introduction of a process for the use of a MEL develop a MEL training program for maintenance personnel and flight crew, which should be in place prior to an operator commencing operations with a MEL. The operator, when required, should conduct recurrent training, or put in place a controlled method to alert staff to any changes in MEL procedures. This will ensure company personnel remain current with those procedures.

Maintenance Personnel Training

8.2.6.66 The training for maintenance personnel should include those sections of the CAME procedures dealing with:

1. The use of, and compliance with, the MEL;
2. Placarding of unserviceable equipment;
3. Return to service of an aircraft;
4. Dispatching an aircraft; and
5. Any other MEL related procedures.

Flight Crew Training

8.2.6.67 The flight crew training should include, but not be limited to, the following:

1. The purpose and use of a MEL;
2. Instruction on operator's procedures for the use and guidance of flight crew;
3. The process and procedures required for supervision and flight authorisation; and
4. The Aircraft Captain's responsibility with respect to the above procedures.

8.3 Maintenance Organisations

8.3.1 Requirements for Maintenance Organisations

Introduction

8.3.1.1 This section provides additional information and guidance to DASR 145 Approval Holder Organisations and those organisations that are applying for approval under DASR 145. Further guidance on applying for a Maintenance Organisation approval can be found in Section 5 Annex G – AMO.

8.3.1.2 For information on maintenance service providers that are approved though other means (i.e. not DASR 145 approval), refer to Chapter 6.5, Recognition of other Aviation Safety Authorities and to Chapter 8.2, Continuing Airworthiness Management.

8.3.1.3 This chapter does not include information already presented at Volume 2 (DASRs), but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3.

Superseded

DASR 145 – Requirements for Maintenance Organisations

8.3.1.4 The Defence Aviation Safety Regulations (DASR) requires individual DASR 145 Approved Maintenance Organisations (AMOs) to define their own line and base maintenance activities in their Maintenance Organisation Exposition (MOE).The scope of maintenance of aircraft and components activities should be in accordance with the Maintenance Organisation's policy and procedures defined in the MOE.

Acceptance of components

8.3.1.5 The AMO must ensure that components are accompanied by appropriate documentation attesting to the legitimacy of the component's maintenance or production history. This is underpinned by the regulatory requirement for the AMO to obtain a DASR Form 1 or equivalent documentation prior to fitment of such components. Where an unserviceable or unsalvageable component is the subject of an occurrence report, the DASR 145 organisation should quarantine the component until the investigation has determined that the component is not required to be retained for further examination Additional information can be found in Chapter 8.3.4 – Acceptance of Components.

Certification of maintenance

8.3.1.6 Maintenance carried out on an aircraft, its systems and its components must be certified at completion and prior to its return to service. The instrument used to achieve this outcome is the Certificate of Release to Service (CRS) that must be issued at the completion of maintenance and before the next flight. Additional guidance for Certification of maintenance can be found in Chapter 8.3.3 - Certification of maintenance.

8.3.2 Performance of Maintenance

Introduction

8.3.2.1 This chapter provides additional guidance on the performance of maintenance including guidance on line and base maintenance, and specialist maintenance qualifications.

8.3.2.2 Not all maintenance personnel in a DASA 145 MO need to be authorised as certifying and/ or support staff. Acting as certifying or support staff is intrinsically a hands-off activity (in contrast to the performance of maintenance being physical hands-on aircraft maintenance). DASA 145 MO personnel perform maintenance under a Task Sign-Off (TSO) authorisation. On-aircraft TSO is overseen, managed and later certified (issue of CRS) by authorised certifying staff.

8.3.2.3 Except for a few speciality areas (e.g. composite repairs), DASA does not prescribe knowledge / experience standards for the performance of maintenance. On-aircraft TSO provides an attestation that the maintenance task has been carried out to the required standard.

8.3.2.4 A DASA 145 MO has flexibility to determine their own Qualification, Training and Experience (QTE) requirements when assessing and authorising personnel to perform the vast majority of maintenance (less some specialist qualifications where DASA will specify acceptable means of compliance). It is up to a DASA 145 MO to determine the scope that maintenance personnel can be authorised to perform, and may also mandate the level of supervision maintenance personnel require – noting supervision can be performed by authorised persons who are not necessarily certifying staff – see GM2 DASR 145.A.35(e). Maintenance personnel do not need to hold a MAML, of any category, to be authorised to perform maintenance.

Superseded

8.3.2.5 DASA oversight of DASA 145 MOs, in the context of foreign trained maintenance personnel employed to perform maintenance, will focus on the procedure that identifies knowledge and experience requirements, to determine the authorised scope of maintenance and supervision required.

8.3.2.6 For information on maintenance service providers that are approved though other means (i.e. not DASR 145 approved), refer Chapter 6.5, Recognition of other Aviation Safety Authorities and Chapter 8.2, Continuing Airworthiness Management.

8.3.2.7 For information on the performance of maintenance relates to the certification of maintenance, see Chapter 8.3.3 – Certification of Maintenance.

Line and Base Maintenance

Background

8.3.2.8 The Defence Aviation Safety Regulations (DASR) requires individual DASR 145 Approved Maintenance Organisations (AMOs) to define their own line and base maintenance activities in their Maintenance Organisation Exposition (MOE). Feedback from the regulated community indicates that there is insufficient DASR guidance on what types of activities constitute line and base maintenance. This chapter describes types of maintenance activities constituting line and base maintenance and describes the intended outcomes in relation to line and base maintenance as interpreted by DASA.

8.3.2.9 The DASR Glossary of Terms describes line and base maintenance as:

1. **Line Maintenance:** Carried out before flight to ensure that the aircraft is fit for the intended flight.
2. **Base Maintenance:** Maintenance tasks falling outside the criteria for line Maintenance.

8.3.2.10 A more detailed definition of aircraft line maintenance is provided in AMC 145.A.20, together with a list of activities which "may" be considered as line maintenance. The word "may" is used because it is not possible to establish a provision giving a strict demarcation between line and base maintenance, having general applicability to all cases.

8.3.2.11 To assist civil MOs, the European Aviation Safety Agency (EASA) has developed an EASA 145 User Guide chapter on 'Privileges and limitations of line maintenance'. This guide provides detailed guidance on what constitutes line and base maintenance. This Annex is has been developed based on the EASA User Guide to provide an EASA aligned approach to guide DASR 145 MOs in defining line and base maintenance.

Organisation responsibilities

8.3.2.12 The maintenance organisation should ensure prior to any intended maintenance event that the activity can be carried out under its line maintenance scope of approval (refer to AMC 145.A.20) and does not fall under paragraph 14 'Examples of maintenance activities considered to be base maintenance' of this Chapter.

8.3.2.13 This assessment may not need to take place each time, but be based on already established MOE procedures (i.e. the fact that a daily check is a line maintenance task is obvious and does not need to be assessed each time).

Superseded

8.3.2.14 Even if this assessment confirms that the activity is line maintenance, the maintenance organisation should also verify if this activity requires other means than the ones already in use at a line maintenance location.

When to assess the maintenance activity

8.3.2.15 The maintenance organisation`s assessment to decide if any maintenance event falls within the definition of line or base maintenance, may be needed in two different situations:

1. for an initial/change of approval, when evaluating the scope of work the maintenance organisation is applying for (refer paragraph 11); or

2. for an already approved maintenance organisation, when evaluating if maintenance requested by the customer (e.g. a new Service Bulletin (SB), defect rectification or work package requested by the customer, etc.) falls within the approved line maintenance scope of work.

Assessment of the intended scope of work (initial/change of approval)

8.3.2.16 It is the responsibility of the maintenance organisation to demonstrate to DASA that the intended scope of work may be carried out in a line maintenance environment, under its line maintenance scope of approval. The main criterion for this assessment is to consider the level of maintenance to be carried out under the line maintenance scope of approval, where the following general criteria apply:

1. **Trouble shooting, Defect Rectification.** Those unscheduled tasks required for the daily operation of an Aircraft and not falling under 'Examples of maintenance activities considered to be base maintenance';

2. **Minor scheduled line maintenance.** Those scheduled tasks not exceeding the weekly check as specified in the Aircraft Maintenance Program (AMP);

3. **Scheduled checks.** Those scheduled tasks which exceed the weekly check (or equivalent as determined by the Authority). In this case, the organisation needs to analyse each of the routine tasks intended to be included in the line maintenance scope of work and identify a clear limit. This assessment needs to be performed using the Type Certificate Holder (TCH) data such as the manufacturer's Maintenance Planning Document (MPD), and/or the operator's AMP. The outcome of this exercise is to identify the intended limitation of the line maintenance scope of approval, in terms of scheduled maintenance checks. In particular, the following is expected:

4. Depending on the AMP logic (i.e. MSG 2, MSG 3, etc) a clear limitation to the line maintenance scope of work may be normally expressed in one of the following ways:

   i. "up to and excluding X check" (i.e. X= R1, R2, etc) for a MPD, where letter checks are identified;

   ii. "up to and excluding "X FH / Y FC / Z calendar time", for a MPD, where progressive task intervals are defined in terms of FH/FC/calendar time (i.e. X=3000FH, Y=750 FC, Z=12 months, etc);

5. The identified limit, to be indicated in the MOE, should be such that all the related routine/scheduled tasks are excluding any of the tasks listed in 'Examples of maintenance activities considered to be base maintenance'

Superseded

6. A “decision making process” (refer paragraph 12 for example) needs to be established in the MOE in order to assess

   i. (the need to access the hangar (even if the activity is permitted under a line maintenance scope of approval), considering in particular the type of aircraft, the maintenance event type/complexity, the environmental and weather conditions;

   ii. any work order / work package received from the customer operator to ensure it may be fully performed under a line maintenance scope of approval, taking into account additional works to the original work package that may be added, leading out to the line maintenance scope of work, such as:

   – addition of previously deferred maintenance tasks; or

   – defects raising from the routine tasks (these defects are not known in advance, however, the related risk in terms of number and level of defects needs to be taken into account and estimated in advance).

8.3.2.17 **Example of ‘decision making process’.** A R1 maintenance check on the Boeing Business Jet (BBJ) aircraft type is normally considered “line maintenance” when the routine tasks are assessed as per the manufacturer MPD/operator AMP. Therefore a maintenance organisation may be approved to perform this check under a line maintenance scope of work. However, a work order to perform the “R1 check”, where the customer operator would request the performance of works in addition to the “R1” routine tasks, such as the addition of Airworthiness Directives (ADs), SBs, deferred tasks, will need to be carefully assessed by the maintenance organisation with the use of the “decision making process”.

8.3.2.18 This type of maintenance check may easily fall within the examples given in Paragraph 14 ‘Examples of maintenance activities considered to be base maintenance’ having the result to be considered as base maintenance and being outside the maintenance organisation scope of work. In such a case, the outcome of the “decision making process”, may be for example:

1. The impossibility to accept such work order from the operating organisation, being outside the scope of work of the maintenance organisation; or

2. to agree with the operating organisation a revised work order, to remove the works which have been identified as base maintenance tasks (e.g. removal of a SB which was requiring extensive disassembly and modification of flight controls, etc.).

Examples of maintenance activities considered to be base maintenance

8.3.2.19 When any of the following tasks are required to be carried out (regardless if contained in a scheduled maintenance check or arising from a defect rectification/AOG situation), a base maintenance scope of approval is needed:

1. High number of different type of tasks to be carried out, even if taken singularly those tasks may still fall under the definition of line maintenance (i.e. a combination of routine task cards, non-routine task cards issued following defects discovered during the check, out of phase tasks, deferred items from previous maintenance, minor repairs, minor modifications, component replacement, etc). Such cases require base maintenance production planning support and/or a base maintenance release to service process (category C Certifying Staff supported by B1/B2 support staff) in order

Superseded

to ensure that all the maintenance ordered has been carried out before issuing the CRS;

2. Replacement of any major component where the related maintenance procedures address the need of a hangar environment requiring special ground support equipment and/or structured production planning and/or complex and lengthy maintenance, such as for example a full landing gear replacement, simultaneous replacement of two engines, etc;

3. Any scheduled maintenance task (i.e. routine task from the AMP) which requires extensive disassembly of the aircraft and/or extensive in depth inspection;

4. Major repairs and/or major modifications;

5. Trouble shooting and/or defect rectification requiring special ground support usually relevant to base maintenance (e.g. special equipment, structured production planning, complex and lengthy maintenance);

6. A scheduled maintenance event, which in the planning phase has been already identified as significant in terms of duration and/or man-hours (i.e. an aircraft down time above 72 hours or four shifts, whichever is less);

7. A work package requiring a complex team composition in terms of high number and categories (avionic, structure, cabin, NDT qualification and skills, etc) of staff involved per shift; or

8. The management of the event by B1 and B2 support staff and the release by a C certifying staff.

8.3.2.20 For AMOs that do not hold a base maintenance approval, the AMO remains responsible to ensure that even if each individual work order constitutes a line maintenance activity, a maintenance event cumulating several of these work orders remains within the AMO's line maintenance scope of approval.

Assessment of maintenance task by an already approved maintenance organisation

8.3.2.21 For AMOs that do not hold a base maintenance approval, the AMO remains responsible to assess if any maintenance requested by the operating organisation falls within the approved line maintenance scope of work. This assessment is expected to be performed based on the "decision making process" described above.

Specialist Task Qualifications

8.3.2.22 **Introduction.** DASR 145.A.30(f) relates to MO personnel who carry out Non-Destructive Testing (NDT) and other specialised tasks such as composite repair and welding. Definitions pertaining to the scope of DASR 145.A.30(f) are as follows:

1. Particular non-destructive test means any one or more of the following; Penetrant Testing (PT), Magnetic Testing (MT), Eddy current Testing (ET), Ultrasonic Testing (UT), Radiographic Testing (RT), Thermographic Testing (TT) and Shearographic Testing (ST) methods (refer GM 21.A.30(f)). Boroscoping and other techniques such as manual tap testing are non-destructive inspections rather than non-destructive testing (refer AMC 145.A.30(f)).

Superseded

2. For the purposes of DASR 145.A.30(f), DASA should be consulted to confirm the complexity and associated training requirements of composite repairs for each platform. The complexity and training requirements for non-specialised composite repairs should be detailed in the DASR 145 MOE.

8.3.2.23 DASR 145.A.30(f) requires that the MO must ensure that personnel who carry out NDT and other specialised tasks are appropriately qualified in accordance with recognised standards. The following paragraphs provide guidance on the standards recognised by DASA and other aspects of personnel training and certification.

8.3.2.24 It should be noted that the training standards required to perform specialist tasks might exceed the training standards to certify this maintenance. For example a licence persons with no structural repair exclusions could certify for a complex composite repair but may not be qualified to perform the maintenance. In this case the certifying staff may require separate specialist supervision in order to very the maintenance has been performed properly.

Qualification of Personnel for Non-Destructive Testing (NDT)

8.3.2.25 **Recognised NDT Qualification Standards.** DASA recognises the following standards for qualification of personnel who carry out and/or control NDT of aircraft structures and/or components (refer DASR 145.A.30(f)):

1. European Standard EN4179 - Qualification and Approval of Personnel for Non-destructive Testing is the primary NDT standard recognised by DASA
2. NAS410 – NAS Certification & Qualification of Non-Destructive Testing Personnel is also recognised by DASA.

8.3.2.26 NAS410 is the only NDT qualification standard DASA recognises as being equivalent to EN4179. Organisations that wish to use an alternative NDT personnel qualification system should apply to DASA with a proposed Alternate Means of Compliance (AltMoC). Note that Australian Standard AS3669 and ATA Spec 105 have been assessed as non-equivalent to EN4179 (refer GM 145.A.30(f)) and will not be approved as AltMoC by DASA.

8.3.2.27 **NDT Personnel Training and Certification.** The appointed NDT Responsible Level 3 (RL3) for each DASR 145 MO is responsible for establishing a training and certification system which supports awarding of task authorisations to NDT personnel working within the DASR 145 MO. This training and certification system should be established in line with EN4179. In cases where the minimum training and experience hour requirements stipulated in EN4179 Section 6 do not align with Defence's requirements, a competency based training program can instead be used, provided the course program is approved by DASA. Refer to GM 145.A.30(f).

8.3.2.28 For details of the approach to NDT training and certification implemented in support of ADF DASR 145 MOs, refer to Volume 3 Section 4.2.3.

8.3.2.29 **Appointment of NDT Responsible Level 3.** AMC 145.A.30 stipulates that the NDT RL3 for a DASR 145 organisation is a nominated management position, and is accepted by DASA through a DASR Form 4 application. Each DASR 145 organisation should only have one appointed NDT RL3. The DASR Form 4 requires applicants to submit details and supporting documentation of relevant qualifications and experience. Specific to NDT RL3 applications:

1. Applicants are requested to provide a copy of all personnel certification records that DASR 145 organisations are required to retain under EN4179 Para 8.2 to demonstrate they meet the EN4179 requirements to be certified as a Level 3.

Superseded

2. If the applicant holds certifications in multiple methods, only evidence from one NDT method is required. The employer is to ensure that certification records for all other methods are retained, as required by EN4179 Para 8.2.

Note: that DASA may request evidence of ongoing EN4179 compliance for NDT RL3s in the course of oversight and enforcement activities.

8.3.2.30 DASA does not require the involvement of the Australian National Aerospace NDT Board (NANDTB) in the certification of Level 3 staff. DASA will not request or rely on NANDTB recognition when assessing NDT RL3 Form 4 applications.

8.3.2.31 For questions about NDT RL3 Form 4 application evidence please email: dasa.dca@defence.gov.au

8.3.2.32 Responsibility for appointment of NDT RL3 personnel is as follows:

1. ADF DASR 145 MOs: the Directorate of Aviation Engineering (DAVENG), as Defence's Structural Integrity Centre of Expertise[3], performs the Defence NDT RL3 function (refer to Section 4.2.3 for further details).

2. Non-ADF DASR 145 MOs (i.e. contractor organisations): are responsible for appointing their own NDT RL3 personnel.

8.3.2.33 Notwithstanding the fact that Level 3 personnel may be qualified via EN4179 to establish and authorise methods, techniques, etc., this does not permit such personnel to deviate from the methods and techniques published in the Instructions for Continuing Airworthiness (ICA)[4] unless the ICA expressly permits such deviations (refer AMC 145.A.30(f)). Although it is recommended that Level 3 personnel have a role in NDT ICA deviations or changes (refer DASP Manual Volume 3 Section 7.2.5), NDT ICA deviations or changes must be approved in accordance with DASR 21.

Qualification of Personnel for Composite Repairs

8.3.2.34 **Recognised composite repair qualification standards.** Some types of composite structure repair are considered a specialised task and therefore personnel conducting those types of composite repairs require appropriate qualification in accordance with an officially recognised standard. DASA recognises SAE AIR4938 - Composite and Bonded Structure Technician Specialist Training Document for qualification of personnel who carry out composite repairs (refer AMC1 145.A.30(f)).

8.3.2.35 SAE AIR4938 Revision C includes requirements for both initial training and on-going certification. Superseded revisions of SAE AIR4938 do not include the requirements for ongoing certification, and also omit the training curriculum for bolted composite repairs. Superseded revisions of SAE AIR4938 should not be used without approval from DASA.

8.3.2.36 Organisations that seek to use an alternative to SAE AIR4938 for the qualification of composite repair personnel to conduct specialised composite repairs should apply to DASA with a proposed AltMoC. Organisations should note MEA405 is considered an introductory composites course only. DASA does not recognise MEA405 Cert IV AME Structures as a suitable equivalent to SAE AIR4938 for the conduct of specialised complex composite repairs. The complexity of composite repairs, and associated training requirements will vary for each platform. When suitable controls can be identified to ensure ongoing airworthiness a lower standard than SAE AIR4938 may be recognised as suitable for specific circumstances. Such controls could include:

1. type of structure being repaired

Superseded

2. type or complexity of composite repair being conducted

3. specific nature of training undertaken

4. experience of personnel

5. supervision requirements

6. OEM or aircraft type specific training

8.3.2.37 Applications to DASA to officially recognise alternate qualification standards should demonstrate that the alternate standard:

1. provides an equivalent level of training to SAE AIR 4938; or

2. is suitable in the context of the specific MO and the scope of the maintenance activities to be performed. In such cases, the application should clearly state the scope of the activities being performed, how the training is suitable for that scope, and the means by which the scope is to be controlled.

8.3.2.38 **Composite repair Personnel Training.** Prior to authorising staff to perform composite repairs, the DASR 145 MO should ensure the staff are trained and qualified in accordance with appropriate standards, SAE AIR49385 or approved AltMOC, for specialised composite repairs. Composite repair training and certification procedures for specialised and non-specialised composite repairs should be specified in the MOE.

8.3.2.39 DASR 145 MOs can utilise any training course that demonstrates compliance to the standard. Note that DASA-DAVENG, as Defence's Structural Integrity Centre of Expertise, conducts the certification (initial and re-certification) for all ADF DASR 145 MO staff who perform composite repairs (refer to DASP Manual Volume 3 Section 4.2.3 for further details).

8.3.2.40 DASR 145 MOs are responsible for establishing training and authorisation systems to ensure that personnel who conduct composite repairs are appropriately qualified. Further guidance for ADF and non-ADF DASR 145 MOs is as follows:

1. ADF DASR 145 MOs: The MO should verify that technicians hold a valid PMKeyS proficiency (refer DASP Manual Volume 3 Section 4.2.3) for composite repair prior to authorising them to conduct composite repairs within an ADF DASR 145 MO. MO authorisations should only remain valid for the validity period of the applicable PMKeyS proficiency.

2. Non-ADF DASR 145 MOs: The MO should document their certification/re-certification process in their MOE. The standard does not impose specific requirements on who can conduct certification.

Qualification of Personnel for Aircraft Welding

8.3.2.41 The following paragraphs are applicable to DASR 145 MOs that perform aircraft welding repairs.

8.3.2.42 Welding is used in the repair of critical and non-critical airframe and engine components within Defence. As a specialist task, personnel conducting welding operations must be appropriately qualified in accordance with officially recognised standards.

Superseded

8.3.2.43 CASA Civil Aviation Advisory Publication (CAAP) 33-1 (1) Aircraft manual welding: Approvals and qualifications provides information on how to apply for the initial issue or renewal of an aircraft welding authority under Civil Aviation Regulations. DASA has determined that a CASA welding authority, granted in accordance with CAAP 33-1 (1), is an appropriate qualification for Defence purposes.

8.3.2.44 **DASR Requirement.** DASR 145 MO that perform aircraft welding repairs must comply with DASR 145.A.30(f), which requires "Personnel who carry out any other specialised task shall be appropriately qualified in accordance with officially recognised Standards."

8.3.2.45 **Acceptable Means of Compliance.** DASA considers a CASA welding authority, granted in accordance with CAAP 33-1 (1), is an appropriate qualification in accordance with DASR 145.A.30(f).

8.3.2.46 Organisations choosing to utilise welders qualified in accordance with CAAP 33-1 (1) must:

1. Ensure technicians hold a valid Civil Aviation Safety Authority (CASA) issued aircraft welding authority prior to task authorisation.
2. Ensure technicians are only authorised to carry out those types of welding processes that are specified in the welding authority document.
3. Ensure MO authorisations only remain valid for the validity period of the CASA-issued welding authority (i.e. renewal is required every 2 years IAW CAAP 33-1 (1)).

Aircraft Welding Questions and Answers

8.3.2.47 **Q:** What does a DASR 145 MO need so that it can use welders with a CASA welding authority?

8.3.2.48 **A:** The DASR 145 is required to:

1. Identify the scope of welding repairs that it requires (that is included in its overall maintenance scope).
2. Update the DASR 145 MO Orders, Instructions and Publications (i.e. MOE and any other associated documentation), to show compliance to DASR 145.A.30(f) and implement the required management framework. The aircraft welding repair training and qualification requirements should be specified in the MOE.
3. Authorise technicians who have obtained CASA welding authority
4. Ensure that authorised staff maintain their competency and CASA welding authority currency.

8.3.2.49 **Q:** How does a person achieve CASA welding authority?

8.3.2.50 **A:** CAAP 33-1 (1) details the framework that CASA applies to provide a welding authority, which is granted to applicants that have:

1. Successfully completed a relevant Australian Quality Training Framework recognised course; and
2. Passed the welding testing set out in the CASA Welding Syllabus.

Superseded

8.3.2.51 Additional training may be required dependent on the specific work scope required by the DASR 145 MO. CASA will confirm any specific training requirements during the application for the welding authority.

8.3.2.52 DASR 145 MOs are responsible for organising CAAP 33-1(1) compliant renewal assessments for their personnel when required. There are a number of commercial organisations who employ CASA-authorised aircraft welding assessors (queries should be addressed to Contact us | Civil Aviation Safety Authority

8.3.2.53 CASA charge a fee to apply for the initial issue and for renewal of a welding authority. Applicants will also require a CASA Aviation Reference Number (ARN) prior to applying for a welding authority.

8.3.2.54 **Q:** Do welders require renewal of their CASA welding authority?

8.3.2.55 **A:** Yes. CAAP 33-1(1) requires a two yearly renewal in order to remain current. DASR 145.A.30(f) requirement that "Personnel who carry out any other specialised task shall be appropriately qualified in accordance with officially recognised Standards" requires a current CASA authorisation.

8.3.2.56 **Q.** Who covers the cost of gaining a CASA welding authority and renewal?

8.3.2.57 **A:** For:

1. Defence Maintenance Organisations, initial authority for ASTTECHs is covered within the Welder Aircraft Course at RAAFSTT, all subsequent renewal costs are to be supported though unit, or parent command funding.
2. Contractor Maintenance Organisations, refer to arrangements detailed in your contract.

8.3.2.58 **Q:** Can a non-welder supervise the conduct of a renewal welding assessment?

8.3.2.59 **A:** No. CASA requires that a CASA-authorised assessor supervise the conduct of welding examinations, and DASA has adopted this position.

8.3.2.60 **Q:** Can an organisation authorise welders with a different qualifications (in lieu a CASA welding authority)?

8.3.2.61 **A:** Yes. DASR 145 MOs who wish to use an alternative qualification to that stipulated in AMC1 145.A.30(f) should seek approval from DASA (as AltMoC).

8.3.2.62 For further information refer to the following:

1. For issues relating to the use of CASA welding authority within the DASR context please contact the DASA Desk Officer assigned to your organisation or email dasa.dca@defence.gov.au.
2. For queries related to gaining and maintaining CASA welding authority and the application of CAAP 33-1 (1), refer Contact us | Civil Aviation Safety Authority

8.3.3 Certification of Maintenance

Introduction

Superseded

8.3.3.1 This chapter provides guidance in relation to the Certificate of Release to Service (CRS) process for aircraft maintenance. The document aims to consolidate the applicable requirements from different sections of the DASR and describes the intended outcomes in relation to Sign-off & subsequent CRS at the completion of maintenance.

Background

8.3.3.2 Maintenance carried out on an aircraft, its systems and its components must be certified at completion and prior to its return to service. The instrument used to achieve this outcome is the CRS which must be issued before flight at the completion of maintenance. The CRS should contain as a minimum (AMC 145.A.50(b)):

1. Basic details of the maintenance that was carried out;
2. Date such maintenance was completed;
3. Identity of the organisation and person issuing the CRS; and
4. Limitations to airworthiness or operations, if there are any.

8.3.3.3 The requirements for CRS reside across multiple regulation subsections (DASR M and DASR 145) that collaboratively inform the regulated community of DASA's requirement. This chapter summarises the applicable requirements for CRS to assist the community in meeting the DASR.

Certification of Maintenance Responsibilities

Continuing Airworthiness Management Organisation responsibilities

8.3.3.4 CAMO responsibilities are described in detail within DASR M and include:

1. the CAMO is responsible for all activities aimed to determine the airworthiness status of the aircraft and to appropriately plan and coordinate maintenance.
2. ensuring that all maintenance requirements (Airworthiness Directives (AD), Aircraft Maintenance Program (AMP) requirements, defect rectification, etc...) are complied with and released by a DASR 145 Maintenance Organisation (DASR 145 MO) (or equivalent (M.A 708(b)).
3. the CAMO is responsible for planning and ordering all required maintenance and for ensuring that all ordered maintenance conducted by the DASR 145 MO or equivalent is complete and has a CRS. The CAME must explain how this is achieved.

DASR 145 Maintenance Organisation responsibilities

8.3.3.5 The DASR 145 MO (or equivalent) responsibilities are described in detail in DASR 145 and include:

1. the development of 'certification of maintenance' procedures that ensures all maintenance actions have been properly coordinated and the CRS is issued within a reasonable timeframe after the actual performance of the tasks;
2. issuing a CRS following maintenance; and
3. the CRS issued has to be recorded in the Continuing Airworthiness (CA) record system. This information shall be available to the aircraft captain (refer to DASR M.A.306 and

Superseded

AMC DASR M.A.306(a), who is ultimately responsible for accepting the aircraft before a flight takes place.

DASR 145 maintenance personnel responsibilities

8.3.3.6 The completion of maintenance requires two actions. They are:

1. a 'sign-off'; and
2. a CRS.

8.3.3.7 These two actions may be performed by a singular person or group of people dependent upon maintenance complexity, qualifications and authorisations.

Maintenance Authorisation

8.3.3.8 A person can only be authorised when they have met all the organisation's applicable qualification requirements, and only for the scope of work applicable to that qualification detailed in the DASR 145 Maintenance Organisation Exposition (MOE). A person can carry out maintenance and sign-off tasks that they have performed for a particular maintenance activity, and also be a support or certifying staff for another. As an example, a person may be authorised to sign-off on an aircraft type, and certifying and/or support staff on a different aircraft type.

8.3.3.9 DASR 145.A.35 (i) requires the maintenance organisation to nominate an individual[6] responsible on behalf of the maintenance organisation for issuing certification authorisations to certifying staff.

Sign-off Authorisation.

8.3.3.10 This is exercised by a competent (IAW AMC1 145.A.30(e)) and appropriately authorised person, that the maintenance has been completed to the standard required in accordance maintenance data specified in DASR 145.A.45.

8.3.3.11 AMC 145.A.65(b)(3)3 states that, in order to prevent omissions, every task or group of tasks should be signed-off by authorised personnel after its completion. It also states that a sign-off relates to one step in the maintenance process and is different from a 'release to service' (CRS). Importantly, a sign-off is a statement by the competent person performing or supervising the work, that the task or group of tasks has been correctly performed.

8.3.3.12 Furthermore, this AMC states that work by 'unauthorised personnel' (temporary staff, trainee/apprentice) must be witnessed by the authorised person before they sign-off. This means the authorised person signing off the task is responsible for the task.

8.3.3.13 IAW AMC1 145.A.30(e) personnel performing the sign-off, "shall be able to carry out tasks to any standard specified in the maintenance data, and will notify supervisors of mistakes requiring rectification to re-establish required maintenance standards".

8.3.3.14 Nevertheless, holding a sign off authorisation doesn't mean that the authorised person can sign off all tasks. It means that they can sign off tasks within the scope of their authorisation, depending on the qualifications, training and experience held, and in accordance with a procedure described in the MOE. Sign-off authorisation does not need to be restricted to singular tasks where the technician is required to/has demonstrated a degree of competence for that task. In contrast, the technician shall demonstrate competence in performing or supervising work applicable to their training and qualifications.

Superseded

8.3.3.15 Further details related to task completion and sign-off can be found in Chapter 8.3.2 – Performance of Maintenance.

Certificate of Release to Service

8.3.3.16 In executing the obligations of DASR 145.A.50(a) the organisation must have procedures in place that ensure:

1. the individual issuing the CRS is appropriately authorised to do so;
2. the individual issuing the CRS has ensured the maintenance has been carried out correctly using appropriate procedures IAW DASR 145.A.45(b); and
3. as a result of the maintenance conducted there are no defects which are known to 'endanger flight safety'.

8.3.3.17 A CRS is an attestation made by Certifying Staff by way of a certification signature after the completion of maintenance within their authorisation scope. The certification signature creates a 'certificate' and thus accountability, signifying that the maintenance or group of maintenance activities can be released to service. In Line maintenance the holder of a category A, B1 or B2 MAML may issue a CRS within the scope of their MAML and authorisation. In Base Maintenance the holder of a category C MAML is required to issue the CRS after the completion maintenance within the scope of their MAML and authorisation. Issue of a CRS in Component Maintenance can be done by appropriately authorised certifying staff, in this instance the individual does not need to hold a MAML.

8.3.3.18 There are two elements that need to be fulfilled by the authorised Certifying Staff before the issuance of a CRS is possible:

1. **Ensure.** Verify through oversight and management to ensure that the maintenance has been properly carried out; and
2. **Assessment.** Ensuring that no non-compliances which are known to exist that could 'endanger flight safety'

How do Certifying Staff "ensure that the maintenance ordered/tasked has been properly carried out"?

8.3.3.19 *Verification through the supervision of the maintenance task.* Certifying Staff ensure that maintenance has been properly carried out by ensuring maintenance has been conducted in accordance with procedures detailed in the MOE and through the correct use of maintenance data as specified in DASR 145.A.45.

8.3.3.20 This statement does not necessarily mean that authorised Certifying Staff have to personally perform or supervise[7] the whole process of every task, rather it is expected that Certifying Staff will (non-exhaustive list):

1. make sure that personnel assigned to perform the maintenance are authorised to sign-off the work for the appropriate scope of their authorisation;
2. coordinate the different tasks associated with the maintenance being performed; and
3. be available to support personnel in case of any mistakes or unexpected difficulties.

Superseded

8.3.3.21 Authorised Certifying Staff are responsible to determine the amount of involvement they require in order to be satisfied that the maintenance can be issued a CRS. Subsequently, the DASR 145 MO cannot limit Certifying Staff in terms of what level of supervision they put in place for the maintenance task. The DASR 145 MO may however set a minimum requirement.

How do Certifying Staff, "make an assessment that there are no non-compliances which are known to endanger flight safety"?

8.3.3.22 This is achieved by a cognitive process that assesses whether an endangerment to flight safety exists as defined within AMC1 DASR 145.A.50(a) against the physical outcomes of maintenance ordered by the CAMO. It does not require the DASR 145 MO to find or become responsible for hidden defects which are not expected to be discovered during the ordered maintenance. Defect assessments, including those endangering flight safety, must be clearly identified in the CA records system along with any corresponding limitations (if any) for further CAMO consideration.

Considerations for when the aircraft is left in a non-airworthy condition

8.3.3.23 In circumstances where after performing the maintenance ordered by the CAMO, the aircraft is left in a non-airworthy configuration, a CRS can still be issued for the maintenance that has been completed. The CRS can be issued as long as the incomplete maintenance or known defects are properly identified in the CA records system and communicated to the CAMO. For example, where the DASR 145 MO removes an engine for preservation (without installing a new one), or where the organisation performs an NDT inspection and identifies a crack outside limits.

8.3.3.24 The circumstances mentioned above (including defects affecting flight safety discovered during maintenance), can be properly addressed by using the provisions contained in DASR 145.A.50(c) and (e).

8.3.3.25 It is important to appreciate that a CRS does not mean that the aircraft is airworthy and ready for flight. A CRS is issued by the DASA 145 MO for the maintenance performed; the CAMO is accountable for ensuring that all CA requirements are met for the aircraft to undertake its assigned mission before releasing to the Operator.

When is a CRS issued?

8.3.3.26 IAW DASR 145.A.50(b) "A certificate of release to service shall be issued before flight at the completion of any maintenance". Subsequently, "any maintenance" can be interpreted in multiple ways, such as:

1. any maintenance task.
2. any combination of maintenance tasks.
3. any maintenance event.

8.3.3.27 Utilising the flexibility afforded by the "any maintenance" interpretation an organisation may choose one or more of the following systems of release to service:

1. Several CRS are issued, each one of them covering a different single maintenance task.
2. Several CRS are issued, each one of them covering a different group of maintenance tasks.
3. A single CRS is issued covering all the maintenance included in a maintenance event.

Superseded

8.3.3.28 The organisation must ensure that the CRS issued to the CAMO clearly identifies what maintenance is complete. If there is any incomplete maintenance, the CRS must clearly identify it in the CA records system and the corresponding limitations (if any). In each of the above cases, it is important to note that there is no change in the accountabilities of the individual authorised Certifying Staff in signing the CRS.

Who can issue a CRS in Line Maintenance?

8.3.3.29 Only appropriately authorised category A, B1 and/or B2 MAML holders can issue a CRS in Line Maintenance. The scope and responsibility of each license category is provided below.

Limited Certification Authorisation

8.3.3.30 By way of exception to paragraph 8.3.3.29, and in accordance with 145.A.30(j) 4, in unforeseen cases where the aircraft is grounded or operating away from a Main Operating Base, and where no appropriate certifying staff are available, the maintenance organisation may issue a limited certification authorisation to the aircraft commander on the basis of the flight crew licence subject to being satisfied the aircraft commander can accomplish the specified task to the required standard. These provisions shall be detailed in a MOE procedure.

One off Certification Authorisation

8.3.3.31 In unforeseen cases, where an aircraft is grounded at a location other than the main base where no appropriate certifying staff are available, the maintenance organisation may issue a one-off certification authorisation in accordance with 145.A.30(j)5.

Category A licence

8.3.3.32 The category A licence permits the authorised MAML holder, in a Line Maintenance environment only, to issue CRS for work that the licence holder has personally performed (‘sign off’) and within the scope of their certification authorisation.

8.3.3.33 A category A licence does not permit the authorised MAML holder to issue a CRS for the work of others, only for their own maintenance. While other personnel may be present and directed by the authorised A MAML holder in providing assistance during the performance of the maintenance task, the category A MAML holder may not undertake a supervisory role.

Category B licence

8.3.3.34 The category B1/B2 licence permits the authorised MAML holder to issue CRS, within the scope of their license and certification authorisation on maintenance that has been ‘signed off’ by themselves or other authorised personnel, within the scope of their license and certification authorisation.

Category C licence

8.3.3.35 The category C licence permits the authorised MAML holder to issue a CRS following Base Maintenance on aircraft carried out by a DASR 145 AMO. By definition, the DASR permits an authorised category C MAML holder to issue a single CRS for all maintenance activities pertaining to the aircraft during a single Base Maintenance visit.

8.3.3.36 Noting the complexity and the volume of the maintenance being carried out during a Base Maintenance activity, it is difficult for the authorised category C MAML holder to be across all tasks,

Superseded

to the extent required, to issue a CRS. For this reason, the authorised category C MAML holder may use Support Staff to enable the CRS to be issued.

8.3.3.37 The authorised category C MAML holder is accountable to ensure that all required maintenance that has been ordered, has been carried out properly, that there are no non-compliances which are known to endanger flight safety and any outstanding or incomplete maintenance has been identified and the CAMO notified before issuance of the CRS.

Support Staff

8.3.3.38 Support Staff are authorised B1 and B2 MAML holders. The role of Support Staff during Base Maintenance is to conduct, within the scope of their MAML and authorisation, activities such that it can be communicated to the authorised category C MAML holder that:

1. the maintenance has been performed properly;
2. that any defects found during the course of maintenance are recorded in the CA records; and
3. that any outstanding or incomplete maintenance is identified and recorded in the CA records.

8.3.3.39 In essence, Support Staff are oversighting and managing allocated maintenance tasks within Base Maintenance in support of the authorised category C MAML holder. Subsequently, the DASR 145 MO must have a mechanism in place and articulated in the MOE WRT how Support Staff communicate to the category C MAML holder when the CRS can be issued.

8.3.3.40 An authorised category C MAML holder may not require Support Staff if they also hold the required B1/B2 license scope and subsequent authorisation with regard to the Base Maintenance being performed. The authorised category C MAML holder in this instance can issue the CRS without the use of additional Support Staff. The procedures with respect to an authorised category C MAML holder acting as their own support staff must be articulated in the MOE.

Summary of Maintenance Authorisations

8.3.3.41 The following figure summarises the different types of authorisations an organisation will require and the scope of work against which they may authorise their staff. It is the DASR 145 that performs and certifies maintenance requested by the DASR M.

Superseded

Type of Authorisation	Line Maintenance		Base Maintenance		Component Maintenance	
	Sign Off*	CRS	Sign Off*	CRS	Sign Off*	CRS* See note 1
Technician (non MAML holder)	✓	[redacted]	✓	[redacted]	✓	✓
Non Type Rated B1/B2 MAML Holder	✓	[redacted]	✓	[redacted]	✓	✓
Type Rated B1/B2 MAML Holder	✓	✓	✓	Support Staff Does not issue CRS See note 2	✓	✓
A MAML Holder	✓	✓ Task Authorised See note 3	✓	[redacted]	✓	✓
C MAML Holder	✓	When Exercising B MAML	✓	✓	✓	✓
Foreign Trained Technician	✓	[redacted]	✓	[redacted]	✓	✓

* Denotes No MAML Required therefore all trained technicians may be authorised to perform maintenance and Sign Off. Authorisation QT&E requirements to issue a CRS in Component Maintenance is determined by the AMO
Note 1: Component CRS may be issued through ARC (Form 1) or via process detailed in the MOE
Note 2: This is not a certification activity. Type Rated B1/B2 Technician may be authorised to confirm tasks carried out to the required standard (i.e.: attest) for maintenance personally conducted or conducted by other technicians, to the scope of their B MAML
Note 3: May be Task Authorised to the scope of the A MAML for maintenance personally conducted

Figure 1 Summary of Maintenance Authorisations

8.3.4 Acceptance of Aircraft Components

Introduction

8.3.4.1 This chapter provides additional guidance on what constitutes a DASR Form 1 or recognised equivalent and outlines how DASR 145 Approved Maintenance Organisations (AMOs) should assess the suitability of component documentation to ensure such components are eligible to be fitted to Defence registered, type-certified products.

8.3.4.2 The Defence Aviation Safety Regulations (DASR) require Approved Maintenance Organisations (AMOs) to ensure the airworthiness[8] of components and materials prior to fitment to Defence registered, type-certified products. To fulfil this requirement, the AMO must ensure that components are accompanied by appropriate documentation attesting to the legitimacy of the component's maintenance or production history. This is underpinned by the regulatory requirement for the AMO to obtain a DASR Form 1 or equivalent documentation prior to fitment of such components.

8.3.4.3 This chapter relates to the acceptance of new and used aircraft components, which are listed by the appropriate design organisation as eligible for installation in/on a product and included in the design data approved by the Authority[9]. The term components broadly covers any product (other than complete aircraft), part or appliance that is, or is intended by its manufacturer to be, a part of or used in operating an aircraft in flight, or is installed in or attached to a product. This may include any self-contained part, combination of parts, assembly, subassemblies or units, which perform a distinctive function necessary to the operation of the airframe, engine, or propeller, or may include any other instrument, mechanism, equipment, apparatus, software or accessory, including communications equipment.

8.3.4.4 Although alternate artefacts can be consumed by a DASR 145 Approved Maintenance Organisation (AMO), DASA requires the relevant CAMO to seek approval for, and manage, the ongoing validity of alternate artefacts for their respective platforms. Further detail on alternate artefacts can be found in Chapter 8.2.3 – Alternate Artefacts.

Superseded

Products, parts and appliances

8.3.4.5 To align with the European Military Airworthiness Requirements (EMAR), the DASR has replaced the term Aeronautical Product with separate definitions for products, parts and appliances. The term 'components' in this document will be used interchangeably with products (other than complete aircraft), parts and appliances for simplicity.

Acceptance of components

8.3.4.5 The AMO is responsible for ensuring the 'eligibility for fitment' of components to type-certified products prior to installation[10].

Eligibility for fitment

8.3.4.6 A component is eligible to be fitted to a type-certified product, or another part or appliance if:

1. the fitting of the component is permitted by the approved design[11] for the product, part or appliance of the higher assembly;
2. the component is in a serviceable condition for safe operation; and
3. the component has been appropriately released or returned to service[12].

8.3.4.7 The AMO should have procedures for the acceptance of components and material, to ensure that the supplied components and material are in satisfactory condition and eligible for fitment. Furthermore, the AMO is responsible for ascertaining the traceability of components and material to their original or authorised source, including the maintenance or production and supplier source, where applicable. Therefore, it is the responsibility of the installer to request the appropriate documentation which establishes the airworthiness status and traceability of components and materials.

8.3.4.8 In determining whether a component is eligible for fitment, the AMO should conduct the following:

1. a physical inspection of components and/or material (including a check for any obvious physical damage and verification that part numbers, serial numbers, lot and/or batch numbers, etc. match the accompanying documentation; and
2. a review of accompanying documentation and data, which should be acceptable IAW DASR 145.A.42.

8.3.4.9 Particular caution should be exercised when the origin of components and materials cannot be established or when the origin is in doubt.

8.3.4.10 The flowcharts provided at Appendix 1 and Appendix 2 illustrate the process for determining the eligibility for fitment of new and used aircraft components, respectively, to type-certified products, or other parts and appliances.

Acceptance of Aircraft Components

What is an Authorised Release Certificate?

Superseded

8.3.4.11 An Authorised Release Certificate (ARC) is a document issued by an entity that has the applicable privilege and attests that a new or used component has been produced or maintained IAW the approved design data/standard, modification standard or applicable maintenance data[13].

8.3.4.12 An acceptable ARC is either:

1. DASR Form 1, or equivalent (refer DASA recognition website); or
2. an 'alternate artefact' accepted by DASA.

8.3.4.13 An acceptable ARC must show traceability back to a recognised CAA/MAA. In general, an Authorised Release Certificate must provide evidence of (where applicable):

1. the name and address of the issuing organisation;
2. the name of the recognised CAA/MAA;
3. evidence that the issuing organisation is working within the recognised authority's system (e.g. organisation approval reference);
4. details of the component(s): description, part number, serial number(s) and/or batch number, as applicable;
5. for used service-life-limited components, complete traceability to the component's service history;
6. a clear indication of the current airworthiness status (serviceability) of the component at the date of issue;
7. a release statement made by a suitably authorised person within the production or maintenance organisation;
8. the name, signature (or electronic equivalent) and approval number (where applicable) of the person making the release statement;
9. for components released from maintenance, a statement that the maintenance was carried out in accordance with the recognised authority's regulation/policy; and
10. for components released from production, a statement that the component(s) was manufactured in conformity with approved data.

8.3.4.14 The ARC does not constitute authority to install the item on a particular product or component, but provides evidence that assists the AMO in determining the item's eligibility for fitment. Furthermore, an ARC cannot be used for the release of complete aircraft.

8.3.4.15 The ARC serves as the official certificate for components from the manufacturer/AMO to users. It should therefore be used for the transfer of components between different airworthiness systems or AMOs. A delivery or shipping note does not constitute an ARC.

8.3.4.16 It should also be noted that a mixture of new and used items is not permitted on the same ARC. Likewise, a mixture of items certified in conformity with 'approved data' and to 'non-approved data' is not permitted on the same certificate.

When is an Authorised Release Certificate required?

Superseded

8.3.4.17 An ARC is necessary for the release to service of either new or used components. The certification of new components is performed IAW DASR 21.A.307, whereas the certification of maintenance on used components is performed IAW DASR 145.A.50.

8.3.4.18 A component is eligible for fitment to a type-certified product when the component is in a condition for safe operation (i.e. serviceable) and accompanied by an ARC. An ARC helps the AMO to determine the airworthiness approval status for components and therefore eligibility for fitment.

8.3.4.19 **Release of new components following production**[14]**.** The component manufacturer is responsible for producing the ARC following the production of a new component. The purpose of the Authorised Released Certificate for new components is to certify that the item has been manufactured in conformity to approved design data and marked in accordance with DASR 21, Subpart Q. An ARC is required for components produced under:

1. type-certificate or supplemental type-certificate and changes thereof;
2. Production Organisational Approval;
3. Parts Manufacturing Approval (PMA) / European Part Approval (EPA)[15]; or
4. AUSMTSO authorisation.

8.3.4.20 Such components will normally be listed within the OEM furnished Illustrated Parts Catalogue (IPC) or Illustrated Parts Breakdown (IPB).

8.3.4.21 **Release of used components following maintenance**[16]**.** The purpose of the ARC for used components is to release components to service after off-aircraft maintenance. The ARC is issued by the AMO and must be within their scope of approval

8.3.4.22 Issuing an ARC following maintenance is an attestation that all maintenance is complete (except for deferred defects agreed to by the CAMO), and there are no non-compliances which are known to endanger flight safety. Any incomplete maintenance ordered/tasked should be clearly stated in the ARC when such non-compliances (i.e. deferred maintenance) are within the approved aircraft limitations.

8.3.4.23 Only personnel authorised by the DASR 145 may issue a DASR Form 1 Authorised Release Certificate following off-aircraft maintenance. Where component maintenance is subcontracted to another maintenance organisation[17], the ARC may be issued either at the:

1. non-DASR 145 contractor/tasked maintenance organisation[18]; or
2. AMO facility by staff holding a certification authorisation, as appropriate[19] .

8.3.4.24 Further, for used components that are service life-limited the ARC shall contain, or be accompanied by, an updated maintenance status with reference to this status in Block 12 of the certificate. In addition to configuration data (modifications, repairs, ADs and SBs), the status should contain information on the utilisation, particularly accumulated service life in relation to component life-limits.

When is an Authorised Release Certificate not required?

8.3.4.25 An ARC is not always required after component production or maintenance. However, documented evidence of conformity to approved design or certified material specification must be

Superseded

obtained prior to fitment to a type-certified product. Such evidence must be traceable back to the organisation that manufactured or maintained the component.

New Components.

8.3.4.26 **Specific equipment.** Components which have been incorporated into the type design as specific equipment[20] and therefore have been shown not to adversely affect the airworthiness of the aircraft and not subject to recognised airworthiness standards[21] do not require an ARC. The CAMO should provide installation instructions that authorise the component's return to service requirements. Examples of specific equipment may include commercial-off-the-shelf (COTS) 'industry supply' equipment. This may include Commercial Parts such as cabin reading light bulbs, curtain rings, sink valves, etc.

8.3.4.27 **Standard Parts.** Standard Parts must be supplied with a CoC referring to the specified standard, the manufacturer and supplier source, the batch/lot number and, if applicable, the shelf life (including expiration date) and storage conditions. Standard Parts are specified within the manufacturer's IPC/IPB or maintenance data. Examples of Standard Parts include, but are not limited to, those conforming to National Aerospace Standard (NAS), Air Force/Navy (AN) Aeronautical Standard, Society of Automotive Engineers (SAE), Aerospace Standard (AS), Military Standard (MS), etc.

8.3.4.28 A part is no longer considered a Standard Part if it is used in a critical application that imposes qualification or quality control requirements beyond the published standard specification. In such a case, the OEM should allocate its own part number reference, and these parts would require an ARC.

8.3.4.29 **Materials.** Both raw and consumable materials, used in the fabrication, maintenance, servicing or operation of an aircraft or component, may be accepted without an ARC[22]. Such materials are required to meet the specification detailed in the approved design, and have appropriate traceability.

Used Components.

8.3.4.30 **Restricted Parts manufactured by the AMO.** Where a maintenance organisation has been granted approval by the Authority to fabricate a restricted range of parts to be used by that maintenance organisation in the course of overhaul, maintenance, modifications or repair within its own facility, such parts do not qualify for certification via an ARC[23].

8.3.4.31 **Unserviceable Parts.** An ARC should not be issued for any unserviceable components, except where such items are undergoing a series of maintenance processes at multiple AMOs. In this case, the receiving AMO requires an ARC to accept the component prior to subsequent maintenance.

8.3.4.32 **In-house release.** An ARC may not be required in the case where an AMO maintains a component for its own use and there is an approved alternative in-house release document as described in the AMO's MOE.

8.3.4.33 **Aircraft on Ground – other than at Main Operating Base (MOB).** When an aircraft is grounded at a location other than the MOB due to the non-availability of a component with an appropriate release certificate, it is permissible to temporarily fit a component with an alternative release certificate, subject to CAMO approval. The component must be removed at a time specified by the CAMO, unless the appropriate release certificate has been subsequently obtained, prior to removal of the component.

Superseded

What do I do with a completed Authorised Release Certificate?

8.3.4.34 The completed ARC becomes part of the technical record for the component to which it relates, and eventually will become part of the technical record of the higher assembly or product on which that component is installed. The certificate is therefore subject to all applicable regulatory requirements related to maintenance and technical records .

When are components not eligible for fitment?

8.3.4.35 A component is not eligible for fitment on a type-certified product where it is known or suspected to have any of the following:

1. Discrepancy between the component's identifying markings (as required by DASR 21 subpart Q) and its accompanying documentation;
2. Non-conformances between the component's physical characteristics and its approved design data/specification or applicable maintenance data (i.e. unacceptable or questionable quality);
3. Damage (due to packaging, etc.) or unserviceability;
4. Absence of or incomplete or inappropriate release documentation to determine the airworthiness status or eligibility for fitment; or
5. Unknown, suspect or unverified origin of the component (i.e. has not or may not have been manufactured or maintained by an approved source).

8.3.5 – Flexibility Provisions for Maintenance Organisations

Introduction

8.3.5.1 This chapter provides guidance on the application of DASR GR.80 Flexibility provisions within the specific context of maintenance organisations. To meet an operational need, there may be circumstances where the authorisation of non-MAML staff in certifying or support staff roles is necessary. These circumstances also extend to where it is not practical for foreign-trained personnel to obtain a MAML in the time available (e.g. short-term secondment).

8.3.5.2 Currently, the scope of guidance provided is related to the authorisation of non-MAML staff as certifying and support staff for on-aircraft maintenance.

DASR GR.80 Flexibility provisions

8.3.5.3 **Provisions.** DASR GR.80 *Flexibility provisions* includes two different avenues to enable regulated entities to deviate from the requirements of applicable DASR. These provisions are available subject to an operational need, where compliance with applicable DASR would impact the ability to meet operational objectives. The two avenues are:

1. **Achieve an equivalent level of protection under GR.80(b).** DASA may approve the deviation using the applicable DASR as the safety standard against which the deviation is assessed and approved.
2. **Equivalent level of protection not demonstrated, but supported by the application of sound risk management, under GR.80(c).** DASA may *allow* the deviation but

Superseded

cannot approve it due to the absence of any established safety standard against which to approve.

8.3.5.4 **Second-order effects.** The use of DASR GR.80 provisions, including GR.80(b) which requires an equivalent level of protection, has the potential to create unintended second-order safety impacts due to the interlinked nature of the DASR (a system of systems). In each instance, the regulated entity seeking to apply these flexibility provisions should identify and address any such impacts.

8.3.5.5 **Increased safety risk.** The application of GR.80 flexibility provisions by service providers, such as maintenance organisations, may result in increased Aviation Safety risk for the relevant Military Air Operator (MAO). Affected MAOs must apply additional due diligence to activities utilising the flexibility provision for the period in which that flexibility provision is in effect, commensurate with the residual risk level. Additionally, GR.80 application does not absolve the organisation of its obligation to continue to comply with all other applicable DASR. Where GR.80 flexibility provisions have been appropriately applied, DASA will not issue a finding for non-compliance against specific DASR clauses covered by the provision.

8.3.5.6 **Remediation.** Any flexibility provision should only be continue to be in place while:

1. the operational need continues to exist; and
2. compliance with relevant DASR would continue to impact operational objectives.

8.3.5.7 **Application to DASA.** DASA expects that proposed implementation of flexibility provisions to be detailed within, or referenced by, draft amendments to the MO exposition submitted under a DASR Form 2 Application for DASR 145 and DASR M Subpart G Approval.

8.3.5.8 **Application by Defence Industry**. Defence Industry organisations may only enact DASR GR.80 provisions through their relevant Military Air Operator (MAO) as the Risk Management Authority. In the event that a MAO's operational need requires a Defence Industry MO to exercise flexibility provisions, Defence Industry would support the MAO through provision of technical considerations and controls.

Use of flexibility provisions to authorise certifying and support Staff

8.3.5.9 **Background.** As discussed in chapter 8.3.3, the DASR requires[24] that certifying staff and support staff for on-aircraft maintenance hold an appropriate MAML. DASA MAMLs are issued when an applicant provides to DASA the relevant evidence, from a DASR 147 Maintenance Training Organisation (MTO) or recognised equivalent, that basic knowledge, basic experience and applicable type training requirements have been met. Gaps in basic knowledge result in MAML exclusions – mostly aircraft system based (e.g. propulsion systems, electrical systems) – and preclude a MAML holder from issuing a CRS or acting as support staff on the excluded aircraft systems.

8.3.5.10 **Granting of MAMLs to foreign-trained personnel.** Provisions within the DASR 147 enable foreign-trained maintenance personnel to obtain a MAML by undergoing an equivalency assessment where time permits. This assessment is conducted by an approved or recognised 147 MTO and will consider knowledge and experience as well as relevant type training.

8.3.5.11 **DASA assurance of procedures and outcomes.** DASA will conduct independent safety assurance differently for DASR GR.80(b) and GR.80(c), commensurate with the level of risk exposure. However, DASA assurance for both DASR GR.80(b and GR.80(c) involves the prior assessment of the procedure used to authorise non-MAML staff in certifying or support staff roles. Where uncertainty

Superseded

exists as to the procedure's applicability or suitability in a particular instance, the DASR 145 MO (through the CAMO, on behalf of the MAO), should seek advice from DASA.

8.3.5.12 Common guidance. The maintenance organisation may choose to utilise a single procedure to address both GR.80(b) and GR.80(c) scenarios. However, the organisation must make it clear how it will meet the different aviation safety performance outcomes. In both scenarios, where practicable, the procedure should require DASA 145 MOs to seek assistance from the ADF DASR 147 MTO to assess training deficiencies and inform decisions.

DASR GR.80(b) equivalent level of protection

8.3.5.13 An application to use the GR.80(b) equivalent level of protection provision must articulate how the procedure to authorise non-MAML staff in certifying or support staff roles will provide an equivalent level of protection to that which would otherwise be attained through compliance with the relevant DASR. If DASA agrees that an equivalent level of protection is achieved through the procedural outcome, DASA will approve the exception from the DASR. DASA will apply assurance to the ongoing application of the procedure(s) through routine oversight unless the DASR 145 MO, through the CAMO (on behalf of the MAO), requests DASA independent assurance prior to the issue of an individual authorisation.

8.3.5.14 An application to DASA for approval of the GR.80(b) equivalent level of protection flexibility provision should describe a method for implementing risk controls equivalent to those inherent in a DASA MAML (e.g. categorisation, exclusions and type ratings). The procedure should require assessment of individual competency, through knowledge and experience considerations, via:

1. an approved foreign nation/service comparison process; or
2. suitable evidence against each relevant module of DASR 66 Appendix I I and relevant chapters of DASR 66 Appendix III, to the appropriate training level, for the scope of the authorisation to be given.

8.3.5.15 Utilisation of DASR GR.80(b) is likely to be complex and time-consuming, requiring detailed analysis that may not be suitable to support agile operations.

DASR GR.80(c) risk management

8.3.5.16 For DASR GR.80(c), the procedure to authorise non-MAML staff in certifying or support staff roles must demonstrate that a credible and defensible level of military aviation safety performance will be maintained through sound management of aviation safety risks arising through the deviation from applicable DASR. DASA will not approve a GR.80(c) procedure but will allow its use subject to the requirement that all instances of the organisation applying the procedure are reported to DASA at the first practical opportunity. The DASA assurance role provides an independent assessment of the credibility and defensibility of the risk-based decision that is made by the organisation.

8.3.5.17 Any application to DASA to implement a GR.80(c) *risk management* approach should address the following:

1. The seven-step risk management guidance provided in Annex A and the format and means in which it will be submitted to DASA.
2. The necessary interfaces to the MAO such that any Decisions to Proceed are appropriately documented.

Superseded

3. Where operational needs allow for prior assurance by DASA, the relevant DASA desk officer should be provided with the output of the procedure, to review prior to enactment.

4. Where operational needs do not allow for prior assurance by DASA, the procedure for authorising non-MAML certifying or support staff may still be enacted by the DASR 145 AMO (through the MAO). Retrospective DASA assurance will be applied where an ongoing operational need supports continued application of the flexibility provision.

Annex:

(a) Contextualised guidance for seven-step risk management

8.4 Aircraft Maintenance Licencing

8.4.1 Introduction and Background

Introduction

8.4.1.1 This chapter provides additional guidance on the Military Aircraft Maintenance Licence (MAML), and for those individuals applying for a "personnel authorisation[25]" under DASR 66, how to comply with DASR 66 requirements.

8.4.1.2 DASR 66 establishes the regulations required to be met by Aircraft Maintenance Training Organisations (AMTO), responsible for either Basic or Type Training, to be eligible for a DASR Military Aircraft Maintenance Licence (MAML).

8.4.1.3 For the purpose of this chapter additional guidance does not include information already presented at Volume 2, but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3. Further information regarding DASR 147 is located within Volume 3, chapter 8.5.

Background

8.4.1.4 During the DASR 66/147 transition, DASA provided a number of interim arrangements which allowed the current workforce to apply for DASR 66 MAMLs, including acceptance of existing Military Aircraft Type Rating training until the DASR were fully implemented.

8.4.1.5 The DASR 66.A.70 conversion provisions were based on the Australian National Competency Training and Assessment framework. These provisions were applied to staff who held valid certifying qualifications prior to the date of these regulations being introduced.

8.4.1.6 All DASA MAMLs are based on objective evidence of an individual's Qualification, Training and Experience (QTE), against the criteria in Appendix I to DASR 66 Basic Knowledge Requirements. DASA has mapped the EMAR syllabus (Appendix I to DASR 66) to associated Australian nationally adopted Competency Based Training and Assessment Units of Competency (UoC), qualifications and non-vocational education and training (VET) service specific training. This mapping resulted in providing a DASA Category A1, A3, B1.1, B1.3 or B2 MAML, with or without exclusions and inclusions.

8.4.1.7 The Defence Airworthiness Safety Regulations (DASR) 66 - Military Aircraft Maintenance Licencing provides Defence personnel who hold a MAML the privilege to issue Certificate of Release

Superseded

to Service (CRS). This regulation is based on the European Military Airworthiness Requirements Part 66 (EMAR Pt 66), but adapted to suit the Australian military maintenance environment.

8.4.1.8 DASR 66 identifies the skills and knowledge requirements for each licence category (refer MAML Categories below) by syllabi. DASA have mapped initial trade training and technical, promotion-related courses (eg Aviation Technician Supervisor Course, LSATT, CPL SUBJ 4 etc) against these syllabi.

8.4.1.9 The MAML is an attestation the holder has met the DASR 66 knowledge and experience requirements, but does not entitle the holder to issue an aircraft CRS until they are authorised within a DASR 145 Maintenance Organisation (MO) to exercise these privileges.

8.4.2 MAML Categories, Limitations and Extensions

DASR 66.A.3 - MAML Categories

8.4.2.1 There are four basic licence categories:

1. The Category A licence is a non-type rated licence for minor scheduled and unscheduled maintenance permitted within Line Maintenance (relevant tasks will be detailed in the relevant DASR 145 MOE). The privileges of a Category A licence are not applicable to Base Maintenance.

2. Category B1 - permits certification privileges for scheduled and unscheduled airframe, engine, structures, mechanical systems and electrical maintenance for more complex Line Maintenance activity. The B1 MAML also permits minor avionics maintenance (eg 'black box' changes, where no specialised support equipment is required). The B1 MAML allows for authorisations as support staff within Base Maintenance.

3. Category B2 - permits certification privileges for scheduled and unscheduled complex avionics and electrical Line Maintenance activities and allows the holder to act as B2 support staff within Base Maintenance.

   Note: The Category B1 and B2 licences are aircraft type-rated licences and permit the holder to certify the release to service only of aircraft types that are endorsed as ratings on their licence.

4. Category C - is required for personnel who issue the CRS following Base Maintenance.

   Note: The Category C licence is an aircraft type-rated licence and permits the holder to issue the CRS of an aircraft following Base Maintenance only. GM to DASR 66.A.20(a) para 3 provides more detail.

DASR 66.A.50 – Limitations and DASR 66.A.52 – Extensions

8.4.2.2 All MAMLs are managed in accordance with the DASA 66 MAML Exclusion Inclusion & Endorsement Manual, available on the DASA Website.

8.4.2.3 The DASA 66 MAML Exclusion, Inclusion & Endorsements Manual outlines the required competency details and provides general guidance that reflects DASR 66.A.20 privileges against the S1000D system of standard numbering to specify particular Systems and Sub-systems.

8.4.2.4 Exclusions (Limitations) introduced on a MAML are omissions from an individual's certification privileges, indicating that the licence holder shall not issue a CRS in

Superseded

8.4.2.5 Line Maintenance or act as B1 or B2 support staff in Base Maintenance if maintenance related to that exclusion has occurred.

8.4.2.6 Inclusions (Extensions) introduced on a MAML are additional privileges to an individual's certification privileges, indicating that the licence holder may issue a CRS or act as B1 or B2 support staff if maintenance related to that Inclusion. Noting that additional military specific systems Inclusions can be achieved through completion of all required competencies & a type course (where appropriate) which incorporates S1000D Air-vehicle system basic knowledge requirements into the type syllabus.

8.4.2.7 The S1000D is a numerical technical classification of all the systems and sub systems on an aircraft, which is largely used in aircraft engineering and maintenance, and helps to standardise data across aircraft manufacturers and programs to facilitate improved maintenance and logistics.

8.4.3 MAML Applications

DASR 66.A. 10 - Application

8.4.3.1 Refer to DASPMAN Volume 3, Chapter 5.3 – Annex W – MAML for details.

Foreign Licence Applications

8.4.3.2 Military Aviation Authority/National Aviation Authority's (MAA/NAA) have differing training requirements for aircraft maintenance personnel based upon their sovereign regulatory maintenance framework. Therefore, there may be considerable differences in each country's licence privileges, regulations, assessment methods/framework and specific guidelines; resulting in gaps and difficulties to enable direct conversion of a foreign MAA/NAA issued licence to a DASA MAML.

8.4.3.3 Australia has nationally adopted competency-based training and assessment in lieu of EASA/ EMAR basic knowledge syllabus and examinations, which results in attainment of Units of Competency (UoC), which in turn lead to Aeroskills qualifications.

8.4.3.4 DASA has mapped these Aeroskills Mechanical and Avionics UoC against DASR 66 syllabi requirements to provide either a Category A, B1.1, B1.3 or B2 MAML, with/without exclusions and inclusions.

8.4.3.5 To enable Non-Australian competencies/qualifications to be used to apply for a MAML, a 147 Maintenance Training Organisation (MTO) RPL assessment must be performed using objective evidence to provide an individual with an RPL report clearly outlining the required theory and practical training requirements that have been met.

Aging Qualifications

8.4.3.6 All MAML applications will need to meet the following requirements:

1. Any grandfathering formally recognised and utilised for a MAML assessment during the transitional period will be honoured and no further action is required by the individual;

2. IAW DASR 66.A.25 any training courses and examinations shall be passed within 10 years prior to the application for:

   i. a MAML; or

Superseded

ii. an addition of a category or subcategory to a MAML; or

iii. the removal/addition of a DASA exclusion/inclusion to a MAML.

3. Qualifications 10 years or older now come into question, as not meeting the requirements of 66.A.25(b). Any of these qualifications provided as evidence for a MAML application (initial or update), will generally not be accepted unless they have been assessed and converted against DASR 66.A.25 Basic knowledge requirements by a DASA/CASA approved 147 Organisation;

4. DASA acknowledges that there may be individual unique circumstances where aging qualifications could be considered in more detail – specifically where the time and effort required for conversion to contemporary standards, by a DASA/CASA approved 147 Organisation, may not be reasonable. To support this, where aging qualifications (>10yr) are used as evidence for a MAML application (initial or update), the applicant must provide detailed justification (with supporting evidence) on why the aging qualification should be considered. This should include relevant work history for the applicant (including objective evidence of previous maintenance authorisations) and detail any factors that support the acceptance of aging qualifications without conversion. MAML applications, with aging qualifications, will be rejected if no supporting justification is provided.

5. Where there is any doubt or ambiguity regarding the requirements for a MAML, contact DASA at dasa.dcadasr66@defence.gov.au, and provide detailed evidence for DASA's consideration

8.4.4 MAML Basic Knowledge and Experience Requirements

DASR 66.A.25 – Basic Knowledge Requirements

8.4.4.1 A MAML applicant must have a demonstrated level of knowledge relevant to the MAML privileges to be granted, and in order to obtain a Category A (Line Maintenance only), B (Line & Base Maintenance) or C (Base Maintenance only) MAML. An applicant requires "Basic Knowledge" in the appropriate subject modules IAW Appendix I toDASR 66.

DASR 66.A.30 – Basic Experience Requirement

8.4.4.2 In addition to Basic Knowledge requirements (DASR 66.A.25), a MAML applicant must also have a demonstrated level of Basic Experience of the requested licence category (DASR 66.A.30). An applicant requires:

1. The practical experience must be gained in the real environment of military aircraft maintenance;

2. Initial employment training (IET) delivered to trainees of all three ADF Services provides the minimum practical training detailed in Appendix I to DASR 66. Therefore, maintenance personnel who have completed their IET are eligible for a category A licence after six months of practical training, following completion of specific aircraft task training in accordance with DASR AMC 66.A.20(b), and having achieved syllabus Module 10 requirements.

8.4.4.3 Experience shall be acquired within 10 years preceding the initial category or subcategory.

Superseded

DASR 66.A.40 - Continued validity of the MAML

8.4.4.4 All MAMLs are perpetual and will remain valid unless suspended, surrendered or revoked.

8.4.4.5 DASA has a process that allows it to assess breaches or suspected breaches of the conditions that a MAML was issued and take appropriate action. Contact DASA at DASA.DCA DASR66 for more information.

8.4.5 MAML Military Aircraft Type Rating Endorsements

DASR 66.A.45 - Military Aircraft Type Rating

8.4.5.1 In order to enact the privileges of a DASR 66 Category B (Line and Base Maintenance) MAML, MAML holders must have a specific Military Aircraft Type Rating (MATR) endorsement and be authorised by the DASA 145 nominated person (generally the Quality Manager) to operate within their approved quality system. In order to obtain a type rating, an applicant requires:

1. Type Training (Theory & Practical) (DASR 66.A.45): and
2. On the Job Training (OJT) for first Type Rating (AMC 66.A.45)

Military Aircraft Type Ratings Guidance

8.4.5.2 Refer to Chapter 8.5.8 – Military Aircraft Type Ratings for further details.

Expectations

8.4.5.3 All MATR applications must confirm that any OJT requirements are completed IAW Appendix III to DASR 66.

8.4.5.4 All MATR type training courses must be started and completed within the 3 years preceding application for the MATR.

8.4.5.5 The "Basic Training Course" requirements stated in 66.A.30 and 147.A.200 must be met before individuals are eligible for the relevant category MAML.

8.4.5.6 OJT requirements stated in Appendix III to DASR 66 must be met for first MATR in licence subcategory. Evidence of completion must be provided with the MAML endorsement application.

8.4.5.7 DASA may accept practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 – Northrop Grumman for applications for P-8A Poseidon or E-7A Wedgetail.

8.4.6 MAML Suspension or Revocation

8.4.6.1 On receipt of notification of fraudulent or unsafe behaviour by a MAML holder, DASA will assess the information to determine what action, if any, is required.

Notice to Show Cause

Superseded

8.4.6.2 Should DASA determine that a suspension or revocation of a MAML be warranted, then a Notice to Show Cause (NTSC) will be issued to the MAML holder. For procedural fairness, the affected MAML holder will be provided the reasons and evidence supporting the decision to issue a NTSC. The NTSC provides the MAML holder the opportunity to respond to the proposed suspension or revocation of their MAML.

8.4.6.3 The response to the NTSC will be assessed by DASA to determine if:

1. No action required; or
2. MAML will be suspended; or
3. MAML will be revoked.

MAML Suspension or Revocation

8.4.6.4 DASA will notify the MAML holder, and the organisation for which the MAML holder held the authorisation, of the suspension or revocation of the MAML. DASA also publishes a list of suspended MAML on the Military Aircraft Maintenance Licencing page on the DASA website.

Review of Suspension or Revocation

8.4.6.5 The organisation for which the MAML holder held the authorisation, can request DASA to review the decision. The request for review should include the results of any internal investigation and any other relevant information to support the request for a review.

8.5 Aircraft Maintenance Training Organisations

8.5.1 Introduction and Background

Introduction

8.5.1.1 This chapter provides additional guidance on the Defence Airworthiness Safety Regulations DASR 147 – Aircraft Maintenance Training Organisations (AMTO), to assist those organisations applying for a DASR 147 approval on how to comply with DASR 147 requirements.

8.5.1.2 DASR 147 establishes the regulations required by an AMTO responsible for either Basic or Type Training of DASR 66 Engineers and Aircraft Maintenance Technicians to be eligible for a Military Aircraft Maintenance Licence (MAML).

8.5.1.3 For the purpose of this chapter additional guidance does not include information already presented at Volume 2, but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3

Requirements for Aircraft Maintenance Training Organisation

8.5.1.4 The Defence Aviation Safety Regulations (DASR) requires individual DASR 147 Maintenance Training Organisations (MTOs) to define their maintenance training activities in their Maintenance Training Organisation Exposition (MTOE). The scope of maintenance training of basic knowledge and/ or Military Aircraft Type Rating (MATR) training should be in accordance with the MTO's policy and procedures defined in the MTOE.

Background

Superseded

8.5.1.5 The Defence Aviation Safety Authority (DASA) and Headquarters Air Force Training Group (HQAFTG) have agreed that the primary framework to meet the DASR 147 requirements for the training of ADF personnel is through the creation of a single Air Domain MTO.

8.5.1.6 The single Air Domain MTO will:

1. leverage existing Joint and Single Service Individual Education and Training governance arrangements to provide an efficient and standardised governance approach for Australian Defence Organisation (ADO) aviation maintenance training.
2. align with the Defence Registered Training Organisation (DRTO) framework to enable standardisation against benchmarked Australian Skills Quality Authority (ASQA) standards.
3. provide a single point of accountability for aviation maintenance training, which will provide better holistic oversight that safety outcomes are being achieved.
4. provide the simplest path to the provision of recognition of Defence Maintenance Training by civil regulators and foreign militaries.

8.5.1.7 Commercial organisations that deliver aircraft maintenance training, either initial technical training (basic training) or Military Aircraft Type Training to meet DASR 66 requirements will be recognised by DASA if they:

1. already have a Part 147 Approval issued by a DASA- recognised Civil Aviation Authority (CAA)/ Military Aviation Authority (MAA); or
2. are included within the Air Domain MTO; or
3. are issued a discrete DASR 147 Approval, where they provide aviation maintenance training to DASR 145 organisation(s), but do not train ADF personnel.

8.5.1.8 The Air Domain MTO includes military aircraft type training courses delivered by Army Aviation Training Centre (AAvnTC), the Navy Training Authority – Aviation (TA-AVN) and the Air Force – Force Element Groups (FEGs). Basic aviation knowledge training delivered by RAAF School of Technical Training (STT) is also included under the Air Domain MTO.

Application to become an MTO

8.5.1.9 Refer to DASPMAN Volume 3, Chapter 5.3 – Annex I – MTO for detailed guidance on the application process.

8.5.2 Facility and Equipment Requirements

8.5.2.1 This regulatory provision outlines the facility requirements for a DASR 147 Aircraft Maintenance Training Organisation (AMTO) and contains several sub-sections, which detail the requirements that AMTOs must meet in terms of facilities, equipment and resources.

Facility Standards

8.5.2.2 AMTOs are to provide adequate facilities, equipment and tools to conduct training. AMTOs must ensure that their facilities meet the appropriate standards for classroom space, simulator training areas and other areas necessary for conducive aviation maintenance training. Additionally, AMTOs must have facilities for storage of maintenance tools, equipment and parts.

Superseded

Workshop Standards

8.5.2.3 Workshops must be equipped with tools, equipment and materials necessary to perform the practical tasks required by the relevant training courses. AMTOs must have appropriate facilities for the storage, testing and calibration of equipment used in the maintenance of the aircraft.

Training Equipment

8.5.2.4 Training equipment must be maintained and calibrated to ensure that it is safe and effective for use in training. AMTOs must ensure that they have the appropriate equipment for training in various aspects of aircraft maintenance including aircraft systems, avionics, structures and powerplant maintenance.

Library Facilities

8.5.2.5 AMTOs are to provide access to relevant aviation related reference materials, manuals and other resources necessary for aviation maintenance training. AMTOs must ensure that their libraries are up to date and have a wide range of materials that are relevant to the training courses they offer.

Computer Facilities

8.5.2.6 AMTOs are to have computer facilities that provide access to relevant aviation related software, databases and other tools necessary for effective aviation maintenance training. AMTOs must ensure that their computer facilities have up to date software and hardware as well as high-speed internet connections.

8.5.3 Personnel Requirements

Personnel Requirements

8.5.3.1 This section specifies the personnel requirements for management personnel employed by DASR 147 AMTOs. The organisation must have sufficient management personnel to ensure the effective management of its operations. The management personnel must be qualified, experienced and possess the necessary skills to oversee the organisation's activities and ensure compliance with all relevant regulations and standards. This includes an Accountable Manager who has overall accountability for the organisation's compliance with DASR regulations and will appoint other necessary resources to accomplish training commitments. The regulation includes requirements for different types of personnel, including management personnel, technical personnel, quality personnel, training personnel, and support personnel.

Records of Instructors, Examiners, Assessors and Invigilators

8.5.3.2 DASR 147.A.110 requires approved maintenance training organisations (AMTOs) in Australia to maintain records of instructors, examiners, and assessors. The records must contain specific details about the personnel including:

1. **Personal Details:** Personal details of the instructor, examiner, or assessor, including their full name, date of birth, and contact information.

2. **Qualifications:** Details of the instructors, examiners, or assessor’s qualifications, including the type of qualification, the date it was obtained, and the organisation that issued it.

Superseded

3. **Experience:** Details of the instructors, examiners, or assessor's experience, including the type of experience, the duration of experience, and the organisation where the experience was gained.

4. **Training:** Details of the training received by the instructor, examiner, or assessor, including the type of training, the duration of training, and the organisation that provided the training.

5. **Authorisations:** Details of any authorisations held by the instructor, examiner, or assessor, including the type of authorisation and scope, the date it was issued, and the organisation that issued it.

6. **Currency:** Details of the instructors, examiners, or assessors currency, including the type of currency, the date it was last achieved, and the date it is due to expire.

7. **Performance:** Details of the instructor's, examiner's or assessor's performance, including any relevant feedback or reviews and professional development plan.

8. **Relevant Training Material:** Details of any relevant training material that the instructor, examiner, or assessor has access to or uses in the performance of their duties.

9. **Verification of Competence:** Details of any verification of competence conducted on the instructor, examiner, or assessor, including the type of verification, the date it was conducted, and the organisation that conducted it.

10. **Compliance:** Details of the instructor's, examiners, or assessor's compliance with all relevant regulations and standards.

8.5.3.3 AMTOs can ensure that their personnel are qualified, competent, and authorised to perform their duties, and comply with all relevant regulations and standards.

Key Personnel Requirements

8.5.3.4 The qualification and experience of the instructors, knowledge examiners, practical assessors and invigilators are fundamental to ensuring the quality of a training course – only appropriately qualified personnel should be appointed to carry out training and examinations. In addition to the published Acceptable Means of Compliance (AMC) and Guidance Material (GM) to DASR 147.A.105(f), the following information provides additional guidance on the knowledge and skills that are expected of authorising instructors, knowledge examiners, practical assessors and invigilators employed by a DASR 147 Maintenance Training Organisation (MTO).

Instructors

8.5.3.5 A nominated person who will deliver a DASR 66 module or unit of competency (DASR 66 appendix I), a DASR 66 element (DASR 66 appendix III), or part thereof either of these. The instructor is not necessarily the person involved in drafting of the course material (content, duration, etc.), however they should be involved in the continued development of the lessons themselves (creation of the instructor notes, slides, sequencing, etc.).

8.5.3.6 Instructors should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO.

Superseded

2. Pedagogic – should know how to organise a lesson and how to efficiently deliver a course that clearly highlights the fundamental points. They should also be able to adapt when communicating to a particular audience including with pre-existing knowledge/experience.

3. Able to promote the appropriate attitude towards regulation and procedures; in particular the strict adherence to approved maintenance practices and quality standards through the lens of their own experience in a regulated aviation environment.

4. Familiar and proficient with the tools and training techniques used by the training organisation to deliver lessons.

5. Appropriately experienced in the aircraft maintenance environment.

6. Able to demonstrate good knowledge, complimented with communication skills in the English language.

7. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.

8. Able to demonstrate good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directives, Service Bulletin, Maintenance Programme, etc.).

9. In receipt of continuous training in the company's procedures and DASRs.

Knowledge Examiners

8.5.3.7 A nominated person who will determine the level of theoretical knowledge of the trainees on a particular module, unit of competency, element, or part thereof. The function may include the drafting and/or the selection of questions (Multi-Choice Questions and Essays), the evaluation of the correctness of answers (except when correct answers are pre-determined) and the final judgement regarding the level of knowledge demonstrated by the trainee.

8.5.3.8 Persons solely supervising an exam session are not considered as examiners but are considered as support staff invigilators and, in this context, are not subject to knowledge and experience requirements, but need to be trained to the examination procedure described in the MTOE.

8.5.3.9 Knowledge examiners should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO, including the examination standards required by DASR 66.

2. Able to demonstrate a responsible attitude to the conduct of examinations, so that the highest integrity is ensured.

3. Trained in contemporary examination techniques and able to conduct an examination in such a way that the true abilities of the candidate are demonstrated.

4. Able to remain neutral at all times and behave in a manner that will not influence or prejudice the final result of the examination, for example by providing undue assistance or clarification to a candidate.

Superseded

5. Familiar and proficient with the tools or the examination techniques used by the training organisation to perform the exams.

6. Appropriately experienced in the aircraft maintenance environment.

7. Able to demonstrate good knowledge, complimented with communication skills in the English language.

8. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.

9. Able to demonstrate good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directive, Service Bulletin, Maintenance Programme, etc.).

10. In receipt of continuous training in company's procedures and DASRs.

Practical Assessors

8.5.3.10 A nominated person who will determine the level of practical knowledge/practical skills of the trainees on a particular module, element, or part thereof. The function may include the drafting and/or the selection of practical tasks, the performance oversight and assessment of the practical activities. Practical assessors should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO.

2. Experienced and show solid judgement regarding the abilities of the assessed trainees – the assessor should have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks in compliance with current regulation, approved procedures, maintenance practices, etc.

3. Trained to contemporary assessment techniques. The assessor should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated.

4. Familiar and proficient with the tools or the techniques used by the training organisation to assess the practical abilities of trainees (maintenance simulators, mock up, etc.).

5. Appropriately experienced in the aircraft maintenance environment.

6. Able to demonstrate good knowledge, complimented with communication skills in the English language.

7. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.

8. Able to demonstrate a good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directive, Service Bulletin, Maintenance Programme, etc.).

9. In receipt of continuous training in company's procedures and DASRs.

Superseded

10. Able to act safely, apply safety precautions and prevent dangerous situations.

11. Able to demonstrate knowledge and understanding of areas requiring special emphasis or novelty (areas peculiar to the aircraft type, domains not covered by DASR-66 Appendix, practical training elements that cannot be imparted through simulation devices, etc.).

12. Able to demonstrate an understanding of the aircraft systems interaction.

13. Able to navigate, execute and obey the prescribed maintenance procedures.

Invigilators

8.5.3.11 A nominated person who will ensure the correct conduct of an examination in accordance with the examination procedures of the DASR 147 organisation. The invigilator is responsible for ensuring that examinations are conducted in accordance with the MTOE and Training Procedures and operates under the direction, responsibility and delegation of the Training Manager. The organisation can nominate permanent exam invigilators who should then be listed in MTOE Part 1 and qualified in accordance with Training Procedures.

8.5.3.12 Training organisations often delegate the invigilation of an examination to staff not listed as an examiner for the particular subject. These “invigilators” do not need to be qualified to the same extent as an examiner, and in particular, they do not need to demonstrate specialty knowledge, as long as their duty is strictly limited to the conduct of the examination itself.

8.5.3.13 Invigilators should however be trained to the organisation’s examination procedures with a specific emphasis on the exam’s integrity aspects and on the handling of cheating or misconduct cases. Such staff should be listed by the organisation with records of their training kept in the individual’s personnel file.

Assessment and acceptance of staff

8.5.3.14 Assessment and acceptance of instructors, examiners and assessors should be performed, and documented by the approved training organisation in accordance with dedicated procedure described in the MTOE. Appropriate staff in the maintenance training organisation should physically interview proposed candidates in order to ensure their competency. Once completed, detailed result of this assessment, including any supporting documents (diplomas, DASR 66 licence, etc.) should be filed in accordance with MTOE procedure. The staff should be listed in MTOE with intended scope of instruction, examination or assessment.

Continued qualification

8.5.3.15 The qualification criteria and experience requirements only address the initial acceptance of instructor, examiners and assessors. The training organisation should develop and document a program in MTOE to ensure the continued competence of these staff.

8.5.4 Instructional Equipment Requirements

8.5.4.1 DASR 147.A.115 requires approved maintenance training organisations (AMTOs) to ensure that they have appropriate instructional equipment available to support their training activities. Here are some important points that must be considered when meeting this regulation:

Superseded

1. **Type of Equipment:** The equipment must be appropriate for the type of training being delivered. This includes a wide range of equipment such as applicable aircraft, training aids, simulators, and computer-based training tools.

2. **Condition:** The equipment must be in good working order, and any faults or defects must be promptly rectified.

3. **Calibration:** The equipment must be calibrated as required, and records of calibration must be maintained.

4. **Availability**: The equipment must be readily available for use when required, and there must be sufficient equipment available to support the number of students being trained.

5. **Security:** The equipment must be stored securely when not in use, and access to the equipment must be controlled to prevent damage or misuse.

6. **Maintenance:** The equipment must be regularly maintained, and records of maintenance activities must be maintained.

7. **Training Material**: The equipment must be used in conjunction with appropriate training material to support effective learning.

8. **Compliance:** The equipment must comply with all relevant regulations and standards.

9. **Training for Equipment Use:** Instructors and trainers must be trained in the correct use of the equipment and any associated software or training materials.

10. **Upgrades and Replacements:** Equipment should be upgraded or replaced as necessary to ensure that it remains effective and meets current training requirements.

Aircraft Maintenance Training Aids

8.5.4.2 These are physical devices used to simulate or replicate various components or systems of an aircraft. For example, a training aid may be used to teach students how to inspect and troubleshoot an engine. Important points to consider for training aids:

1. The training aid must accurately represent the aircraft component or system being taught.

2. The training aid should be durable and long-lasting.

3. The training aid should be kept clean and well-maintained.

8.5.4.3 **Computer-Based Training Tools:** These are software applications or programs that are used to deliver training material to students. For example, a computer-based training tool may be used to teach students how to use a maintenance management system. Important points to consider for computer-based training tools:

1. The software should be up-to-date and compatible with the AMTO's computer hardware.

2. The software should be easy to use and navigate.

3. The AMTO should have a system for monitoring and tracking student progress.

Superseded

8.5.4.4 **Simulator Devices:** These are devices that replicate real-world situations or scenarios to provide hands-on training to students. For example, a simulator may be used to teach students how to perform a maintenance task on an aircraft. Important points to consider for simulator devices:

1. The simulator should accurately represent the real-world situation or scenario being taught.
2. The simulator should be well-maintained and regularly calibrated.
3. The AMTO should have a system for monitoring and tracking student progress.

8.5.4.5 **Training Videos and Audio Recordings:** These are pre-recorded videos or audio recordings that are used to deliver training material to students. For example, a training video may be used to teach students about safety procedures.

8.5.4.6 Important points to consider for training videos and audio recordings:

1. The video or audio recording should be up-to-date and relevant to the training being provided.
2. The AMTO should have a system for monitoring and tracking student progress.
3. The AMTO should ensure that the video or audio recording is of high quality and easy to understand.

8.5.5 Maintenance Training Material

8.5.5.1 DASR 147.A.120 requires approved maintenance training organisations (AMTOs) to develop and use maintenance training material that is appropriate for the type and level of training being delivered. DASR 66 specifies requirements for both basic and type course training material. Here are some important points to consider for each Basic course training material:

1. The training material used for basic courses must cover a broad range of topics and must be suitable for entry-level students. The following are some important points to consider when developing or using training material for basic courses:
    i. The training material must cover the theoretical and practical aspects of the aircraft, system, or component being taught.
    ii. The training material must be easy to understand and follow.
    iii. The training material must include practical exercises that reinforce theoretical knowledge.
    iv. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.
    v. The training material must be appropriate for the level of experience and education of the students being trained.

Type Course Training Material

8.5.5.2 The training material used for type courses must cover the specific make and model of the aircraft, system, or component being taught. The following are some important points to consider when developing or using training material for type courses:

Superseded

1. The training material must cover all relevant aspects of the aircraft, system, or component, including maintenance, inspection, troubleshooting, and repair.

2. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.

3. The training material must be appropriate for the level of experience and education of the students being trained.

8.5.5.3 Some additional important points to consider when developing or using maintenance training material include:

1. The training material must be structured in a logical and organized manner.

2. The training material must be consistent with the relevant regulations and standards.

3. The training material must be presented in a manner that is engaging and interesting for students.

4. The AMTO must have a system for tracking and monitoring the use of training material, including the progress and performance of students.

8.5.5.4 By meeting the requirements of DASR 147.A.120, AMTOs can ensure that they are providing high-quality maintenance training material that is appropriate for the level and type of training being delivered. This can help to ensure that students receive the knowledge and skills they need to perform maintenance tasks safely and effectively.

8.5.6 Examinations

8.5.6.1 DASR 147.A.135 specifies the requirements for conducting examinations for aircraft maintenance training organisations (AMTOs) to ensure that their students have the necessary knowledge and skills to perform their maintenance duties effectively and safely. Here are some key points regarding the examination requirements:

Examination Development

8.5.6.2 The AMTO should develop examination questions that are aligned with the training objectives and outcomes. The questions should be designed to test the knowledge and skills that the student has acquired during the training program. The AMTO should also ensure that the examination questions are reviewed and approved by qualified personnel.

Examination Administration

8.5.6.3 The AMTO should have procedures in place for administering examinations. This includes ensuring that students are aware of the examination format, rules and regulations, and any special instructions that apply. The AMTO should also ensure that the examination environment is conducive to learning and that the examination is conducted in a fair and unbiased manner.

Examination Security

8.5.6.4 The AMTO should have procedures in place for ensuring the security of all the question, examinations and databanks. Particular attention should be made to the storage and transportation of the examination between venues and whilst onsite. Care must be taken to ensure the examination

Superseded

questions are secure at all times. Electronic means of storage may be utilised where available, providing that suitable security arrangements are in place.

Examination Grading

8.5.6.5 The AMTO should have procedures in place for grading and evaluating examination results. The grading procedures should be fair, consistent, and transparent, and should be based on established criteria. The AMTO should also ensure that examination results are communicated to students in a timely manner and that students have access to feedback on their performance.

Examination Records

8.5.6.6 The AMTO should maintain records of examination results, including the student's performance and any relevant feedback. These records should be kept in a secure location and retained for a specified period of time in accordance with regulatory requirements (e.g. Annex A to AMC 147.A.125)

Examination Review

8.5.6.7 The AMTO should have procedures in place for reviewing and evaluating examination results to identify any areas where improvements can be made. This includes analysing trends in examination results, identifying areas where students are struggling, and taking corrective actions to improve the effectiveness of the training program.

8.5.6.8 In summary, the examination requirements outlined in DASR 147.A.135 are designed to ensure that the AMTO's training program is effective and that students have the necessary knowledge and skills to perform their maintenance duties safely and effectively. By following these requirements, the AMTO can maintain a high standard of training and contribute to the overall safety of the aviation industry.

8.5.7 Training Procedures and Quality System

8.5.7.1 DASR 147.A.130 requires Aircraft Maintenance Training Organizations (AMTOs) to establish and maintain effective training procedures and a quality system to ensure that their training programs are of a high standard and meet the requirements of all applicable regulations and standards including DASRs. Some important points to be considered when developing or maintaining training procedures and a quality system are:

Training Procedures

8.5.7.2 The training procedures must include a description of the training program, including the objectives, scope, and content of the training. This should include the methods and materials used for training, the sequencing of the training, and the assessments used to measure the effectiveness of the training.

Courseware

8.5.7.3 The AMTO should have a system in place to develop, review, and update courseware, including lesson plans, training manuals, visual aids, and other materials used for training. The courseware should be reviewed and updated regularly to ensure that it remains relevant and effective.

Instructor Qualifications and Training

Superseded

8.5.7.4 The AMTO should have procedures in place to ensure that their instructors are qualified and competent to deliver the training. This includes requirements for instructor qualifications and training, such as experience in the industry, knowledge of the subject matter, and teaching skills. The AMTO should also have a system in place to regularly assess the performance of their instructors and provide them with feedback / training as necessary.

Assessment Procedures

8.5.7.5 The AMTO should have a system in place to assess the effectiveness of their training, including the use of assessments and evaluations to measure the knowledge and skills of the students. The assessments should be designed to provide a fair and accurate measure of the student's performance, and be reviewed and updated regularly to ensure that they remain valid and reliable.

Quality System

8.5.7.6 The AMTO should have a quality system in place to ensure that their training program meets the requirements of DASRs and any other applicable regulations and standards. This includes procedures for monitoring and evaluating the effectiveness of the training by identifying, correcting and preventing recurrence of any deficiencies and continuously improving the training program.

8.5.7.7 Some additional important points to consider when developing or maintaining training procedures and a quality system include:

1. The AMTO should ensure that all training is conducted in a safe and secure environment, and that appropriate safety procedures are followed at all times.
2. The AMTO should ensure that their training programs are accessible to all students and meet their needs.
3. The AMTO should ensure that all training is conducted in accordance with relevant laws and regulations including those related to privacy and data protection.
4. The AMTO should ensure that all training is conducted in a professional and ethical manner, and that all students are treated fairly and with respect.

Quality Policy

8.5.7.8 The AMTO should have a quality policy that outlines the organisation's commitment to quality and its goals for maintaining a high standard of training. The policy should be communicated to all staff and stakeholders, and reviewed and updated regularly.

Quality Objectives

8.5.7.9 The AMTO should establish quality objectives that are measurable and aligned with the goals of the organisation. The objectives should be reviewed and updated regularly, and progress towards meeting the objectives should be monitored.

Document Control

8.5.7.10 The AMTO should have a system in place to manage and control documents related to training procedures and the quality system. This includes procedures for document creation, control, review, approval, distribution and revision.

Record Keeping

Superseded

8.5.7.11 The AMTO should maintain records related to the training programs and the quality system, including records of student performance, instructor qualifications, audit results, corrective actions taken, and other relevant information.

Records of Students

8.5.7.12 DASR 147.A.125 requires approved maintenance training organisations (AMTOs) to maintain accurate and complete records of their students. These records must include a variety of information to demonstrate that the student has successfully completed the required training and has the necessary knowledge and skills to perform maintenance tasks safely and effectively. Here are some important points to consider when developing or maintaining student records:

1. Student Identification: The record must include the student's full name, date of birth, contact information, and any relevant identification numbers or codes.
2. Training History: The record must include a detailed history of the student's training, including the courses they have completed, the date of completion, and the grade they received. This information should also include any remedial training or retesting that was required.
3. Assessment Records: The record must include documentation of any assessments or examinations the student has completed, including the results and any feedback or comments provided by the examiner.
4. Attendance and Absences: The record must include information on the student's attendance and any absences from training, including the reason for the absence and any make-up training that was required.
5. Certification: The record must include information on any certifications the student has received as a result of their training, including the type of certification, the date it was issued, and any restrictions or limitations.
6. Other Relevant Information: The record should also include any other relevant information about the student, such as their prior education or experience in the field of maintenance, any disciplinary actions taken, or any other notable achievements or accomplishments.
7. Some additional important points to consider when developing or maintaining student records include:
    i. The record must be maintained in a secure and confidential manner to protect the privacy of the student.
    ii. The record must be accurate, complete, and up-to-date at all times.
    iii. The record must be available for review by relevant authorities, such as regulatory agencies or potential employers.
    iv. The AMTO must have a system in place to ensure that student records are regularly reviewed and updated as necessary.

8.5.7.13 By meeting the requirements of DASR 147.A.125, AMTOs can ensure that they are maintaining accurate and complete records of their students, which can help to demonstrate that the students have received the necessary training and are qualified to perform maintenance tasks safely and effectively.

Superseded

Corrective and Preventive Actions

8.5.7.14 The AMTO should have a system in place to identify and address non-conformities or areas where the procedures and system can be improved. This includes procedures for taking corrective and preventive actions to avoid recurrence including causal or root cause analysis, tracking and monitoring the effectiveness of the actions taken, and documenting the results.

Management Review

8.5.7.15 The AMTO should conduct regular management reviews of the training procedures and quality system to ensure that they are effective and meeting the goals of the organisation. The management review should include a review of audit results, quality objectives, corrective and preventive actions, and other relevant information.

Audit Procedures

8.5.7.16 Auditing is an important part of ensuring that the training procedures and quality system of the AMTO are effective and meeting the requirements of the applicable regulations. Audits should be conducted by an independent auditor, who can be an internal auditor or an external auditor.

Internal Auditing

8.5.7.17 The AMTO should conduct internal audits of their training procedures and quality system on a regular basis to ensure that all aspects of DASR 147 compliance are checked at least once in every 12 months and may be carried out as one complete single exercise or subdivided over a 12-month period in accordance with a scheduled plan. The purpose of internal audits is to identify any non-conformities or areas where the procedures and system can be improved. The results of the internal audits should be documented and corrective actions should be taken to address any non-conformities.

External Auditing

8.5.7.19 The AMTO should also undergo external audits by an independent auditor, who is not part of the AMTO organisation. The purpose of external audits is to ensure that the training procedures and quality system of the AMTO are in compliance with the requirements of the regulation. The results of the external audits should be documented, and any corrective and preventive actions that need to be taken should be identified and addressed.

8.5.7.20 By meeting the requirements of DASR 147.A.130, AMTOs can ensure that their training programs are of a high standard and meet the requirements of the regulation, which can help to ensure the safety and effectiveness of maintenance operations in the aviation industry.

8.5.8 Military Aircraft Type Ratings

Introduction

8.5.8.1 Military Aircraft Type Rating Training consists of theory and examination, practical and assessment, plus On-the-Job Training (OJT) – see DASR 66.A.45(c) – for first aircraft in licence category/subcategory. Any subsequent Military Aircraft Type Rating (MATR) within the same category/sub-category require both theory and practical elements but will only require further OJT if stipulated by DASA during the approval of the course.

Superseded

Note: A minimum of only theory and examination is required for the Category C Military Aircraft Maintenance Licence (MAML) rating (AMC 66.A.45).

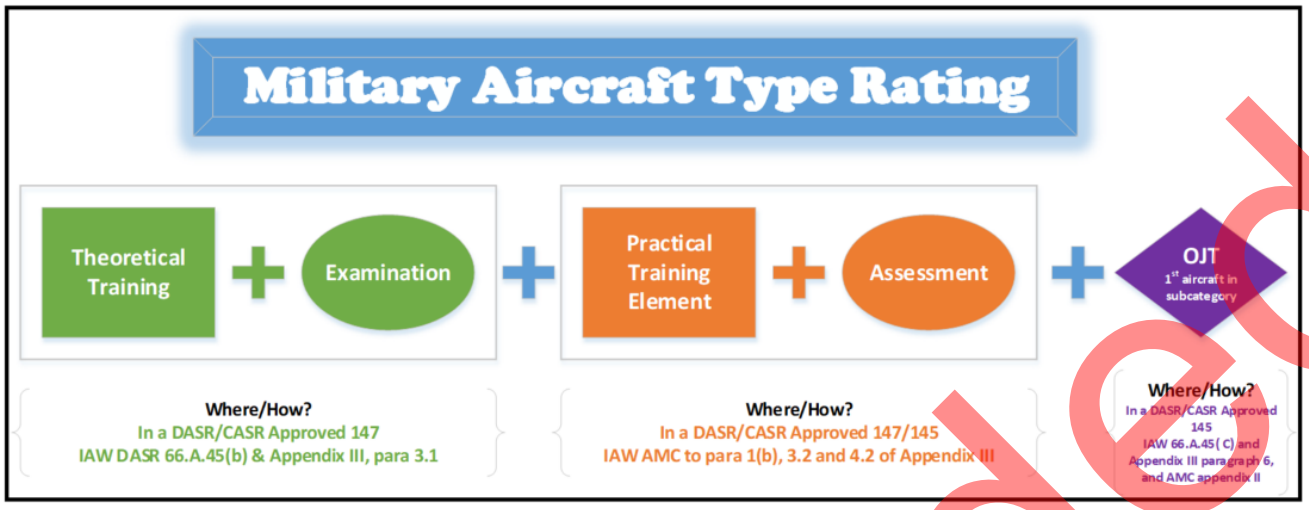

Figure 1: Military Aircraft Type Rating (MATR) - Required Elements

Privileges

8.5.8.2 In order to be entitled to exercise certification privileges for B and C categories on a specific aircraft type, the holder of a MAML shall have their MAML endorsed with the relevant Military Aircraft Type Ratings.

ADF Course Design and Development

8.5.8.3 To ensure consistency across all ADF courses, the design and development of courses, including the course curriculum, should follow the System Approach to Defence Learning (SADL) – see SADL Website.

MATR Course – Initial Approval / Change Management

8.5.8.4 In order to facilitate approval by the authority, the following relevant DASR Forms are to be completed and submitted as appropriate:

1. DASR Form 12 - Application for DASR 147 Initial-Changes of Approval. The DASR Form 12 is the official DASA form to apply for a DASR 147 Maintenance Training Organisation approval. This form is considered part of an application pack and should be submitted with the appropriate evidence as detailed within the form to support the application.

2. DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval. The DASR Form 12A is to accompany the DASR Form 12 when the application is for an initial course approval. For an update to an existing approved course, only the completed Form 12A and associated evidence documents are required for submission.

8.5.8.5 As a minimum standard, the following documents must be submitted as evidence for MATR courseware approval:

1. Training Needs Analysis (TNA) or equivalent as accepted by DASA

Superseded

2. Completed DASR 66 Appendix III MATR Courseware Assessment Matrix

3. MATR Theory Element (Learning Management Plan)

4. MATR Practical Element (Practical Training Logbooks)

5. On-The-Job-Training (OJT) logbook.

DASA Notification Requirements

8.5.8.6 Changes to MATR Courses shall be defined as either a Major or Minor Change.

8.5.8.7 A Major Change is any amendment, alteration or change to a MATR Course that is not accurately categorised as a Minor Change within the relevant Maintenance Training Organisation (MTO) Exposition procedure. A DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval must be submitted and approved prior to any Major Change to a MATR Course.

8.5.8.8 A Minor Change is any amendment, alteration or change to a MATR Course that does not affect the DASR related approval. Minor Changes may be acceptable to DASA without prior approval by the Authority; contingent to endorsement by the relevant MTO QMS that no adverse material effect is posed to safety, quality of training or the knowledge, skills and attitudes of course graduates, course learning outcomes or location.

8.5.8.9 An internally reportable process for approval of Minor Changes to MATR Courseware must be included within the relevant MTO Exposition/Annex; containing either a specific predefined listing of all actions, or defining statement considered by the MTO to fall within the scope of a 'Minor Change'.

8.5.8.10 Subject to the endorsement of the MTO QMS, listed actions could include (but are not limited to):

1. Grammatical and typographic changes

2. Changes that incorporate updates from the relevant platform specific technical publications (e.g. updated maintenance procedures, configuration changes etc.)

3. Changes of content (provided the learning outcomes are not affected).

Theoretical Element of the Military Aircraft Type Rating Training

8.5.8.11 The theoretical element of the Type Course shall provide the person with detailed theoretical knowledge of the applicable systems, structure, operations, maintenance, repair, and troubleshooting of the aircraft type according to the approved maintenance data, including:

1. The appropriate use of manuals and approved procedures, including any relevant inspections and limitations;

2. How to perform system, power-plant and component functional checks as specified in the maintenance manual;

3. Related information for the purpose of making decisions in respect of fault diagnosis and rectification within the scope of the maintenance manual;

4. Describing procedures for replacement of components unique to the aircraft.

Superseded

8.5.8.12 Theory training shall be conducted by an appropriately approved DASA 147 MTO or an organisation recognised by DASA.

8.5.8.13 In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA.

8.5.8.14 Theory training shall have been started and completed within the 3 years preceding the application for a MATR endorsement.

8.5.8.15 The minimum pass mark for the theoretical exam is 75%.

8.5.8.16 The theoretical type training shall describe how the type training is delivered (i.e. classrooms, training equipment, instructors qualifications, TNA etc.) meeting the requirements of DASR 66 and 147, as appropriate.

8.5.8.17 The course content and duration shall be demonstrated by:

1. a detailed curriculum showing the levels for each chapter of the type training, which should be assessed for equivalence to Appendix III to DASR 66 for the relevant certifying staff category; and
2. verifying that both content and duration are justified through a comprehensive TNA (or equivalent as accepted by DASA).

8.5.8.18 Evidence is required for the following elements:

1. the teaching methods and instructional equipment;
2. the material and documentation provided to the student;
3. the qualification of instructors, examiners;
4. the documentation and records provided to the student to justify the satisfactory completion of the training course and related assessment.

Note: For further information about these elements, refer to the MTO exposition.

Practical Element of the Military Aircraft Type Rating Training

8.5.8.19 Practical training is a structured training activity that consolidates the knowledge gained during the theoretical phase of type training and as such, may be performed after or integrated within the theory training. Practical training should:

1. Address the different parts of the aircraft and its associated engines, which are representative of the structure, the systems/components installed and the cabin.
2. Include the use of technical manuals, maintenance procedures and the operational interfaces with the aircraft (e.g. FMC, electronic flight bag, etc.)
3. Include common maintenance and ground handling activities.
4. Cover both type specific and generic safety elements of the aircraft's maintenance.
5. Develop the student's competence in performing safe maintenance, prior to the practical assessment.

Superseded

8.5.8.20 The purpose of practical training is not to include all the maintenance tasks associated with a particular type, but a representative sample of them that will allow the student to acquire the required knowledge, attitude and skills to safely carry out maintenance on that type.

8.5.8.21 The practical element of the MATR Training can be performed concurrently with the OJT element if both are performed on the same military aircraft type and in a real maintenance environment.

8.5.8.22 Practical training may be performed either following or integrated with the theoretical elements however, it should not be performed before theoretical training.

8.5.8.23 Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.24 Table 1 summarises the MATR Training requirements contained in DASR 66.A.45, and Appendix III to DASR 66.

Military Aircraft Type Rating Training requirements		
Aircraft Group	**B1/B2 MAML**	**C MAML**
All military aircraft are considered to be complex motor-powered aircraft	**Military Aircraft Type Rating Training:** Theory + examination Practical + assessment PLUS OJT (for first aircraft in licence category/subcategory. For subsequent Military Aircraft Type Rating within the same category/sub-category, further OJT only if required by DASA)	**Military Aircraft Type Rating Training:** Theory + examination Note: In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA

Table 1: Military Aircraft Type Rating Training requirements

8.5.8.25 IAW AMC to Para 3.2 of Appendix III to DASR 66 - "The practical training may include instruction in a classroom or in simulators, but part of the practical training should be conducted in a real maintenance, or manufacturer, environment." It would be acceptable to complete practical training in a classroom or in simulators, if the practical training could be effectively delivered in this environment.

1. Practical training conducted in a real maintenance environment implies practical training on live aircraft or high fidelity maintenance training aids that are representative of the live aircraft. Practical training in a real maintenance environment should always be conducted on the highest fidelity training device reasonably available and include the use of maintenance data and specialist tooling.

2. Practical training should always be conducted in a real maintenance environment, where it is:

   i. the only reasonable method due to the complexity of the task, or

   ii. the only method available to enable familiarity with component location/ identification, or

   iii. the only method available to demonstrate the use of special equipment / tools.

Superseded

8.5.8.26 Para 3.2 g. of Appendix III to DASR 66 states “The objective of practical training is to gain the required competence in performing safe maintenance, inspections and routine work…”. In the context of practical elements of the military aircraft type training, competence to perform safe maintenance, inspections and routine work does not require the actual performance of the maintenance (e.g. it is acceptable to use a live aircraft as a training aid without physical removal / installation of components). Practical training could be a visit to / walk around of an aircraft in the maintenance environment, identifying specialised tooling / equipment used on the aircraft, process walkthroughs for removal / installations tasks, and scenario based activities for troubleshooting. Practical training should also ensure students are knowledgeable in the use of technical literature, documentation, specialised tooling and test equipment.

8.5.8.27 Selected tasks should consist of a group of representative maintenance tasks drawn from the type training and examination curriculum, at the indicated level and shall cover all the relevant chapters described in the table contained in paragraph 3.2 of Appendix III to DASR 66.

8.5.8.28 The task curriculum must:

1. Be distributed in order to cover all applicable S1000D chapters.
2. Include all of the task categories (LOC, FOT, SGH, R/I, MEL, TS - Refer table 2 below) and may include others deemed appropriate to the type (e.g. ‘INS’pection, ‘ADJ’ustment).
3. Include an appropriate number of tasks in each task category for the aircraft type’s training requirements to be met.
4. Be sufficient to cover at least 50% of the crossed tasks in Appendix III to DASR 66 para 3.2. (Refer to “How should the 50% of tasks required for practical training be selected?” below).

Note: for further information on the S100D Specification refer to the following links on the DASA website. S1000D - International specification for technical publications.

8.5.8.29 The duration of the practical training should ensure that the content of training required by paragraph 3.2 of Appendix III to DASR 66 is completed.

8.5.8.30 A record of the tasks completed should be entered into a logbook which should be designed such that each task or group of tasks may be countersigned by the designated assessor. The logbook format and its use should be clearly defined.

8.5.8.31 The practical element (for power-plant and avionics systems, armaments, escape systems and other relevant military-specific systems) of the MATR Training may be subcontracted by the approved DASA 147 organisation under its quality system according to the provisions of DASR 147.A.145(d)3 and the corresponding Guidance Material.

How should the 50% of tasks required for practical training be selected?

8.5.8.32 When selecting the tasks, the usage of a filtering method based on the criteria similar to that described in AMC to paragraph 3.1(d) of Appendix III to DASR 66, point 5f) is recommended.

8.5.8.33 The selection of 50% of tasks cannot be selected according to the glossary only (e.g. LOC, FOT, SGH, R/I, etc.):

Superseded

1. Paragraph 3.2 of Appendix III to DASR 666 states that 'the tasks selected shall be representative of the aircraft and systems both in complexity and diversity'. In addition, the practical training should particularly address the tasks which cannot be explained by theoretical training only. While relatively simple tasks may be included, other more complex tasks shall also be incorporated and completed as appropriate to the aircraft type.

2. Guidelines on complex / simple tasks (taken from CASA AMC/GM Part 66, V7.4 of December 2024) are as follows:

   i. Complex tasks may have the following attributes:

      – involve several comprehensive steps to perform
      – have multiple decision points in order to complete
      – may use specialised test equipment
      – often requires more than one person to perform
      – have direct impact on flight safety

   ii. Simple tasks may have the following attributes:

      – does not use specialised test equipment
      – can be completed by a single person
      – does not require any in-depth skill/knowledge
      – does not involve decision steps (no troubleshooting)
      – may involve an on-board maintenance system BITE check to determine serviceability

3. How each task is selected (LOC, SGH, etc.), should be based upon the potential gains for the students' competency or its impact on safety. Availability should not be a reason to omit a pertinent task and consideration should be made to include a 'real maintenance environment' to complete an important or critical learning objective.

4. All pertinent sub-tasks, associated with the safe completion of each main task, such as Isolating mechanical/electrical systems, opening/closing CBs, locking flight controls, etc., should be included and the applicable aircraft maintenance manuals used.

5. Regarding the way to read the table in paragraph 3.2, each line aims to cover each of the main systems so that no line relevant to the particular aircraft type should be omitted in the selection. Inside each line applicable to the aircraft type, half or more of the crosses can be selected. From a learning point of view, selecting 2 simple tasks as LOC and SGH would not be "representative", while selecting LOC and TS, for example, would be much more appropriate of the aircraft and systems both in complexity and diversity.

6. The intent of the following tables are to provide a compliance report demonstrating that the practical type training meets the standard required by Appendix III to DASR 666. In particular, the tables shall indicate the percentage of tasks effectively performed against the tasks contained in the Appendix III to DASR 66 which are applicable to the aircraft type.

Superseded

8.5.8.34 The following tables have been developed as a guide for assessment of MATR practical courseware elements. These tables are included in the MATR courseware assessment which can be found at the following link - DASR 66 Appendix III MATR Courseware Assessment Matrix. This assessment matrix should be completed by the MTO delivering the MATR practical type training in order to enable approval of courseware by the authority.

Percentage by Task Type

Type of task	Number of tasks applicable to the A/C type	Total number of tasks selected	Percentage (%) effectively performed against applicable tasks (should be at least 50% of the applicable tasks)
LOC			
FOT			
SGH			
R/I			
MEL			
TS			

Table 2 – Practical Task Training Requirements (By Task Type)

Glossary of the table: LOC: Location; FOT: Functional/Operational Test; SGH: Service and Ground Handling; R/I: Removal/Installation; MEL: Minimum Equipment List; TS: Trouble-Shooting.

Percentage by Chapter

Chapter	Number of Practical Requirements for Each Chapter	Total number of Practical Elements Included Within Courseware	Percentage (%) included against applicable Chapter (should be at least 50% of the applicable practical requioirements within each Chapter)
05 Time limits / maintenance checks			
06 Dimensions/Areas (MTOM, etc.)			
.....			

Superseded

99 Electronic Warfare			

Table 3 - Practical Task Training Requirements (By Chapter)

Practical Training Logbook

8.5.8.35 A Military Aircraft Type specific Practical Training Logbook (PTL) must be developed by a DASA 147 MTO, completed by the student and a certified true copy retained by the MTO delivering the training. It will record the training activities carried out during the practical training course and the subsequent assessment of trainee competence.

8.5.8.36 The PTL shall list all of the applicable S1000D systems, as specified within Appendix III to DASR 66, Section 3.2.

8.5.8.37 After the practical element of the MATR Training has been completed, an assessment must be performed, which must comply with the following:

1. The assessment shall be performed by designated assessors appropriately qualified (AMC to Appendix III).
2. The assessment shall evaluate the knowledge and demonstrated understanding of the trainee.

8.5.8.38 The PTL should include:

1. Trainee attendance sheet.
2. Course and Instructor's details.
3. S1000D system number and title.
4. Aircraft Maintenance Manual or work-pack reference for each training task.
5. A list and detailed description of the training tasks.
6. Each task must have a method of denoting the training technique (Synthetic, Aircraft registration, Classroom, etc.).
7. Task type (R/I, LOC, SGH etc.).
8. Date of each individual task completion.
9. Instructor signatures or stamps.
10. Spare entries for documenting additional/replacement "ad hoc" training tasks.

Note: Additional/replacement tasks must be of relevance to those they replace, be of benefit to the training objective and only replace planned tasks in exceptional circumstances.

8.5.8.39 EASA provide Practical type training logbook examples for both B1 and B2 PTL that can be used for guidance.

Practical Instructors and Assessors

8.5.8.40 In the majority of cases, the Practical instructor will be the same as that used for the Theory phase of the type training. They are a logical choice, as they possess an in-depth knowledge of

Superseded

the aircraft's systems and will have developed an understanding of each student's specific academic requirements.

8.5.8.41 Using the same instructor for both the Theory and Practical phases will often suit the business model of many organisations. In some cases, however, especially where a DASA 147 / DASA 145 affiliation exists, the organisation may choose to utilise experienced MAML holders / technicians, as appropirate, from their own maintenance workforce to deliver the Practical training.

8.5.8.42 These individuals must be given suitable training on the organisational processes involved, particularly the use of the Practical training record. It is recommended that they attended a train the trainer course, whether delivered by an external or internal source, which should specifically target the training techniques required for Practical training and set the organisation's bench mark for the conduct of this training. They should be familiar with the tools or the techniques used by the training organisation to assess the competence of the practical abilities of trainees (maintenance simulators, mock up and etc.).

8.5.8.43 They should be experienced and show solid judgement regarding the abilities of the assessed trainees, they must have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks IAW current regulation, utilising approved procedures, maintenance practices etc. They should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated to maintain the system.

8.5.8.44 Workforce sourced Instructors will be qualified and managed by the DASA 147 organisation. Refer to DASR 147.A.105 for details.

8.5.8.45 They must be included in the list Instructional staff (point 1.5 of the MTOE) and be subject to the same Instructor records and update training requirements as the directly employed Instructors.

8.5.8.46 Practical assessments may be conducted by either the Practical Instructor or a dedicated assessor, who has undergone a similar training and qualification process to that detailed above.

8.5.8.47 Upon completion of the PTL, it must be reviewed, assessed and approved by the relevant DASA 147 in its entirety.

OJT Element of the Military Aircraft Type Rating

8.5.8.48 OJT is required for the initial type rating being sought in each licence category or sub-category:

8.5.8.49 For example; If a B1.1/B2 MAML is endorsed with the P-8A type in the B1.1 category and the MAML holder wishes to add the P-8A in the B2 category, he/she will have to complete B2 related OJT representative of that aircraft and its systems.

8.5.8.50 If the same B1.1 MAML holder adds the B1.3 category to their MAML, and wishes to add their first helicopter type, he/she must complete OJT representative of that first helicopter type. Any subsequent MATR within the same category/sub-category will only require further OJT if stipulated by DASA during the approval of the course.

8.5.8.51 A DASA 145 maintenance organisation appropriately approved for the maintenance of the particular aircraft type can conduct OJT for that type rating:

Superseded

1. The OJT content shall be approved by DASA (Appendix III to DASR 66, sec. 6) and supported by a detailed curriculum showing its content and recorded within detailed worksheets/logbook;

2. OJT tasks shall be signed off by the student and countersigned by a 'designated supervisor';

3. Final assessment of OJT is mandatory and shall be performed by a 'designated assessor';

4. It can be carried out in an approved DASA 145 maintenance organisation with a Category A rating (maintenance on aircraft) and the procedures for OJT should be included in the exposition (MOE chapter 3.15 "OJT procedure") approved by DASA.

5. Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.52 The OJT should include a sufficient number of tasks that are carried out under 'one to one' supervision (i.e. one supervisor dedicated to one trainee) and should involve actual work task performance on aircraft/components, covering line and/or base maintenance tasks.

8.5.8.53 AMC to Appendix II to DASR 66 contains a list of tasks, from which a representative sample appropriate to the type and licence (sub-) category applied for, should be extracted and approved by the MAA. The OJT should cover at least 50% of this approved extracted list.

8.5.8.54 Up to 50% of the required OJT may be undertaken before the aircraft theoretical MATR Training starts, noting that:

1. the ADF Initial Employment Training (IET) workplace journals are the primary means of meeting the practical requirements for the Defence Registered Training Organisation issuance of selected MEA Unit of Competency;

2. portions of these workplace journals may also be utilised as a means of meeting the requirements of OJT, as long as they are completed in a DASA 145, and on the platform/components which the individual is completing their Type Rating training (Appendix III to DASR 66, para 6).

8.5.8.55 If these journal tasks are not carried out on the aircraft type (or its components) required for their subcategory, then these tasks cannot be constituted as OJT.

8.5.8.56 As a minimum, the OJT procedure should describe the following elements:

1. Content of the OJT: the list of tasks that should be performed during the OJT or a list of generic tasks and the process how to develop a list of particular tasks out of this list of generic tasks,

2. Qualifications of the assessor and supervisors performing the OJT,

3. OJT logbook/worksheets format and content,

4. OJT compliance report format and content,

Superseded

5. Production planning for the implementation of OJT (how to plan the tasks),

6. Supervision process and the assessment process, what to do if the assessment is not positive,

7. Safe release to service of the aircraft after OJT,

8. OJT Log Book final assessment process and associated forms:

    i. An OJT Logbook assessment is carried out on an OJT Logbook to ensure that all required tasks have been carried out and certified for in accordance with the OJT Logbook assessment procedure.

    ii. MTOE procedure and associated documents should contain a procedure for the final assessment of an OJT Logbook and who it is completed as well as any associated forms needed and who is qualified to carry out such assessment.

Note: AMC to Section 6. of Appendix III to DASR-66 should be used when defining the content of the procedure.

Practical Assessment Vs On the Job Training (OJT) for Military Aircraft Type Ratings

8.5.8.57 The objective of OJT is to gain the required competence and experience in performing safe, effective and efficient maintenance. The practical assessment addresses the practical portion of any type training, whereas the OJT assessment addresses the additional hands-on experience necessary in a true maintenance environment as part of the first type rating in a (sub)category, as illustrated by the table below:

Superseded

Practical Assessment Vs On the Job Training		
	Practical Assessment	**OJT Assessment** ***For the purpose of DASR 66.A.45(c)***
What/Who is assessed	Candidates following practical element of Military Aircraft Type Ratings training.	Completeness of OJT
	Reference: 66.A.45 (a)(b); Appendix III, 4.2.; AMC Appendix III	Reference: 66.A.45 (c); Appendix III, section 6; AMC to Section 6 of Appendix III
Function of assessor:	To perform the final evaluation of the knowledge, skills and attitude of the trainee following the practical element of the type training	To conduct the final assessment of the completed OJT, whereas the candidate's competence is indirectly justified.
	Reference: Appendix III 4.2.; AMC Appendix III	Reference: Appendix III, 6.; AMC to Section 6 of Appendix III 8.
Organisation :	• DASA-147 • Approved maintenance environment (DASR-145, M.A. Subpart F with A rating, manufacturer) under the DASA-147 approval • Defined maintenance environment as described in the direct approved procedure by the competent authority	Always in a maintenance organisation approved under DASA-145 with an aircraft rating.
	Reference: Appendix III 1(b)	Reference: Appendix III 6.; AMC to Section 6 of Appendix III 1.
Objectives:	To evaluate if the candidate has gained the required competence in performing safe maintenance, inspections and routine work according to the aircraft documentation and other relevant instructions and tasks as appropriate for the type of aircraft.	To confirm the completion of the required diversity and quantity of OJT, based on the supervisor(s) reports and feedback. It is sufficient that the completion of individual OJT tasks is confirmed by the direct supervisor(s), without necessary being the direct evaluation of the assessor.
	Reference: Appendix III, 3.2.	Reference: AMC to Section 6 of Appendix III 7. & 8.
Type of assessment:	The assessment may be: • diagnostic (prior to a course), • formative • summative (partial or final evaluation) • performed task-by-task • performed as a group of tasks • partly executed on simulation devices • performed as a final assessment	• Continuous during OJT (confirmed by the direct supervisor) • Summative, as a final evaluation by a designated assessor of the completeness of the OJT (based on the supervisor(s) reports and feedback)
	Reference: AMC to DASR-66 Appendix III 2)	Reference: AMC to Section 6 of Appendix III to DASR-66
Qualification of the assessor:	The assessment shall be performed by designated assessors appropriately qualified. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Guidance about the qualification is given in AMC to DASR-66 Appendix III 3.)	The OJT shall be assessed by appropriately qualified and designated assessors. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Guidance about the qualification is given in AMC to DASR-66 Appendix III 3.)

Practical DASR 147 MILITARY AIRCRAFT TYPE TRAINING LEVELS VS SERVICE LEARNING LEVELS

Superseded

The following table provides guidance on the correlation between the DASR Military Aircraft Type Training levels (TL), Air Force (MAFET) Learning Levels (LL), Army (ATI 1-3/20), SADL TLs and Navy LLs;

DASR		RAAF			ARA			SADL		RAN
TL	Description	LL	Definition	Description of graduate	LL	Definition	Assessment	TL	Description	
1	Graduate is: • Able to define descriptions and maintenance practices • Identify appropriate manuals and maintenance practices • Define layout of major systems • Define layout and characteristics of power plant • Identify special tooling and testing equipment	1	Training provides background knowledge only. It is familiarising in nature or is an introduction to further training.	The graduate has completed learning that either has no clear links to identified workplace requirements or supports underpinning knowledge, skills or range of variables.	1	**Low** - Unable to perform, little to no experience.	Skill and Knowledge are not assessed, but confirmation of learning may occur during training	1	Trained, but not against a prescribed standard.	Navy do not use Training Levels.
N/A		2	Trained to a level below that required for successful assessment against identified workplace requirements, without further training and/or practice.	The graduate has limited knowledge and has performed components of, but not the complete task, during training.	2	**Basic** - Limited in ability or knowledge, needs significant help from others.	Skill and Knowledge are assessed against a restricted set of performance criteria	2	Partially trained against a prescribed standard.	
2	Graduate is able to: • Understand theoretical fundamentals • Apply knowledge in a practical manner • Recall safety precautions • Describe systems and aircraft handling • Identify locations of principal components • Explain normal functioning of major systems • Perform procedures for servicing • Demonstrate proficiency in interpreting crew reports and reporting systems and determine airworthiness • Demonstrate the use, interpretation and application of appropriate documentation	3	Trained to the level to achieve the identified workplace requirement, but unable to be assessed in the context of the training environment. Subsequent experience and assessment using the prescribed workplace requirements or UoC is needed in the workplace environment.	The graduate is trained and ready for assessment against the identified workplace requirements or UoC. The graduate will be aware of common problems in standard workplace contexts but will likely encounter new situations with limited confidence.	3	**Demonstrable** - Able to perform at basic level, has some experience, needs help from time to time.	Skill and Knowledge are to be formally assessed against a set of defined performance criteria	3	Fully trained and ready for assessment against prescribed standard.	
3	Graduate is able to: • Demonstrate theoretical knowledge of systems, structures and their relationship with other systems. Provide detailed descriptions and interpret results applying corrective action where appropriate • Perform checks as specified in maintenance manuals • Demonstrate use, interpretation and application of appropriate documentation • Correlate information for the purpose of decision making • Describe procedures for replacement of components	4	Trained to the level required to achieve the workplace requirements, without the need for further workplace training or practice. Assessment, using the prescribed workplace requirements or UoC, is completed in training environment.	The graduate is trained and assessed, and can be employed effectively on the job. The graduate will be able to cope with common problems in standard workplace contexts and will encounter new situations with moderate confidence.	4	**Advanced** - Capable and experienced, demonstrated proficiency, able to work independently with little help.	Skill and Knowledge are assured under defined employment conditions	4	Trained and assessed competent against the prescribed standard.	
N/A		5	Training reflects outcomes related to values and/or feelings prescribed for the workplace.	The graduate has chosen a certain course of personal action, as prescribed for the workplace.	5	**Expert** - Fully capable and experienced, sought for help by others, needs no assistance to complete tasks, ability to train and lead others, seen as SME.	Skill and Knowledge are internalised by practice and reflection and expressed as autonomous professionalism	N/A

8.3.5 – Flexibility Provisions for Maintenance Organisations

8.1 Introduction

8.1.1 This chapter is intended to provide additional guidance on continuing airworthiness regulations to supplement the DASR (DASP Manual Volume 2). This chapter provides additional guidance on aviation safety outcomes that may incorporate compliance with multiple regulations.

8.1.2 The sub-chapters within this chapter are associated with Continuing Airworthiness Management, Maintenance Organisations, Maintenance Licencing and Maintenance Training Organisations. These sub-chapters will also reference, where appropriate, other chapters and sub-chapters within DASP Manual Volume 3 for common aviation safety elements (e.g. occurrence reporting). Other DASP content relevant to continuing airworthiness will also be referenced where possible.

8.1.3 This chapter will contain information that has historically been communicated via Factsheets, Advisory Circulars (ACs) and Frequently Asked Questions (FAQs). In some instances, these historical methods of communicating guidance will remain – particularly for guidance that has a limited period of applicability or when inclusion in DASP Manual Volume 3 is not an intuitive way to communicate specific information. Use of separate Factsheets, enduring ACs and FAQs will be the exception, with the intent that DASP Manual Volume 3 to be the central repository for continuing airworthiness guidance outside of DASR.

8.1.4 The content in this chapter will evolve as the need for additional guidance is identified, with new content and/or new sub-chapters being added over time to support optimal capability outcomes. Accordingly, DASA welcomes any suggestions for future continuing airworthiness guidance noting that awareness training is available via the DASA website.

8.2 Continuing Airworthiness

8.2.1 Continuing Airworthiness Management

Introduction

8.2.1.1 The following chapters provide additional guidance on DASR M regulations – they cover activities such as Deferment of Defects, Acceptance of Components and Aircraft Maintenance Programs.

8.2.1.2 The Continuing Airworthiness Management Organisation (CAMO) should be principally located within the aircraft's operational organisation, although the majority of DASR M functions may be outsourced/assigned to other organisations or service providers.

8.2.1.3 Continuing airworthiness management regulation is summarised in the requirements of DASR M.A.101 as 'This [DASR M] establishes the measures to be taken to ensure that [continuing] airworthiness is maintained, including maintenance. It also specifies the conditions to be met by organisations involved in such continuing airworthiness management'.

Superseded

8.2.1.4 Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including other chapters of DASP Manual Volume 3.

DASR M - Continuing Airworthiness Management

8.2.1.5 CAMOs are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided. The scope of continuing airworthiness management activities should be in accordance with the Operating Organisation's policy and procedures defined in the Continuing Airworthiness Management Exposition (CAME). The CAME is approved by DASA and sets out the procedures, means and methods of how the CAMO intends to comply with the requirements of DASR M. A list of key management positions will be listed in the CAME. The CAME also includes all functions and privileges required to ensure the aircraft are maintained in an airworthy condition, the issue of Military Airworthiness Review Certificates (MARC), and/or changes to the Aircraft Maintenance Programme (AMP). Additional Information on gaining DASA approval to become a CAMO can be found in Chapter 5.3 Annex H –CAMO.

8.2.1.6 CAMOs are responsible for ensuring that maintenance of aircraft is performed by an organisation approved by DASA or another organisation acceptable to DASA. A maintenance organisation is acceptable to DASA if its services are accessed in accordance with the terms of a recognition certificate.

8.2.1.7 Recognition certificates may enable a CAMO to fulfil the aircraft Certificate of Release to Service (CRS) requirement using a maintenance organisation not approved by DASA. These provisions are applicable where DASA has recognised another airworthiness authority in the area of aircraft maintenance. Chapter 6.5, Recognition of Other Aviation Safety Authorities, provides further guidance on the application of recognition.

8.2.1.8 Recognised systems may include an artefact equivalent to an aircraft CRS; however, maintenance organisations may be prevented from issuing a native artefact against a Defence-registered aircraft by legal or policy constraints. Instead, the CAMO should request an artefact that meets the requirements set out in DASR M.A.801.

Airworthiness Directives

8.2.1.9 Airworthiness Directives (ADs) mandate actions to be performed on an aircraft to restore an acceptable level of safety. Furthermore it is mandatory that CAMOs comply with any AD applicable to its aircraft, guidance on Airworthiness Directives can be found in Section 7.4.3 – Airworthiness Directives.

Data for modifications and repairs

8.2.1.10 DASR M.A.304(d) provides for the consumption of data already approved within a recognised airworthiness framework. A CAMO may consume data for repairs and 'minor' modifications when the data is produced by an organisation accepted by DASA. An organisation is accepted by DASA if its design products are being accessed in accordance with the terms of a recognition certificate and a suitable procedure. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. The suitability assessment will consider, among other things, the effect of the design classification and its compatibility with the ADF Configuration, Role and Environment (CRE). Additional guidance can be found in Section 7.2.4 – Repair Designs.

Superseded

Aircraft continuing airworthiness record system

8.2.1.11 An Authorised Release Certificate is necessary for the release to service of either new or used components. It is a document issued by an entity that has the applicable privilege and attests that a new or used component has been produced or maintained in accordance with the approved design data/standard, modification standard or applicable maintenance data. Additional guidance on tracking status of service life-limited components and other usage data for aircraft structures and propulsion systems can be found in Chapter 6.6.4.

Airworthiness review staff

8.2.1.12 Airworthiness review entails a full documented review of the aircraft records and a physical survey of the aircraft. Airworthiness Review Staff are authorised by the CAMO and accepted by DASA to perform Airworthiness Reviews on aircraft which are listed on the CAMO approval certificate.

8.2.2 Operation of an Aircraft with a known Defect

Introduction

8.2.2.1 This chapter provides direction on what constitutes a Defect, how Defence aircraft can operate with a known defect and who can authorise an aircraft to operate with a known Defect.

Background

8.2.2.2 To meet the demands of operational availability, where it is not reasonably practicable to rectify defects, deferment of defects may be considered. The regulations provide Operators the flexibility to defer defects once assessed. The mechanism used should ensure due consideration is given to the impact to capability and safety. Organisations should ultimately prioritise, to the maximum practicable extent, rectifying defects prior to operating an aircraft.

What Constitutes a Defects?

8.2.2.3 A defect is an imperfection that impairs the structure, composition, or system of a product part or appliance or exceedance of operational limitations in the Instructions for Continuing Airworthiness (ICA).

Defect Management

8.2.2.4 Defects can be identified during operations or during the conduct of maintenance. However, regardless of how a defect is identified the CAMO must ensure that all defects discovered or reported are managed appropriately until rectified by a DASR 145 AMO. Annex A outlines the process for defect deferment.

8.2.2.5 Where a defect cannot be rectified before the next flight due to operational requirements, lack of spares or unavailability of maintenance services the CAMO may IAW a DASA approved procedure described at AMC M.A.301(a)(2) choose to defer the defect until it is reasonably practicable to rectify.

Deferment Options

8.2.2.6 Deferment of MEL/CDL allowable defects can be accomplished by a DASR 145 AMO or Operator in compliance with the relevant aircraft technical log procedures. MEL/CDL allowable defects are subject to acceptance by the aircraft commander.

Superseded

8.2.2.7 Where a MEL/CDL does not exist and there is credible data available, IAW GM M.A.301(a)(2), a determination can be made as to the impact to airworthiness for the aircraft. AMC M.A.301(a)(2) allows the CAMO to defer such a defect IAW a procedure documented in the CAME and approved by the MAA.

8.2.2.8 The procedure must ensure:

1. Airworthiness[1] is maintained, using only credible data, in the defect deferment determination;
    i. Within the context of Airworthiness, 'without significant hazard' is considered to mean that no credible hazard exists that would impact airworthiness.
    ii. A non-credible hazard is a defect that is considered so implausible as to its affect on Airworthiness that it does not need to be accounted for. To manifest into an Issue would require a series of exceptional failures or conditions to happen simultaneously making it impractical to consider for a given operational period.
2. potential hazards arising from the cumulative effect of any combination of defects and restrictions/limitations on the same aircraft are considered as to the impact on airworthiness;
3. deferred defects are documented in the continuing airworthiness record system, including the deferment period and any associated limitations/restrictions as described at M.A.306(a);
4. any conditions, limitations or restrictions are clearly identified and visible to aircrew;
5. monitoring on a continuous basis, defects occurring in flight and defects found during maintenance, highlighting any defects that are repetitive;
    i. Where repetitive defects are identified the CAMO may develop a list of pre-assessed defects that have been documented with consideration to the requirements of the DASA approved procedure. However, the accountability remains on the authorised person approving the defect to ensure the context in which the credible data used to assess the defect and the aircraft condition remains appropriate for the specific pre-assessed defect application.
    ii. In each instance of a pre-assessed defect MTCH engagement should be sought. This will allow consideration of inclusion of the repetitive defect in the relevant platform MEL/CDL or review of existing ICA for possible improvements.
6. Persons who determine whether a defect affects Airworthiness are competent and authorised to defer defects.

8.2.2.9 The procedure should also address how ongoing analysis of the effectiveness of the CAMO's defect control system is carried out.

8.2.2.10 If the defect does not allow the aircraft to remain airworthy the Operator may seek to use the following for ongoing operations:

1. Military Permit to Fly, or

Superseded

2. Command Clearance.

8.2.2.11 Where the CAMO has contracted/tasked the day-to-day control of aircraft technical log deferred defects to another Organisation or the DASR 145 has identified a defect in the course of maintenance that entity may defer that defect IAW M.A.306 (a) subject the following:

1. The defect has been assessed using maintenance data defined in DASR 145.A.45, by appropriately authorised certifying staff IAW DASR 145.A.48 (c), as not a Hazard to flight safety;

   i. Authorised certifying staff may only use maintenance data, as defined through DASR 145.A.45 in making an Endangerment to Flight Safety Assessment (EFSA). The authorised certifying staff may only consider the consequence of failure to determine if a defect hazards flight safety.

   ii. If available maintenance data is insufficient to enable a data driven assessment to identify if the defect either does or does not hazard flight safety the DASR 145 should seek additional maintenance data from the CAMO. If further maintenance data is not available or a definitive assessment cannot be made then the defect is to be processed as if it does hazard flight safety.

   iii. Where a defect does hazard flight safety this does not preclude the CAMO from operating the aircraft. However, the CAMO must establish, for the context of the intended aircraft operation, through the procedure described under 8.2.2.1 that the aircraft remains airworthy with the defect deferred.

2. potential hazards arising from the cumulative effect of any combination of defects and restrictions/limitations has been considered as to the impact on the Flight Safety Assessment; and

3. CAMO has been notified as described under DASR 145.A.48 (c) of the defect and agrees to its deferment.

8.2.2.12 Where a CAMO does not agree to the deferment of a defect they are to task a DASR 145 MO as described under DASR M.A.201(g) to rectify the defect.

Annex:

A. Deferred Defect Management Process – Flowchart

8.2.3 Alternate Artefacts

Introduction

8.2.3.1 This chapter provides additional guidance on acceptance of components – specifically the acceptance of alternate documentation, where components are not supplied with a DASA Form 1 or equivalent recognised document.

8.2.3.2 The introduction of DASRs brought with it a change to the information requirements accompanying components to be consumed on ADF aircraft. DASRs require that components be supplied with a DASA Form 1, or recognised equivalent, that declares the airworthiness of a component.

Superseded

8.2.3.3 This chapter relates to the acceptance of new and used aircraft components, which are listed by the appropriate design organisation as eligible for installation in/on a product and included in the design data approved by the Authority[1]. The term components broadly covers any product (other than complete aircraft), part or appliance that is, or is intended by its manufacturer to be, a part of or used in operating an aircraft in flight, or is installed in or attached to a product. This may include any self-contained part, combination of parts, assembly, subassemblies or units, which perform a distinctive function necessary to the operation of the airframe, engine, or propeller, or may include any other instrument, mechanism, equipment, apparatus, software or accessory, including communications equipment.

8.2.3.4 Although alternate artefacts are consumed by a DASR 145 Approved Maintenance Organisation (AMO), DASA requires the relevant CAMO to seek approval for and manage the ongoing validity of alternate artefacts for their respective platforms. Further detail on alternate artefacts can be found in Chapter 8.3.4 – Acceptance of Aircraft Components

What constitutes an 'alternate artefact' accepted by DASA?

8.2.3.5 DASA may agree that an AMO may consume an alternate artefact other than a DASA Form 1, or recognised equivalent Authorised Release Certificate, that is produced by an organisation accepted by DASA. A CAMO can seek approval of an Alternate Artefact from DASA using DASR Form 155 – Application for Acceptance of Alternate Artefact. AMC to DASR M.A.201(g) and M.A.802(c) provide detail on when an alternate artefact would be acceptable. Chapter 8.3.4 – Acceptance of Aircraft Components provides further detail.

Consumption of United States (US) Department of Defence (DoD) products

8.2.3.6 There has been confusion with consumption of US DoD supplied products where associated documentation, such as DD Form 250, does not meet the requirements of a DASA Form 1 or recognised equivalent. The DASR provide a path for the regulated community to accommodate the consumption of products where the product supplied does not meet the requirements of a DASA Form 1. This is:

1. AMOs and CAMOs comply with DASR 145.A.42 and DASR M.A.201 (g) (e.g. via direct recognition or DASR Form 155 Application for Acceptance of Alternate Artefact).
2. Where (a) above is not reasonably practicable, CAMOs can develop a procedure within their exposition to demonstrate to DASA how these products can be consumed whilst maintaining an equivalent level of protection. DASA will then assess this procedure against the requirements of DASR GR.80(b), and if appropriate, approve the procedure for use.
3. Where (a) is not reasonably practicable, and an equivalent level of protection cannot be ensured (b), CAMOs can develop a procedure within their exposition to demonstrate to DASA how these components will be consumed; accompanied by a demonstration that the resultant risks are appropriately managed by the applicable MAO. DASA will then assess this procedure against the requirements of DASR GR.80(c), and if appropriate, allow the use of the procedure.

8.2.4 Aircraft Maintenance Programme

Introduction

Superseded

8.2.4.1 This chapter provides guidance on Aircraft Maintenance Programmes (AMPs) and Reliability Programmes (RPs).

Aircraft Maintenance Programme (AMP)

8.2.4.2 DASR M.A.302(a) requires that maintenance of each aircraft shall be organised in accordance with an AMP. The AMP encompasses the actual maintenance programme in its entirety. An AMP provides the scheduled maintenance tasks, their associated maintenance procedures and standard maintenance practices that are applied to the maintenance of an aircraft. The RP, which continually reviews the applicability of the AMP to the aircraft and operator, is also considered a part of the AMP.

8.2.4.3 Guidance on the application and approval of AMPs can be found in Chapter 5.3 Annex T – AMP with additional guidance in Chapter 6.6.4 (particularly guidance on how integrity programs can support the development and ongoing validity of the AMP).

Extension of promulgated maintenance interval

8.2.4.4 If a contracted/tasked maintenance organisation advises the CAMO that the maintenance cannot be carried out by the required timeframe and requests an extension of the promulgated maintenance interval, the CAMO when processing the request for an extension, has the following options available:

1. where the packaged/promulgated interval is less than the engineering justified interval, extend the interval up to a maximum of the engineering interval;
2. extend the task interval using the CAMO's indirect approval procedure, if suitably privileged, either once-off or permanently,
3. request DASR 21J design support for the requested interval extension; or
4. utilise the Command Clearance process to operate the aircraft IAW DASR M.A.301(a)(2) .

8.2.4.5 **Extending the Packaged Interval.** Interval flexibility may exist between a maintenance task's packaged/promulgated interval and its engineering/design interval in the AMP. The task may be packaged at a lesser interval maintenance efficiency due to tasks required in the same area or aligning maintenance to be conducted in blocks. If this is the case, and provided the CAMO has the underlying analysis that identifies the engineering interval and the reasons why the task was packaged at a lesser interval, the CAMO may authorise an extension to the packaged interval up to a maximum of the recorded engineering interval.

8.2.4.6 **Extend the AMP Task Interval.** If the AMP task interval has been reached, the CAMO may have sufficient data to extend the AMP task interval either once off, for a defined period, or permanently. To amend the AMP the CAMO must have the privilege from the MAA and sufficient scope as agreed in the indirect approval procedure. Note: where a task's interval has been extended permanently, the task may still be packaged as desired (not exceeding the extended interval).

8.2.4.7 **Request DASR 21J Design Support.** If the two options at para 8.2.4.4a and b above are not applicable, the CAMO may request DASR 21J design support to either extend the interval once off, for a defined period, or permanently.

8.2.4.8 **Utilise the Command Clearance process.** DASR M.A.301(a)(2) contains provisions for the Operating Organisation to deviate from the Initial / Continued / Continuing regulations.

Superseded

8.2.4.9 For servicings with multiple tasks, the decision on extending the interval and the method used will be dependent on the individual circumstances of each task within the servicing. A combination of paragraphs 8.2.4.4a to d may be necessary.

8.2.4.10 Note, that extending a maintenance task beyond its promulgated interval may reduce the preventive effect of the task by increasing the risk of exposure to the failure consequences of the failure mode being addressed. Extension of maintenance could adversely affect the operational capability and/or safety of the aircraft. Also, the percentage by which the interval is extended does not universally reflect the increase in risk in exposure to the failure consequences of the failure mode(s) the task is addressing. The increase in risk with the extension of a task's interval needs to be assessed individually based on the underlying Reliability Centered Maintenance (RCM) analysis that justified the existing interval and the context in which the interval extension is being asked.

8.2.5 Airworthiness Review

Introduction

8.2.5.1 This chapter provides guidance on Airworthiness Reviews (AWRs) to supplement the AMC M.A.710(a)

Airworthiness Review

8.2.5.2 During airworthiness review of an aircraft, the airworthiness review staff must examine continuing airworthiness records for the aircraft and perform a physical survey of the aircraft to determine whether the aircraft continues to comply with the airworthiness requirements as set out in DASR M.A.710(a) and DASR M.A710(b).

8.2.5.3 For many aircraft, the quantity of records that must be examined and the level of examination required will be extensive. It is anticipated that the airworthiness review staff will be assisted by other employees of the CAMO and/or appropriately experienced personnel in this regard. This does not prevent other personnel from assisting to retrieve records, compile information and prepare reports etc. for the examination by the airworthiness review staff. However, it is up to the airworthiness review staff carrying out the airworthiness review to be satisfied with the source, authenticity and accuracy of the information made available to them.

8.2.5.4 The airworthiness review staff are expected to have a level of understanding of the continuing airworthiness records system for the aircraft that allows them to carry out the review without error.

8.2.5.5 **Rectification of defects.** AWR staff shall examine the aircraft's continuing airworthiness record system to determine if any defects need rectification before flight. Defects that require rectification before flight must be rectified before the issue of an airworthiness review certificate.

8.2.5.6 **Deferred defects.** AWR staff shall examine the existing deferred defects as recorded in the aircraft's continuing airworthiness record system to determine whether deferral of rectification has been carried out.

8.2.5.7 **Airworthiness Directives (AD).** AWR staff shall examine the records containing compliance with ADs to determine whether actions required by each AD that applies to the aircraft, product, parts or appliances fitted to the aircraft have been complied with. An examination of documents that substantiate each AD has been complied with should verify that information kept is correct. Examples of documents that may substantiate an AD has been complied with, includes:

Superseded

1. maintenance records for maintenance carried out on the aircraft;

2. copies of authorised release certificates for product, parts or appliances; and

3. log books for products such as engines and propellers.

8.2.5.8 For a product, parts or appliances, the document that substantiates compliance with the AD should relate to the product that is identified in the records by part number and serial number.

8.2.5.9 Where an AD requires compliance with requirements contained in another document such as a service bulletin (SB), a record of compliance with the service bulletin would be acceptable as evidence of compliance with the AD.

8.2.5.10 **Modifications.** AWR staff shall examine the records of modifications kept to determine whether there is a DASR 21 (see DASR M.A.304—Data for modifications and repairs) approval for each design of the modification. For the purpose of this paragraph, a modification includes a repair that involves change to the approved design of the aircraft.

8.2.5.11 **Life Limited Components**. AWR staff should examine the records of life-limited components kept to determine whether part number, serial number, has correctly identified each life-limited part and whether the life limit has been exceeded for any of the parts.

8.2.5.12 In addition, documents that have been used to substantiate remaining life at installation shall be checked to verify that information kept for life-limited components is correct. Examples of such substantiating documents include:

1. maintenance records for installation of the parts;

2. authorised release certificates for the parts; and

3. life limited component history/log card.

8.2.5.13 **Weight and Balance.** AWR staff shall examine the record of the aircraft's weight and balance kept to determine if it is consistent with all the changes made to the weight and balance since the last weighing of the aircraft. All changes made to the weight and balance should be substantiated by documents such as a modification approval and an equipment list for the aircraft.

8.2.5.14 **Aircraft Configuration.** AWR staff shall examine the aircraft's continuing airworthiness records to determine whether the aircraft's configuration as recorded complies with the specification in the military type certificate data sheet (TCDS) for the aircraft, engine and propeller.

8.2.5.15 **Findings.** All findings discovered during an airworthiness review should be documented and managed in accordance with the CAMO's quality management system / safety management system, consistent with requirements of M.A.905.

8.2.6 Master Minimum Equipment List (MMEL) and Minimum Equipment List (MEL)

Introduction

8.2.6.1 This chapter provides guidance on Master Minimum Equipment List (MMEL) and Minimum Equipment List (MEL) development and approval.

Background

Superseded

8.2.6.2 Under certain conditions the required level of safety can be maintained with specific aircraft components being unserviceable, for a limited period of time, until repairs can be made. Many aircraft also have equipment installed that is not required for safe operation under certain operating conditions (e.g. aircraft with multiple VHF radios can operate with single radio if operations do not require the use of the systems associated). Equipment, such as entertainment systems, galley equipment, mission equipment or systems, may have no impact of flight safety.

8.2.6.3 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment, based on the aircraft type certification. An MEL consists of an approved list of the specific unserviceable equipment for a particular aircraft by serial and registration mark, based on the MMEL and the Operator's Configuration, Role and operating Environment (CRE).

8.2.6.4 An MEL can be used as the first step in a defect management process in accordance with procedures developed by the CAMO and approved by the DASA to meet the requirements of DASR M.A.301 (a) 2, for the deferral of defects.

8.2.6.5 Useful background information when developing a MEL can be found in:

1. CASA CAAP 37-1(5) - Minimum Equipment Lists (MEL)
2. EASA Rules for Master Minimum Equipment List (CS-MMEL)

DASA Regulatory Basis

8.2.6.6 DASR GM 21.A.15(a) - Application for a Military Type Certificate may include the MMEL as Operational Suitability Data (OSD) that may be approved as part of Type Certification and form part of the Military Type Certificate (MTC) .

8.2.6.7 DASR M.A.301 Continuing airworthiness tasks, refers to MEL and Configuration Deviation List (CDL) for use in the deferment of defect rectification.

8.2.6.8 DASR AO Gen.05 Management of OIP, ORO.05 Conduct of Flying Operations and ORO.30 Flight Authorisation support discharging flight operations requirements referred to in this chapter.

Configuration Deviation List

8.2.6.9 A Configuration Deviation List (CDL) is a listing of regulator-approved non-structural external parts that may be missing but the aircraft remains airworthy. A CDL provides options to dispatch an aircraft for flight when listed parts may be missing, provided the necessary performance corrections are adhered to (including limits or restrictions if required and specified rectification periods). Refer DASR M.A.301(a)2 and associated AMC/GM.

8.2.6.10 CDLs are part of the certified type for any civil derivative aircraft (certified by the European Aviation Safety Agency (EASA) or the Federal Aviation Administration (FAA)). Within the ADF context, as part of Military Type Certification, the CDLs are presented as part of the Aircraft Flight Manual (AFM) for approval during Type Certification. Usually, they are contained in a standalone section of the AFM. The AFM is approved as part of Military Type Certification (DASR 21 Subpart B) and changes would be approved under (DASR 21 Subpart D).

8.2.6.11 The CDL should not be confused with the Minimum Equipment List (MEL). While the MEL describes the limitations of aircraft operation in case of a system being inoperative or having malfunctioned (e.g. transponder failure), the CDL deals with situations where external parts of an aircraft are missing (e.g. fairings, aerodynamic seals or panels).

Superseded

MMEL

What is a MMEL?

8.2.6.12 A MMEL is a document created specifically to permit the continued operation of an aircraft type (e.g. C-130J-30) with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL does not take into account the operating circumstances of individual operators of that type. The MMEL cannot, in itself, be regarded as providing operational permission. It can, however, be the basis for the development of an individual Operator's MEL.

MMEL Characteristics

8.2.6.13 **Aircraft Type.** MMEL relief for a particular item may be unique to a specific aircraft type. Therefore, MMEL relief for an item for one aircraft type may not be the same as the relief allowed for the same item found in another aircraft type.

8.2.6.14 **Items required by an Airworthiness Directive (AD) are prohibited.** An MMEL will not include items that an AD requires to be operative, unless the AD specifically allows them.

8.2.6.15 **Variable Number of Items Required for Dispatch.** A MMEL may depict a variable number of items required for dispatch based on various makes and models of the same series aircraft. The MMEL must clearly articulate which makes and models each MMEL item is applicable to.

8.2.6.16 **Multiple Versions of the Same Item.** A MMEL may contain multiple versions of particular items (e.g., very high frequency (VHF) communications systems and fire extinguishers) that are installed on different models or series of the aircraft covered by the MMEL. The MMEL must clearly articulate which versions each MMEL item is applicable to.

8.2.6.17 **Repair Categories.** A MMEL will contain a repair category for each item. Each repair category allows for a certain amount of time until repairs must be accomplished.

8.2.6.18 **Prohibited Items.** A MMEL will not include items of the aircraft that are required for basic flight (wings, flaps, rudder, etc.), nor will it include instruments and equipment required for specific operations.

MEL

What is a MEL?

8.2.6.19 A MEL is a document created specifically to manage the continued operation of an aircraft with unserviceable equipment consisting of an approved list of the specific unserviceable equipment for a particular make and model of aircraft by serial/production number and registration mark (e.g. C-130J-30, 5440, A97-440) as applicable. Its use is authorised by accepting the associated application procedures contained in an operator's Continuing Airworthiness Management Exposition (CAME) and/or operations manual, or other appropriately documented procedures.

MEL Transferability

8.2.6.20 An approved MEL for an aircraft is a non-transferable document, i.e. if the MAO of the aircraft changes, then a new approval for the MEL is required even if the aircraft retains the same registration mark.

Superseded

8.2.6.21 If an aircraft moves from one Military Air Operator Certificate (MAOC) holder to another, the new MAOC holder cannot automatically use the approved MEL for the aircraft. The new MAOC holder will be authorised by DASA only if they have acceptable associated application procedures contained in their CAME and/or operations manual and have assessed the operator's CRE.

Use of the MMEL/MEL

MMEL/MEL Considerations for Use

8.2.6.22 The MMEL/MEL is an alleviating document. Its purpose is not to encourage the operation of aircraft with unserviceable equipment. It is never desirable that aircraft continue operations with unserviceable equipment. Such operations are permitted only as a result of careful analysis of each item to ensure that the required level of safety is maintained. A fundamental consideration in permitting the operation of aircraft with unserviceable equipment is that the continued operation of an aircraft in this condition is to be eliminated or otherwise minimised so far as reasonably practicable (SFARP).

Invoking the MEL

8.2.6.23 The Aircraft Captain or appropriately licenced and authorised Military Aircraft Maintenance Licence (MAML) holder invokes the MEL on behalf of the CAMO. It is the decision of the Aircraft Captain to accept the aircraft for flight with unserviceable systems or equipment listed in the MEL. The overriding principle is that, notwithstanding the provision of an approved MEL, a MAML holder should not release an aircraft for flight, and the Aircraft Captain should not accept an aircraft for flight, if it is considered unsafe for a particular flight.

8.2.6.24 A MAO may authorise Aircraft Captains to invoke MEL items through provisions in the Operations Manual. Where an Aircraft Captain is not authorised to invoke a MEL item the Aircraft Captain is to refer to local procedures for actions required to invoke the MEL item.

Developing a MMEL

MMEL Development Options

8.2.6.25 **Existing CAA/MAA MMEL as part of Operational Suitability Data (OSD).** As part of the introduction of a new type to Defence the initial certification package may contain a MMEL that has been developed by the OEM as part of the OEM state of design certification process. This MMEL document can be submitted as OSD, as part of the Australian MTC certification package and be assessed for approval as the DASA approved MMEL. Similarly, for an existing type with no DASA approved MMEL, an existing Civil Aviation Authority (CAA) / Military Aviation Authority (MAA) approved MMEL may be submitted for approval as a change to the type certificate.

8.2.6.26 In both cases above, foreign CAA/MAA approval of a MMEL does not constitute automatic approval under DASRs. DASA issues its own sovereign Military Type Certificates (MTC) for each aircraft type and does not 'accept' foreign civil or military TCs. Therefore, in order for a MMEL to be approved under DASRs it must be approved under the initial issue of, or as a change to, the DASA issued MTC and be included on the DASA issued Type Certificate Data Sheet (TCDS).

8.2.6.27 **MEL submitted in lieu of MMEL.** If the operator has access to an existing, or has developed, a MEL for the type, for which no MMEL exists, the operator may submit the MEL through the Military Type Certificate Holder (MTCH), for assessment as a MMEL. If the MEL is submitted, DASA

Superseded

will consider it a MMEL submission and assess it as such. It may then be used as the basis for acceptance as a MEL.

8.2.6.28 **Development of a new MMEL.** A MTCH may elect to submit a new MMEL to DASA for approval. DASA does not stipulate any specific format and/or contents of a MMEL. However, the Certification Programme must propose an appropriate Certification Basis that the MMEL will comply to, and that may include content and format requirements. Establishing the Certification Basis early and following the associated format will avoid delays in assessment and approval of the MMEL.

8.2.6.29 **Suitable Certification Specifications.** The Certification Programme should be submitted to DASA, proposing a Certification Basis for the MMEL. The following two certification specifications will likely be suitable for development of MMELs:

1. EASA CS-MMEL. CS-MMEL is the Certification Specification (CS) mandated by EASA for MMEL development and is likely to provide an acceptable basis for MMEL approval for Defence aircraft.

2. FAA FOEB process. FAA policy for MMEL approval is through the Flight Operational Evaluation Board process. MMEL document templates, guidance on specific systems, general format requirements, and guidance on justification requirements are available on the FAA FSIMS website. (Reference ICAO Manual – MMEL/MEL5 and Flight Standards Information Management System).

8.2.6.30 Alternate Certification Bases may be proposed in the Certification Programme but will require further justification.

MMEL development process

8.2.6.31 As the MMEL forms part of the Military Type Certificate, any MMEL change is to be classified IAW the guidance in DASR 21.A.91. On initial issue of the MMEL or identification of a MMEL change as Major, the Major Change to Type Certificate process as per DASR 21 subpart D applies. Minor changes to MMELs are to be processed IAW DASR 21.A.95. This process is depicted at Appendix 2.

8.2.6.32 **MMEL Change Classification Criteria.** The following guidance for classification of MMEL changes elaborates upon the generic classification advice in GM to DASR 21.A.91.

8.2.6.33 Conditions requiring classification of a MMEL change as Major:

1. Where the change requires an adjustment of the MMEL certification basis;
2. Where the applicant proposes changes to the Means of Compliance (MoC) with the requirements for the MMEL certification basis (i.e. MMEL safety assessment methodology);
3. Where the extent of substantiation data and the degree to which the substantiation data has to be assessed and evaluated is considerable, in particular but not only when:
    i. The substantiation data involving review of failure conditions that are classified as hazardous or catastrophic has to be evaluated;
    ii. The assessment of the failure effects (including next worst failure/event effects) on crew workload and the applicable crew procedures has to be evaluated; or

Superseded

iii. The capability of the aircraft to perform types of operation (e.g. Defence Long Range Operations (DLRO), Instrument Flight Rules (IFR)) under MMEL is extended.

8.2.6.34 Conditions where the MMEL change can be considered Minor:

1. Modifications to an item/s when:

   i. The change is only to the applicability of an item for configuration management purposes;

   ii. The change is the removal of an item;

   iii. The change is an increase in the number of items required for dispatch; and

   iv. The change is a reduction in the rectification interval of an item.

2. Addition of a new item when:

   i. It is considered as non-safety related IAW FAA MEL Requirements for 14 CFR Parts 91 Subpart K (Part 91K), 121, 125, 125 LODA, 129, and 135 Operations CS-MMEL GM2 MMEL.110; or

   ii. It is indicated as eligible for minor change classification in FAA MEL Requirements for 14 CFR Parts 91 Subpart K (Part 91K), 121, 125, 125 LODA, 129, and 135 Operations, GM1 CS MMEL.145.

8.2.6.35 **Justification and development of supporting data.** Items must be justified for inclusion in the MMEL against the agreed certification basis. Any risk associated with inclusion of items is to be eliminated or minimised to the level inherent in the applicable design standards. Alternate methodologies for justification of changes must be presented to the Authority during the Certification Programme agreement (CP) process.

8.2.6.36 If the conditions and limitations applied against a MMEL item are assessed as insufficient to fully eliminate the associated risk, or an Equivalent Safety argument cannot be made that the risk meets the level of safety inherent in the applicable design standards in the aircraft Type Certification Basis (TCB), the MMEL item is NOT to be included in the MMEL.

8.2.6.37 Operational endorsement should be sought from the MAO (e.g. Hazard Tracking Authority or Standards Officer (STANDO) for any operational conditions or limitations identified against MMEL items. The MTCH in developing the MMEL considers the operational conditions/limitations of the aircraft against the type certification. The MMEL operational procedures are not specific to an individual Operator's Configuration Role and operating Environment (CRE).

8.2.6.38 **Relief from Development of Compliance Demonstration Evidence.** Relief from the requirement to develop compliance demonstration evidence can be sought on an item by item basis for MMELs. The requirements for leveraging prior certification from another CAA/MAA as per AMC to DASR 21.A.20 still apply when relief is applied in this manner.

MMEL approval process

8.2.6.39 Initial Type Certification

1. The applicant for initial DASA MTC would submit the MMEL as part of the application package.

Superseded

8.2.6.40 MMEL for an aircraft with an existing DASA MTC

1. An MTCH submitting a MMEL for DASA approval must do so in accordance with the Change to Type Design process as described in DASR 21

2. Refer to Appendix 2: for the process flow to seek DASA approval of a MMEL.

Developing a MEL

Developing a MEL using an existing/relevant MMEL

8.2.6.41 DASA do not stipulate any specific format and/or contents of a MEL. Using an international recognised format could avoid delays in assessing the MEL. In the development of an MEL, DASA recommends that the MEL be developed in accordance with international standards as referenced in the Certification Programme from the MMEL (detailed above).

8.2.6.42 The MEL should be developed from the latest issue of the applicable MMEL on an item-by-item basis and keeping in view the relevant regulatory requirements.

8.2.6.43 If an operator chooses to add items that are not found in the MMEL (due to its particular type of operation) an assessment of those items must be carried out. This assessment is required to ensure that these items do not affect the design standards or safe operation of the aircraft and are not in conflict with the flight manual and any DASR requirements. Refer to the International standards as referenced in the Certification Programme from the MMEL for guidance on how to assess the criteria for these items.

8.2.6.44 In general, a MEL should be as, or more, restrictive than the applicable MMEL for the type of aircraft. If a certain item(s) of the applicant's MEL is less restrictive than the applicable MMEL, DASA will require an extensive qualitative and/or quantitative analysis to substantiate the proposed departure from the MMEL.

MEL Development with no MMEL

8.2.6.45 If a platform has no MMEL or MEL available from the manufacturer or other CAA/MAA and the operator wants to utilise the flexibility that a MEL affords, the Operator may choose to engage the MTCH to develop a MMEL from previously available deferment options.

8.2.6.46 The MMEL should be developed in accordance with the guidance provided earlier in this chapter.

8.2.6.47 Once the MMEL is approved by DASA the operator can seek approval of the MMEL for use as an MEL from DASA.

MEL approval process

8.2.6.48 An Operator submitting a MEL for approval must provide DASA with:

1. A minute of application from the CAMO requesting approval of the MEL;

2. Digital access to a copy of the proposed MEL;

3. All OIP created for use of the MEL; and

Superseded

4. If the MEL has no associated DASA approved MMEL, the MEL must be submitted for approval as a MMEL.

8.2.6.49 A MEL may cover more than one aircraft of the same type. However, all differences in the equipment/systems installed, if any, should be clearly identified by the aircraft registration mark.

8.2.6.50 Refer to Appendix 1: for the DASA process flow of MMEL/MEL approval.

Application for amendment to the MEL

8.2.6.51 Amendments to MELs are either mandatory or voluntary, depending upon the particular circumstances. Mandatory amendment of a MEL is required either:

1. When the applicable MMEL is amended so as to become more restrictive; or
2. When required by DASA in light of in-service experience.

8.2.6.52 Voluntary amendment of a MEL may be carried out when either:

1. The MMEL is amended so as to become less restrictive; or
2. As required by the operator, provided the proposed change is no less restrictive than the MMEL; or
3. Regulatory changes occur.

8.2.6.53 An application for amendment to an approved MEL, together with appropriate substantiation, should be forwarded to DASA.

MMEL/MEL Development Considerations

Operations and maintenance procedures

8.2.6.54 The objective of operations ((O)) and maintenance ((M)) procedures is to provide everyone using the document with clear and concise directions on how they are to proceed in case of unserviceability. The (O) and (M) procedures form part of the approved MEL.

8.2.6.55 **(O) Procedures:** Where the (O) symbol appears in the MMEL, an operations procedure must be developed that provides clear direction to the flight crew. These procedures may be included in the MEL. Where they are not included in the MEL, they must be available to the aircrew in another document that is always available to the aircrew (i.e. an operations manual or in an approved electronic form). In these cases, the MEL shall refer to a section of the appropriate document(s).

8.2.6.56 **(M) Procedures:** The MMEL may identify items that require a maintenance procedure. If this is the case, the operator must ensure that relevant (M) procedures have been developed for the MEL. These procedures must provide clear direction to the maintenance personnel.

Procedures for the use and guidance of flight crews and maintenance personnel

8.2.6.57 The operator must establish procedures for the use and guidance of flight crews and maintenance personnel, in relation to the MEL. These procedures must agree with those in the operator's CAME, Aircraft Maintenance Program (AMP), operations manual, and other operating documents. These procedures should include, but are not limited to, procedures for:

1. Deferring rectification action or invoking MEL item(s) for unserviceable equipment;

Superseded

2. Placarding requirements as per the MEL;

3. Ensuring that a dispatched aircraft with an invoked MEL item(s) complies with the limits and conditions of the MEL;

4. Ensuring that existing deferred defects / MPTF / Command Clearances do not impact invoking of MEL provisions;

5. Controlling categorised repair intervals; and

6. The training of organisations personnel who are responsible for compliance with MEL procedures.

8.2.6.58 Procedures for invoking MEL items are normally contained in the operator's CAME, operations manual or an alternative document. Prior to issuing a MEL approval, DASA will ensure that the MEL references these procedures in the CAME, operations manual or similar document, if not already included in the MEL. If no procedures for the invoking of MEL items exist within the operator's organisation, then DASA will, in addition to vetting the MEL, require amendment to the CAME/MOE and/or operations manual.

8.2.6.59 A placarding procedure should be established and set out in the CAME/MOE and operations manual or, at least, within the approved MEL document.

8.2.6.60 When invoking a MEL item, the person responsible must:

1. Identify, in the aircraft technical log or appropriate document/maintenance information system, that this action has occurred;

2. Identify the item with its MEL number; and

3. Ensure that an unserviceable label is placed in an appropriate location (where applicable).

8.2.6.61 A procedure documenting the above requirement in the appropriate operator's documentation is acceptable for compliance purposes.

Repair intervals

8.2.6.62 Each item of a MEL must be repaired within the specified repair interval. These intervals are set to limit the maximum time an aircraft may fly with an unserviceable item(s) of equipment, and are designated Category 'A, B, C or D'. The definition of repair intervals should align with the selected certification basis for the MMEL as defined at para 8.2.6.29.

8.2.6.63 The operator must establish procedures whereby the maintenance support periodically reviews the deferred items. This is done to ensure that any accumulation of deferred items neither conflict each other nor present an unacceptable increase in crew workload. Notwithstanding the categorisation of item repair intervals, it should be the aim of each MEL document holder to ensure that unserviceable items are repaired as quickly as possible.

Repair interval extension

8.2.6.64 Each operator's MEL management program needs to contain procedures for controlling extensions to item repair intervals. Procedures must include the limitations of each extension and the method by which the operator approves an extension.

Superseded

MEL training program

Training Requirement

8.2.6.65 The operator should as part of the introduction of a process for the use of a MEL develop a MEL training program for maintenance personnel and flight crew, which should be in place prior to an operator commencing operations with a MEL. The operator, when required, should conduct recurrent training, or put in place a controlled method to alert staff to any changes in MEL procedures. This will ensure company personnel remain current with those procedures.

Maintenance Personnel Training

8.2.6.66 The training for maintenance personnel should include those sections of the CAME procedures dealing with:

1. The use of, and compliance with, the MEL;
2. Placarding of unserviceable equipment;
3. Return to service of an aircraft;
4. Dispatching an aircraft; and
5. Any other MEL related procedures.

Flight Crew Training

8.2.6.67 The flight crew training should include, but not be limited to, the following:

1. The purpose and use of a MEL;
2. Instruction on operator's procedures for the use and guidance of flight crew;
3. The process and procedures required for supervision and flight authorisation; and
4. The Aircraft Captain's responsibility with respect to the above procedures.

8.3 Maintenance Organisations

8.3.1 Requirements for Maintenance Organisations

Introduction

8.3.1.1 This section provides additional information and guidance to DASR 145 Approval Holder Organisations and those organisations that are applying for approval under DASR 145. Further guidance on applying for a Maintenance Organisation approval can be found in Section 5 Annex G – AMO.

8.3.1.2 For information on maintenance service providers that are approved though other means (i.e. not DASR 145 approval), refer to Chapter 6.5, Recognition of other Aviation Safety Authorities and to Chapter 8.2, Continuing Airworthiness Management.

8.3.1.3 This chapter does not include information already presented at Volume 2 (DASRs), but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3.

Superseded

DASR 145 – Requirements for Maintenance Organisations

8.3.1.4 The Defence Aviation Safety Regulations (DASR) requires individual DASR 145 Approved Maintenance Organisations (AMOs) to define their own line and base maintenance activities in their Maintenance Organisation Exposition (MOE).The scope of maintenance of aircraft and components activities should be in accordance with the Maintenance Organisation's policy and procedures defined in the MOE.

Acceptance of components

8.3.1.5 The AMO must ensure that components are accompanied by appropriate documentation attesting to the legitimacy of the component's maintenance or production history. This is underpinned by the regulatory requirement for the AMO to obtain a DASR Form 1 or equivalent documentation prior to fitment of such components. Where an unserviceable or unsalvageable component is the subject of an occurrence report, the DASR 145 organisation should quarantine the component until the investigation has determined that the component is not required to be retained for further examination Additional information can be found in Chapter 8.3.4 – Acceptance of Components.

Certification of maintenance

8.3.1.6 Maintenance carried out on an aircraft, its systems and its components must be certified at completion and prior to its return to service. The instrument used to achieve this outcome is the Certificate of Release to Service (CRS) that must be issued at the completion of maintenance and before the next flight. Additional guidance for Certification of maintenance can be found in Chapter 8.3.3 - Certification of maintenance.

8.3.2 Performance of Maintenance

Introduction

8.3.2.1 This chapter provides additional guidance on the performance of maintenance including guidance on line and base maintenance, and specialist maintenance qualifications.

8.3.2.2 Not all maintenance personnel in a DASA 145 MO need to be authorised as certifying and/ or support staff. Acting as certifying or support staff is intrinsically a hands-off activity (in contrast to the performance of maintenance being physical hands-on aircraft maintenance). DASA 145 MO personnel perform maintenance under a Task Sign-Off (TSO) authorisation. On-aircraft TSO is overseen, managed and later certified (issue of CRS) by authorised certifying staff.

8.3.2.3 Except for a few speciality areas (e.g. composite repairs), DASA does not prescribe knowledge / experience standards for the performance of maintenance. On-aircraft TSO provides an attestation that the maintenance task has been carried out to the required standard.

8.3.2.4 A DASA 145 MO has flexibility to determine their own Qualification, Training and Experience (QTE) requirements when assessing and authorising personnel to perform the vast majority of maintenance (less some specialist qualifications where DASA will specify acceptable means of compliance). It is up to a DASA 145 MO to determine the scope that maintenance personnel can be authorised to perform, and may also mandate the level of supervision maintenance personnel require – noting supervision can be performed by authorised persons who are not necessarily certifying staff – see GM2 DASR 145.A.35(e). Maintenance personnel do not need to hold a MAML, of any category, to be authorised to perform maintenance.

Superseded

8.3.2.5 DASA oversight of DASA 145 MOs, in the context of foreign trained maintenance personnel employed to perform maintenance, will focus on the procedure that identifies knowledge and experience requirements, to determine the authorised scope of maintenance and supervision required.

8.3.2.6 For information on maintenance service providers that are approved though other means (i.e. not DASR 145 approved), refer Chapter 6.5, Recognition of other Aviation Safety Authorities and Chapter 8.2, Continuing Airworthiness Management.

8.3.2.7 For information on the performance of maintenance relates to the certification of maintenance, see Chapter 8.3.3 – Certification of Maintenance.

Line and Base Maintenance

Background

8.3.2.8 The Defence Aviation Safety Regulations (DASR) requires individual DASR 145 Approved Maintenance Organisations (AMOs) to define their own line and base maintenance activities in their Maintenance Organisation Exposition (MOE). Feedback from the regulated community indicates that there is insufficient DASR guidance on what types of activities constitute line and base maintenance. This chapter describes types of maintenance activities constituting line and base maintenance and describes the intended outcomes in relation to line and base maintenance as interpreted by DASA.

8.3.2.9 The DASR Glossary of Terms describes line and base maintenance as:

1. **Line Maintenance:** Carried out before flight to ensure that the aircraft is fit for the intended flight.
2. **Base Maintenance:** Maintenance tasks falling outside the criteria for line Maintenance.

8.3.2.10 A more detailed definition of aircraft line maintenance is provided in AMC 145.A.20, together with a list of activities which "may" be considered as line maintenance. The word "may" is used because it is not possible to establish a provision giving a strict demarcation between line and base maintenance, having general applicability to all cases.

8.3.2.11 To assist civil MOs, the European Aviation Safety Agency (EASA) has developed an EASA 145 User Guide chapter on 'Privileges and limitations of line maintenance'. This guide provides detailed guidance on what constitutes line and base maintenance. This Annex is has been developed based on the EASA User Guide to provide an EASA aligned approach to guide DASR 145 MOs in defining line and base maintenance.

Organisation responsibilities

8.3.2.12 The maintenance organisation should ensure prior to any intended maintenance event that the activity can be carried out under its line maintenance scope of approval (refer to AMC 145.A.20) and does not fall under paragraph 14 'Examples of maintenance activities considered to be base maintenance' of this Chapter.

8.3.2.13 This assessment may not need to take place each time, but be based on already established MOE procedures (i.e. the fact that a daily check is a line maintenance task is obvious and does not need to be assessed each time).

Superseded

8.3.2.14 Even if this assessment confirms that the activity is line maintenance, the maintenance organisation should also verify if this activity requires other means than the ones already in use at a line maintenance location.

When to assess the maintenance activity

8.3.2.15 The maintenance organisation`s assessment to decide if any maintenance event falls within the definition of line or base maintenance, may be needed in two different situations:

1. for an initial/change of approval, when evaluating the scope of work the maintenance organisation is applying for (refer paragraph 11); or

2. for an already approved maintenance organisation, when evaluating if maintenance requested by the customer (e.g. a new Service Bulletin (SB), defect rectification or work package requested by the customer, etc.) falls within the approved line maintenance scope of work.

Assessment of the intended scope of work (initial/change of approval)

8.3.2.16 It is the responsibility of the maintenance organisation to demonstrate to DASA that the intended scope of work may be carried out in a line maintenance environment, under its line maintenance scope of approval. The main criterion for this assessment is to consider the level of maintenance to be carried out under the line maintenance scope of approval, where the following general criteria apply:

1. **Trouble shooting, Defect Rectification.** Those unscheduled tasks required for the daily operation of an Aircraft and not falling under 'Examples of maintenance activities considered to be base maintenance';

2. **Minor scheduled line maintenance.** Those scheduled tasks not exceeding the weekly check as specified in the Aircraft Maintenance Program (AMP);

3. **Scheduled checks.** Those scheduled tasks which exceed the weekly check (or equivalent as determined by the Authority). In this case, the organisation needs to analyse each of the routine tasks intended to be included in the line maintenance scope of work and identify a clear limit. This assessment needs to be performed using the Type Certificate Holder (TCH) data such as the manufacturer's Maintenance Planning Document (MPD), and/or the operator's AMP. The outcome of this exercise is to identify the intended limitation of the line maintenance scope of approval, in terms of scheduled maintenance checks. In particular, the following is expected:

4. Depending on the AMP logic (i.e. MSG 2, MSG 3, etc) a clear limitation to the line maintenance scope of work may be normally expressed in one of the following ways:

   i. "up to and excluding X check" (i.e. X= R1, R2, etc) for a MPD, where letter checks are identified;

   ii. "up to and excluding "X FH / Y FC / Z calendar time", for a MPD, where progressive task intervals are defined in terms of FH/FC/calendar time (i.e. X=3000FH, Y=750 FC, Z=12 months, etc);

5. The identified limit, to be indicated in the MOE, should be such that all the related routine/scheduled tasks are excluding any of the tasks listed in 'Examples of maintenance activities considered to be base maintenance'

Superseded

6. A “decision making process” (refer paragraph 12 for example) needs to be established in the MOE in order to assess

   i. (the need to access the hangar (even if the activity is permitted under a line maintenance scope of approval), considering in particular the type of aircraft, the maintenance event type/complexity, the environmental and weather conditions;

   ii. any work order / work package received from the customer operator to ensure it may be fully performed under a line maintenance scope of approval, taking into account additional works to the original work package that may be added, leading out to the line maintenance scope of work, such as:

   – addition of previously deferred maintenance tasks; or

   – defects raising from the routine tasks (these defects are not known in advance, however, the related risk in terms of number and level of defects needs to be taken into account and estimated in advance).

8.3.2.17 **Example of ‘decision making process’.** A R1 maintenance check on the Boeing Business Jet (BBJ) aircraft type is normally considered “line maintenance” when the routine tasks are assessed as per the manufacturer MPD/operator AMP. Therefore a maintenance organisation may be approved to perform this check under a line maintenance scope of work. However, a work order to perform the “R1 check”, where the customer operator would request the performance of works in addition to the “R1” routine tasks, such as the addition of Airworthiness Directives (ADs), SBs, deferred tasks, will need to be carefully assessed by the maintenance organisation with the use of the “decision making process”.

8.3.2.18 This type of maintenance check may easily fall within the examples given in Paragraph 14 ‘Examples of maintenance activities considered to be base maintenance’ having the result to be considered as base maintenance and being outside the maintenance organisation scope of work. In such a case, the outcome of the “decision making process”, may be for example:

1. The impossibility to accept such work order from the operating organisation, being outside the scope of work of the maintenance organisation; or

2. to agree with the operating organisation a revised work order, to remove the works which have been identified as base maintenance tasks (e.g. removal of a SB which was requiring extensive disassembly and modification of flight controls, etc.).

Examples of maintenance activities considered to be base maintenance

8.3.2.19 When any of the following tasks are required to be carried out (regardless if contained in a scheduled maintenance check or arising from a defect rectification/AOG situation), a base maintenance scope of approval is needed:

1. High number of different type of tasks to be carried out, even if taken singularly those tasks may still fall under the definition of line maintenance (i.e. a combination of routine task cards, non-routine task cards issued following defects discovered during the check, out of phase tasks, deferred items from previous maintenance, minor repairs, minor modifications, component replacement, etc). Such cases require base maintenance production planning support and/or a base maintenance release to service process (category C Certifying Staff supported by B1/B2 support staff) in order

Superseded

to ensure that all the maintenance ordered has been carried out before issuing the CRS;

2. Replacement of any major component where the related maintenance procedures address the need of a hangar environment requiring special ground support equipment and/or structured production planning and/or complex and lengthy maintenance, such as for example a full landing gear replacement, simultaneous replacement of two engines, etc;

3. Any scheduled maintenance task (i.e. routine task from the AMP) which requires extensive disassembly of the aircraft and/or extensive in depth inspection;

4. Major repairs and/or major modifications;

5. Trouble shooting and/or defect rectification requiring special ground support usually relevant to base maintenance (e.g. special equipment, structured production planning, complex and lengthy maintenance);

6. A scheduled maintenance event, which in the planning phase has been already identified as significant in terms of duration and/or man-hours (i.e. an aircraft down time above 72 hours or four shifts, whichever is less);

7. A work package requiring a complex team composition in terms of high number and categories (avionic, structure, cabin, NDT qualification and skills, etc) of staff involved per shift; or

8. The management of the event by B1 and B2 support staff and the release by a C certifying staff.

8.3.2.20 For AMOs that do not hold a base maintenance approval, the AMO remains responsible to ensure that even if each individual work order constitutes a line maintenance activity, a maintenance event cumulating several of these work orders remains within the AMO's line maintenance scope of approval.

Assessment of maintenance task by an already approved maintenance organisation

8.3.2.21 For AMOs that do not hold a base maintenance approval, the AMO remains responsible to assess if any maintenance requested by the operating organisation falls within the approved line maintenance scope of work. This assessment is expected to be performed based on the "decision making process" described above.

Specialist Task Qualifications

8.3.2.22 **Introduction.** DASR 145.A.30(f) relates to MO personnel who carry out Non-Destructive Testing (NDT) and other specialised tasks such as composite repair and welding. Definitions pertaining to the scope of DASR 145.A.30(f) are as follows:

1. Particular non-destructive test means any one or more of the following; Penetrant Testing (PT), Magnetic Testing (MT), Eddy current Testing (ET), Ultrasonic Testing (UT), Radiographic Testing (RT), Thermographic Testing (TT) and Shearographic Testing (ST) methods (refer GM 21.A.30(f)). Boroscoping and other techniques such as manual tap testing are non-destructive inspections rather than non-destructive testing (refer AMC 145.A.30(f)).

Superseded

2. For the purposes of DASR 145.A.30(f), DASA should be consulted to confirm the complexity and associated training requirements of composite repairs for each platform. The complexity and training requirements for non-specialised composite repairs should be detailed in the DASR 145 MOE.

8.3.2.23 DASR 145.A.30(f) requires that the MO must ensure that personnel who carry out NDT and other specialised tasks are appropriately qualified in accordance with recognised standards. The following paragraphs provide guidance on the standards recognised by DASA and other aspects of personnel training and certification.

8.3.2.24 It should be noted that the training standards required to perform specialist tasks might exceed the training standards to certify this maintenance. For example a licence persons with no structural repair exclusions could certify for a complex composite repair but may not be qualified to perform the maintenance. In this case the certifying staff may require separate specialist supervision in order to very the maintenance has been performed properly.

Qualification of Personnel for Non-Destructive Testing (NDT)

8.3.2.25 **Recognised NDT Qualification Standards.** DASA recognises the following standards for qualification of personnel who carry out and/or control NDT of aircraft structures and/or components (refer DASR 145.A.30(f)):

1. European Standard EN4179 - Qualification and Approval of Personnel for Non-destructive Testing is the primary NDT standard recognised by DASA
2. NAS410 – NAS Certification & Qualification of Non-Destructive Testing Personnel is also recognised by DASA.

8.3.2.26 NAS410 is the only NDT qualification standard DASA recognises as being equivalent to EN4179. Organisations that wish to use an alternative NDT personnel qualification system should apply to DASA with a proposed Alternate Means of Compliance (AltMoC). Note that Australian Standard AS3669 and ATA Spec 105 have been assessed as non-equivalent to EN4179 (refer GM 145.A.30(f)) and will not be approved as AltMoC by DASA.

8.3.2.27 **NDT Personnel Training and Certification.** The appointed NDT Responsible Level 3 (RL3) for each DASR 145 MO is responsible for establishing a training and certification system which supports awarding of task authorisations to NDT personnel working within the DASR 145 MO. This training and certification system should be established in line with EN4179. In cases where the minimum training and experience hour requirements stipulated in EN4179 Section 6 do not align with Defence's requirements, a competency based training program can instead be used, provided the course program is approved by DASA. Refer to GM 145.A.30(f).

8.3.2.28 For details of the approach to NDT training and certification implemented in support of ADF DASR 145 MOs, refer to Volume 3 Section 4.2.3.

8.3.2.29 **Appointment of NDT Responsible Level 3.** AMC 145.A.30 stipulates that the NDT RL3 for a DASR 145 organisation is a nominated management position, and is accepted by DASA through a DASR Form 4 application. Each DASR 145 organisation should only have one appointed NDT RL3. The DASR Form 4 requires applicants to submit details and supporting documentation of relevant qualifications and experience. Specific to NDT RL3 applications:

1. Applicants are requested to provide a copy of all personnel certification records that DASR 145 organisations are required to retain under EN4179 Para 8.2 to demonstrate they meet the EN4179 requirements to be certified as a Level 3.

Superseded

2. If the applicant holds certifications in multiple methods, only evidence from one NDT method is required. The employer is to ensure that certification records for all other methods are retained, as required by EN4179 Para 8.2.

Note: that DASA may request evidence of ongoing EN4179 compliance for NDT RL3s in the course of oversight and enforcement activities.

8.3.2.30 DASA does not require the involvement of the Australian National Aerospace NDT Board (NANDTB) in the certification of Level 3 staff. DASA will not request or rely on NANDTB recognition when assessing NDT RL3 Form 4 applications.

8.3.2.31 For questions about NDT RL3 Form 4 application evidence please email: dasa.dca@defence.gov.au

8.3.2.32 Responsibility for appointment of NDT RL3 personnel is as follows:

1. ADF DASR 145 MOs: the Directorate of Aviation Engineering (DAVENG), as Defence's Structural Integrity Centre of Expertise[3], performs the Defence NDT RL3 function (refer to Section 4.2.3 for further details).

2. Non-ADF DASR 145 MOs (i.e. contractor organisations): are responsible for appointing their own NDT RL3 personnel.

8.3.2.33 Notwithstanding the fact that Level 3 personnel may be qualified via EN4179 to establish and authorise methods, techniques, etc., this does not permit such personnel to deviate from the methods and techniques published in the Instructions for Continuing Airworthiness (ICA)[4] unless the ICA expressly permits such deviations (refer AMC 145.A.30(f)). Although it is recommended that Level 3 personnel have a role in NDT ICA deviations or changes (refer DASP Manual Volume 3 Section 7.2.5), NDT ICA deviations or changes must be approved in accordance with DASR 21.

Qualification of Personnel for Composite Repairs

8.3.2.34 **Recognised composite repair qualification standards.** Some types of composite structure repair are considered a specialised task and therefore personnel conducting those types of composite repairs require appropriate qualification in accordance with an officially recognised standard. DASA recognises SAE AIR4938 - Composite and Bonded Structure Technician Specialist Training Document for qualification of personnel who carry out composite repairs (refer AMC1 145.A.30(f)).

8.3.2.35 SAE AIR4938 Revision C includes requirements for both initial training and on-going certification. Superseded revisions of SAE AIR4938 do not include the requirements for ongoing certification, and also omit the training curriculum for bolted composite repairs. Superseded revisions of SAE AIR4938 should not be used without approval from DASA.

8.3.2.36 Organisations that seek to use an alternative to SAE AIR4938 for the qualification of composite repair personnel to conduct specialised composite repairs should apply to DASA with a proposed AltMoC. Organisations should note MEA405 is considered an introductory composites course only. DASA does not recognise MEA405 Cert IV AME Structures as a suitable equivalent to SAE AIR4938 for the conduct of specialised complex composite repairs. The complexity of composite repairs, and associated training requirements will vary for each platform. When suitable controls can be identified to ensure ongoing airworthiness a lower standard than SAE AIR4938 may be recognised as suitable for specific circumstances. Such controls could include:

1. type of structure being repaired

Superseded

2. type or complexity of composite repair being conducted

3. specific nature of training undertaken

4. experience of personnel

5. supervision requirements

6. OEM or aircraft type specific training

8.3.2.37 Applications to DASA to officially recognise alternate qualification standards should demonstrate that the alternate standard:

1. provides an equivalent level of training to SAE AIR 4938; or

2. is suitable in the context of the specific MO and the scope of the maintenance activities to be performed. In such cases, the application should clearly state the scope of the activities being performed, how the training is suitable for that scope, and the means by which the scope is to be controlled.

8.3.2.38 **Composite repair Personnel Training.** Prior to authorising staff to perform composite repairs, the DASR 145 MO should ensure the staff are trained and qualified in accordance with appropriate standards, SAE AIR49385 or approved AltMOC, for specialised composite repairs. Composite repair training and certification procedures for specialised and non-specialised composite repairs should be specified in the MOE.

8.3.2.39 DASR 145 MOs can utilise any training course that demonstrates compliance to the standard. Note that DASA-DAVENG, as Defence's Structural Integrity Centre of Expertise, conducts the certification (initial and re-certification) for all ADF DASR 145 MO staff who perform composite repairs (refer to DASP Manual Volume 3 Section 4.2.3 for further details).

8.3.2.40 DASR 145 MOs are responsible for establishing training and authorisation systems to ensure that personnel who conduct composite repairs are appropriately qualified. Further guidance for ADF and non-ADF DASR 145 MOs is as follows:

1. ADF DASR 145 MOs: The MO should verify that technicians hold a valid PMKeyS proficiency (refer DASP Manual Volume 3 Section 4.2.3) for composite repair prior to authorising them to conduct composite repairs within an ADF DASR 145 MO. MO authorisations should only remain valid for the validity period of the applicable PMKeyS proficiency.

2. Non-ADF DASR 145 MOs: The MO should document their certification/re-certification process in their MOE. The standard does not impose specific requirements on who can conduct certification.

Qualification of Personnel for Aircraft Welding

8.3.2.41 The following paragraphs are applicable to DASR 145 MOs that perform aircraft welding repairs.

8.3.2.42 Welding is used in the repair of critical and non-critical airframe and engine components within Defence. As a specialist task, personnel conducting welding operations must be appropriately qualified in accordance with officially recognised standards.

Superseded

8.3.2.43 CASA Civil Aviation Advisory Publication (CAAP) 33-1 (1) Aircraft manual welding: Approvals and qualifications provides information on how to apply for the initial issue or renewal of an aircraft welding authority under Civil Aviation Regulations. DASA has determined that a CASA welding authority, granted in accordance with CAAP 33-1 (1), is an appropriate qualification for Defence purposes.

8.3.2.44 **DASR Requirement.** DASR 145 MO that perform aircraft welding repairs must comply with DASR 145.A.30(f), which requires "Personnel who carry out any other specialised task shall be appropriately qualified in accordance with officially recognised Standards."

8.3.2.45 **Acceptable Means of Compliance.** DASA considers a CASA welding authority, granted in accordance with CAAP 33-1 (1), is an appropriate qualification in accordance with DASR 145.A.30(f).

8.3.2.46 Organisations choosing to utilise welders qualified in accordance with CAAP 33-1 (1) must:

1. Ensure technicians hold a valid Civil Aviation Safety Authority (CASA) issued aircraft welding authority prior to task authorisation.
2. Ensure technicians are only authorised to carry out those types of welding processes that are specified in the welding authority document.
3. Ensure MO authorisations only remain valid for the validity period of the CASA-issued welding authority (i.e. renewal is required every 2 years IAW CAAP 33-1 (1)).

Aircraft Welding Questions and Answers

8.3.2.47 **Q:** What does a DASR 145 MO need so that it can use welders with a CASA welding authority?

8.3.2.48 **A:** The DASR 145 is required to:

1. Identify the scope of welding repairs that it requires (that is included in its overall maintenance scope).
2. Update the DASR 145 MO Orders, Instructions and Publications (i.e. MOE and any other associated documentation), to show compliance to DASR 145.A.30(f) and implement the required management framework. The aircraft welding repair training and qualification requirements should be specified in the MOE.
3. Authorise technicians who have obtained CASA welding authority
4. Ensure that authorised staff maintain their competency and CASA welding authority currency.

8.3.2.49 **Q:** How does a person achieve CASA welding authority?

8.3.2.50 **A:** CAAP 33-1 (1) details the framework that CASA applies to provide a welding authority, which is granted to applicants that have:

1. Successfully completed a relevant Australian Quality Training Framework recognised course; and
2. Passed the welding testing set out in the CASA Welding Syllabus.

Superseded

8.3.2.51 Additional training may be required dependent on the specific work scope required by the DASR 145 MO. CASA will confirm any specific training requirements during the application for the welding authority.

8.3.2.52 DASR 145 MOs are responsible for organising CAAP 33-1(1) compliant renewal assessments for their personnel when required. There are a number of commercial organisations who employ CASA-authorised aircraft welding assessors (queries should be addressed to Contact us | Civil Aviation Safety Authority

8.3.2.53 CASA charge a fee to apply for the initial issue and for renewal of a welding authority. Applicants will also require a CASA Aviation Reference Number (ARN) prior to applying for a welding authority.

8.3.2.54 **Q:** Do welders require renewal of their CASA welding authority?

8.3.2.55 **A:** Yes. CAAP 33-1(1) requires a two yearly renewal in order to remain current. DASR 145.A.30(f) requirement that "Personnel who carry out any other specialised task shall be appropriately qualified in accordance with officially recognised Standards" requires a current CASA authorisation.

8.3.2.56 **Q.** Who covers the cost of gaining a CASA welding authority and renewal?

8.3.2.57 **A:** For:

1. Defence Maintenance Organisations, initial authority for ASTTECHs is covered within the Welder Aircraft Course at RAAFSTT, all subsequent renewal costs are to be supported though unit, or parent command funding.
2. Contractor Maintenance Organisations, refer to arrangements detailed in your contract.

8.3.2.58 **Q:** Can a non-welder supervise the conduct of a renewal welding assessment?

8.3.2.59 **A:** No. CASA requires that a CASA-authorised assessor supervise the conduct of welding examinations, and DASA has adopted this position.

8.3.2.60 **Q:** Can an organisation authorise welders with a different qualifications (in lieu a CASA welding authority)?

8.3.2.61 **A:** Yes. DASR 145 MOs who wish to use an alternative qualification to that stipulated in AMC1 145.A.30(f) should seek approval from DASA (as AltMoC).

8.3.2.62 For further information refer to the following:

1. For issues relating to the use of CASA welding authority within the DASR context please contact the DASA Desk Officer assigned to your organisation or email dasa.dca@defence.gov.au.
2. For queries related to gaining and maintaining CASA welding authority and the application of CAAP 33-1 (1), refer Contact us | Civil Aviation Safety Authority

8.3.3 Certification of Maintenance

Introduction

Superseded

8.3.3.1 This chapter provides guidance in relation to the Certificate of Release to Service (CRS) process for aircraft maintenance. The document aims to consolidate the applicable requirements from different sections of the DASR and describes the intended outcomes in relation to Sign-off & subsequent CRS at the completion of maintenance.

Background

8.3.3.2 Maintenance carried out on an aircraft, its systems and its components must be certified at completion and prior to its return to service. The instrument used to achieve this outcome is the CRS which must be issued before flight at the completion of maintenance. The CRS should contain as a minimum (AMC 145.A.50(b)):

1. Basic details of the maintenance that was carried out;
2. Date such maintenance was completed;
3. Identity of the organisation and person issuing the CRS; and
4. Limitations to airworthiness or operations, if there are any.

8.3.3.3 The requirements for CRS reside across multiple regulation subsections (DASR M and DASR 145) that collaboratively inform the regulated community of DASA's requirement. This chapter summarises the applicable requirements for CRS to assist the community in meeting the DASR.

Certification of Maintenance Responsibilities

Continuing Airworthiness Management Organisation responsibilities

8.3.3.4 CAMO responsibilities are described in detail within DASR M and include:

1. the CAMO is responsible for all activities aimed to determine the airworthiness status of the aircraft and to appropriately plan and coordinate maintenance.
2. ensuring that all maintenance requirements (Airworthiness Directives (AD), Aircraft Maintenance Program (AMP) requirements, defect rectification, etc...) are complied with and released by a DASR 145 Maintenance Organisation (DASR 145 MO) (or equivalent (M.A 708(b)).
3. the CAMO is responsible for planning and ordering all required maintenance and for ensuring that all ordered maintenance conducted by the DASR 145 MO or equivalent is complete and has a CRS. The CAME must explain how this is achieved.

DASR 145 Maintenance Organisation responsibilities

8.3.3.5 The DASR 145 MO (or equivalent) responsibilities are described in detail in DASR 145 and include:

1. the development of 'certification of maintenance' procedures that ensures all maintenance actions have been properly coordinated and the CRS is issued within a reasonable timeframe after the actual performance of the tasks;
2. issuing a CRS following maintenance; and
3. the CRS issued has to be recorded in the Continuing Airworthiness (CA) record system. This information shall be available to the aircraft captain (refer to DASR M.A.306 and

Superseded

AMC DASR M.A.306(a), who is ultimately responsible for accepting the aircraft before a flight takes place.

DASR 145 maintenance personnel responsibilities

8.3.3.6 The completion of maintenance requires two actions. They are:

1. a 'sign-off'; and
2. a CRS.

8.3.3.7 These two actions may be performed by a singular person or group of people dependent upon maintenance complexity, qualifications and authorisations.

Maintenance Authorisation

8.3.3.8 A person can only be authorised when they have met all the organisation's applicable qualification requirements, and only for the scope of work applicable to that qualification detailed in the DASR 145 Maintenance Organisation Exposition (MOE). A person can carry out maintenance and sign-off tasks that they have performed for a particular maintenance activity, and also be a support or certifying staff for another. As an example, a person may be authorised to sign-off on an aircraft type, and certifying and/or support staff on a different aircraft type.

8.3.3.9 DASR 145.A.35 (i) requires the maintenance organisation to nominate an individual[6] responsible on behalf of the maintenance organisation for issuing certification authorisations to certifying staff.

Sign-off Authorisation.

8.3.3.10 This is exercised by a competent (IAW AMC1 145.A.30(e)) and appropriately authorised person, that the maintenance has been completed to the standard required in accordance maintenance data specified in DASR 145.A.45.

8.3.3.11 AMC 145.A.65(b)(3)3 states that, in order to prevent omissions, every task or group of tasks should be signed-off by authorised personnel after its completion. It also states that a sign-off relates to one step in the maintenance process and is different from a 'release to service' (CRS). Importantly, a sign-off is a statement by the competent person performing or supervising the work, that the task or group of tasks has been correctly performed.

8.3.3.12 Furthermore, this AMC states that work by 'unauthorised personnel' (temporary staff, trainee/apprentice) must be witnessed by the authorised person before they sign-off. This means the authorised person signing off the task is responsible for the task.

8.3.3.13 IAW AMC1 145.A.30(e) personnel performing the sign-off, "shall be able to carry out tasks to any standard specified in the maintenance data, and will notify supervisors of mistakes requiring rectification to re-establish required maintenance standards".

8.3.3.14 Nevertheless, holding a sign off authorisation doesn't mean that the authorised person can sign off all tasks. It means that they can sign off tasks within the scope of their authorisation, depending on the qualifications, training and experience held, and in accordance with a procedure described in the MOE. Sign-off authorisation does not need to be restricted to singular tasks where the technician is required to/has demonstrated a degree of competence for that task. In contrast, the technician shall demonstrate competence in performing or supervising work applicable to their training and qualifications.

Superseded

8.3.3.15 Further details related to task completion and sign-off can be found in Chapter 8.3.2 – Performance of Maintenance.

Certificate of Release to Service

8.3.3.16 In executing the obligations of DASR 145.A.50(a) the organisation must have procedures in place that ensure:

1. the individual issuing the CRS is appropriately authorised to do so;
2. the individual issuing the CRS has ensured the maintenance has been carried out correctly using appropriate procedures IAW DASR 145.A.45(b); and
3. as a result of the maintenance conducted there are no defects which are known to 'endanger flight safety'.

8.3.3.17 A CRS is an attestation made by Certifying Staff by way of a certification signature after the completion of maintenance within their authorisation scope. The certification signature creates a 'certificate' and thus accountability, signifying that the maintenance or group of maintenance activities can be released to service. In Line maintenance the holder of a category A, B1 or B2 MAML may issue a CRS within the scope of their MAML and authorisation. In Base Maintenance the holder of a category C MAML is required to issue the CRS after the completion maintenance within the scope of their MAML and authorisation. Issue of a CRS in Component Maintenance can be done by appropriately authorised certifying staff, in this instance the individual does not need to hold a MAML.

8.3.3.18 There are two elements that need to be fulfilled by the authorised Certifying Staff before the issuance of a CRS is possible:

1. **Ensure.** Verify through oversight and management to ensure that the maintenance has been properly carried out; and
2. **Assessment.** Ensuring that no non-compliances which are known to exist that could 'endanger flight safety'

How do Certifying Staff "ensure that the maintenance ordered/tasked has been properly carried out"?

8.3.3.19 *Verification through the supervision of the maintenance task.* Certifying Staff ensure that maintenance has been properly carried out by ensuring maintenance has been conducted in accordance with procedures detailed in the MOE and through the correct use of maintenance data as specified in DASR 145.A.45.

8.3.3.20 This statement does not necessarily mean that authorised Certifying Staff have to personally perform or supervise[7] the whole process of every task, rather it is expected that Certifying Staff will (non-exhaustive list):

1. make sure that personnel assigned to perform the maintenance are authorised to sign-off the work for the appropriate scope of their authorisation;
2. coordinate the different tasks associated with the maintenance being performed; and
3. be available to support personnel in case of any mistakes or unexpected difficulties.

Superseded

8.3.3.21 Authorised Certifying Staff are responsible to determine the amount of involvement they require in order to be satisfied that the maintenance can be issued a CRS. Subsequently, the DASR 145 MO cannot limit Certifying Staff in terms of what level of supervision they put in place for the maintenance task. The DASR 145 MO may however set a minimum requirement.

How do Certifying Staff, "make an assessment that there are no non-compliances which are known to endanger flight safety"?

8.3.3.22 This is achieved by a cognitive process that assesses whether an endangerment to flight safety exists as defined within AMC1 DASR 145.A.50(a) against the physical outcomes of maintenance ordered by the CAMO. It does not require the DASR 145 MO to find or become responsible for hidden defects which are not expected to be discovered during the ordered maintenance. Defect assessments, including those endangering flight safety, must be clearly identified in the CA records system along with any corresponding limitations (if any) for further CAMO consideration.

Considerations for when the aircraft is left in a non-airworthy condition

8.3.3.23 In circumstances where after performing the maintenance ordered by the CAMO, the aircraft is left in a non-airworthy configuration, a CRS can still be issued for the maintenance that has been completed. The CRS can be issued as long as the incomplete maintenance or known defects are properly identified in the CA records system and communicated to the CAMO. For example, where the DASR 145 MO removes an engine for preservation (without installing a new one), or where the organisation performs an NDT inspection and identifies a crack outside limits.

8.3.3.24 The circumstances mentioned above (including defects affecting flight safety discovered during maintenance), can be properly addressed by using the provisions contained in DASR 145.A.50(c) and (e).

8.3.3.25 It is important to appreciate that a CRS does not mean that the aircraft is airworthy and ready for flight. A CRS is issued by the DASA 145 MO for the maintenance performed; the CAMO is accountable for ensuring that all CA requirements are met for the aircraft to undertake its assigned mission before releasing to the Operator.

When is a CRS issued?

8.3.3.26 IAW DASR 145.A.50(b) "A certificate of release to service shall be issued before flight at the completion of any maintenance". Subsequently, "any maintenance" can be interpreted in multiple ways, such as:

1. any maintenance task.
2. any combination of maintenance tasks.
3. any maintenance event.

8.3.3.27 Utilising the flexibility afforded by the "any maintenance" interpretation an organisation may choose one or more of the following systems of release to service:

1. Several CRS are issued, each one of them covering a different single maintenance task.
2. Several CRS are issued, each one of them covering a different group of maintenance tasks.
3. A single CRS is issued covering all the maintenance included in a maintenance event.

Superseded

8.3.3.28 The organisation must ensure that the CRS issued to the CAMO clearly identifies what maintenance is complete. If there is any incomplete maintenance, the CRS must clearly identify it in the CA records system and the corresponding limitations (if any). In each of the above cases, it is important to note that there is no change in the accountabilities of the individual authorised Certifying Staff in signing the CRS.

Who can issue a CRS in Line Maintenance?

8.3.3.29 Only appropriately authorised category A, B1 and/or B2 MAML holders can issue a CRS in Line Maintenance. The scope and responsibility of each license category is provided below.

Limited Certification Authorisation

8.3.3.30 By way of exception to paragraph 8.3.3.29, and in accordance with 145.A.30(j) 4, in unforeseen cases where the aircraft is grounded or operating away from a Main Operating Base, and where no appropriate certifying staff are available, the maintenance organisation may issue a limited certification authorisation to the aircraft commander on the basis of the flight crew licence subject to being satisfied the aircraft commander can accomplish the specified task to the required standard. These provisions shall be detailed in a MOE procedure.

One off Certification Authorisation

8.3.3.31 In unforeseen cases, where an aircraft is grounded at a location other than the main base where no appropriate certifying staff are available, the maintenance organisation may issue a one-off certification authorisation in accordance with 145.A.30(j)5.

Category A licence

8.3.3.32 The category A licence permits the authorised MAML holder, in a Line Maintenance environment only, to issue CRS for work that the licence holder has personally performed ('sign off') and within the scope of their certification authorisation.

8.3.3.33 A category A licence does not permit the authorised MAML holder to issue a CRS for the work of others, only for their own maintenance. While other personnel may be present and directed by the authorised A MAML holder in providing assistance during the performance of the maintenance task, the category A MAML holder may not undertake a supervisory role.

Category B licence

8.3.3.34 The category B1/B2 licence permits the authorised MAML holder to issue CRS, within the scope of their license and certification authorisation on maintenance that has been 'signed off' by themselves or other authorised personnel, within the scope of their license and certification authorisation.

Category C licence

8.3.3.35 The category C licence permits the authorised MAML holder to issue a CRS following Base Maintenance on aircraft carried out by a DASR 145 AMO. By definition, the DASR permits an authorised category C MAML holder to issue a single CRS for all maintenance activities pertaining to the aircraft during a single Base Maintenance visit.

8.3.3.36 Noting the complexity and the volume of the maintenance being carried out during a Base Maintenance activity, it is difficult for the authorised category C MAML holder to be across all tasks,

Superseded

to the extent required, to issue a CRS. For this reason, the authorised category C MAML holder may use Support Staff to enable the CRS to be issued.

8.3.3.37 The authorised category C MAML holder is accountable to ensure that all required maintenance that has been ordered, has been carried out properly, that there are no non-compliances which are known to endanger flight safety and any outstanding or incomplete maintenance has been identified and the CAMO notified before issuance of the CRS.

Support Staff

8.3.3.38 Support Staff are authorised B1 and B2 MAML holders. The role of Support Staff during Base Maintenance is to conduct, within the scope of their MAML and authorisation, activities such that it can be communicated to the authorised category C MAML holder that:

1. the maintenance has been performed properly;
2. that any defects found during the course of maintenance are recorded in the CA records; and
3. that any outstanding or incomplete maintenance is identified and recorded in the CA records.

8.3.3.39 In essence, Support Staff are oversighting and managing allocated maintenance tasks within Base Maintenance in support of the authorised category C MAML holder. Subsequently, the DASR 145 MO must have a mechanism in place and articulated in the MOE WRT how Support Staff communicate to the category C MAML holder when the CRS can be issued.

8.3.3.40 An authorised category C MAML holder may not require Support Staff if they also hold the required B1/B2 license scope and subsequent authorisation with regard to the Base Maintenance being performed. The authorised category C MAML holder in this instance can issue the CRS without the use of additional Support Staff. The procedures with respect to an authorised category C MAML holder acting as their own support staff must be articulated in the MOE.

Summary of Maintenance Authorisations

8.3.3.41 The following figure summarises the different types of authorisations an organisation will require and the scope of work against which they may authorise their staff. It is the DASR 145 that performs and certifies maintenance requested by the DASR M.

Superseded

Type of Authorisation	Line Maintenance		Base Maintenance		Component Maintenance	
	Sign Off*	CRS	Sign Off*	CRS	Sign Off*	CRS* See note 1
Technician (non MAML holder)	✓		✓		✓	✓
Non Type Rated B1/B2 MAML Holder	✓		✓		✓	✓
Type Rated B1/B2 MAML Holder	✓	✓	✓	Support Staff Does not issue CRS **See note 2**	✓	✓
A MAML Holder	✓	✓ Task Authorised **See note 3**	✓		✓	✓
C MAML Holder	✓	When Exercising B MAML	✓	✓	✓	✓
Foreign Trained Technician	✓		✓		✓	✓

* Denotes No MAML Required therefore all trained technicians may be authorised to perform maintenance and Sign Off. Authorisation QT&E requirements to issue a CRS in Component Maintenance is determined by the AMO
Note 1: Component CRS may be issued through ARC (Form 1) or via process detailed in the MOE
Note 2: This is not a certification activity. Type Rated B1/B2 Technician may be authorised to confirm tasks carried out to the required standard (i.e.: attest) for maintenance personally conducted or conducted by other technicians, to the scope of their B MAML
Note 3: May be Task Authorised to the scope of the A MAML for maintenance personally conducted

Figure 1 Summary of Maintenance Authorisations

8.3.4 Acceptance of Aircraft Components

Introduction

8.3.4.1 This chapter provides additional guidance on what constitutes a DASR Form 1 or recognised equivalent and outlines how DASR 145 Approved Maintenance Organisations (AMOs) should assess the suitability of component documentation to ensure such components are eligible to be fitted to Defence registered, type-certified products.

8.3.4.2 The Defence Aviation Safety Regulations (DASR) require Approved Maintenance Organisations (AMOs) to ensure the airworthiness[8] of components and materials prior to fitment to Defence registered, type-certified products. To fulfil this requirement, the AMO must ensure that components are accompanied by appropriate documentation attesting to the legitimacy of the component's maintenance or production history. This is underpinned by the regulatory requirement for the AMO to obtain a DASR Form 1 or equivalent documentation prior to fitment of such components.

8.3.4.3 This chapter relates to the acceptance of new and used aircraft components, which are listed by the appropriate design organisation as eligible for installation in/on a product and included in the design data approved by the Authority[9]. The term components broadly covers any product (other than complete aircraft), part or appliance that is, or is intended by its manufacturer to be, a part of or used in operating an aircraft in flight, or is installed in or attached to a product. This may include any self-contained part, combination of parts, assembly, subassemblies or units, which perform a distinctive function necessary to the operation of the airframe, engine, or propeller, or may include any other instrument, mechanism, equipment, apparatus, software or accessory, including communications equipment.

8.3.4.4 Although alternate artefacts can be consumed by a DASR 145 Approved Maintenance Organisation (AMO), DASA requires the relevant CAMO to seek approval for, and manage, the ongoing validity of alternate artefacts for their respective platforms. Further detail on alternate artefacts can be found in Chapter 8.2.3 – Alternate Artefacts.

Superseded

Products, parts and appliances

8.3.4.5 To align with the European Military Airworthiness Requirements (EMAR), the DASR has replaced the term Aeronautical Product with separate definitions for products, parts and appliances. The term 'components' in this document will be used interchangeably with products (other than complete aircraft), parts and appliances for simplicity.

Acceptance of components

8.3.4.5 The AMO is responsible for ensuring the 'eligibility for fitment' of components to type-certified products prior to installation[10].

Eligibility for fitment

8.3.4.6 A component is eligible to be fitted to a type-certified product, or another part or appliance if:

1. the fitting of the component is permitted by the approved design[11] for the product, part or appliance of the higher assembly;
2. the component is in a serviceable condition for safe operation; and
3. the component has been appropriately released or returned to service[12].

8.3.4.7 The AMO should have procedures for the acceptance of components and material, to ensure that the supplied components and material are in satisfactory condition and eligible for fitment. Furthermore, the AMO is responsible for ascertaining the traceability of components and material to their original or authorised source, including the maintenance or production and supplier source, where applicable. Therefore, it is the responsibility of the installer to request the appropriate documentation which establishes the airworthiness status and traceability of components and materials.

8.3.4.8 In determining whether a component is eligible for fitment, the AMO should conduct the following:

1. a physical inspection of components and/or material (including a check for any obvious physical damage and verification that part numbers, serial numbers, lot and/or batch numbers, etc. match the accompanying documentation; and
2. a review of accompanying documentation and data, which should be acceptable IAW DASR 145.A.42.

8.3.4.9 Particular caution should be exercised when the origin of components and materials cannot be established or when the origin is in doubt.

8.3.4.10 The flowcharts provided at Appendix 1 and Appendix 2 illustrate the process for determining the eligibility for fitment of new and used aircraft components, respectively, to type-certified products, or other parts and appliances.

Acceptance of Aircraft Components

What is an Authorised Release Certificate?

Superseded

8.3.4.11 An Authorised Release Certificate (ARC) is a document issued by an entity that has the applicable privilege and attests that a new or used component has been produced or maintained IAW the approved design data/standard, modification standard or applicable maintenance data[13].

8.3.4.12 An acceptable ARC is either:

1. DASR Form 1, or equivalent (refer DASA recognition website); or
2. an 'alternate artefact' accepted by DASA.

8.3.4.13 An acceptable ARC must show traceability back to a recognised CAA/MAA. In general, an Authorised Release Certificate must provide evidence of (where applicable):

1. the name and address of the issuing organisation;
2. the name of the recognised CAA/MAA;
3. evidence that the issuing organisation is working within the recognised authority's system (e.g. organisation approval reference);
4. details of the component(s): description, part number, serial number(s) and/or batch number, as applicable;
5. for used service-life-limited components, complete traceability to the component's service history;
6. a clear indication of the current airworthiness status (serviceability) of the component at the date of issue;
7. a release statement made by a suitably authorised person within the production or maintenance organisation;
8. the name, signature (or electronic equivalent) and approval number (where applicable) of the person making the release statement;
9. for components released from maintenance, a statement that the maintenance was carried out in accordance with the recognised authority's regulation/policy; and
10. for components released from production, a statement that the component(s) was manufactured in conformity with approved data.

8.3.4.14 The ARC does not constitute authority to install the item on a particular product or component, but provides evidence that assists the AMO in determining the item's eligibility for fitment. Furthermore, an ARC cannot be used for the release of complete aircraft.

8.3.4.15 The ARC serves as the official certificate for components from the manufacturer/AMO to users. It should therefore be used for the transfer of components between different airworthiness systems or AMOs. A delivery or shipping note does not constitute an ARC.

8.3.4.16 It should also be noted that a mixture of new and used items is not permitted on the same ARC. Likewise, a mixture of items certified in conformity with 'approved data' and to 'non-approved data' is not permitted on the same certificate.

When is an Authorised Release Certificate required?

Superseded

8.3.4.17 An ARC is necessary for the release to service of either new or used components. The certification of new components is performed IAW DASR 21.A.307, whereas the certification of maintenance on used components is performed IAW DASR 145.A.50.

8.3.4.18 A component is eligible for fitment to a type-certified product when the component is in a condition for safe operation (i.e. serviceable) and accompanied by an ARC. An ARC helps the AMO to determine the airworthiness approval status for components and therefore eligibility for fitment.

8.3.4.19 **Release of new components following production**[14]**.** The component manufacturer is responsible for producing the ARC following the production of a new component. The purpose of the Authorised Released Certificate for new components is to certify that the item has been manufactured in conformity to approved design data and marked in accordance with DASR 21, Subpart Q. An ARC is required for components produced under:

1. type-certificate or supplemental type-certificate and changes thereof;
2. Production Organisational Approval;
3. Parts Manufacturing Approval (PMA) / European Part Approval (EPA)[15]; or
4. AUSMTSO authorisation.

8.3.4.20 Such components will normally be listed within the OEM furnished Illustrated Parts Catalogue (IPC) or Illustrated Parts Breakdown (IPB).

8.3.4.21 **Release of used components following maintenance**[16]**.** The purpose of the ARC for used components is to release components to service after off-aircraft maintenance. The ARC is issued by the AMO and must be within their scope of approval

8.3.4.22 Issuing an ARC following maintenance is an attestation that all maintenance is complete (except for deferred defects agreed to by the CAMO), and there are no non-compliances which are known to endanger flight safety. Any incomplete maintenance ordered/tasked should be clearly stated in the ARC when such non-compliances (i.e. deferred maintenance) are within the approved aircraft limitations.

8.3.4.23 Only personnel authorised by the DASR 145 may issue a DASR Form 1 Authorised Release Certificate following off-aircraft maintenance. Where component maintenance is subcontracted to another maintenance organisation[17], the ARC may be issued either at the:

1. non-DASR 145 contractor/tasked maintenance organisation[18]; or
2. AMO facility by staff holding a certification authorisation, as appropriate[19] .

8.3.4.24 Further, for used components that are service life-limited the ARC shall contain, or be accompanied by, an updated maintenance status with reference to this status in Block 12 of the certificate. In addition to configuration data (modifications, repairs, ADs and SBs), the status should contain information on the utilisation, particularly accumulated service life in relation to component life-limits.

When is an Authorised Release Certificate not required?

8.3.4.25 An ARC is not always required after component production or maintenance. However, documented evidence of conformity to approved design or certified material specification must be

Superseded

obtained prior to fitment to a type-certified product. Such evidence must be traceable back to the organisation that manufactured or maintained the component.

New Components.

8.3.4.26 **Specific equipment.** Components which have been incorporated into the type design as specific equipment[20] and therefore have been shown not to adversely affect the airworthiness of the aircraft and not subject to recognised airworthiness standards[21] do not require an ARC. The CAMO should provide installation instructions that authorise the component's return to service requirements. Examples of specific equipment may include commercial-off-the-shelf (COTS) 'industry supply' equipment. This may include Commercial Parts such as cabin reading light bulbs, curtain rings, sink valves, etc.

8.3.4.27 **Standard Parts.** Standard Parts must be supplied with a CoC referring to the specified standard, the manufacturer and supplier source, the batch/lot number and, if applicable, the shelf life (including expiration date) and storage conditions. Standard Parts are specified within the manufacturer's IPC/IPB or maintenance data. Examples of Standard Parts include, but are not limited to, those conforming to National Aerospace Standard (NAS), Air Force/Navy (AN) Aeronautical Standard, Society of Automotive Engineers (SAE), Aerospace Standard (AS), Military Standard (MS), etc.

8.3.4.28 A part is no longer considered a Standard Part if it is used in a critical application that imposes qualification or quality control requirements beyond the published standard specification. In such a case, the OEM should allocate its own part number reference, and these parts would require an ARC.

8.3.4.29 **Materials.** Both raw and consumable materials, used in the fabrication, maintenance, servicing or operation of an aircraft or component, may be accepted without an ARC[22]. Such materials are required to meet the specification detailed in the approved design, and have appropriate traceability.

Used Components.

8.3.4.30 **Restricted Parts manufactured by the AMO.** Where a maintenance organisation has been granted approval by the Authority to fabricate a restricted range of parts to be used by that maintenance organisation in the course of overhaul, maintenance, modifications or repair within its own facility, such parts do not qualify for certification via an ARC[23].

8.3.4.31 **Unserviceable Parts.** An ARC should not be issued for any unserviceable components, except where such items are undergoing a series of maintenance processes at multiple AMOs. In this case, the receiving AMO requires an ARC to accept the component prior to subsequent maintenance.

8.3.4.32 **In-house release.** An ARC may not be required in the case where an AMO maintains a component for its own use and there is an approved alternative in-house release document as described in the AMO's MOE.

8.3.4.33 **Aircraft on Ground – other than at Main Operating Base (MOB).** When an aircraft is grounded at a location other than the MOB due to the non-availability of a component with an appropriate release certificate, it is permissible to temporarily fit a component with an alternative release certificate, subject to CAMO approval. The component must be removed at a time specified by the CAMO, unless the appropriate release certificate has been subsequently obtained, prior to removal of the component.

Superseded

What do I do with a completed Authorised Release Certificate?

8.3.4.34 The completed ARC becomes part of the technical record for the component to which it relates, and eventually will become part of the technical record of the higher assembly or product on which that component is installed. The certificate is therefore subject to all applicable regulatory requirements related to maintenance and technical records .

When are components not eligible for fitment?

8.3.4.35 A component is not eligible for fitment on a type-certified product where it is known or suspected to have any of the following:

1. Discrepancy between the component's identifying markings (as required by DASR 21 subpart Q) and its accompanying documentation;
2. Non-conformances between the component's physical characteristics and its approved design data/specification or applicable maintenance data (i.e. unacceptable or questionable quality);
3. Damage (due to packaging, etc.) or unserviceability;
4. Absence of or incomplete or inappropriate release documentation to determine the airworthiness status or eligibility for fitment; or
5. Unknown, suspect or unverified origin of the component (i.e. has not or may not have been manufactured or maintained by an approved source).

8.3.5 – Flexibility Provisions for Maintenance Organisations

Introduction

8.3.5.1 This chapter provides guidance on the application of DASR GR.80 Flexibility provisions within the specific context of maintenance organisations. To meet an operational need, there may be circumstances where the authorisation of non-MAML staff in certifying or support staff roles is necessary. These circumstances also extend to where it is not practical for foreign-trained personnel to obtain a MAML in the time available (e.g. short-term secondment).

8.3.5.2 Currently, the scope of guidance provided is related to the authorisation of non-MAML staff as certifying and support staff for on-aircraft maintenance.

DASR GR.80 Flexibility provisions

8.3.5.3 **Provisions.** DASR GR.80 *Flexibility provisions* includes two different avenues to enable regulated entities to deviate from the requirements of applicable DASR. These provisions are available subject to an operational need, where compliance with applicable DASR would impact the ability to meet operational objectives. The two avenues are:

1. **Achieve an equivalent level of protection under GR.80(b).** DASA may approve the deviation using the applicable DASR as the safety standard against which the deviation is assessed and approved.
2. **Equivalent level of protection not demonstrated, but supported by the application of sound risk management, under GR.80(c).** DASA may *allow* the deviation but

Superseded

cannot approve it due to the absence of any established safety standard against which to approve.

8.3.5.4 **Second-order effects.** The use of DASR GR.80 provisions, including GR.80(b) which requires an equivalent level of protection, has the potential to create unintended second-order safety impacts due to the interlinked nature of the DASR (a system of systems). In each instance, the regulated entity seeking to apply these flexibility provisions should identify and address any such impacts.

8.3.5.5 **Increased safety risk.** The application of GR.80 flexibility provisions by service providers, such as maintenance organisations, may result in increased Aviation Safety risk for the relevant Military Air Operator (MAO). Affected MAOs must apply additional due diligence to activities utilising the flexibility provision for the period in which that flexibility provision is in effect, commensurate with the residual risk level. Additionally, GR.80 application does not absolve the organisation of its obligation to continue to comply with all other applicable DASR. Where GR.80 flexibility provisions have been appropriately applied, DASA will not issue a finding for non-compliance against specific DASR clauses covered by the provision.

8.3.5.6 **Remediation.** Any flexibility provision should only be continue to be in place while:

1. the operational need continues to exist; and
2. compliance with relevant DASR would continue to impact operational objectives.

8.3.5.7 **Application to DASA.** DASA expects that proposed implementation of flexibility provisions to be detailed within, or referenced by, draft amendments to the MO exposition submitted under a DASR Form 2 Application for DASR 145 and DASR M Subpart G Approval.

8.3.5.8 **Application by Defence Industry**. Defence Industry organisations may only enact DASR GR.80 provisions through their relevant Military Air Operator (MAO) as the Risk Management Authority. In the event that a MAO's operational need requires a Defence Industry MO to exercise flexibility provisions, Defence Industry would support the MAO through provision of technical considerations and controls.

Use of flexibility provisions to authorise certifying and support Staff

8.3.5.9 **Background.** As discussed in chapter 8.3.3, the DASR requires[24] that certifying staff and support staff for on-aircraft maintenance hold an appropriate MAML. DASA MAMLs are issued when an applicant provides to DASA the relevant evidence, from a DASR 147 Maintenance Training Organisation (MTO) or recognised equivalent, that basic knowledge, basic experience and applicable type training requirements have been met. Gaps in basic knowledge result in MAML exclusions – mostly aircraft system based (e.g. propulsion systems, electrical systems) – and preclude a MAML holder from issuing a CRS or acting as support staff on the excluded aircraft systems.

8.3.5.10 **Granting of MAMLs to foreign-trained personnel.** Provisions within the DASR 147 enable foreign-trained maintenance personnel to obtain a MAML by undergoing an equivalency assessment where time permits. This assessment is conducted by an approved or recognised 147 MTO and will consider knowledge and experience as well as relevant type training.

8.3.5.11 **DASA assurance of procedures and outcomes.** DASA will conduct independent safety assurance differently for DASR GR.80(b) and GR.80(c), commensurate with the level of risk exposure. However, DASA assurance for both DASR GR.80(b and GR.80(c) involves the prior assessment of the procedure used to authorise non-MAML staff in certifying or support staff roles. Where uncertainty

Superseded

exists as to the procedure's applicability or suitability in a particular instance, the DASR 145 MO (through the CAMO, on behalf of the MAO), should seek advice from DASA.

8.3.5.12 Common guidance. The maintenance organisation may choose to utilise a single procedure to address both GR.80(b) and GR.80(c) scenarios. However, the organisation must make it clear how it will meet the different aviation safety performance outcomes. In both scenarios, where practicable, the procedure should require DASA 145 MOs to seek assistance from the ADF DASR 147 MTO to assess training deficiencies and inform decisions.

DASR GR.80(b) equivalent level of protection

8.3.5.13 An application to use the GR.80(b) equivalent level of protection provision must articulate how the procedure to authorise non-MAML staff in certifying or support staff roles will provide an equivalent level of protection to that which would otherwise be attained through compliance with the relevant DASR. If DASA agrees that an equivalent level of protection is achieved through the procedural outcome, DASA will approve the exception from the DASR. DASA will apply assurance to the ongoing application of the procedure(s) through routine oversight unless the DASR 145 MO, through the CAMO (on behalf of the MAO), requests DASA independent assurance prior to the issue of an individual authorisation.

8.3.5.14 An application to DASA for approval of the GR.80(b) equivalent level of protection flexibility provision should describe a method for implementing risk controls equivalent to those inherent in a DASA MAML (e.g. categorisation, exclusions and type ratings). The procedure should require assessment of individual competency, through knowledge and experience considerations, via:

1. an approved foreign nation/service comparison process; or
2. suitable evidence against each relevant module of DASR 66 Appendix I I and relevant chapters of DASR 66 Appendix III, to the appropriate training level, for the scope of the authorisation to be given.

8.3.5.15 Utilisation of DASR GR.80(b) is likely to be complex and time-consuming, requiring detailed analysis that may not be suitable to support agile operations.

DASR GR.80(c) risk management

8.3.5.16 For DASR GR.80(c), the procedure to authorise non-MAML staff in certifying or support staff roles must demonstrate that a credible and defensible level of military aviation safety performance will be maintained through sound management of aviation safety risks arising through the deviation from applicable DASR. DASA will not approve a GR.80(c) procedure but will allow its use subject to the requirement that all instances of the organisation applying the procedure are reported to DASA at the first practical opportunity. The DASA assurance role provides an independent assessment of the credibility and defensibility of the risk-based decision that is made by the organisation.

8.3.5.17 Any application to DASA to implement a GR.80(c) *risk management* approach should address the following:

1. The seven-step risk management guidance provided in Annex A and the format and means in which it will be submitted to DASA.
2. The necessary interfaces to the MAO such that any Decisions to Proceed are appropriately documented.

Superseded

3. Where operational needs allow for prior assurance by DASA, the relevant DASA desk officer should be provided with the output of the procedure, to review prior to enactment.

4. Where operational needs do not allow for prior assurance by DASA, the procedure for authorising non-MAML certifying or support staff may still be enacted by the DASR 145 AMO (through the MAO). Retrospective DASA assurance will be applied where an ongoing operational need supports continued application of the flexibility provision.

Annex:

(a) Contextualised guidance for seven-step risk management

8.4 Aircraft Maintenance Licencing

8.4.1 Introduction and Background

Introduction

8.4.1.1 This chapter provides additional guidance on the Military Aircraft Maintenance Licence (MAML), and for those individuals applying for a "personnel authorisation[25]" under DASR 66, how to comply with DASR 66 requirements.

8.4.1.2 DASR 66 establishes the regulations required to be met by Aircraft Maintenance Training Organisations (AMTO), responsible for either Basic or Type Training, to be eligible for a DASR Military Aircraft Maintenance Licence (MAML).

8.4.1.3 For the purpose of this chapter additional guidance does not include information already presented at Volume 2, but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3. Further information regarding DASR 147 is located within Volume 3, chapter 8.5.

Background

8.4.1.4 During the DASR 66/147 transition, DASA provided a number of interim arrangements which allowed the current workforce to apply for DASR 66 MAMLs, including acceptance of existing Military Aircraft Type Rating training until the DASR were fully implemented.

8.4.1.5 The DASR 66.A.70 conversion provisions were based on the Australian National Competency Training and Assessment framework. These provisions were applied to staff who held valid certifying qualifications prior to the date of these regulations being introduced.

8.4.1.6 All DASA MAMLs are based on objective evidence of an individual's Qualification, Training and Experience (QTE), against the criteria in Appendix I to DASR 66 Basic Knowledge Requirements. DASA has mapped the EMAR syllabus (Appendix I to DASR 66) to associated Australian nationally adopted Competency Based Training and Assessment Units of Competency (UoC), qualifications and non-vocational education and training (VET) service specific training. This mapping resulted in providing a DASA Category A1, A3, B1.1, B1.3 or B2 MAML, with or without exclusions and inclusions.

8.4.1.7 The Defence Airworthiness Safety Regulations (DASR) 66 - Military Aircraft Maintenance Licencing provides Defence personnel who hold a MAML the privilege to issue Certificate of Release

Superseded

to Service (CRS). This regulation is based on the European Military Airworthiness Requirements Part 66 (EMAR Pt 66), but adapted to suit the Australian military maintenance environment.

8.4.1.8 DASR 66 identifies the skills and knowledge requirements for each licence category (refer MAML Categories below) by syllabi. DASA have mapped initial trade training and technical, promotion-related courses (eg Aviation Technician Supervisor Course, LSATT, CPL SUBJ 4 etc) against these syllabi.

8.4.1.9 The MAML is an attestation the holder has met the DASR 66 knowledge and experience requirements, but does not entitle the holder to issue an aircraft CRS until they are authorised within a DASR 145 Maintenance Organisation (MO) to exercise these privileges.

8.4.2 MAML Categories, Limitations and Extensions

DASR 66.A.3 - MAML Categories

8.4.2.1 There are four basic licence categories:

1. The Category A licence is a non-type rated licence for minor scheduled and unscheduled maintenance permitted within Line Maintenance (relevant tasks will be detailed in the relevant DASR 145 MOE). The privileges of a Category A licence are not applicable to Base Maintenance.

2. Category B1 - permits certification privileges for scheduled and unscheduled airframe, engine, structures, mechanical systems and electrical maintenance for more complex Line Maintenance activity. The B1 MAML also permits minor avionics maintenance (eg 'black box' changes, where no specialised support equipment is required). The B1 MAML allows for authorisations as support staff within Base Maintenance.

3. Category B2 - permits certification privileges for scheduled and unscheduled complex avionics and electrical Line Maintenance activities and allows the holder to act as B2 support staff within Base Maintenance.

   Note: The Category B1 and B2 licences are aircraft type-rated licences and permit the holder to certify the release to service only of aircraft types that are endorsed as ratings on their licence.

4. Category C - is required for personnel who issue the CRS following Base Maintenance.

   Note: The Category C licence is an aircraft type-rated licence and permits the holder to issue the CRS of an aircraft following Base Maintenance only. GM to DASR 66.A.20(a) para 3 provides more detail.

DASR 66.A.50 – Limitations and DASR 66.A.52 – Extensions

8.4.2.2 All MAMLs are managed in accordance with the DASA 66 MAML Exclusion Inclusion & Endorsement Manual, available on the DASA Website.

8.4.2.3 The DASA 66 MAML Exclusion, Inclusion & Endorsements Manual outlines the required competency details and provides general guidance that reflects DASR 66.A.20 privileges against the S1000D system of standard numbering to specify particular Systems and Sub-systems.

8.4.2.4 Exclusions (Limitations) introduced on a MAML are omissions from an individual's certification privileges, indicating that the licence holder shall not issue a CRS in

Superseded

8.4.2.5 Line Maintenance or act as B1 or B2 support staff in Base Maintenance if maintenance related to that exclusion has occurred.

8.4.2.6 Inclusions (Extensions) introduced on a MAML are additional privileges to an individual's certification privileges, indicating that the licence holder may issue a CRS or act as B1 or B2 support staff if maintenance related to that Inclusion. Noting that additional military specific systems Inclusions can be achieved through completion of all required competencies & a type course (where appropriate) which incorporates S1000D Air-vehicle system basic knowledge requirements into the type syllabus.

8.4.2.7 The S1000D is a numerical technical classification of all the systems and sub systems on an aircraft, which is largely used in aircraft engineering and maintenance, and helps to standardise data across aircraft manufacturers and programs to facilitate improved maintenance and logistics.

8.4.3 MAML Applications

DASR 66.A. 10 - Application

8.4.3.1 Refer to DASPMAN Volume 3, Chapter 5.3 – Annex W – MAML for details.

Foreign Licence Applications

8.4.3.2 Military Aviation Authority/National Aviation Authority's (MAA/NAA) have differing training requirements for aircraft maintenance personnel based upon their sovereign regulatory maintenance framework. Therefore, there may be considerable differences in each country's licence privileges, regulations, assessment methods/framework and specific guidelines; resulting in gaps and difficulties to enable direct conversion of a foreign MAA/NAA issued licence to a DASA MAML.

8.4.3.3 Australia has nationally adopted competency-based training and assessment in lieu of EASA/ EMAR basic knowledge syllabus and examinations, which results in attainment of Units of Competency (UoC), which in turn lead to Aeroskills qualifications.

8.4.3.4 DASA has mapped these Aeroskills Mechanical and Avionics UoC against DASR 66 syllabi requirements to provide either a Category A, B1.1, B1.3 or B2 MAML, with/without exclusions and inclusions.

8.4.3.5 To enable Non-Australian competencies/qualifications to be used to apply for a MAML, a 147 Maintenance Training Organisation (MTO) RPL assessment must be performed using objective evidence to provide an individual with an RPL report clearly outlining the required theory and practical training requirements that have been met.

Aging Qualifications

8.4.3.6 All MAML applications will need to meet the following requirements:

1. Any grandfathering formally recognised and utilised for a MAML assessment during the transitional period will be honoured and no further action is required by the individual;

2. IAW DASR 66.A.25 any training courses and examinations shall be passed within 10 years prior to the application for:

   i. a MAML; or

Superseded

ii. an addition of a category or subcategory to a MAML; or

iii. the removal/addition of a DASA exclusion/inclusion to a MAML.

3. Qualifications 10 years or older now come into question, as not meeting the requirements of 66.A.25(b). Any of these qualifications provided as evidence for a MAML application (initial or update), will generally not be accepted unless they have been assessed and converted against DASR 66.A.25 Basic knowledge requirements by a DASA/CASA approved 147 Organisation;

4. DASA acknowledges that there may be individual unique circumstances where aging qualifications could be considered in more detail – specifically where the time and effort required for conversion to contemporary standards, by a DASA/CASA approved 147 Organisation, may not be reasonable. To support this, where aging qualifications (>10yr) are used as evidence for a MAML application (initial or update), the applicant must provide detailed justification (with supporting evidence) on why the aging qualification should be considered. This should include relevant work history for the applicant (including objective evidence of previous maintenance authorisations) and detail any factors that support the acceptance of aging qualifications without conversion. MAML applications, with aging qualifications, will be rejected if no supporting justification is provided.

5. Where there is any doubt or ambiguity regarding the requirements for a MAML, contact DASA at dasa.dcadasr66@defence.gov.au, and provide detailed evidence for DASA's consideration

8.4.4 MAML Basic Knowledge and Experience Requirements

DASR 66.A.25 – Basic Knowledge Requirements

8.4.4.1 A MAML applicant must have a demonstrated level of knowledge relevant to the MAML privileges to be granted, and in order to obtain a Category A (Line Maintenance only), B (Line & Base Maintenance) or C (Base Maintenance only) MAML. An applicant requires "Basic Knowledge" in the appropriate subject modules IAW Appendix I toDASR 66.

DASR 66.A.30 – Basic Experience Requirement

8.4.4.2 In addition to Basic Knowledge requirements (DASR 66.A.25), a MAML applicant must also have a demonstrated level of Basic Experience of the requested licence category (DASR 66.A.30). An applicant requires:

1. The practical experience must be gained in the real environment of military aircraft maintenance;

2. Initial employment training (IET) delivered to trainees of all three ADF Services provides the minimum practical training detailed in Appendix I to DASR 66. Therefore, maintenance personnel who have completed their IET are eligible for a category A licence after six months of practical training, following completion of specific aircraft task training in accordance with DASR AMC 66.A.20(b), and having achieved syllabus Module 10 requirements.

8.4.4.3 Experience shall be acquired within 10 years preceding the initial category or subcategory.

Superseded

DASR 66.A.40 - Continued validity of the MAML

8.4.4.4 All MAMLs are perpetual and will remain valid unless suspended, surrendered or revoked.

8.4.4.5 DASA has a process that allows it to assess breaches or suspected breaches of the conditions that a MAML was issued and take appropriate action. Contact DASA at DASA.DCA DASR66 for more information.

8.4.5 MAML Military Aircraft Type Rating Endorsements

DASR 66.A.45 - Military Aircraft Type Rating

8.4.5.1 In order to enact the privileges of a DASR 66 Category B (Line and Base Maintenance) MAML, MAML holders must have a specific Military Aircraft Type Rating (MATR) endorsement and be authorised by the DASA 145 nominated person (generally the Quality Manager) to operate within their approved quality system. In order to obtain a type rating, an applicant requires:

1. Type Training (Theory & Practical) (DASR 66.A.45): and
2. On the Job Training (OJT) for first Type Rating (AMC 66.A.45)

Military Aircraft Type Ratings Guidance

8.4.5.2 Refer to Chapter 8.5.8 – Military Aircraft Type Ratings for further details.

Expectations

8.4.5.3 All MATR applications must confirm that any OJT requirements are completed IAW Appendix III to DASR 66.

8.4.5.4 All MATR type training courses must be started and completed within the 3 years preceding application for the MATR.

8.4.5.5 The "Basic Training Course" requirements stated in 66.A.30 and 147.A.200 must be met before individuals are eligible for the relevant category MAML.

8.4.5.6 OJT requirements stated in Appendix III to DASR 66 must be met for first MATR in licence subcategory. Evidence of completion must be provided with the MAML endorsement application.

8.4.5.7 DASA may accept practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 – Northrop Grumman for applications for P-8A Poseidon or E-7A Wedgetail.

8.4.6 MAML Suspension or Revocation

8.4.6.1 On receipt of notification of fraudulent or unsafe behaviour by a MAML holder, DASA will assess the information to determine what action, if any, is required.

Notice to Show Cause

Superseded

8.4.6.2 Should DASA determine that a suspension or revocation of a MAML be warranted, then a Notice to Show Cause (NTSC) will be issued to the MAML holder. For procedural fairness, the affected MAML holder will be provided the reasons and evidence supporting the decision to issue a NTSC. The NTSC provides the MAML holder the opportunity to respond to the proposed suspension or revocation of their MAML.

8.4.6.3 The response to the NTSC will be assessed by DASA to determine if:

1. No action required; or
2. MAML will be suspended; or
3. MAML will be revoked.

MAML Suspension or Revocation

8.4.6.4 DASA will notify the MAML holder, and the organisation for which the MAML holder held the authorisation, of the suspension or revocation of the MAML. DASA also publishes a list of suspended MAML on the Military Aircraft Maintenance Licencing page on the DASA website.

Review of Suspension or Revocation

8.4.6.5 The organisation for which the MAML holder held the authorisation, can request DASA to review the decision. The request for review should include the results of any internal investigation and any other relevant information to support the request for a review.

8.5 Aircraft Maintenance Training Organisations

8.5.1 Introduction and Background

Introduction

8.5.1.1 This chapter provides additional guidance on the Defence Airworthiness Safety Regulations DASR 147 – Aircraft Maintenance Training Organisations (AMTO), to assist those organisations applying for a DASR 147 approval on how to comply with DASR 147 requirements.

8.5.1.2 DASR 147 establishes the regulations required by an AMTO responsible for either Basic or Type Training of DASR 66 Engineers and Aircraft Maintenance Technicians to be eligible for a Military Aircraft Maintenance Licence (MAML).

8.5.1.3 For the purpose of this chapter additional guidance does not include information already presented at Volume 2, but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3

Requirements for Aircraft Maintenance Training Organisation

8.5.1.4 The Defence Aviation Safety Regulations (DASR) requires individual DASR 147 Maintenance Training Organisations (MTOs) to define their maintenance training activities in their Maintenance Training Organisation Exposition (MTOE). The scope of maintenance training of basic knowledge and/ or Military Aircraft Type Rating (MATR) training should be in accordance with the MTO's policy and procedures defined in the MTOE.

Background

Superseded

8.5.1.5 The Defence Aviation Safety Authority (DASA) and Headquarters Air Force Training Group (HQAFTG) have agreed that the primary framework to meet the DASR 147 requirements for the training of ADF personnel is through the creation of a single Air Domain MTO.

8.5.1.6 The single Air Domain MTO will:

1. leverage existing Joint and Single Service Individual Education and Training governance arrangements to provide an efficient and standardised governance approach for Australian Defence Organisation (ADO) aviation maintenance training.
2. align with the Defence Registered Training Organisation (DRTO) framework to enable standardisation against benchmarked Australian Skills Quality Authority (ASQA) standards.
3. provide a single point of accountability for aviation maintenance training, which will provide better holistic oversight that safety outcomes are being achieved.
4. provide the simplest path to the provision of recognition of Defence Maintenance Training by civil regulators and foreign militaries.

8.5.1.7 Commercial organisations that deliver aircraft maintenance training, either initial technical training (basic training) or Military Aircraft Type Training to meet DASR 66 requirements will be recognised by DASA if they:

1. already have a Part 147 Approval issued by a DASA- recognised Civil Aviation Authority (CAA)/ Military Aviation Authority (MAA); or
2. are included within the Air Domain MTO; or
3. are issued a discrete DASR 147 Approval, where they provide aviation maintenance training to DASR 145 organisation(s), but do not train ADF personnel.

8.5.1.8 The Air Domain MTO includes military aircraft type training courses delivered by Army Aviation Training Centre (AAvnTC), the Navy Training Authority – Aviation (TA-AVN) and the Air Force – Force Element Groups (FEGs). Basic aviation knowledge training delivered by RAAF School of Technical Training (STT) is also included under the Air Domain MTO.

Application to become an MTO

8.5.1.9 Refer to DASPMAN Volume 3, Chapter 5.3 – Annex I – MTO for detailed guidance on the application process.

8.5.2 Facility and Equipment Requirements

8.5.2.1 This regulatory provision outlines the facility requirements for a DASR 147 Aircraft Maintenance Training Organisation (AMTO) and contains several sub-sections, which detail the requirements that AMTOs must meet in terms of facilities, equipment and resources.

Facility Standards

8.5.2.2 AMTOs are to provide adequate facilities, equipment and tools to conduct training. AMTOs must ensure that their facilities meet the appropriate standards for classroom space, simulator training areas and other areas necessary for conducive aviation maintenance training. Additionally, AMTOs must have facilities for storage of maintenance tools, equipment and parts.

Superseded

Workshop Standards

8.5.2.3 Workshops must be equipped with tools, equipment and materials necessary to perform the practical tasks required by the relevant training courses. AMTOs must have appropriate facilities for the storage, testing and calibration of equipment used in the maintenance of the aircraft.

Training Equipment

8.5.2.4 Training equipment must be maintained and calibrated to ensure that it is safe and effective for use in training. AMTOs must ensure that they have the appropriate equipment for training in various aspects of aircraft maintenance including aircraft systems, avionics, structures and powerplant maintenance.

Library Facilities

8.5.2.5 AMTOs are to provide access to relevant aviation related reference materials, manuals and other resources necessary for aviation maintenance training. AMTOs must ensure that their libraries are up to date and have a wide range of materials that are relevant to the training courses they offer.

Computer Facilities

8.5.2.6 AMTOs are to have computer facilities that provide access to relevant aviation related software, databases and other tools necessary for effective aviation maintenance training. AMTOs must ensure that their computer facilities have up to date software and hardware as well as high-speed internet connections.

8.5.3 Personnel Requirements

Personnel Requirements

8.5.3.1 This section specifies the personnel requirements for management personnel employed by DASR 147 AMTOs. The organisation must have sufficient management personnel to ensure the effective management of its operations. The management personnel must be qualified, experienced and possess the necessary skills to oversee the organisation's activities and ensure compliance with all relevant regulations and standards. This includes an Accountable Manager who has overall accountability for the organisation's compliance with DASR regulations and will appoint other necessary resources to accomplish training commitments. The regulation includes requirements for different types of personnel, including management personnel, technical personnel, quality personnel, training personnel, and support personnel.

Records of Instructors, Examiners, Assessors and Invigilators

8.5.3.2 DASR 147.A.110 requires approved maintenance training organisations (AMTOs) in Australia to maintain records of instructors, examiners, and assessors. The records must contain specific details about the personnel including:

1. **Personal Details:** Personal details of the instructor, examiner, or assessor, including their full name, date of birth, and contact information.

2. **Qualifications:** Details of the instructors, examiners, or assessor’s qualifications, including the type of qualification, the date it was obtained, and the organisation that issued it.

Superseded

3. **Experience:** Details of the instructors, examiners, or assessor's experience, including the type of experience, the duration of experience, and the organisation where the experience was gained.

4. **Training:** Details of the training received by the instructor, examiner, or assessor, including the type of training, the duration of training, and the organisation that provided the training.

5. **Authorisations:** Details of any authorisations held by the instructor, examiner, or assessor, including the type of authorisation and scope, the date it was issued, and the organisation that issued it.

6. **Currency:** Details of the instructors, examiners, or assessors currency, including the type of currency, the date it was last achieved, and the date it is due to expire.

7. **Performance:** Details of the instructor's, examiner's or assessor's performance, including any relevant feedback or reviews and professional development plan.

8. **Relevant Training Material:** Details of any relevant training material that the instructor, examiner, or assessor has access to or uses in the performance of their duties.

9. **Verification of Competence:** Details of any verification of competence conducted on the instructor, examiner, or assessor, including the type of verification, the date it was conducted, and the organisation that conducted it.

10. **Compliance:** Details of the instructor's, examiners, or assessor's compliance with all relevant regulations and standards.

8.5.3.3 AMTOs can ensure that their personnel are qualified, competent, and authorised to perform their duties, and comply with all relevant regulations and standards.

Key Personnel Requirements

8.5.3.4 The qualification and experience of the instructors, knowledge examiners, practical assessors and invigilators are fundamental to ensuring the quality of a training course – only appropriately qualified personnel should be appointed to carry out training and examinations. In addition to the published Acceptable Means of Compliance (AMC) and Guidance Material (GM) to DASR 147.A.105(f), the following information provides additional guidance on the knowledge and skills that are expected of authorising instructors, knowledge examiners, practical assessors and invigilators employed by a DASR 147 Maintenance Training Organisation (MTO).

Instructors

8.5.3.5 A nominated person who will deliver a DASR 66 module or unit of competency (DASR 66 appendix I), a DASR 66 element (DASR 66 appendix III), or part thereof either of these. The instructor is not necessarily the person involved in drafting of the course material (content, duration, etc.), however they should be involved in the continued development of the lessons themselves (creation of the instructor notes, slides, sequencing, etc.).

8.5.3.6 Instructors should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO.

Superseded

2. Pedagogic – should know how to organise a lesson and how to efficiently deliver a course that clearly highlights the fundamental points. They should also be able to adapt when communicating to a particular audience including with pre-existing knowledge/experience.

3. Able to promote the appropriate attitude towards regulation and procedures; in particular the strict adherence to approved maintenance practices and quality standards through the lens of their own experience in a regulated aviation environment.

4. Familiar and proficient with the tools and training techniques used by the training organisation to deliver lessons.

5. Appropriately experienced in the aircraft maintenance environment.

6. Able to demonstrate good knowledge, complimented with communication skills in the English language.

7. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.

8. Able to demonstrate good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directives, Service Bulletin, Maintenance Programme, etc.).

9. In receipt of continuous training in the company's procedures and DASRs.

Knowledge Examiners

8.5.3.7 A nominated person who will determine the level of theoretical knowledge of the trainees on a particular module, unit of competency, element, or part thereof. The function may include the drafting and/or the selection of questions (Multi-Choice Questions and Essays), the evaluation of the correctness of answers (except when correct answers are pre-determined) and the final judgement regarding the level of knowledge demonstrated by the trainee.

8.5.3.8 Persons solely supervising an exam session are not considered as examiners but are considered as support staff invigilators and, in this context, are not subject to knowledge and experience requirements, but need to be trained to the examination procedure described in the MTOE.

8.5.3.9 Knowledge examiners should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO, including the examination standards required by DASR 66.

2. Able to demonstrate a responsible attitude to the conduct of examinations, so that the highest integrity is ensured.

3. Trained in contemporary examination techniques and able to conduct an examination in such a way that the true abilities of the candidate are demonstrated.

4. Able to remain neutral at all times and behave in a manner that will not influence or prejudice the final result of the examination, for example by providing undue assistance or clarification to a candidate.

Superseded

5. Familiar and proficient with the tools or the examination techniques used by the training organisation to perform the exams.

6. Appropriately experienced in the aircraft maintenance environment.

7. Able to demonstrate good knowledge, complimented with communication skills in the English language.

8. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.

9. Able to demonstrate good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directive, Service Bulletin, Maintenance Programme, etc.).

10. In receipt of continuous training in company's procedures and DASRs.

Practical Assessors

8.5.3.10 A nominated person who will determine the level of practical knowledge/practical skills of the trainees on a particular module, element, or part thereof. The function may include the drafting and/or the selection of practical tasks, the performance oversight and assessment of the practical activities. Practical assessors should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO.

2. Experienced and show solid judgement regarding the abilities of the assessed trainees – the assessor should have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks in compliance with current regulation, approved procedures, maintenance practices, etc.

3. Trained to contemporary assessment techniques. The assessor should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated.

4. Familiar and proficient with the tools or the techniques used by the training organisation to assess the practical abilities of trainees (maintenance simulators, mock up, etc.).

5. Appropriately experienced in the aircraft maintenance environment.

6. Able to demonstrate good knowledge, complimented with communication skills in the English language.

7. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.

8. Able to demonstrate a good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directive, Service Bulletin, Maintenance Programme, etc.).

9. In receipt of continuous training in company's procedures and DASRs.

Superseded

10. Able to act safely, apply safety precautions and prevent dangerous situations.

11. Able to demonstrate knowledge and understanding of areas requiring special emphasis or novelty (areas peculiar to the aircraft type, domains not covered by DASR-66 Appendix, practical training elements that cannot be imparted through simulation devices, etc.).

12. Able to demonstrate an understanding of the aircraft systems interaction.

13. Able to navigate, execute and obey the prescribed maintenance procedures.

Invigilators

8.5.3.11 A nominated person who will ensure the correct conduct of an examination in accordance with the examination procedures of the DASR 147 organisation. The invigilator is responsible for ensuring that examinations are conducted in accordance with the MTOE and Training Procedures and operates under the direction, responsibility and delegation of the Training Manager. The organisation can nominate permanent exam invigilators who should then be listed in MTOE Part 1 and qualified in accordance with Training Procedures.

8.5.3.12 Training organisations often delegate the invigilation of an examination to staff not listed as an examiner for the particular subject. These “invigilators” do not need to be qualified to the same extent as an examiner, and in particular, they do not need to demonstrate specialty knowledge, as long as their duty is strictly limited to the conduct of the examination itself.

8.5.3.13 Invigilators should however be trained to the organisation’s examination procedures with a specific emphasis on the exam’s integrity aspects and on the handling of cheating or misconduct cases. Such staff should be listed by the organisation with records of their training kept in the individual’s personnel file.

Assessment and acceptance of staff

8.5.3.14 Assessment and acceptance of instructors, examiners and assessors should be performed, and documented by the approved training organisation in accordance with dedicated procedure described in the MTOE. Appropriate staff in the maintenance training organisation should physically interview proposed candidates in order to ensure their competency. Once completed, detailed result of this assessment, including any supporting documents (diplomas, DASR 66 licence, etc.) should be filed in accordance with MTOE procedure. The staff should be listed in MTOE with intended scope of instruction, examination or assessment.

Continued qualification

8.5.3.15 The qualification criteria and experience requirements only address the initial acceptance of instructor, examiners and assessors. The training organisation should develop and document a program in MTOE to ensure the continued competence of these staff.

8.5.4 Instructional Equipment Requirements

8.5.4.1 DASR 147.A.115 requires approved maintenance training organisations (AMTOs) to ensure that they have appropriate instructional equipment available to support their training activities. Here are some important points that must be considered when meeting this regulation:

Superseded

1. **Type of Equipment:** The equipment must be appropriate for the type of training being delivered. This includes a wide range of equipment such as applicable aircraft, training aids, simulators, and computer-based training tools.

2. **Condition:** The equipment must be in good working order, and any faults or defects must be promptly rectified.

3. **Calibration:** The equipment must be calibrated as required, and records of calibration must be maintained.

4. **Availability**: The equipment must be readily available for use when required, and there must be sufficient equipment available to support the number of students being trained.

5. **Security:** The equipment must be stored securely when not in use, and access to the equipment must be controlled to prevent damage or misuse.

6. **Maintenance:** The equipment must be regularly maintained, and records of maintenance activities must be maintained.

7. **Training Material**: The equipment must be used in conjunction with appropriate training material to support effective learning.

8. **Compliance:** The equipment must comply with all relevant regulations and standards.

9. **Training for Equipment Use:** Instructors and trainers must be trained in the correct use of the equipment and any associated software or training materials.

10. **Upgrades and Replacements:** Equipment should be upgraded or replaced as necessary to ensure that it remains effective and meets current training requirements.

Aircraft Maintenance Training Aids

8.5.4.2 These are physical devices used to simulate or replicate various components or systems of an aircraft. For example, a training aid may be used to teach students how to inspect and troubleshoot an engine. Important points to consider for training aids:

1. The training aid must accurately represent the aircraft component or system being taught.

2. The training aid should be durable and long-lasting.

3. The training aid should be kept clean and well-maintained.

8.5.4.3 **Computer-Based Training Tools:** These are software applications or programs that are used to deliver training material to students. For example, a computer-based training tool may be used to teach students how to use a maintenance management system. Important points to consider for computer-based training tools:

1. The software should be up-to-date and compatible with the AMTO's computer hardware.

2. The software should be easy to use and navigate.

3. The AMTO should have a system for monitoring and tracking student progress.

Superseded

8.5.4.4 **Simulator Devices:** These are devices that replicate real-world situations or scenarios to provide hands-on training to students. For example, a simulator may be used to teach students how to perform a maintenance task on an aircraft. Important points to consider for simulator devices:

1. The simulator should accurately represent the real-world situation or scenario being taught.
2. The simulator should be well-maintained and regularly calibrated.
3. The AMTO should have a system for monitoring and tracking student progress.

8.5.4.5 **Training Videos and Audio Recordings:** These are pre-recorded videos or audio recordings that are used to deliver training material to students. For example, a training video may be used to teach students about safety procedures.

8.5.4.6 Important points to consider for training videos and audio recordings:

1. The video or audio recording should be up-to-date and relevant to the training being provided.
2. The AMTO should have a system for monitoring and tracking student progress.
3. The AMTO should ensure that the video or audio recording is of high quality and easy to understand.

8.5.5 Maintenance Training Material

8.5.5.1 DASR 147.A.120 requires approved maintenance training organisations (AMTOs) to develop and use maintenance training material that is appropriate for the type and level of training being delivered. DASR 66 specifies requirements for both basic and type course training material. Here are some important points to consider for each Basic course training material:

1. The training material used for basic courses must cover a broad range of topics and must be suitable for entry-level students. The following are some important points to consider when developing or using training material for basic courses:
    i. The training material must cover the theoretical and practical aspects of the aircraft, system, or component being taught.
    ii. The training material must be easy to understand and follow.
    iii. The training material must include practical exercises that reinforce theoretical knowledge.
    iv. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.
    v. The training material must be appropriate for the level of experience and education of the students being trained.

Type Course Training Material

8.5.5.2 The training material used for type courses must cover the specific make and model of the aircraft, system, or component being taught. The following are some important points to consider when developing or using training material for type courses:

Superseded

1. The training material must cover all relevant aspects of the aircraft, system, or component, including maintenance, inspection, troubleshooting, and repair.

2. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.

3. The training material must be appropriate for the level of experience and education of the students being trained.

8.5.5.3 Some additional important points to consider when developing or using maintenance training material include:

1. The training material must be structured in a logical and organized manner.

2. The training material must be consistent with the relevant regulations and standards.

3. The training material must be presented in a manner that is engaging and interesting for students.

4. The AMTO must have a system for tracking and monitoring the use of training material, including the progress and performance of students.

8.5.5.4 By meeting the requirements of DASR 147.A.120, AMTOs can ensure that they are providing high-quality maintenance training material that is appropriate for the level and type of training being delivered. This can help to ensure that students receive the knowledge and skills they need to perform maintenance tasks safely and effectively.

8.5.6 Examinations

8.5.6.1 DASR 147.A.135 specifies the requirements for conducting examinations for aircraft maintenance training organisations (AMTOs) to ensure that their students have the necessary knowledge and skills to perform their maintenance duties effectively and safely. Here are some key points regarding the examination requirements:

Examination Development

8.5.6.2 The AMTO should develop examination questions that are aligned with the training objectives and outcomes. The questions should be designed to test the knowledge and skills that the student has acquired during the training program. The AMTO should also ensure that the examination questions are reviewed and approved by qualified personnel.

Examination Administration

8.5.6.3 The AMTO should have procedures in place for administering examinations. This includes ensuring that students are aware of the examination format, rules and regulations, and any special instructions that apply. The AMTO should also ensure that the examination environment is conducive to learning and that the examination is conducted in a fair and unbiased manner.

Examination Security

8.5.6.4 The AMTO should have procedures in place for ensuring the security of all the question, examinations and databanks. Particular attention should be made to the storage and transportation of the examination between venues and whilst onsite. Care must be taken to ensure the examination

Superseded

questions are secure at all times. Electronic means of storage may be utilised where available, providing that suitable security arrangements are in place.

Examination Grading

8.5.6.5 The AMTO should have procedures in place for grading and evaluating examination results. The grading procedures should be fair, consistent, and transparent, and should be based on established criteria. The AMTO should also ensure that examination results are communicated to students in a timely manner and that students have access to feedback on their performance.

Examination Records

8.5.6.6 The AMTO should maintain records of examination results, including the student's performance and any relevant feedback. These records should be kept in a secure location and retained for a specified period of time in accordance with regulatory requirements (e.g. Annex A to AMC 147.A.125)

Examination Review

8.5.6.7 The AMTO should have procedures in place for reviewing and evaluating examination results to identify any areas where improvements can be made. This includes analysing trends in examination results, identifying areas where students are struggling, and taking corrective actions to improve the effectiveness of the training program.

8.5.6.8 In summary, the examination requirements outlined in DASR 147.A.135 are designed to ensure that the AMTO's training program is effective and that students have the necessary knowledge and skills to perform their maintenance duties safely and effectively. By following these requirements, the AMTO can maintain a high standard of training and contribute to the overall safety of the aviation industry.

8.5.7 Training Procedures and Quality System

8.5.7.1 DASR 147.A.130 requires Aircraft Maintenance Training Organizations (AMTOs) to establish and maintain effective training procedures and a quality system to ensure that their training programs are of a high standard and meet the requirements of all applicable regulations and standards including DASRs. Some important points to be considered when developing or maintaining training procedures and a quality system are:

Training Procedures

8.5.7.2 The training procedures must include a description of the training program, including the objectives, scope, and content of the training. This should include the methods and materials used for training, the sequencing of the training, and the assessments used to measure the effectiveness of the training.

Courseware

8.5.7.3 The AMTO should have a system in place to develop, review, and update courseware, including lesson plans, training manuals, visual aids, and other materials used for training. The courseware should be reviewed and updated regularly to ensure that it remains relevant and effective.

Instructor Qualifications and Training

Superseded

8.5.7.4 The AMTO should have procedures in place to ensure that their instructors are qualified and competent to deliver the training. This includes requirements for instructor qualifications and training, such as experience in the industry, knowledge of the subject matter, and teaching skills. The AMTO should also have a system in place to regularly assess the performance of their instructors and provide them with feedback / training as necessary.

Assessment Procedures

8.5.7.5 The AMTO should have a system in place to assess the effectiveness of their training, including the use of assessments and evaluations to measure the knowledge and skills of the students. The assessments should be designed to provide a fair and accurate measure of the student's performance, and be reviewed and updated regularly to ensure that they remain valid and reliable.

Quality System

8.5.7.6 The AMTO should have a quality system in place to ensure that their training program meets the requirements of DASRs and any other applicable regulations and standards. This includes procedures for monitoring and evaluating the effectiveness of the training by identifying, correcting and preventing recurrence of any deficiencies and continuously improving the training program.

8.5.7.7 Some additional important points to consider when developing or maintaining training procedures and a quality system include:

1. The AMTO should ensure that all training is conducted in a safe and secure environment, and that appropriate safety procedures are followed at all times.
2. The AMTO should ensure that their training programs are accessible to all students and meet their needs.
3. The AMTO should ensure that all training is conducted in accordance with relevant laws and regulations including those related to privacy and data protection.
4. The AMTO should ensure that all training is conducted in a professional and ethical manner, and that all students are treated fairly and with respect.

Quality Policy

8.5.7.8 The AMTO should have a quality policy that outlines the organisation's commitment to quality and its goals for maintaining a high standard of training. The policy should be communicated to all staff and stakeholders, and reviewed and updated regularly.

Quality Objectives

8.5.7.9 The AMTO should establish quality objectives that are measurable and aligned with the goals of the organisation. The objectives should be reviewed and updated regularly, and progress towards meeting the objectives should be monitored.

Document Control

8.5.7.10 The AMTO should have a system in place to manage and control documents related to training procedures and the quality system. This includes procedures for document creation, control, review, approval, distribution and revision.

Record Keeping

Superseded

8.5.7.11 The AMTO should maintain records related to the training programs and the quality system, including records of student performance, instructor qualifications, audit results, corrective actions taken, and other relevant information.

Records of Students

8.5.7.12 DASR 147.A.125 requires approved maintenance training organisations (AMTOs) to maintain accurate and complete records of their students. These records must include a variety of information to demonstrate that the student has successfully completed the required training and has the necessary knowledge and skills to perform maintenance tasks safely and effectively. Here are some important points to consider when developing or maintaining student records:

1. Student Identification: The record must include the student's full name, date of birth, contact information, and any relevant identification numbers or codes.
2. Training History: The record must include a detailed history of the student's training, including the courses they have completed, the date of completion, and the grade they received. This information should also include any remedial training or retesting that was required.
3. Assessment Records: The record must include documentation of any assessments or examinations the student has completed, including the results and any feedback or comments provided by the examiner.
4. Attendance and Absences: The record must include information on the student's attendance and any absences from training, including the reason for the absence and any make-up training that was required.
5. Certification: The record must include information on any certifications the student has received as a result of their training, including the type of certification, the date it was issued, and any restrictions or limitations.
6. Other Relevant Information: The record should also include any other relevant information about the student, such as their prior education or experience in the field of maintenance, any disciplinary actions taken, or any other notable achievements or accomplishments.
7. Some additional important points to consider when developing or maintaining student records include:
    i. The record must be maintained in a secure and confidential manner to protect the privacy of the student.
    ii. The record must be accurate, complete, and up-to-date at all times.
    iii. The record must be available for review by relevant authorities, such as regulatory agencies or potential employers.
    iv. The AMTO must have a system in place to ensure that student records are regularly reviewed and updated as necessary.

8.5.7.13 By meeting the requirements of DASR 147.A.125, AMTOs can ensure that they are maintaining accurate and complete records of their students, which can help to demonstrate that the students have received the necessary training and are qualified to perform maintenance tasks safely and effectively.

Superseded

Corrective and Preventive Actions

8.5.7.14 The AMTO should have a system in place to identify and address non-conformities or areas where the procedures and system can be improved. This includes procedures for taking corrective and preventive actions to avoid recurrence including causal or root cause analysis, tracking and monitoring the effectiveness of the actions taken, and documenting the results.

Management Review

8.5.7.15 The AMTO should conduct regular management reviews of the training procedures and quality system to ensure that they are effective and meeting the goals of the organisation. The management review should include a review of audit results, quality objectives, corrective and preventive actions, and other relevant information.

Audit Procedures

8.5.7.16 Auditing is an important part of ensuring that the training procedures and quality system of the AMTO are effective and meeting the requirements of the applicable regulations. Audits should be conducted by an independent auditor, who can be an internal auditor or an external auditor.

Internal Auditing

8.5.7.17 The AMTO should conduct internal audits of their training procedures and quality system on a regular basis to ensure that all aspects of DASR 147 compliance are checked at least once in every 12 months and may be carried out as one complete single exercise or subdivided over a 12-month period in accordance with a scheduled plan. The purpose of internal audits is to identify any non-conformities or areas where the procedures and system can be improved. The results of the internal audits should be documented and corrective actions should be taken to address any non-conformities.

External Auditing

8.5.7.19 The AMTO should also undergo external audits by an independent auditor, who is not part of the AMTO organisation. The purpose of external audits is to ensure that the training procedures and quality system of the AMTO are in compliance with the requirements of the regulation. The results of the external audits should be documented, and any corrective and preventive actions that need to be taken should be identified and addressed.

8.5.7.20 By meeting the requirements of DASR 147.A.130, AMTOs can ensure that their training programs are of a high standard and meet the requirements of the regulation, which can help to ensure the safety and effectiveness of maintenance operations in the aviation industry.

8.5.8 Military Aircraft Type Ratings

Introduction

8.5.8.1 Military Aircraft Type Rating Training consists of theory and examination, practical and assessment, plus On-the-Job Training (OJT) – see DASR 66.A.45(c) – for first aircraft in licence category/subcategory. Any subsequent Military Aircraft Type Rating (MATR) within the same category/sub-category require both theory and practical elements but will only require further OJT if stipulated by DASA during the approval of the course.

Superseded

Note: A minimum of only theory and examination is required for the Category C Military Aircraft Maintenance Licence (MAML) rating (AMC 66.A.45).

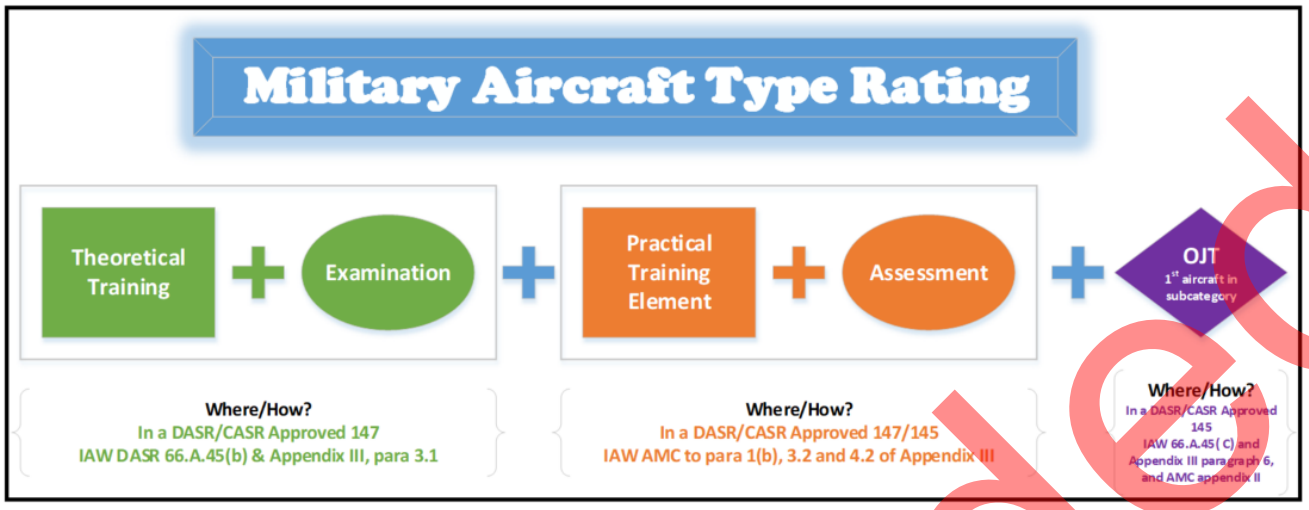

Figure 1: Military Aircraft Type Rating (MATR) - Required Elements

Privileges

8.5.8.2 In order to be entitled to exercise certification privileges for B and C categories on a specific aircraft type, the holder of a MAML shall have their MAML endorsed with the relevant Military Aircraft Type Ratings.

ADF Course Design and Development

8.5.8.3 To ensure consistency across all ADF courses, the design and development of courses, including the course curriculum, should follow the System Approach to Defence Learning (SADL) – see SADL Website.

MATR Course – Initial Approval / Change Management

8.5.8.4 In order to facilitate approval by the authority, the following relevant DASR Forms are to be completed and submitted as appropriate:

1. DASR Form 12 - Application for DASR 147 Initial-Changes of Approval. The DASR Form 12 is the official DASA form to apply for a DASR 147 Maintenance Training Organisation approval. This form is considered part of an application pack and should be submitted with the appropriate evidence as detailed within the form to support the application.

2. DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval. The DASR Form 12A is to accompany the DASR Form 12 when the application is for an initial course approval. For an update to an existing approved course, only the completed Form 12A and associated evidence documents are required for submission.

8.5.8.5 As a minimum standard, the following documents must be submitted as evidence for MATR courseware approval:

1. Training Needs Analysis (TNA) or equivalent as accepted by DASA

Superseded

2. Completed DASR 66 Appendix III MATR Courseware Assessment Matrix

3. MATR Theory Element (Learning Management Plan)

4. MATR Practical Element (Practical Training Logbooks)

5. On-The-Job-Training (OJT) logbook.

DASA Notification Requirements

8.5.8.6 Changes to MATR Courses shall be defined as either a Major or Minor Change.

8.5.8.7 A Major Change is any amendment, alteration or change to a MATR Course that is not accurately categorised as a Minor Change within the relevant Maintenance Training Organisation (MTO) Exposition procedure. A DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval must be submitted and approved prior to any Major Change to a MATR Course.

8.5.8.8 A Minor Change is any amendment, alteration or change to a MATR Course that does not affect the DASR related approval. Minor Changes may be acceptable to DASA without prior approval by the Authority; contingent to endorsement by the relevant MTO QMS that no adverse material effect is posed to safety, quality of training or the knowledge, skills and attitudes of course graduates, course learning outcomes or location.

8.5.8.9 An internally reportable process for approval of Minor Changes to MATR Courseware must be included within the relevant MTO Exposition/Annex; containing either a specific predefined listing of all actions, or defining statement considered by the MTO to fall within the scope of a 'Minor Change'.

8.5.8.10 Subject to the endorsement of the MTO QMS, listed actions could include (but are not limited to):

1. Grammatical and typographic changes

2. Changes that incorporate updates from the relevant platform specific technical publications (e.g. updated maintenance procedures, configuration changes etc.)

3. Changes of content (provided the learning outcomes are not affected).

Theoretical Element of the Military Aircraft Type Rating Training

8.5.8.11 The theoretical element of the Type Course shall provide the person with detailed theoretical knowledge of the applicable systems, structure, operations, maintenance, repair, and troubleshooting of the aircraft type according to the approved maintenance data, including:

1. The appropriate use of manuals and approved procedures, including any relevant inspections and limitations;

2. How to perform system, power-plant and component functional checks as specified in the maintenance manual;

3. Related information for the purpose of making decisions in respect of fault diagnosis and rectification within the scope of the maintenance manual;

4. Describing procedures for replacement of components unique to the aircraft.

Superseded

8.5.8.12 Theory training shall be conducted by an appropriately approved DASA 147 MTO or an organisation recognised by DASA.

8.5.8.13 In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA.

8.5.8.14 Theory training shall have been started and completed within the 3 years preceding the application for a MATR endorsement.

8.5.8.15 The minimum pass mark for the theoretical exam is 75%.

8.5.8.16 The theoretical type training shall describe how the type training is delivered (i.e. classrooms, training equipment, instructors qualifications, TNA etc.) meeting the requirements of DASR 66 and 147, as appropriate.

8.5.8.17 The course content and duration shall be demonstrated by:

1. a detailed curriculum showing the levels for each chapter of the type training, which should be assessed for equivalence to Appendix III to DASR 66 for the relevant certifying staff category; and
2. verifying that both content and duration are justified through a comprehensive TNA (or equivalent as accepted by DASA).

8.5.8.18 Evidence is required for the following elements:

1. the teaching methods and instructional equipment;
2. the material and documentation provided to the student;
3. the qualification of instructors, examiners;
4. the documentation and records provided to the student to justify the satisfactory completion of the training course and related assessment.

Note: For further information about these elements, refer to the MTO exposition.

Practical Element of the Military Aircraft Type Rating Training

8.5.8.19 Practical training is a structured training activity that consolidates the knowledge gained during the theoretical phase of type training and as such, may be performed after or integrated within the theory training. Practical training should:

1. Address the different parts of the aircraft and its associated engines, which are representative of the structure, the systems/components installed and the cabin.
2. Include the use of technical manuals, maintenance procedures and the operational interfaces with the aircraft (e.g. FMC, electronic flight bag, etc.)
3. Include common maintenance and ground handling activities.
4. Cover both type specific and generic safety elements of the aircraft's maintenance.
5. Develop the student's competence in performing safe maintenance, prior to the practical assessment.

Superseded

8.5.8.20 The purpose of practical training is not to include all the maintenance tasks associated with a particular type, but a representative sample of them that will allow the student to acquire the required knowledge, attitude and skills to safely carry out maintenance on that type.

8.5.8.21 The practical element of the MATR Training can be performed concurrently with the OJT element if both are performed on the same military aircraft type and in a real maintenance environment.

8.5.8.22 Practical training may be performed either following or integrated with the theoretical elements however, it should not be performed before theoretical training.

8.5.8.23 Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.24 Table 1 summarises the MATR Training requirements contained in DASR 66.A.45, and Appendix III to DASR 66.

Military Aircraft Type Rating Training requirements		
Aircraft Group	**B1/B2 MAML**	**C MAML**
All military aircraft are considered to be complex motor-powered aircraft	**Military Aircraft Type Rating Training:** Theory + examination Practical + assessment PLUS OJT (for first aircraft in licence category/subcategory. For subsequent Military Aircraft Type Rating within the same category/sub-category, further OJT only if required by DASA)	**Military Aircraft Type Rating Training:** Theory + examination Note: In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA

Table 1: Military Aircraft Type Rating Training requirements

8.5.8.25 IAW AMC to Para 3.2 of Appendix III to DASR 66 - "The practical training may include instruction in a classroom or in simulators, but part of the practical training should be conducted in a real maintenance, or manufacturer, environment." It would be acceptable to complete practical training in a classroom or in simulators, if the practical training could be effectively delivered in this environment.

1. Practical training conducted in a real maintenance environment implies practical training on live aircraft or high fidelity maintenance training aids that are representative of the live aircraft. Practical training in a real maintenance environment should always be conducted on the highest fidelity training device reasonably available and include the use of maintenance data and specialist tooling.

2. Practical training should always be conducted in a real maintenance environment, where it is:

   i. the only reasonable method due to the complexity of the task, or

   ii. the only method available to enable familiarity with component location/ identification, or

   iii. the only method available to demonstrate the use of special equipment / tools.

Superseded

8.5.8.26 Para 3.2 g. of Appendix III to DASR 66 states “The objective of practical training is to gain the required competence in performing safe maintenance, inspections and routine work…”. In the context of practical elements of the military aircraft type training, competence to perform safe maintenance, inspections and routine work does not require the actual performance of the maintenance (e.g. it is acceptable to use a live aircraft as a training aid without physical removal / installation of components). Practical training could be a visit to / walk around of an aircraft in the maintenance environment, identifying specialised tooling / equipment used on the aircraft, process walkthroughs for removal / installations tasks, and scenario based activities for troubleshooting. Practical training should also ensure students are knowledgeable in the use of technical literature, documentation, specialised tooling and test equipment.

8.5.8.27 Selected tasks should consist of a group of representative maintenance tasks drawn from the type training and examination curriculum, at the indicated level and shall cover all the relevant chapters described in the table contained in paragraph 3.2 of Appendix III to DASR 66.

8.5.8.28 The task curriculum must:

1. Be distributed in order to cover all applicable S1000D chapters.
2. Include all of the task categories (LOC, FOT, SGH, R/I, MEL, TS - Refer table 2 below) and may include others deemed appropriate to the type (e.g. ‘INS’pection, ‘ADJ’ustment).
3. Include an appropriate number of tasks in each task category for the aircraft type’s training requirements to be met.
4. Be sufficient to cover at least 50% of the crossed tasks in Appendix III to DASR 66 para 3.2. (Refer to “How should the 50% of tasks required for practical training be selected?” below).

Note: for further information on the S100D Specification refer to the following links on the DASA website. S1000D - International specification for technical publications.

8.5.8.29 The duration of the practical training should ensure that the content of training required by paragraph 3.2 of Appendix III to DASR 66 is completed.

8.5.8.30 A record of the tasks completed should be entered into a logbook which should be designed such that each task or group of tasks may be countersigned by the designated assessor. The logbook format and its use should be clearly defined.

8.5.8.31 The practical element (for power-plant and avionics systems, armaments, escape systems and other relevant military-specific systems) of the MATR Training may be subcontracted by the approved DASA 147 organisation under its quality system according to the provisions of DASR 147.A.145(d)3 and the corresponding Guidance Material.

How should the 50% of tasks required for practical training be selected?

8.5.8.32 When selecting the tasks, the usage of a filtering method based on the criteria similar to that described in AMC to paragraph 3.1(d) of Appendix III to DASR 66, point 5f) is recommended.

8.5.8.33 The selection of 50% of tasks cannot be selected according to the glossary only (e.g. LOC, FOT, SGH, R/I, etc.):

Superseded

1. Paragraph 3.2 of Appendix III to DASR 666 states that 'the tasks selected shall be representative of the aircraft and systems both in complexity and diversity'. In addition, the practical training should particularly address the tasks which cannot be explained by theoretical training only. While relatively simple tasks may be included, other more complex tasks shall also be incorporated and completed as appropriate to the aircraft type.

2. Guidelines on complex / simple tasks (taken from CASA AMC/GM Part 66, V7.4 of December 2024) are as follows:

   i. Complex tasks may have the following attributes:

      – involve several comprehensive steps to perform
      – have multiple decision points in order to complete
      – may use specialised test equipment
      – often requires more than one person to perform
      – have direct impact on flight safety

   ii. Simple tasks may have the following attributes:

      – does not use specialised test equipment
      – can be completed by a single person
      – does not require any in-depth skill/knowledge
      – does not involve decision steps (no troubleshooting)
      – may involve an on-board maintenance system BITE check to determine serviceability

3. How each task is selected (LOC, SGH, etc.), should be based upon the potential gains for the students' competency or its impact on safety. Availability should not be a reason to omit a pertinent task and consideration should be made to include a 'real maintenance environment' to complete an important or critical learning objective.

4. All pertinent sub-tasks, associated with the safe completion of each main task, such as Isolating mechanical/electrical systems, opening/closing CBs, locking flight controls, etc., should be included and the applicable aircraft maintenance manuals used.

5. Regarding the way to read the table in paragraph 3.2, each line aims to cover each of the main systems so that no line relevant to the particular aircraft type should be omitted in the selection. Inside each line applicable to the aircraft type, half or more of the crosses can be selected. From a learning point of view, selecting 2 simple tasks as LOC and SGH would not be "representative", while selecting LOC and TS, for example, would be much more appropriate of the aircraft and systems both in complexity and diversity.

6. The intent of the following tables are to provide a compliance report demonstrating that the practical type training meets the standard required by Appendix III to DASR 666. In particular, the tables shall indicate the percentage of tasks effectively performed against the tasks contained in the Appendix III to DASR 66 which are applicable to the aircraft type.

Superseded

8.5.8.34 The following tables have been developed as a guide for assessment of MATR practical courseware elements. These tables are included in the MATR courseware assessment which can be found at the following link - DASR 66 Appendix III MATR Courseware Assessment Matrix. This assessment matrix should be completed by the MTO delivering the MATR practical type training in order to enable approval of courseware by the authority.

Percentage by Task Type

Type of task	Number of tasks applicable to the A/C type	Total number of tasks selected	Percentage (%) effectively performed against applicable tasks (should be at least 50% of the applicable tasks)
LOC			
FOT			
SGH			
R/I			
MEL			
TS			

Table 2 – Practical Task Training Requirements (By Task Type)

Glossary of the table: LOC: Location; FOT: Functional/Operational Test; SGH: Service and Ground Handling; R/I: Removal/Installation; MEL: Minimum Equipment List; TS: Trouble-Shooting.

Percentage by Chapter

Chapter	Number of Practical Requirements for Each Chapter	Total number of Practical Elements Included Within Courseware	Percentage (%) included against applicable Chapter (should be at least 50% of the applicable practical requioerements within each Chapter)
05 Time limits / maintenance checks			
06 Dimensions/Areas (MTOM, etc.)			
.....			

Superseded

99 Electronic Warfare			

Table 3 - Practical Task Training Requirements (By Chapter)

Practical Training Logbook

8.5.8.35 A Military Aircraft Type specific Practical Training Logbook (PTL) must be developed by a DASA 147 MTO, completed by the student and a certified true copy retained by the MTO delivering the training. It will record the training activities carried out during the practical training course and the subsequent assessment of trainee competence.

8.5.8.36 The PTL shall list all of the applicable S1000D systems, as specified within Appendix III to DASR 66, Section 3.2.

8.5.8.37 After the practical element of the MATR Training has been completed, an assessment must be performed, which must comply with the following:

1. The assessment shall be performed by designated assessors appropriately qualified (AMC to Appendix III).
2. The assessment shall evaluate the knowledge and demonstrated understanding of the trainee.

8.5.8.38 The PTL should include:

1. Trainee attendance sheet.
2. Course and Instructor's details.
3. S1000D system number and title.
4. Aircraft Maintenance Manual or work-pack reference for each training task.
5. A list and detailed description of the training tasks.
6. Each task must have a method of denoting the training technique (Synthetic, Aircraft registration, Classroom, etc.).
7. Task type (R/I, LOC, SGH etc.).
8. Date of each individual task completion.
9. Instructor signatures or stamps.
10. Spare entries for documenting additional/replacement "ad hoc" training tasks.

Note: Additional/replacement tasks must be of relevance to those they replace, be of benefit to the training objective and only replace planned tasks in exceptional circumstances.

8.5.8.39 EASA provide Practical type training logbook examples for both B1 and B2 PTL that can be used for guidance.

Practical Instructors and Assessors

8.5.8.40 In the majority of cases, the Practical instructor will be the same as that used for the Theory phase of the type training. They are a logical choice, as they possess an in-depth knowledge of

Superseded

the aircraft's systems and will have developed an understanding of each student's specific academic requirements.

8.5.8.41 Using the same instructor for both the Theory and Practical phases will often suit the business model of many organisations. In some cases, however, especially where a DASA 147 / DASA 145 affiliation exists, the organisation may choose to utilise experienced MAML holders / technicians, as appropirate, from their own maintenance workforce to deliver the Practical training.

8.5.8.42 These individuals must be given suitable training on the organisational processes involved, particularly the use of the Practical training record. It is recommended that they attended a train the trainer course, whether delivered by an external or internal source, which should specifically target the training techniques required for Practical training and set the organisation's bench mark for the conduct of this training. They should be familiar with the tools or the techniques used by the training organisation to assess the competence of the practical abilities of trainees (maintenance simulators, mock up and etc.).

8.5.8.43 They should be experienced and show solid judgement regarding the abilities of the assessed trainees, they must have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks IAW current regulation, utilising approved procedures, maintenance practices etc. They should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated to maintain the system.

8.5.8.44 Workforce sourced Instructors will be qualified and managed by the DASA 147 organisation. Refer to DASR 147.A.105 for details.

8.5.8.45 They must be included in the list Instructional staff (point 1.5 of the MTOE) and be subject to the same Instructor records and update training requirements as the directly employed Instructors.

8.5.8.46 Practical assessments may be conducted by either the Practical Instructor or a dedicated assessor, who has undergone a similar training and qualification process to that detailed above.

8.5.8.47 Upon completion of the PTL, it must be reviewed, assessed and approved by the relevant DASA 147 in its entirety.

OJT Element of the Military Aircraft Type Rating

8.5.8.48 OJT is required for the initial type rating being sought in each licence category or sub-category:

8.5.8.49 For example; If a B1.1/B2 MAML is endorsed with the P-8A type in the B1.1 category and the MAML holder wishes to add the P-8A in the B2 category, he/she will have to complete B2 related OJT representative of that aircraft and its systems.

8.5.8.50 If the same B1.1 MAML holder adds the B1.3 category to their MAML, and wishes to add their first helicopter type, he/she must complete OJT representative of that first helicopter type. Any subsequent MATR within the same category/sub-category will only require further OJT if stipulated by DASA during the approval of the course.

8.5.8.51 A DASA 145 maintenance organisation appropriately approved for the maintenance of the particular aircraft type can conduct OJT for that type rating:

Superseded

1. The OJT content shall be approved by DASA (Appendix III to DASR 66, sec. 6) and supported by a detailed curriculum showing its content and recorded within detailed worksheets/logbook;

2. OJT tasks shall be signed off by the student and countersigned by a 'designated supervisor';

3. Final assessment of OJT is mandatory and shall be performed by a 'designated assessor';

4. It can be carried out in an approved DASA 145 maintenance organisation with a Category A rating (maintenance on aircraft) and the procedures for OJT should be included in the exposition (MOE chapter 3.15 "OJT procedure") approved by DASA.

5. Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.52 The OJT should include a sufficient number of tasks that are carried out under 'one to one' supervision (i.e. one supervisor dedicated to one trainee) and should involve actual work task performance on aircraft/components, covering line and/or base maintenance tasks.

8.5.8.53 AMC to Appendix II to DASR 66 contains a list of tasks, from which a representative sample appropriate to the type and licence (sub-) category applied for, should be extracted and approved by the MAA. The OJT should cover at least 50% of this approved extracted list.

8.5.8.54 Up to 50% of the required OJT may be undertaken before the aircraft theoretical MATR Training starts, noting that:

1. the ADF Initial Employment Training (IET) workplace journals are the primary means of meeting the practical requirements for the Defence Registered Training Organisation issuance of selected MEA Unit of Competency;

2. portions of these workplace journals may also be utilised as a means of meeting the requirements of OJT, as long as they are completed in a DASA 145, and on the platform/components which the individual is completing their Type Rating training (Appendix III to DASR 66, para 6).

8.5.8.55 If these journal tasks are not carried out on the aircraft type (or its components) required for their subcategory, then these tasks cannot be constituted as OJT.

8.5.8.56 As a minimum, the OJT procedure should describe the following elements:

1. Content of the OJT: the list of tasks that should be performed during the OJT or a list of generic tasks and the process how to develop a list of particular tasks out of this list of generic tasks,

2. Qualifications of the assessor and supervisors performing the OJT,

3. OJT logbook/worksheets format and content,

4. OJT compliance report format and content,

Superseded

5. Production planning for the implementation of OJT (how to plan the tasks),

6. Supervision process and the assessment process, what to do if the assessment is not positive,

7. Safe release to service of the aircraft after OJT,

8. OJT Log Book final assessment process and associated forms:

    i. An OJT Logbook assessment is carried out on an OJT Logbook to ensure that all required tasks have been carried out and certified for in accordance with the OJT Logbook assessment procedure.

    ii. MTOE procedure and associated documents should contain a procedure for the final assessment of an OJT Logbook and who it is completed as well as any associated forms needed and who is qualified to carry out such assessment.

Note: AMC to Section 6. of Appendix III to DASR-66 should be used when defining the content of the procedure.

Practical Assessment Vs On the Job Training (OJT) for Military Aircraft Type Ratings

8.5.8.57 The objective of OJT is to gain the required competence and experience in performing safe, effective and efficient maintenance. The practical assessment addresses the practical portion of any type training, whereas the OJT assessment addresses the additional hands-on experience necessary in a true maintenance environment as part of the first type rating in a (sub)category, as illustrated by the table below:

Superseded

Practical Assessment Vs On the Job Training		
	Practical Assessment	**OJT Assessment** ***For the purpose of DASR 66.A.45(c)***
What/Who is assessed	Candidates following practical element of Military Aircraft Type Ratings training.	Completeness of OJT
	Reference: 66.A.45 (a)(b); Appendix III, 4.2.; AMC Appendix III	Reference: 66.A.45 (c); Appendix III, section 6; AMC to Section 6 of Appendix III
Function of assessor:	To perform the final evaluation of the knowledge, skills and attitude of the trainee following the practical element of the type training	To conduct the final assessment of the completed OJT, whereas the candidate's competence is indirectly justified.
	Reference: Appendix III 4.2.; AMC Appendix III	Reference: Appendix III, 6.; AMC to Section 6 of Appendix III 8.
Organisation :	• DASA-147 • Approved maintenance environment (DASR-145, M.A. Subpart F with A rating, manufacturer) under the DASA-147 approval • Defined maintenance environment as described in the direct approved procedure by the competent authority	Always in a maintenance organisation approved under DASA-145 with an aircraft rating.
	Reference: Appendix III 1(b)	Reference: Appendix III 6.; AMC to Section 6 of Appendix III 1.
Objectives:	To evaluate if the candidate has gained the required competence in performing safe maintenance, inspections and routine work according to the aircraft documentation and other relevant instructions and tasks as appropriate for the type of aircraft.	To confirm the completion of the required diversity and quantity of OJT, based on the supervisor(s) reports and feedback. It is sufficient that the completion of individual OJT tasks is confirmed by the direct supervisor(s), without necessary being the direct evaluation of the assessor.
	Reference: Appendix III, 3.2.	Reference: AMC to Section 6 of Appendix III 7. & 8.
Type of assessment:	The assessment may be: • diagnostic (prior to a course), • formative • summative (partial or final evaluation) • performed task-by-task • performed as a group of tasks • partly executed on simulation devices • performed as a final assessment	• Continuous during OJT (confirmed by the direct supervisor) • Summative, as a final evaluation by a designated assessor of the completeness of the OJT (based on the supervisor(s) reports and feedback)
	Reference: AMC to DASR-66 Appendix III 2)	Reference: AMC to Section 6 of Appendix III to DASR-66
Qualification of the assessor:	The assessment shall be performed by designated assessors appropriately qualified. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Guidance about the qualification is given in AMC to DASR-66 Appendix III 3.)	The OJT shall be assessed by appropriately qualified and designated assessors. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Guidance about the qualification is given in AMC to DASR-66 Appendix III 3.)

Table 4 – Practical Assessment Vs On the Job Training

Practical DASR 147 MILITARY AIRCRAFT TYPE TRAINING LEVELS VS SERVICE LEARNING LEVELS

Superseded

The following table provides guidance on the correlation between the DASR Military Aircraft Type Training levels (TL), Air Force (MAFET) Learning Levels (LL), Army (ATI 1-3/20), SADL TLs and Navy LLs;

DASR		RAAF			ARA			SADL		RAN
TL	Description	LL	Definition	Description of graduate	LL	Definition	Assessment	TL	Description	
1	Graduate is: • Able to define descriptions and maintenance practices • Identify appropriate manuals and maintenance practices • Define layout of major systems • Define layout and characteristics of power plant • Identify special tooling and testing equipment	1	Training provides background knowledge only. It is familiarising in nature or is an introduction to further training.	The graduate has completed learning that either has no clear links to identified workplace requirements or supports underpinning knowledge, skills or range of variables.	1	**Low** - Unable to perform, little to no experience.	Skill and Knowledge are not assessed, but confirmation of learning may occur during training	1	Trained, but not against a prescribed standard.	Navy do not use Training Levels.
N/A		2	Trained to a level below that required for successful assessment against identified workplace requirements, without further training and/or practice.	The graduate has limited knowledge and has performed components of, but not the complete task, during training.	2	**Basic** - Limited in ability or knowledge, needs significant help from others.	Skill and Knowledge are assessed against a restricted set of performance criteria	2	Partially trained against a prescribed standard.	
2	Graduate is able to: • Understand theoretical fundamentals • Apply knowledge in a practical manner • Recall safety precautions • Describe systems and aircraft handling • Identify locations of principal components • Explain normal functioning of major systems • Perform procedures for servicing • Demonstrate proficiency in interpreting crew reports and reporting systems and determine airworthiness • Demonstrate the use, interpretation and application of appropriate documentation	3	Trained to the level to achieve the identified workplace requirement, but unable to be assessed in the context of the training environment. Subsequent experience and assessment using the prescribed workplace requirements or UoC is needed in the workplace environment.	The graduate is trained and ready for assessment against the identified workplace requirements or UoC. The graduate will be aware of common problems in standard workplace contexts but will likely encounter new situations with limited confidence.	3	**Demonstrable** - Able to perform at basic level, has some experience, needs help from time to time.	Skill and Knowledge are to be formally assessed against a set of defined performance criteria	3	Fully trained and ready for assessment against prescribed standard.	
3	Graduate is able to: • Demonstrate theoretical knowledge of systems, structures and their relationship with other systems. Provide detailed descriptions and interpret results applying corrective action where appropriate • Perform checks as specified in maintenance manuals • Demonstrate use, interpretation and application of appropriate documentation • Correlate information for the purpose of decision making • Describe procedures for replacement of components	4	Trained to the level required to achieve the workplace requirements, without the need for further workplace training or practice. Assessment, using the prescribed workplace requirements or UoC, is completed in training environment.	The graduate is trained and assessed, and can be employed effectively on the job. The graduate will be able to cope with common problems in standard workplace contexts and will encounter new situations with moderate confidence.	4	**Advanced** - Capable and experienced, demonstrated proficiency, able to work independently with little help.	Skill and Knowledge are assured under defined employment conditions	4	Trained and assessed competent against the prescribed standard.	
N/A		5	Training reflects outcomes related to values and/or feelings prescribed for the workplace.	The graduate has chosen a certain course of personal action, as prescribed for the workplace.	5	**Expert** - Fully capable and experienced, sought for help by others, needs no assistance to complete tasks, ability to train and lead others, seen as SME.	Skill and Knowledge are internalised by practice and reflection and expressed as autonomous professionalism	N/A

Annex A - Contextualised guidance for seven-step risk management

(a) Risk management should be conducted IAW DASR SMS, supported by guidance within Advisory Circular 003/2008 *Risk Management in the DASP*. The following paragraphs provide general guidance on applying seven-step risk management associated with a DASR 145 MO authorising non-MAML staff as certifying or support staff. DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander. The purpose of this guidance is to support clear articulation of the risk by MAOs to enable DASA to provide timely independent assurance over the decision making process. The approach described by this guidance maybe tailored relative to the available time to document the risk assessment rationale and specific context of the operational need.

(b) **Step 1 – Establish the context, including a robust operational need statement.** What is the resulting cost to capability (including capability preparedness) associated with the lack of sufficient MAML holders at the 145 MO? This should:

1. Explain the hazard context (airworthiness impact) as it relates to the issue of a CRS or acting as support staff (DASR 145.A.50, 145.A.35, 145.A.30 & 66.A.20).

(1) Consequence (not likelihood) associated with granting certification authorisation to personnel not holding an appropriate MAML (eg the granting of unrestricted CRS authorisation equivalent to privileges of a Category B MAML would involve complex flight-critical maintenance and the hazard level would need to reflect this).

b. Detail insufficient numbers of certifying staff.

(1) Asset vs requirement (rank independent) – requirement needs to be contextualised (e.g. the MAO needs to be able to maintain five separate deployed locations but current operations/tempo only allow three).

(2) Numbers should not include total maintenance staff – focus should be on certifying staff only and be expressed in absolute quantities rather than percentages.

(3) Can include information on number of category B MAML holders with MAML E62 exclusion who can only certify maintenance they have personally performed.

(4) Can include information on MAML holders who are not able to certify for maintenance due to essential command and management duties.

c. Describe what capability risk would be realised if the DASA 145 MO did not authorise non-MAML staff as certifying or support staff (the operational need).

(1) Can include immediate effect on operations or impact on Raise, Train, Sustain activities that would lead to a future degradation of capability.

(2) Be as specific as possible but can include commentary on generalised capability deficiencies that would likely occur such as failure to meet preparedness objectives (DASA assurance will focus the documented evidence defining a clear and unambiguous capability need not the validity of the capability need).

Superseded

d. Describe how the DASR non-compliance is being remediated.

(1) For short-term exchanges / secondments of foreign-trained personnel, obtaining a MAML may be grossly disproportionate. In these cases, cancelling risk-based authorisations as soon as they are no longer needed may be a reasonable remediation action. By contrast, gaining a MAML is likely to be a reasonable action for a permanent lateral recruit.

3. **Step 2 – Be reasonably informed.** Through understanding the risk controls inherent in a holding a MAML (e.g. categorisation, exclusions and type ratings). This should address:

a. What is the Qualification, Training and Experience (QTE) difference from DASR 66 requirements?

(1) Needs to be based on individual documented QTE and could include relevant prior authorisations.

(2) Should not just look at collective Initial Employment Training (IET) comparisons but may contain this analysis.

(3) Can include an assessment of experience against specific basic knowledge elements (e.g. specific aircraft systems).

b. Does each individual have a military aircraft type rating or equivalent?

(1) If not, describe the risk associated with this person certifying maintenance in a DASA 145 MO.

(2) Could include information related to experience working on relevant or similar types.

c. Has each individual held a certification authorisation within an EMAR 145 organisation?

(1) If not, describe the risk associated with this person certifying maintenance in a DASA 145 MO.

(2) If so, what was the scope of this authorisation (e.g. currency as well as trade limitations and any restrictions) and the risk associated with this person certifying maintenance in a DASA 145 MO.

d. Has each individual completed unit operational induction, including instruction/ training specific to the MOE, maintenance recording/management systems, and all relevant unit instructions/procedures?

(1) If not, describe the risk associated with this person certifying maintenance in a DASA 145 MO.

4. **Step 3 – Eliminate risk SFARP.** This should address:

a. Why is it grossly disproportionate not to restrict capability (e.g. reduce ROE or restrict number of operating locations)?

b. Why is it grossly disproportionate not to limit authorisations to Task Sign Off?

(1) For example why is it unreasonable for foreign-trained personnel to perform but not certify maintenance in terms of capability impact. This includes

Superseded

authorising personnel as supervisors (not certifying staff) as detailed in AMC to DASR 145.A.65(b)3.

c. Where existing MAML holders are not available due to command and management duties, is it possible to have others backfill command and management duties or leave command and management duties unfulfilled?

5. **Step 4 – Minimise risk SFARP.** This should:

a. Identify any area of remaining risk.

b. Describe how controls will be implemented to minimise risk including: type training, locally developed training, limiting the scope of certification authorisation, and completion of unit operational induction. If controls are not implemented, describe why those controls are grossly disproportionate.

c. Will non-MAML staff as certifying or support staff only be used in the absence of certifying staff with a MAML? If not, why it is grossly disproportionate to do this?

d. Describe how the scope of authorisation will be limited to particular systems or complexity of work to minimise risk.

e. Describe any additional controls/restrictions that can reasonably be placed on non-MAML staff as certifying or support staff to minimise risk SFARP.

6. **Step 5 – Characterise risk.** This is to be done in accordance with the MAO SMS.

7. **Step 6 – Decision to Proceed.** Describe why the residual risk is reasonable to retain in the context of the capability impact that would occur if the risk were not retained.

8. **Step 7 – Review risk.** This should:

a. Describe risk review process

b. Include a plan, including a timeline, to remediate non-compliance with DASR.

Superseded

8.4. Aircraft Maintenance Licencing

8.1 Introduction

8.1.1 This chapter is intended to provide additional guidance on continuing airworthiness regulations to supplement the DASR (DASP Manual Volume 2). This chapter provides additional guidance on aviation safety outcomes that may incorporate compliance with multiple regulations.

8.1.2 The sub-chapters within this chapter are associated with Continuing Airworthiness Management, Maintenance Organisations, Maintenance Licencing and Maintenance Training Organisations. These sub-chapters will also reference, where appropriate, other chapters and sub-chapters within DASP Manual Volume 3 for common aviation safety elements (e.g. occurrence reporting). Other DASP content relevant to continuing airworthiness will also be referenced where possible.

8.1.3 This chapter will contain information that has historically been communicated via Factsheets, Advisory Circulars (ACs) and Frequently Asked Questions (FAQs). In some instances, these historical methods of communicating guidance will remain – particularly for guidance that has a limited period of applicability or when inclusion in DASP Manual Volume 3 is not an intuitive way to communicate specific information. Use of separate Factsheets, enduring ACs and FAQs will be the exception, with the intent that DASP Manual Volume 3 to be the central repository for continuing airworthiness guidance outside of DASR.

8.1.4 The content in this chapter will evolve as the need for additional guidance is identified, with new content and/or new sub-chapters being added over time to support optimal capability outcomes. Accordingly, DASA welcomes any suggestions for future continuing airworthiness guidance noting that awareness training is available via the DASA website.

8.2 Continuing Airworthiness

8.2.1 Continuing Airworthiness Management

Introduction

8.2.1.1 The following chapters provide additional guidance on DASR M regulations – they cover activities such as Deferment of Defects, Acceptance of Components and Aircraft Maintenance Programs.

8.2.1.2 The Continuing Airworthiness Management Organisation (CAMO) should be principally located within the aircraft's operational organisation, although the majority of DASR M functions may be outsourced/assigned to other organisations or service providers.

8.2.1.3 Continuing airworthiness management regulation is summarised in the requirements of DASR M.A.101 as 'This [DASR M] establishes the measures to be taken to ensure that [continuing] airworthiness is maintained, including maintenance. It also specifies the conditions to be met by organisations involved in such continuing airworthiness management'.

Superseded

8.2.1.4 Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including other chapters of DASP Manual Volume 3.

DASR M - Continuing Airworthiness Management

8.2.1.5 CAMOs are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided. The scope of continuing airworthiness management activities should be in accordance with the Operating Organisation's policy and procedures defined in the Continuing Airworthiness Management Exposition (CAME). The CAME is approved by DASA and sets out the procedures, means and methods of how the CAMO intends to comply with the requirements of DASR M. A list of key management positions will be listed in the CAME. The CAME also includes all functions and privileges required to ensure the aircraft are maintained in an airworthy condition, the issue of Military Airworthiness Review Certificates (MARC), and/or changes to the Aircraft Maintenance Programme (AMP). Additional Information on gaining DASA approval to become a CAMO can be found in Chapter 5.3 Annex H –CAMO.

8.2.1.6 CAMOs are responsible for ensuring that maintenance of aircraft is performed by an organisation approved by DASA or another organisation acceptable to DASA. A maintenance organisation is acceptable to DASA if its services are accessed in accordance with the terms of a recognition certificate.

8.2.1.7 Recognition certificates may enable a CAMO to fulfil the aircraft Certificate of Release to Service (CRS) requirement using a maintenance organisation not approved by DASA. These provisions are applicable where DASA has recognised another airworthiness authority in the area of aircraft maintenance. Chapter 6.5, Recognition of Other Aviation Safety Authorities, provides further guidance on the application of recognition.

8.2.1.8 Recognised systems may include an artefact equivalent to an aircraft CRS; however, maintenance organisations may be prevented from issuing a native artefact against a Defence-registered aircraft by legal or policy constraints. Instead, the CAMO should request an artefact that meets the requirements set out in DASR M.A.801.

Airworthiness Directives

8.2.1.9 Airworthiness Directives (ADs) mandate actions to be performed on an aircraft to restore an acceptable level of safety. Furthermore it is mandatory that CAMOs comply with any AD applicable to its aircraft, guidance on Airworthiness Directives can be found in Section 7.4.3 – Airworthiness Directives.

Data for modifications and repairs

8.2.1.10 DASR M.A.304(d) provides for the consumption of data already approved within a recognised airworthiness framework. A CAMO may consume data for repairs and 'minor' modifications when the data is produced by an organisation accepted by DASA. An organisation is accepted by DASA if its design products are being accessed in accordance with the terms of a recognition certificate and a suitable procedure. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. The suitability assessment will consider, among other things, the effect of the design classification and its compatibility with the ADF Configuration, Role and Environment (CRE). Additional guidance can be found in Section 7.2.4 – Repair Designs.

Superseded

Aircraft continuing airworthiness record system

8.2.1.11 An Authorised Release Certificate is necessary for the release to service of either new or used components. It is a document issued by an entity that has the applicable privilege and attests that a new or used component has been produced or maintained in accordance with the approved design data/standard, modification standard or applicable maintenance data. Additional guidance on tracking status of service life-limited components and other usage data for aircraft structures and propulsion systems can be found in Chapter 6.6.4.

Airworthiness review staff

8.2.1.12 Airworthiness review entails a full documented review of the aircraft records and a physical survey of the aircraft. Airworthiness Review Staff are authorised by the CAMO and accepted by DASA to perform Airworthiness Reviews on aircraft which are listed on the CAMO approval certificate.

8.2.2 Operation of an Aircraft with a known Defect

Introduction

8.2.2.1 This chapter provides direction on what constitutes a Defect, how Defence aircraft can operate with a known defect and who can authorise an aircraft to operate with a known Defect.

Background

8.2.2.2 To meet the demands of operational availability, where it is not reasonably practicable to rectify defects, deferment of defects may be considered. The regulations provide Operators the flexibility to defer defects once assessed. The mechanism used should ensure due consideration is given to the impact to capability and safety. Organisations should ultimately prioritise, to the maximum practicable extent, rectifying defects prior to operating an aircraft.

What Constitutes a Defects?

8.2.2.3 A defect is an imperfection that impairs the structure, composition, or system of a product part or appliance or exceedance of operational limitations in the Instructions for Continuing Airworthiness (ICA).

Defect Management

8.2.2.4 Defects can be identified during operations or during the conduct of maintenance. However, regardless of how a defect is identified the CAMO must ensure that all defects discovered or reported are managed appropriately until rectified by a DASR 145 AMO. Annex A outlines the process for defect deferment.

8.2.2.5 Where a defect cannot be rectified before the next flight due to operational requirements, lack of spares or unavailability of maintenance services the CAMO may IAW a DASA approved procedure described at AMC M.A.301(a)(2) choose to defer the defect until it is reasonably practicable to rectify.

Deferment Options

Superseded

8.2.2.6 Deferment of MEL/CDL allowable defects can be accomplished by a DASR 145 AMO or Operator in compliance with the relevant aircraft technical log procedures. MEL/CDL allowable defects are subject to acceptance by the aircraft commander.

8.2.2.7 Where a MEL/CDL does not exist and there is credible data available, IAW GM M.A.301(a)(2), a determination can be made as to the impact to airworthiness for the aircraft. AMC M.A.301(a)(2) allows the CAMO to defer such a defect IAW a procedure documented in the CAME and approved by the MAA.

8.2.2.8 The procedure must ensure:

1. Airworthiness[1] is maintained, using only credible data, in the defect deferment determination;
    i. Within the context of Airworthiness, 'without significant hazard' is considered to mean that no credible hazard exists that would impact airworthiness.
    ii. A non-credible hazard is a defect that is considered so implausible as to its affect on Airworthiness that it does not need to be accounted for. To manifest into an Issue would require a series of exceptional failures or conditions to happen simultaneously making it impractical to consider for a given operational period.
2. potential hazards arising from the cumulative effect of any combination of defects and restrictions/limitations on the same aircraft are considered as to the impact on airworthiness;
3. deferred defects are documented in the continuing airworthiness record system, including the deferment period and any associated limitations/restrictions as described at M.A.306(a);
4. any conditions, limitations or restrictions are clearly identified and visible to aircrew;
5. monitoring on a continuous basis, defects occurring in flight and defects found during maintenance, highlighting any defects that are repetitive;
    i. Where repetitive defects are identified the CAMO may develop a list of pre-assessed defects that have been documented with consideration to the requirements of the DASA approved procedure. However, the accountability remains on the authorised person approving the defect to ensure the context in which the credible data used to assess the defect and the aircraft condition remains appropriate for the specific pre-assessed defect application.
    ii. In each instance of a pre-assessed defect MTCH engagement should be sought. This will allow consideration of inclusion of the repetitive defect in the relevant platform MEL/CDL or review of existing ICA for possible improvements.
6. Persons who determine whether a defect affects Airworthiness are competent and authorised to defer defects.

8.2.2.9 The procedure should also address how ongoing analysis of the effectiveness of the CAMO's defect control system is carried out.

Superseded

8.2.2.10 If the defect does not allow the aircraft to remain airworthy the Operator may seek to use the following for ongoing operations:

1. Military Permit to Fly, or
2. Command Clearance.

8.2.2.11 Where the CAMO has contracted/tasked the day-to-day control of aircraft technical log deferred defects to another Organisation or the DASR 145 has identified a defect in the course of maintenance that entity may defer that defect IAW M.A.306 (a) subject the following:

1. The defect has been assessed using maintenance data defined in DASR 145.A.45, by appropriately authorised certifying staff IAW DASR 145.A.48 (c), as not a Hazard to flight safety;
    i. Authorised certifying staff may only use maintenance data, as defined through DASR 145.A.45 in making an Endangerment to Flight Safety Assessment (EFSA). The authorised certifying staff may only consider the consequence of failure to determine if a defect hazards flight safety.
    ii. If available maintenance data is insufficient to enable a data driven assessment to identify if the defect either does or does not hazard flight safety the DASR 145 should seek additional maintenance data from the CAMO. If further maintenance data is not available or a definitive assessment cannot be made then the defect is to be processed as if it does hazard flight safety.
    iii. Where a defect does hazard flight safety this does not preclude the CAMO from operating the aircraft. However, the CAMO must establish, for the context of the intended aircraft operation, through the procedure described under 8.2.2.1 that the aircraft remains airworthy with the defect deferred.
2. potential hazards arising from the cumulative effect of any combination of defects and restrictions/limitations has been considered as to the impact on the Flight Safety Assessment; and
3. CAMO has been notified as described under DASR 145.A.48 (c) of the defect and agrees to its deferment.

8.2.2.12 Where a CAMO does not agree to the deferment of a defect they are to task a DASR 145 MO as described under DASR M.A.201(g) to rectify the defect.

Annex:

A. Deferred Defect Management Process – Flowchart

8.2.3 Alternate Artefacts

Introduction

8.2.3.1 This chapter provides additional guidance on acceptance of components – specifically the acceptance of alternate documentation, where components are not supplied with a DASA Form 1 or equivalent recognised document.

Superseded

8.2.3.2 The introduction of DASRs brought with it a change to the information requirements accompanying components to be consumed on ADF aircraft. DASRs require that components be supplied with a DASA Form 1, or recognised equivalent, that declares the airworthiness of a component.

8.2.3.3 This chapter relates to the acceptance of new and used aircraft components, which are listed by the appropriate design organisation as eligible for installation in/on a product and included in the design data approved by the Authority[1]. The term components broadly covers any product (other than complete aircraft), part or appliance that is, or is intended by its manufacturer to be, a part of or used in operating an aircraft in flight, or is installed in or attached to a product. This may include any self-contained part, combination of parts, assembly, subassemblies or units, which perform a distinctive function necessary to the operation of the airframe, engine, or propeller, or may include any other instrument, mechanism, equipment, apparatus, software or accessory, including communications equipment.

8.2.3.4 Although alternate artefacts are consumed by a DASR 145 Approved Maintenance Organisation (AMO), DASA requires the relevant CAMO to seek approval for and manage the ongoing validity of alternate artefacts for their respective platforms. Further detail on alternate artefacts can be found in Chapter 8.3.4 – Acceptance of Aircraft Components

What constitutes an 'alternate artefact' accepted by DASA?

8.2.3.5 DASA may agree that an AMO may consume an alternate artefact other than a DASA Form 1, or recognised equivalent Authorised Release Certificate, that is produced by an organisation accepted by DASA. A CAMO can seek approval of an Alternate Artefact from DASA using DASR Form 155 – Application for Acceptance of Alternate Artefact. AMC to DASR M.A.201(g) and M.A.802(c) provide detail on when an alternate artefact would be acceptable. Chapter 8.3.4 – Acceptance of Aircraft Components provides further detail.

Consumption of United States (US) Department of Defence (DoD) products

8.2.3.6 There has been confusion with consumption of US DoD supplied products where associated documentation, such as DD Form 250, does not meet the requirements of a DASA Form 1 or recognised equivalent. The DASR provide a path for the regulated community to accommodate the consumption of products where the product supplied does not meet the requirements of a DASA Form 1. This is:

1. AMOs and CAMOs comply with DASR 145.A.42 and DASR M.A.201 (g) (e.g. via direct recognition or DASR Form 155 Application for Acceptance of Alternate Artefact).
2. Where (a) above is not reasonably practicable, CAMOs can develop a procedure within their exposition to demonstrate to DASA how these products can be consumed whilst maintaining an equivalent level of protection. DASA will then assess this procedure against the requirements of DASR GR.80(b), and if appropriate, approve the procedure for use.
3. Where (a) is not reasonably practicable, and an equivalent level of protection cannot be ensured (b), CAMOs can develop a procedure within their exposition to demonstrate to DASA how these components will be consumed; accompanied by a demonstration that the resultant risks are appropriately managed by the applicable MAO. DASA will then assess this procedure against the requirements of DASR GR.80(c), and if appropriate, allow the use of the procedure.

Superseded

8.2.4 Aircraft Maintenance Programme

Introduction

8.2.4.1 This chapter provides guidance on Aircraft Maintenance Programmes (AMPs) and Reliability Programmes (RPs).

Aircraft Maintenance Programme (AMP)

8.2.4.2 DASR M.A.302(a) requires that maintenance of each aircraft shall be organised in accordance with an AMP. The AMP encompasses the actual maintenance programme in its entirety. An AMP provides the scheduled maintenance tasks, their associated maintenance procedures and standard maintenance practices that are applied to the maintenance of an aircraft. The RP, which continually reviews the applicability of the AMP to the aircraft and operator, is also considered a part of the AMP.

8.2.4.3 Guidance on the application and approval of AMPs can be found in Chapter 5.3 Annex T – AMP with additional guidance in Chapter 6.6.4 (particularly guidance on how integrity programs can support the development and ongoing validity of the AMP).

Extension of promulgated maintenance interval

8.2.4.4 If a contracted/tasked maintenance organisation advises the CAMO that the maintenance cannot be carried out by the required timeframe and requests an extension of the promulgated maintenance interval, the CAMO when processing the request for an extension, has the following options available:

1. where the packaged/promulgated interval is less than the engineering justified interval, extend the interval up to a maximum of the engineering interval;
2. extend the task interval using the CAMO's indirect approval procedure, if suitably privileged, either once-off or permanently,
3. request DASR 21J design support for the requested interval extension; or
4. utilise the Command Clearance process to operate the aircraft IAW DASR M.A.301(a)(2) .

8.2.4.5 **Extending the Packaged Interval.** Interval flexibility may exist between a maintenance task's packaged/promulgated interval and its engineering/design interval in the AMP. The task may be packaged at a lesser interval maintenance efficiency due to tasks required in the same area or aligning maintenance to be conducted in blocks. If this is the case, and provided the CAMO has the underlying analysis that identifies the engineering interval and the reasons why the task was packaged at a lesser interval, the CAMO may authorise an extension to the packaged interval up to a maximum of the recorded engineering interval.

8.2.4.6 **Extend the AMP Task Interval.** If the AMP task interval has been reached, the CAMO may have sufficient data to extend the AMP task interval either once off, for a defined period, or permanently. To amend the AMP the CAMO must have the privilege from the MAA and sufficient scope as agreed in the indirect approval procedure. Note: where a task's interval has been extended permanently, the task may still be packaged as desired (not exceeding the extended interval).

Superseded

8.2.4.7 **Request DASR 21J Design Support.** If the two options at para 8.2.4.4a and b above are not applicable, the CAMO may request DASR 21J design support to either extend the interval once off, for a defined period, or permanently.

8.2.4.8 **Utilise the Command Clearance process.** DASR M.A.301(a)(2) contains provisions for the Operating Organisation to deviate from the Initial / Continued / Continuing regulations.

8.2.4.9 For servicings with multiple tasks, the decision on extending the interval and the method used will be dependent on the individual circumstances of each task within the servicing. A combination of paragraphs 8.2.4.4a to d may be necessary.

8.2.4.10 Note, that extending a maintenance task beyond its promulgated interval may reduce the preventive effect of the task by increasing the risk of exposure to the failure consequences of the failure mode being addressed. Extension of maintenance could adversely affect the operational capability and/or safety of the aircraft. Also, the percentage by which the interval is extended does not universally reflect the increase in risk in exposure to the failure consequences of the failure mode(s) the task is addressing. The increase in risk with the extension of a task's interval needs to be assessed individually based on the underlying Reliability Centered Maintenance (RCM) analysis that justified the existing interval and the context in which the interval extension is being asked.

8.2.5 Airworthiness Review

Introduction

8.2.5.1 This chapter provides guidance on Airworthiness Reviews (AWRs) to supplement the AMC M.A.710(a)

Airworthiness Review

8.2.5.2 During airworthiness review of an aircraft, the airworthiness review staff must examine continuing airworthiness records for the aircraft and perform a physical survey of the aircraft to determine whether the aircraft continues to comply with the airworthiness requirements as set out in DASR M.A.710(a) and DASR M.A710(b).

8.2.5.3 For many aircraft, the quantity of records that must be examined and the level of examination required will be extensive. It is anticipated that the airworthiness review staff will be assisted by other employees of the CAMO and/or appropriately experienced personnel in this regard. This does not prevent other personnel from assisting to retrieve records, compile information and prepare reports etc. for the examination by the airworthiness review staff. However, it is up to the airworthiness review staff carrying out the airworthiness review to be satisfied with the source, authenticity and accuracy of the information made available to them.

8.2.5.4 The airworthiness review staff are expected to have a level of understanding of the continuing airworthiness records system for the aircraft that allows them to carry out the review without error.

8.2.5.5 **Rectification of defects.** AWR staff shall examine the aircraft's continuing airworthiness record system to determine if any defects need rectification before flight. Defects that require rectification before flight must be rectified before the issue of an airworthiness review certificate.

Superseded

8.2.5.6 **Deferred defects.** AWR staff shall examine the existing deferred defects as recorded in the aircraft's continuing airworthiness record system to determine whether deferral of rectification has been carried out.

8.2.5.7 **Airworthiness Directives (AD).** AWR staff shall examine the records containing compliance with ADs to determine whether actions required by each AD that applies to the aircraft, product, parts or appliances fitted to the aircraft have been complied with. An examination of documents that substantiate each AD has been complied with should verify that information kept is correct. Examples of documents that may substantiate an AD has been complied with, includes:

1. maintenance records for maintenance carried out on the aircraft;
2. copies of authorised release certificates for product, parts or appliances; and
3. log books for products such as engines and propellers.

8.2.5.8 For a product, parts or appliances, the document that substantiates compliance with the AD should relate to the product that is identified in the records by part number and serial number.

8.2.5.9 Where an AD requires compliance with requirements contained in another document such as a service bulletin (SB), a record of compliance with the service bulletin would be acceptable as evidence of compliance with the AD.

8.2.5.10 **Modifications.** AWR staff shall examine the records of modifications kept to determine whether there is a DASR 21 (see DASR M.A.304—Data for modifications and repairs) approval for each design of the modification. For the purpose of this paragraph, a modification includes a repair that involves change to the approved design of the aircraft.

8.2.5.11 **Life Limited Components**. AWR staff should examine the records of life-limited components kept to determine whether part number, serial number, has correctly identified each life-limited part and whether the life limit has been exceeded for any of the parts.

8.2.5.12 In addition, documents that have been used to substantiate remaining life at installation shall be checked to verify that information kept for life-limited components is correct. Examples of such substantiating documents include:

1. maintenance records for installation of the parts;
2. authorised release certificates for the parts; and
3. life limited component history/log card.

8.2.5.13 **Weight and Balance.** AWR staff shall examine the record of the aircraft's weight and balance kept to determine if it is consistent with all the changes made to the weight and balance since the last weighing of the aircraft. All changes made to the weight and balance should be substantiated by documents such as a modification approval and an equipment list for the aircraft.

8.2.5.14 **Aircraft Configuration.** AWR staff shall examine the aircraft's continuing airworthiness records to determine whether the aircraft's configuration as recorded complies with the specification in the military type certificate data sheet (TCDS) for the aircraft, engine and propeller.

8.2.5.15 **Findings.** All findings discovered during an airworthiness review should be documented and managed in accordance with the CAMO's quality management system / safety management system, consistent with requirements of M.A.905.

Superseded

8.2.6 Master Minimum Equipment List (MMEL) and Minimum Equipment List (MEL)

Introduction

8.2.6.1 This chapter provides guidance on Master Minimum Equipment List (MMEL) and Minimum Equipment List (MEL) development and approval.

Background

8.2.6.2 Under certain conditions the required level of safety can be maintained with specific aircraft components being unserviceable, for a limited period of time, until repairs can be made. Many aircraft also have equipment installed that is not required for safe operation under certain operating conditions (e.g. aircraft with multiple VHF radios can operate with single radio if operations do not require the use of the systems associated). Equipment, such as entertainment systems, galley equipment, mission equipment or systems, may have no impact of flight safety.

8.2.6.3 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment, based on the aircraft type certification. An MEL consists of an approved list of the specific unserviceable equipment for a particular aircraft by serial and registration mark, based on the MMEL and the Operator's Configuration, Role and operating Environment (CRE).

8.2.6.4 An MEL can be used as the first step in a defect management process in accordance with procedures developed by the CAMO and approved by the DASA to meet the requirements of DASR M.A.301 (a) 2, for the deferral of defects.

8.2.6.5 Useful background information when developing a MEL can be found in:

1. CASA CAAP 37-1(5) - Minimum Equipment Lists (MEL)
2. EASA Rules for Master Minimum Equipment List (CS-MMEL)

DASA Regulatory Basis

8.2.6.6 DASR GM 21.A.15(a) - Application for a Military Type Certificate may include the MMEL as Operational Suitability Data (OSD) that may be approved as part of Type Certification and form part of the Military Type Certificate (MTC) .

8.2.6.7 DASR M.A.301 Continuing airworthiness tasks, refers to MEL and Configuration Deviation List (CDL) for use in the deferment of defect rectification.

8.2.6.8 DASR AO Gen.05 Management of OIP, ORO.05 Conduct of Flying Operations and ORO.30 Flight Authorisation support discharging flight operations requirements referred to in this chapter.

Configuration Deviation List

8.2.6.9 A Configuration Deviation List (CDL) is a listing of regulator-approved non-structural external parts that may be missing but the aircraft remains airworthy. A CDL provides options to dispatch an aircraft for flight when listed parts may be missing, provided the necessary performance corrections are adhered to (including limits or restrictions if required and specified rectification periods). Refer DASR M.A.301(a)2 and associated AMC/GM.

Superseded

8.2.6.10 CDLs are part of the certified type for any civil derivative aircraft (certified by the European Aviation Safety Agency (EASA) or the Federal Aviation Administration (FAA)). Within the ADF context, as part of Military Type Certification, the CDLs are presented as part of the Aircraft Flight Manual (AFM) for approval during Type Certification. Usually, they are contained in a standalone section of the AFM. The AFM is approved as part of Military Type Certification (DASR 21 Subpart B) and changes would be approved under (DASR 21 Subpart D).

8.2.6.11 The CDL should not be confused with the Minimum Equipment List (MEL). While the MEL describes the limitations of aircraft operation in case of a system being inoperative or having malfunctioned (e.g. transponder failure), the CDL deals with situations where external parts of an aircraft are missing (e.g. fairings, aerodynamic seals or panels).

MMEL

What is a MMEL?

8.2.6.12 A MMEL is a document created specifically to permit the continued operation of an aircraft type (e.g. C-130J-30) with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL does not take into account the operating circumstances of individual operators of that type. The MMEL cannot, in itself, be regarded as providing operational permission. It can, however, be the basis for the development of an individual Operator's MEL.

MMEL Characteristics

8.2.6.13 **Aircraft Type.** MMEL relief for a particular item may be unique to a specific aircraft type. Therefore, MMEL relief for an item for one aircraft type may not be the same as the relief allowed for the same item found in another aircraft type.

8.2.6.14 **Items required by an Airworthiness Directive (AD) are prohibited.** An MMEL will not include items that an AD requires to be operative, unless the AD specifically allows them.

8.2.6.15 **Variable Number of Items Required for Dispatch.** A MMEL may depict a variable number of items required for dispatch based on various makes and models of the same series aircraft. The MMEL must clearly articulate which makes and models each MMEL item is applicable to.

8.2.6.16 **Multiple Versions of the Same Item.** A MMEL may contain multiple versions of particular items (e.g., very high frequency (VHF) communications systems and fire extinguishers) that are installed on different models or series of the aircraft covered by the MMEL. The MMEL must clearly articulate which versions each MMEL item is applicable to.

8.2.6.17 **Repair Categories.** A MMEL will contain a repair category for each item. Each repair category allows for a certain amount of time until repairs must be accomplished.

8.2.6.18 **Prohibited Items.** A MMEL will not include items of the aircraft that are required for basic flight (wings, flaps, rudder, etc.), nor will it include instruments and equipment required for specific operations.

MEL

What is a MEL?

Superseded

8.2.6.19 A MEL is a document created specifically to manage the continued operation of an aircraft with unserviceable equipment consisting of an approved list of the specific unserviceable equipment for a particular make and model of aircraft by serial/production number and registration mark (e.g. C-130J-30, 5440, A97-440) as applicable. Its use is authorised by accepting the associated application procedures contained in an operator's Continuing Airworthiness Management Exposition (CAME) and/or operations manual, or other appropriately documented procedures.

MEL Transferability

8.2.6.20 An approved MEL for an aircraft is a non-transferable document, i.e. if the MAO of the aircraft changes, then a new approval for the MEL is required even if the aircraft retains the same registration mark.

8.2.6.21 If an aircraft moves from one Military Air Operator Certificate (MAOC) holder to another, the new MAOC holder cannot automatically use the approved MEL for the aircraft. The new MAOC holder will be authorised by DASA only if they have acceptable associated application procedures contained in their CAME and/or operations manual and have assessed the operator's CRE.

Use of the MMEL/MEL

MMEL/MEL Considerations for Use

8.2.6.22 The MMEL/MEL is an alleviating document. Its purpose is not to encourage the operation of aircraft with unserviceable equipment. It is never desirable that aircraft continue operations with unserviceable equipment. Such operations are permitted only as a result of careful analysis of each item to ensure that the required level of safety is maintained. A fundamental consideration in permitting the operation of aircraft with unserviceable equipment is that the continued operation of an aircraft in this condition is to be eliminated or otherwise minimised so far as reasonably practicable (SFARP).

Invoking the MEL

8.2.6.23 The Aircraft Captain or appropriately licenced and authorised Military Aircraft Maintenance Licence (MAML) holder invokes the MEL on behalf of the CAMO. It is the decision of the Aircraft Captain to accept the aircraft for flight with unserviceable systems or equipment listed in the MEL. The overriding principle is that, notwithstanding the provision of an approved MEL, a MAML holder should not release an aircraft for flight, and the Aircraft Captain should not accept an aircraft for flight, if it is considered unsafe for a particular flight.

8.2.6.24 A MAO may authorise Aircraft Captains to invoke MEL items through provisions in the Operations Manual. Where an Aircraft Captain is not authorised to invoke a MEL item the Aircraft Captain is to refer to local procedures for actions required to invoke the MEL item.

Developing a MMEL

MMEL Development Options

8.2.6.25 **Existing CAA/MAA MMEL as part of Operational Suitability Data (OSD).** As part of the introduction of a new type to Defence the initial certification package may contain a MMEL that has

Superseded

been developed by the OEM as part of the OEM state of design certification process. This MMEL document can be submitted as OSD, as part of the Australian MTC certification package and be assessed for approval as the DASA approved MMEL. Similarly, for an existing type with no DASA approved MMEL, an existing Civil Aviation Authority (CAA) / Military Aviation Authority (MAA) approved MMEL may be submitted for approval as a change to the type certificate.

8.2.6.26 In both cases above, foreign CAA/MAA approval of a MMEL does not constitute automatic approval under DASRs. DASA issues its own sovereign Military Type Certificates (MTC) for each aircraft type and does not 'accept' foreign civil or military TCs. Therefore, in order for a MMEL to be approved under DASRs it must be approved under the initial issue of, or as a change to, the DASA issued MTC and be included on the DASA issued Type Certificate Data Sheet (TCDS).

8.2.6.27 **MEL submitted in lieu of MMEL.** If the operator has access to an existing, or has developed, a MEL for the type, for which no MMEL exists, the operator may submit the MEL through the Military Type Certificate Holder (MTCH), for assessment as a MMEL. If the MEL is submitted, DASA will consider it a MMEL submission and assess it as such. It may then be used as the basis for acceptance as a MEL.

8.2.6.28 **Development of a new MMEL.** A MTCH may elect to submit a new MMEL to DASA for approval. DASA does not stipulate any specific format and/or contents of a MMEL. However, the Certification Programme must propose an appropriate Certification Basis that the MMEL will comply to, and that may include content and format requirements. Establishing the Certification Basis early and following the associated format will avoid delays in assessment and approval of the MMEL.

8.2.6.29 **Suitable Certification Specifications.** The Certification Programme should be submitted to DASA, proposing a Certification Basis for the MMEL. The following two certification specifications will likely be suitable for development of MMELs:

1. EASA CS-MMEL. CS-MMEL is the Certification Specification (CS) mandated by EASA for MMEL development and is likely to provide an acceptable basis for MMEL approval for Defence aircraft.

2. FAA FOEB process. FAA policy for MMEL approval is through the Flight Operational Evaluation Board process. MMEL document templates, guidance on specific systems, general format requirements, and guidance on justification requirements are available on the FAA FSIMS website. (Reference ICAO Manual – MMEL/MEL5 and Flight Standards Information Management System).

8.2.6.30 Alternate Certification Bases may be proposed in the Certification Programme but will require further justification.

MMEL development process

8.2.6.31 As the MMEL forms part of the Military Type Certificate, any MMEL change is to be classified IAW the guidance in DASR 21.A.91. On initial issue of the MMEL or identification of a MMEL change as Major, the Major Change to Type Certificate process as per DASR 21 subpart D applies. Minor changes to MMELs are to be processed IAW DASR 21.A.95. This process is depicted at Appendix 2.

8.2.6.32 **MMEL Change Classification Criteria.** The following guidance for classification of MMEL changes elaborates upon the generic classification advice in GM to DASR 21.A.91.

8.2.6.33 Conditions requiring classification of a MMEL change as Major:

Superseded

1. Where the change requires an adjustment of the MMEL certification basis;

2. Where the applicant proposes changes to the Means of Compliance (MoC) with the requirements for the MMEL certification basis (i.e. MMEL safety assessment methodology);

3. Where the extent of substantiation data and the degree to which the substantiation data has to be assessed and evaluated is considerable, in particular but not only when:

    i. The substantiation data involving review of failure conditions that are classified as hazardous or catastrophic has to be evaluated;

    ii. The assessment of the failure effects (including next worst failure/event effects) on crew workload and the applicable crew procedures has to be evaluated; or

    iii. The capability of the aircraft to perform types of operation (e.g. Defence Long Range Operations (DLRO), Instrument Flight Rules (IFR)) under MMEL is extended.

8.2.6.34 Conditions where the MMEL change can be considered Minor:

1. Modifications to an item/s when:

    i. The change is only to the applicability of an item for configuration management purposes;

    ii. The change is the removal of an item;

    iii. The change is an increase in the number of items required for dispatch; and

    iv. The change is a reduction in the rectification interval of an item.

2. Addition of a new item when:

    i. It is considered as non-safety related IAW FAA MEL Requirements for 14 CFR Parts 91 Subpart K (Part 91K), 121, 125, 125 LODA, 129, and 135 Operations CS-MMEL GM2 MMEL.110; or

    ii. It is indicated as eligible for minor change classification in FAA MEL Requirements for 14 CFR Parts 91 Subpart K (Part 91K), 121, 125, 125 LODA, 129, and 135 Operations, GM1 CS MMEL.145.

8.2.6.35 **Justification and development of supporting data.** Items must be justified for inclusion in the MMEL against the agreed certification basis. Any risk associated with inclusion of items is to be eliminated or minimised to the level inherent in the applicable design standards. Alternate methodologies for justification of changes must be presented to the Authority during the Certification Programme agreement (CP) process.

8.2.6.36 If the conditions and limitations applied against a MMEL item are assessed as insufficient to fully eliminate the associated risk, or an Equivalent Safety argument cannot be made that the risk meets the level of safety inherent in the applicable design standards in the aircraft Type Certification Basis (TCB), the MMEL item is NOT to be included in the MMEL.

8.2.6.37 Operational endorsement should be sought from the MAO (e.g. Hazard Tracking Authority or Standards Officer (STANDO) for any operational conditions or limitations identified against MMEL

Superseded

items. The MTCH in developing the MMEL considers the operational conditions/limitations of the aircraft against the type certification. The MMEL operational procedures are not specific to an individual Operator's Configuration Role and operating Environment (CRE).

8.2.6.38 **Relief from Development of Compliance Demonstration Evidence.** Relief from the requirement to develop compliance demonstration evidence can be sought on an item by item basis for MMELs. The requirements for leveraging prior certification from another CAA/MAA as per AMC to DASR 21.A.20 still apply when relief is applied in this manner.

MMEL approval process

8.2.6.39 Initial Type Certification

1. The applicant for initial DASA MTC would submit the MMEL as part of the application package.

8.2.6.40 MMEL for an aircraft with an existing DASA MTC

1. An MTCH submitting a MMEL for DASA approval must do so in accordance with the Change to Type Design process as described in DASR 21
2. Refer to Appendix 2: for the process flow to seek DASA approval of a MMEL.

Developing a MEL

Developing a MEL using an existing/relevant MMEL

8.2.6.41 DASA do not stipulate any specific format and/or contents of a MEL. Using an international recognised format could avoid delays in assessing the MEL. In the development of an MEL, DASA recommends that the MEL be developed in accordance with international standards as referenced in the Certification Programme from the MMEL (detailed above).

8.2.6.42 The MEL should be developed from the latest issue of the applicable MMEL on an item-by-item basis and keeping in view the relevant regulatory requirements.

8.2.6.43 If an operator chooses to add items that are not found in the MMEL (due to its particular type of operation) an assessment of those items must be carried out. This assessment is required to ensure that these items do not affect the design standards or safe operation of the aircraft and are not in conflict with the flight manual and any DASR requirements. Refer to the International standards as referenced in the Certification Programme from the MMEL for guidance on how to assess the criteria for these items.

8.2.6.44 In general, a MEL should be as, or more, restrictive than the applicable MMEL for the type of aircraft. If a certain item(s) of the applicant's MEL is less restrictive than the applicable MMEL, DASA will require an extensive qualitative and/or quantitative analysis to substantiate the proposed departure from the MMEL.

MEL Development with no MMEL

8.2.6.45 If a platform has no MMEL or MEL available from the manufacturer or other CAA/MAA and the operator wants to utilise the flexibility that a MEL affords, the Operator may choose to engage the MTCH to develop a MMEL from previously available deferment options.

Superseded

8.2.6.46 The MMEL should be developed in accordance with the guidance provided earlier in this chapter.

8.2.6.47 Once the MMEL is approved by DASA the operator can seek approval of the MMEL for use as an MEL from DASA.

MEL approval process

8.2.6.48 An Operator submitting a MEL for approval must provide DASA with:

1. A minute of application from the CAMO requesting approval of the MEL;
2. Digital access to a copy of the proposed MEL;
3. All OIP created for use of the MEL; and
4. If the MEL has no associated DASA approved MMEL, the MEL must be submitted for approval as a MMEL.

8.2.6.49 A MEL may cover more than one aircraft of the same type. However, all differences in the equipment/systems installed, if any, should be clearly identified by the aircraft registration mark.

8.2.6.50 Refer to Appendix 1: for the DASA process flow of MMEL/MEL approval.

Application for amendment to the MEL

8.2.6.51 Amendments to MELs are either mandatory or voluntary, depending upon the particular circumstances. Mandatory amendment of a MEL is required either:

1. When the applicable MMEL is amended so as to become more restrictive; or
2. When required by DASA in light of in-service experience.

8.2.6.52 Voluntary amendment of a MEL may be carried out when either:

1. The MMEL is amended so as to become less restrictive; or
2. As required by the operator, provided the proposed change is no less restrictive than the MMEL; or
3. Regulatory changes occur.

8.2.6.53 An application for amendment to an approved MEL, together with appropriate substantiation, should be forwarded to DASA.

MMEL/MEL Development Considerations

Operations and maintenance procedures

8.2.6.54 The objective of operations ((O)) and maintenance ((M)) procedures is to provide everyone using the document with clear and concise directions on how they are to proceed in case of unserviceability. The (O) and (M) procedures form part of the approved MEL.

8.2.6.55 **(O) Procedures:** Where the (O) symbol appears in the MMEL, an operations procedure must be developed that provides clear direction to the flight crew. These procedures may be included in the MEL. Where they are not included in the MEL, they must be available to the aircrew in another

Superseded

document that is always available to the aircrew (i.e. an operations manual or in an approved electronic form). In these cases, the MEL shall refer to a section of the appropriate document(s).

8.2.6.56 **(M) Procedures:** The MMEL may identify items that require a maintenance procedure. If this is the case, the operator must ensure that relevant (M) procedures have been developed for the MEL. These procedures must provide clear direction to the maintenance personnel.

Procedures for the use and guidance of flight crews and maintenance personnel

8.2.6.57 The operator must establish procedures for the use and guidance of flight crews and maintenance personnel, in relation to the MEL. These procedures must agree with those in the operator's CAME, Aircraft Maintenance Program (AMP), operations manual, and other operating documents. These procedures should include, but are not limited to, procedures for:

1. Deferring rectification action or invoking MEL item(s) for unserviceable equipment;
2. Placarding requirements as per the MEL;
3. Ensuring that a dispatched aircraft with an invoked MEL item(s) complies with the limits and conditions of the MEL;
4. Ensuring that existing deferred defects / MPTF / Command Clearances do not impact invoking of MEL provisions;
5. Controlling categorised repair intervals; and
6. The training of organisations personnel who are responsible for compliance with MEL procedures.

8.2.6.58 Procedures for invoking MEL items are normally contained in the operator's CAME, operations manual or an alternative document. Prior to issuing a MEL approval, DASA will ensure that the MEL references these procedures in the CAME, operations manual or similar document, if not already included in the MEL. If no procedures for the invoking of MEL items exist within the operator's organisation, then DASA will, in addition to vetting the MEL, require amendment to the CAME/MOE and/or operations manual.

8.2.6.59 A placarding procedure should be established and set out in the CAME/MOE and operations manual or, at least, within the approved MEL document.

8.2.6.60 When invoking a MEL item, the person responsible must:

1. Identify, in the aircraft technical log or appropriate document/maintenance information system, that this action has occurred;
2. Identify the item with its MEL number; and
3. Ensure that an unserviceable label is placed in an appropriate location (where applicable).

8.2.6.61 A procedure documenting the above requirement in the appropriate operator's documentation is acceptable for compliance purposes.

Repair intervals

8.2.6.62 Each item of a MEL must be repaired within the specified repair interval. These intervals are set to limit the maximum time an aircraft may fly with an unserviceable item(s) of equipment, and

Superseded

are designated Category 'A, B, C or D'. The definition of repair intervals should align with the selected certification basis for the MMEL as defined at para 8.2.6.29.

8.2.6.63 The operator must establish procedures whereby the maintenance support periodically reviews the deferred items. This is done to ensure that any accumulation of deferred items neither conflict each other nor present an unacceptable increase in crew workload. Notwithstanding the categorisation of item repair intervals, it should be the aim of each MEL document holder to ensure that unserviceable items are repaired as quickly as possible.

Repair interval extension

8.2.6.64 Each operator's MEL management program needs to contain procedures for controlling extensions to item repair intervals. Procedures must include the limitations of each extension and the method by which the operator approves an extension.

MEL training program

Training Requirement

8.2.6.65 The operator should as part of the introduction of a process for the use of a MEL develop a MEL training program for maintenance personnel and flight crew, which should be in place prior to an operator commencing operations with a MEL. The operator, when required, should conduct recurrent training, or put in place a controlled method to alert staff to any changes in MEL procedures. This will ensure company personnel remain current with those procedures.

Maintenance Personnel Training

8.2.6.66 The training for maintenance personnel should include those sections of the CAME procedures dealing with:

1. The use of, and compliance with, the MEL;
2. Placarding of unserviceable equipment;
3. Return to service of an aircraft;
4. Dispatching an aircraft; and
5. Any other MEL related procedures.

Flight Crew Training

8.2.6.67 The flight crew training should include, but not be limited to, the following:

1. The purpose and use of a MEL;
2. Instruction on operator's procedures for the use and guidance of flight crew;
3. The process and procedures required for supervision and flight authorisation; and
4. The Aircraft Captain's responsibility with respect to the above procedures.

Superseded

8.3.1 Requirements for Maintenance Organisations

Introduction

8.3.1.1 This section provides additional information and guidance to DASR 145 Approval Holder Organisations and those organisations that are applying for approval under DASR 145. Further guidance on applying for a Maintenance Organisation approval can be found in Section 5 Annex G – AMO.

8.3.1.2 For information on maintenance service providers that are approved though other means (i.e. not DASR 145 approval), refer to Chapter 6.5, Recognition of other Aviation Safety Authorities and to Chapter 8.2, Continuing Airworthiness Management.

8.3.1.3 This chapter does not include information already presented at Volume 2 (DASRs), but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3.

DASR 145 – Requirements for Maintenance Organisations

8.3.1.4 The Defence Aviation Safety Regulations (DASR) requires individual DASR 145 Approved Maintenance Organisations (AMOs) to define their own line and base maintenance activities in their Maintenance Organisation Exposition (MOE).The scope of maintenance of aircraft and components activities should be in accordance with the Maintenance Organisation's policy and procedures defined in the MOE.

Acceptance of components

8.3.1.5 The AMO must ensure that components are accompanied by appropriate documentation attesting to the legitimacy of the component's maintenance or production history. This is underpinned by the regulatory requirement for the AMO to obtain a DASR Form 1 or equivalent documentation prior to fitment of such components. Where an unserviceable or unsalvageable component is the subject of an occurrence report, the DASR 145 organisation should quarantine the component until the investigation has determined that the component is not required to be retained for further examination Additional information can be found in Chapter 8.3.4 – Acceptance of Components.

Certification of maintenance

8.3.1.6 Maintenance carried out on an aircraft, its systems and its components must be certified at completion and prior to its return to service. The instrument used to achieve this outcome is the Certificate of Release to Service (CRS) that must be issued at the completion of maintenance and before the next flight. Additional guidance for Certification of maintenance can be found in Chapter 8.3.3 - Certification of maintenance.

8.3.2 Performance of Maintenance

Introduction

Superseded

8.3.2.1 This chapter provides additional guidance on the performance of maintenance including guidance on line and base maintenance, and specialist maintenance qualifications.

8.3.2.2 Not all maintenance personnel in a DASA 145 MO need to be authorised as certifying and/ or support staff. Acting as certifying or support staff is intrinsically a hands-off activity (in contrast to the performance of maintenance being physical hands-on aircraft maintenance). DASA 145 MO personnel perform maintenance under a Task Sign-Off (TSO) authorisation. On-aircraft TSO is overseen, managed and later certified (issue of CRS) by authorised certifying staff.

8.3.2.3 Except for a few speciality areas (e.g. composite repairs), DASA does not prescribe knowledge / experience standards for the performance of maintenance. On-aircraft TSO provides an attestation that the maintenance task has been carried out to the required standard.

8.3.2.4 A DASA 145 MO has flexibility to determine their own Qualification, Training and Experience (QTE) requirements when assessing and authorising personnel to perform the vast majority of maintenance (less some specialist qualifications where DASA will specify acceptable means of compliance). It is up to a DASA 145 MO to determine the scope that maintenance personnel can be authorised to perform, and may also mandate the level of supervision maintenance personnel require – noting supervision can be performed by authorised persons who are not necessarily certifying staff – see GM2 DASR 145.A.35(e). Maintenance personnel do not need to hold a MAML, of any category, to be authorised to perform maintenance.

8.3.2.5 DASA oversight of DASA 145 MOs, in the context of foreign trained maintenance personnel employed to perform maintenance, will focus on the procedure that identifies knowledge and experience requirements, to determine the authorised scope of maintenance and supervision required.

8.3.2.6 For information on maintenance service providers that are approved though other means (i.e. not DASR 145 approved), refer Chapter 6.5, Recognition of other Aviation Safety Authorities and Chapter 8.2, Continuing Airworthiness Management.

8.3.2.7 For information on the performance of maintenance relates to the certification of maintenance, see Chapter 8.3.3 – Certification of Maintenance.

Line and Base Maintenance

Background

8.3.2.8 The Defence Aviation Safety Regulations (DASR) requires individual DASR 145 Approved Maintenance Organisations (AMOs) to define their own line and base maintenance activities in their Maintenance Organisation Exposition (MOE). Feedback from the regulated community indicates that there is insufficient DASR guidance on what types of activities constitute line and base maintenance. This chapter describes types of maintenance activities constituting line and base maintenance and describes the intended outcomes in relation to line and base maintenance as interpreted by DASA.

8.3.2.9 The DASR Glossary of Terms describes line and base maintenance as:

1. **Line Maintenance:** Carried out before flight to ensure that the aircraft is fit for the intended flight.

2. **Base Maintenance:** Maintenance tasks falling outside the criteria for line Maintenance.

Superseded

8.3.2.10 A more detailed definition of aircraft line maintenance is provided in AMC 145.A.20, together with a list of activities which “may” be considered as line maintenance. The word “may” is used because it is not possible to establish a provision giving a strict demarcation between line and base maintenance, having general applicability to all cases.

8.3.2.11 To assist civil MOs, the European Aviation Safety Agency (EASA) has developed an EASA 145 User Guide chapter on ‘Privileges and limitations of line maintenance’. This guide provides detailed guidance on what constitutes line and base maintenance. This Annex is has been developed based on the EASA User Guide to provide an EASA aligned approach to guide DASR 145 MOs in defining line and base maintenance.

Organisation responsibilities

8.3.2.12 The maintenance organisation should ensure prior to any intended maintenance event that the activity can be carried out under its line maintenance scope of approval (refer to AMC 145.A.20) and does not fall under paragraph 14 ‘Examples of maintenance activities considered to be base maintenance’ of this Chapter.

8.3.2.13 This assessment may not need to take place each time, but be based on already established MOE procedures (i.e. the fact that a daily check is a line maintenance task is obvious and does not need to be assessed each time).

8.3.2.14 Even if this assessment confirms that the activity is line maintenance, the maintenance organisation should also verify if this activity requires other means than the ones already in use at a line maintenance location.

When to assess the maintenance activity

8.3.2.15 The maintenance organisation`s assessment to decide if any maintenance event falls within the definition of line or base maintenance, may be needed in two different situations:

1. for an initial/change of approval, when evaluating the scope of work the maintenance organisation is applying for (refer paragraph 11); or
2. for an already approved maintenance organisation, when evaluating if maintenance requested by the customer (e.g. a new Service Bulletin (SB), defect rectification or work package requested by the customer, etc.) falls within the approved line maintenance scope of work.

Assessment of the intended scope of work (initial/change of approval)

8.3.2.16 It is the responsibility of the maintenance organisation to demonstrate to DASA that the intended scope of work may be carried out in a line maintenance environment, under its line maintenance scope of approval. The main criterion for this assessment is to consider the level of maintenance to be carried out under the line maintenance scope of approval, where the following general criteria apply:

1. **Trouble shooting, Defect Rectification.** Those unscheduled tasks required for the daily operation of an Aircraft and not falling under ‘Examples of maintenance activities considered to be base maintenance’;
2. **Minor scheduled line maintenance.** Those scheduled tasks not exceeding the weekly check as specified in the Aircraft Maintenance Program (AMP);

Superseded

3. **Scheduled checks.** Those scheduled tasks which exceed the weekly check (or equivalent as determined by the Authority). In this case, the organisation needs to analyse each of the routine tasks intended to be included in the line maintenance scope of work and identify a clear limit. This assessment needs to be performed using the Type Certificate Holder (TCH) data such as the manufacturer's Maintenance Planning Document (MPD), and/or the operator's AMP. The outcome of this exercise is to identify the intended limitation of the line maintenance scope of approval, in terms of scheduled maintenance checks. In particular, the following is expected:

4. Depending on the AMP logic (i.e. MSG 2, MSG 3, etc) a clear limitation to the line maintenance scope of work may be normally expressed in one of the following ways:

   i. "up to and excluding X check" (i.e. X= R1, R2, etc) for a MPD, where letter checks are identified;

   ii. "up to and excluding "X FH / Y FC / Z calendar time", for a MPD, where progressive task intervals are defined in terms of FH/FC/calendar time (i.e. X=3000FH, Y=750 FC, Z=12 months, etc);

5. The identified limit, to be indicated in the MOE, should be such that all the related routine/scheduled tasks are excluding any of the tasks listed in 'Examples of maintenance activities considered to be base maintenance'

6. A "decision making process" (refer paragraph 12 for example) needs to be established in the MOE in order to assess

   i. (the need to access the hangar (even if the activity is permitted under a line maintenance scope of approval), considering in particular the type of aircraft, the maintenance event type/complexity, the environmental and weather conditions;

   ii. any work order / work package received from the customer operator to ensure it may be fully performed under a line maintenance scope of approval, taking into account additional works to the original work package that may be added, leading out to the line maintenance scope of work, such as:

   – addition of previously deferred maintenance tasks; or

   – defects raising from the routine tasks (these defects are not known in advance, however, the related risk in terms of number and level of defects needs to be taken into account and estimated in advance).

8.3.2.17 **Example of 'decision making process'.** A R1 maintenance check on the Boeing Business Jet (BBJ) aircraft type is normally considered "line maintenance" when the routine tasks are assessed as per the manufacturer MPD/operator AMP. Therefore a maintenance organisation may be approved to perform this check under a line maintenance scope of work. However, a work order to perform the "R1 check", where the customer operator would request the performance of works in addition to the "R1" routine tasks, such as the addition of Airworthiness Directives (ADs), SBs, deferred tasks, will need to be carefully assessed by the maintenance organisation with the use of the "decision making process".

8.3.2.18 This type of maintenance check may easily fall within the examples given in Paragraph 14 'Examples of maintenance activities considered to be base maintenance' having the result to be considered as base maintenance and being outside the maintenance organisation scope of work. In such a case, the outcome of the "decision making process", may be for example:

Superseded

1. The impossibility to accept such work order from the operating organisation, being outside the scope of work of the maintenance organisation; or

2. to agree with the operating organisation a revised work order, to remove the works which have been identified as base maintenance tasks (e.g. removal of a SB which was requiring extensive disassembly and modification of flight controls, etc.).

Examples of maintenance activities considered to be base maintenance

8.3.2.19 When any of the following tasks are required to be carried out (regardless if contained in a scheduled maintenance check or arising from a defect rectification/AOG situation), a base maintenance scope of approval is needed:

1. High number of different type of tasks to be carried out, even if taken singularly those tasks may still fall under the definition of line maintenance (i.e. a combination of routine task cards, non-routine task cards issued following defects discovered during the check, out of phase tasks, deferred items from previous maintenance, minor repairs, minor modifications, component replacement, etc). Such cases require base maintenance production planning support and/or a base maintenance release to service process (category C Certifying Staff supported by B1/B2 support staff) in order to ensure that all the maintenance ordered has been carried out before issuing the CRS;

2. Replacement of any major component where the related maintenance procedures address the need of a hangar environment requiring special ground support equipment and/or structured production planning and/or complex and lengthy maintenance, such as for example a full landing gear replacement, simultaneous replacement of two engines, etc;

3. Any scheduled maintenance task (i.e. routine task from the AMP) which requires extensive disassembly of the aircraft and/or extensive in depth inspection;

4. Major repairs and/or major modifications;

5. Trouble shooting and/or defect rectification requiring special ground support usually relevant to base maintenance (e.g. special equipment, structured production planning, complex and lengthy maintenance);

6. A scheduled maintenance event, which in the planning phase has been already identified as significant in terms of duration and/or man-hours (i.e. an aircraft down time above 72 hours or four shifts, whichever is less);

7. A work package requiring a complex team composition in terms of high number and categories (avionic, structure, cabin, NDT qualification and skills, etc) of staff involved per shift; or

8. The management of the event by B1 and B2 support staff and the release by a C certifying staff.

8.3.2.20 For AMOs that do not hold a base maintenance approval, the AMO remains responsible to ensure that even if each individual work order constitutes a line maintenance activity, a maintenance event cumulating several of these work orders remains within the AMO's line maintenance scope of approval.

Assessment of maintenance task by an already approved maintenance organisation

Superseded

8.3.2.21 For AMOs that do not hold a base maintenance approval, the AMO remains responsible to assess if any maintenance requested by the operating organisation falls within the approved line maintenance scope of work. This assessment is expected to be performed based on the "decision making process" described above.

Specialist Task Qualifications

8.3.2.22 **Introduction.** DASR 145.A.30(f) relates to MO personnel who carry out Non-Destructive Testing (NDT) and other specialised tasks such as composite repair and welding. Definitions pertaining to the scope of DASR 145.A.30(f) are as follows:

1. Particular non-destructive test means any one or more of the following; Penetrant Testing (PT), Magnetic Testing (MT), Eddy current Testing (ET), Ultrasonic Testing (UT), Radiographic Testing (RT), Thermographic Testing (TT) and Shearographic Testing (ST) methods (refer GM 21.A.30(f)). Boroscoping and other techniques such as manual tap testing are non-destructive inspections rather than non-destructive testing (refer AMC 145.A.30(f)).

2. For the purposes of DASR 145.A.30(f), DASA should be consulted to confirm the complexity and associated training requirements of composite repairs for each platform. The complexity and training requirements for non-specialised composite repairs should be detailed in the DASR 145 MOE.

8.3.2.23 DASR 145.A.30(f) requires that the MO must ensure that personnel who carry out NDT and other specialised tasks are appropriately qualified in accordance with recognised standards. The following paragraphs provide guidance on the standards recognised by DASA and other aspects of personnel training and certification.

8.3.2.24 It should be noted that the training standards required to perform specialist tasks might exceed the training standards to certify this maintenance. For example a licence persons with no structural repair exclusions could certify for a complex composite repair but may not be qualified to perform the maintenance. In this case the certifying staff may require separate specialist supervision in order to very the maintenance has been performed properly.

Qualification of Personnel for Non-Destructive Testing (NDT)

8.3.2.25 **Recognised NDT Qualification Standards.** DASA recognises the following standards for qualification of personnel who carry out and/or control NDT of aircraft structures and/or components (refer DASR 145.A.30(f)):

1. European Standard EN4179 - Qualification and Approval of Personnel for Non-destructive Testing is the primary NDT standard recognised by DASA

2. NAS410 – NAS Certification & Qualification of Non-Destructive Testing Personnel is also recognised by DASA.

8.3.2.26 NAS410 is the only NDT qualification standard DASA recognises as being equivalent to EN4179. Organisations that wish to use an alternative NDT personnel qualification system should apply to DASA with a proposed Alternate Means of Compliance (AltMoC). Note that Australian Standard AS3669 and ATA Spec 105 have been assessed as non-equivalent to EN4179 (refer GM 145.A.30(f)) and will not be approved as AltMoC by DASA.

8.3.2.27 **NDT Personnel Training and Certification.** The appointed NDT Responsible Level 3 (RL3) for each DASR 145 MO is responsible for establishing a training and certification system which

Superseded

supports awarding of task authorisations to NDT personnel working within the DASR 145 MO. This training and certification system should be established in line with EN4179. In cases where the minimum training and experience hour requirements stipulated in EN4179 Section 6 do not align with Defence's requirements, a competency based training program can instead be used, provided the course program is approved by DASA. Refer to GM 145.A.30(f).

8.3.2.28 For details of the approach to NDT training and certification implemented in support of ADF DASR 145 MOs, refer to Volume 3 Section 4.2.3.

8.3.2.29 **Appointment of NDT Responsible Level 3.** AMC 145.A.30 stipulates that the NDT RL3 for a DASR 145 organisation is a nominated management position, and is accepted by DASA through a DASR Form 4 application. Each DASR 145 organisation should only have one appointed NDT RL3. The DASR Form 4 requires applicants to submit details and supporting documentation of relevant qualifications and experience. Specific to NDT RL3 applications:

1. Applicants are requested to provide a copy of all personnel certification records that DASR 145 organisations are required to retain under EN4179 Para 8.2 to demonstrate they meet the EN4179 requirements to be certified as a Level 3.

2. If the applicant holds certifications in multiple methods, only evidence from one NDT method is required. The employer is to ensure that certification records for all other methods are retained, as required by EN4179 Para 8.2.

Note: that DASA may request evidence of ongoing EN4179 compliance for NDT RL3s in the course of oversight and enforcement activities.

8.3.2.30 DASA does not require the involvement of the Australian National Aerospace NDT Board (NANDTB) in the certification of Level 3 staff. DASA will not request or rely on NANDTB recognition when assessing NDT RL3 Form 4 applications.

8.3.2.31 For questions about NDT RL3 Form 4 application evidence please email: dasa.dca@defence.gov.au

8.3.2.32 Responsibility for appointment of NDT RL3 personnel is as follows:

1. ADF DASR 145 MOs: the Directorate of Aviation Engineering (DAVENG), as Defence's Structural Integrity Centre of Expertise[3], performs the Defence NDT RL3 function (refer to Section 4.2.3 for further details).

2. Non-ADF DASR 145 MOs (i.e. contractor organisations): are responsible for appointing their own NDT RL3 personnel.

8.3.2.33 Notwithstanding the fact that Level 3 personnel may be qualified via EN4179 to establish and authorise methods, techniques, etc., this does not permit such personnel to deviate from the methods and techniques published in the Instructions for Continuing Airworthiness (ICA)[4] unless the ICA expressly permits such deviations (refer AMC 145.A.30(f)). Although it is recommended that Level 3 personnel have a role in NDT ICA deviations or changes (refer DASP Manual Volume 3 Section 7.2.5), NDT ICA deviations or changes must be approved in accordance with DASR 21.

Qualification of Personnel for Composite Repairs

8.3.2.34 **Recognised composite repair qualification standards.** Some types of composite structure repair are considered a specialised task and therefore personnel conducting those types of composite repairs require appropriate qualification in accordance with an officially recognised standard. DASA

Superseded

recognises SAE AIR4938 - Composite and Bonded Structure Technician Specialist Training Document for qualification of personnel who carry out composite repairs (refer AMC1 145.A.30(f)).

8.3.2.35 SAE AIR4938 Revision C includes requirements for both initial training and on-going certification. Superseded revisions of SAE AIR4938 do not include the requirements for ongoing certification, and also omit the training curriculum for bolted composite repairs. Superseded revisions of SAE AIR4938 should not be used without approval from DASA.

8.3.2.36 Organisations that seek to use an alternative to SAE AIR4938 for the qualification of composite repair personnel to conduct specialised composite repairs should apply to DASA with a proposed AltMoC. Organisations should note MEA405 is considered an introductory composites course only. DASA does not recognise MEA405 Cert IV AME Structures as a suitable equivalent to SAE AIR4938 for the conduct of specialised complex composite repairs. The complexity of composite repairs, and associated training requirements will vary for each platform. When suitable controls can be identified to ensure ongoing airworthiness a lower standard than SAE AIR4938 may be recognised as suitable for specific circumstances. Such controls could include:

1. type of structure being repaired
2. type or complexity of composite repair being conducted
3. specific nature of training undertaken
4. experience of personnel
5. supervision requirements
6. OEM or aircraft type specific training

8.3.2.37 Applications to DASA to officially recognise alternate qualification standards should demonstrate that the alternate standard:

1. provides an equivalent level of training to SAE AIR 4938; or
2. is suitable in the context of the specific MO and the scope of the maintenance activities to be performed. In such cases, the application should clearly state the scope of the activities being performed, how the training is suitable for that scope, and the means by which the scope is to be controlled.

8.3.2.38 **Composite repair Personnel Training.** Prior to authorising staff to perform composite repairs, the DASR 145 MO should ensure the staff are trained and qualified in accordance with appropriate standards, SAE AIR49385 or approved AltMOC, for specialised composite repairs. Composite repair training and certification procedures for specialised and non-specialised composite repairs should be specified in the MOE.

8.3.2.39 DASR 145 MOs can utilise any training course that demonstrates compliance to the standard. Note that DASA-DAVENG, as Defence's Structural Integrity Centre of Expertise, conducts the certification (initial and re-certification) for all ADF DASR 145 MO staff who perform composite repairs (refer to DASP Manual Volume 3 Section 4.2.3 for further details).

8.3.2.40 DASR 145 MOs are responsible for establishing training and authorisation systems to ensure that personnel who conduct composite repairs are appropriately qualified. Further guidance for ADF and non-ADF DASR 145 MOs is as follows:

Superseded

1. ADF DASR 145 MOs: The MO should verify that technicians hold a valid PMKeyS proficiency (refer DASP Manual Volume 3 Section 4.2.3) for composite repair prior to authorising them to conduct composite repairs within an ADF DASR 145 MO. MO authorisations should only remain valid for the validity period of the applicable PMKeyS proficiency.

2. Non-ADF DASR 145 MOs: The MO should document their certification/re-certification process in their MOE. The standard does not impose specific requirements on who can conduct certification.

Qualification of Personnel for Aircraft Welding

8.3.2.41 The following paragraphs are applicable to DASR 145 MOs that perform aircraft welding repairs.

8.3.2.42 Welding is used in the repair of critical and non-critical airframe and engine components within Defence. As a specialist task, personnel conducting welding operations must be appropriately qualified in accordance with officially recognised standards.

8.3.2.43 CASA Civil Aviation Advisory Publication (CAAP) 33-1 (1) Aircraft manual welding: Approvals and qualifications provides information on how to apply for the initial issue or renewal of an aircraft welding authority under Civil Aviation Regulations. DASA has determined that a CASA welding authority, granted in accordance with CAAP 33-1 (1), is an appropriate qualification for Defence purposes.

8.3.2.44 **DASR Requirement.** DASR 145 MO that perform aircraft welding repairs must comply with DASR 145.A.30(f), which requires "Personnel who carry out any other specialised task shall be appropriately qualified in accordance with officially recognised Standards."

8.3.2.45 **Acceptable Means of Compliance.** DASA considers a CASA welding authority, granted in accordance with CAAP 33-1 (1), is an appropriate qualification in accordance with DASR 145.A.30(f).

8.3.2.46 Organisations choosing to utilise welders qualified in accordance with CAAP 33-1 (1) must:

1. Ensure technicians hold a valid Civil Aviation Safety Authority (CASA) issued aircraft welding authority prior to task authorisation.

2. Ensure technicians are only authorised to carry out those types of welding processes that are specified in the welding authority document.

3. Ensure MO authorisations only remain valid for the validity period of the CASA-issued welding authority (i.e. renewal is required every 2 years IAW CAAP 33-1 (1)).

Aircraft Welding Questions and Answers

8.3.2.47 **Q:** What does a DASR 145 MO need so that it can use welders with a CASA welding authority?

8.3.2.48 **A:** The DASR 145 is required to:

1. Identify the scope of welding repairs that it requires (that is included in its overall maintenance scope).

2. Update the DASR 145 MO Orders, Instructions and Publications (i.e. MOE and any other associated documentation), to show compliance to DASR 145.A.30(f) and

Superseded

implement the required management framework. The aircraft welding repair training and qualification requirements should be specified in the MOE.

3. Authorise technicians who have obtained CASA welding authority

4. Ensure that authorised staff maintain their competency and CASA welding authority currency.

8.3.2.49 **Q:** How does a person achieve CASA welding authority?

8.3.2.50 **A:** CAAP 33-1 (1) details the framework that CASA applies to provide a welding authority, which is granted to applicants that have:

1. Successfully completed a relevant Australian Quality Training Framework recognised course; and

2. Passed the welding testing set out in the CASA Welding Syllabus.

8.3.2.51 Additional training may be required dependent on the specific work scope required by the DASR 145 MO. CASA will confirm any specific training requirements during the application for the welding authority.

8.3.2.52 DASR 145 MOs are responsible for organising CAAP 33-1(1) compliant renewal assessments for their personnel when required. There are a number of commercial organisations who employ CASA-authorised aircraft welding assessors (queries should be addressed to Contact us | Civil Aviation Safety Authority

8.3.2.53 CASA charge a fee to apply for the initial issue and for renewal of a welding authority. Applicants will also require a CASA Aviation Reference Number (ARN) prior to applying for a welding authority.

8.3.2.54 **Q:** Do welders require renewal of their CASA welding authority?

8.3.2.55 **A:** Yes. CAAP 33-1(1) requires a two yearly renewal in order to remain current. DASR 145.A.30(f) requirement that "Personnel who carry out any other specialised task shall be appropriately qualified in accordance with officially recognised Standards" requires a current CASA authorisation.

8.3.2.56 **Q.** Who covers the cost of gaining a CASA welding authority and renewal?

8.3.2.57 **A:** For:

1. Defence Maintenance Organisations, initial authority for ASTTECHs is covered within the Welder Aircraft Course at RAAFSTT, all subsequent renewal costs are to be supported though unit, or parent command funding.

2. Contractor Maintenance Organisations, refer to arrangements detailed in your contract.

8.3.2.58 **Q:** Can a non-welder supervise the conduct of a renewal welding assessment?

8.3.2.59 **A:** No. CASA requires that a CASA-authorised assessor supervise the conduct of welding examinations, and DASA has adopted this position.

8.3.2.60 **Q:** Can an organisation authorise welders with a different qualifications (in lieu a CASA welding authority)?

Superseded

8.3.2.61 **A:** Yes. DASR 145 MOs who wish to use an alternative qualification to that stipulated in AMC1 145.A.30(f) should seek approval from DASA (as AltMoC).

8.3.2.62 For further information refer to the following:

1. For issues relating to the use of CASA welding authority within the DASR context please contact the DASA Desk Officer assigned to your organisation or email dasa.dca@defence.gov.au.

2. For queries related to gaining and maintaining CASA welding authority and the application of CAAP 33-1 (1), refer Contact us | Civil Aviation Safety Authority

8.3.3 Certification of Maintenance

Introduction

8.3.3.1 This chapter provides guidance in relation to the Certificate of Release to Service (CRS) process for aircraft maintenance. The document aims to consolidate the applicable requirements from different sections of the DASR and describes the intended outcomes in relation to Sign-off & subsequent CRS at the completion of maintenance.

Background

8.3.3.2 Maintenance carried out on an aircraft, its systems and its components must be certified at completion and prior to its return to service. The instrument used to achieve this outcome is the CRS which must be issued before flight at the completion of maintenance. The CRS should contain as a minimum (AMC 145.A.50(b)):

1. Basic details of the maintenance that was carried out;

2. Date such maintenance was completed;

3. Identity of the organisation and person issuing the CRS; and

4. Limitations to airworthiness or operations, if there are any.

8.3.3.3 The requirements for CRS reside across multiple regulation subsections (DASR M and DASR 145) that collaboratively inform the regulated community of DASA's requirement. This chapter summarises the applicable requirements for CRS to assist the community in meeting the DASR.

Certification of Maintenance Responsibilities

Continuing Airworthiness Management Organisation responsibilities

8.3.3.4 CAMO responsibilities are described in detail within DASR M and include:

1. the CAMO is responsible for all activities aimed to determine the airworthiness status of the aircraft and to appropriately plan and coordinate maintenance.

2. ensuring that all maintenance requirements (Airworthiness Directives (AD), Aircraft Maintenance Program (AMP) requirements, defect rectification, etc...) are complied with and released by a DASR 145 Maintenance Organisation (DASR 145 MO) (or equivalent (M.A 708(b)).

Superseded

3. the CAMO is responsible for planning and ordering all required maintenance and for ensuring that all ordered maintenance conducted by the DASR 145 MO or equivalent is complete and has a CRS. The CAME must explain how this is achieved.

DASR 145 Maintenance Organisation responsibilities

8.3.3.5 The DASR 145 MO (or equivalent) responsibilities are described in detail in DASR 145 and include:

1. the development of 'certification of maintenance' procedures that ensures all maintenance actions have been properly coordinated and the CRS is issued within a reasonable timeframe after the actual performance of the tasks;
2. issuing a CRS following maintenance; and
3. the CRS issued has to be recorded in the Continuing Airworthiness (CA) record system. This information shall be available to the aircraft captain (refer to DASR M.A.306 and AMC DASR M.A.306(a), who is ultimately responsible for accepting the aircraft before a flight takes place.

DASR 145 maintenance personnel responsibilities

8.3.3.6 The completion of maintenance requires two actions. They are:

1. a 'sign-off'; and
2. a CRS.

8.3.3.7 These two actions may be performed by a singular person or group of people dependent upon maintenance complexity, qualifications and authorisations.

Maintenance Authorisation

8.3.3.8 A person can only be authorised when they have met all the organisation's applicable qualification requirements, and only for the scope of work applicable to that qualification detailed in the DASR 145 Maintenance Organisation Exposition (MOE). A person can carry out maintenance and sign-off tasks that they have performed for a particular maintenance activity, and also be a support or certifying staff for another. As an example, a person may be authorised to sign-off on an aircraft type, and certifying and/or support staff on a different aircraft type.

8.3.3.9 DASR 145.A.35 (i) requires the maintenance organisation to nominate an individual[6] responsible on behalf of the maintenance organisation for issuing certification authorisations to certifying staff.

Sign-off Authorisation.

8.3.3.10 This is exercised by a competent (IAW AMC1 145.A.30(e)) and appropriately authorised person, that the maintenance has been completed to the standard required in accordance maintenance data specified in DASR 145.A.45.

8.3.3.11 AMC 145.A.65(b)(3)3 states that, in order to prevent omissions, every task or group of tasks should be signed-off by authorised personnel after its completion. It also states that a sign-off relates to one step in the maintenance process and is different from a 'release to service' (CRS). Importantly,

Superseded

a sign-off is a statement by the competent person performing or supervising the work, that the task or group of tasks has been correctly performed.

8.3.3.12 Furthermore, this AMC states that work by 'unauthorised personnel' (temporary staff, trainee/apprentice) must be witnessed by the authorised person before they sign-off. This means the authorised person signing off the task is responsible for the task.

8.3.3.13 IAW AMC1 145.A.30(e) personnel performing the sign-off, "shall be able to carry out tasks to any standard specified in the maintenance data, and will notify supervisors of mistakes requiring rectification to re-establish required maintenance standards".

8.3.3.14 Nevertheless, holding a sign off authorisation doesn't mean that the authorised person can sign off all tasks. It means that they can sign off tasks within the scope of their authorisation, depending on the qualifications, training and experience held, and in accordance with a procedure described in the MOE. Sign-off authorisation does not need to be restricted to singular tasks where the technician is required to/has demonstrated a degree of competence for that task. In contrast, the technician shall demonstrate competence in performing or supervising work applicable to their training and qualifications.

8.3.3.15 Further details related to task completion and sign-off can be found in Chapter 8.3.2 – Performance of Maintenance.

Certificate of Release to Service

8.3.3.16 In executing the obligations of DASR 145.A.50(a) the organisation must have procedures in place that ensure:

1. the individual issuing the CRS is appropriately authorised to do so;
2. the individual issuing the CRS has ensured the maintenance has been carried out correctly using appropriate procedures IAW DASR 145.A.45(b); and
3. as a result of the maintenance conducted there are no defects which are known to 'endanger flight safety'.

8.3.3.17 A CRS is an attestation made by Certifying Staff by way of a certification signature after the completion of maintenance within their authorisation scope. The certification signature creates a 'certificate' and thus accountability, signifying that the maintenance or group of maintenance activities can be released to service. In Line maintenance the holder of a category A, B1 or B2 MAML may issue a CRS within the scope of their MAML and authorisation. In Base Maintenance the holder of a category C MAML is required to issue the CRS after the completion maintenance within the scope of their MAML and authorisation. Issue of a CRS in Component Maintenance can be done by appropriately authorised certifying staff, in this instance the individual does not need to hold a MAML.

8.3.3.18 There are two elements that need to be fulfilled by the authorised Certifying Staff before the issuance of a CRS is possible:

1. **Ensure.** Verify through oversight and management to ensure that the maintenance has been properly carried out; and
2. **Assessment.** Ensuring that no non-compliances which are known to exist that could 'endanger flight safety'

Superseded

How do Certifying Staff "ensure that the maintenance ordered/tasked has been properly carried out"?

8.3.3.19 *Verification through the supervision of the maintenance task.* Certifying Staff ensure that maintenance has been properly carried out by ensuring maintenance has been conducted in accordance with procedures detailed in the MOE and through the correct use of maintenance data as specified in DASR 145.A.45.

8.3.3.20 This statement does not necessarily mean that authorised Certifying Staff have to personally perform or supervise[7] the whole process of every task, rather it is expected that Certifying Staff will (non-exhaustive list):

1. make sure that personnel assigned to perform the maintenance are authorised to sign-off the work for the appropriate scope of their authorisation;
2. coordinate the different tasks associated with the maintenance being performed; and
3. be available to support personnel in case of any mistakes or unexpected difficulties.

8.3.3.21 Authorised Certifying Staff are responsible to determine the amount of involvement they require in order to be satisfied that the maintenance can be issued a CRS. Subsequently, the DASR 145 MO cannot limit Certifying Staff in terms of what level of supervision they put in place for the maintenance task. The DASR 145 MO may however set a minimum requirement.

How do Certifying Staff, "make an assessment that there are no non-compliances which are known to endanger flight safety"?

8.3.3.22 This is achieved by a cognitive process that assesses whether an endangerment to flight safety exists as defined within AMC1 DASR 145.A.50(a) against the physical outcomes of maintenance ordered by the CAMO. It does not require the DASR 145 MO to find or become responsible for hidden defects which are not expected to be discovered during the ordered maintenance. Defect assessments, including those endangering flight safety, must be clearly identified in the CA records system along with any corresponding limitations (if any) for further CAMO consideration.

Considerations for when the aircraft is left in a non-airworthy condition

8.3.3.23 In circumstances where after performing the maintenance ordered by the CAMO, the aircraft is left in a non-airworthy configuration, a CRS can still be issued for the maintenance that has been completed. The CRS can be issued as long as the incomplete maintenance or known defects are properly identified in the CA records system and communicated to the CAMO. For example, where the DASR 145 MO removes an engine for preservation (without installing a new one), or where the organisation performs an NDT inspection and identifies a crack outside limits.

8.3.3.24 The circumstances mentioned above (including defects affecting flight safety discovered during maintenance), can be properly addressed by using the provisions contained in DASR 145.A.50(c) and (e).

8.3.3.25 It is important to appreciate that a CRS does not mean that the aircraft is airworthy and ready for flight. A CRS is issued by the DASA 145 MO for the maintenance performed; the CAMO is accountable for ensuring that all CA requirements are met for the aircraft to undertake its assigned mission before releasing to the Operator.

When is a CRS issued?

Superseded

8.3.3.26 IAW DASR 145.A.50(b) “A certificate of release to service shall be issued before flight at the completion of any maintenance”. Subsequently, “any maintenance” can be interpreted in multiple ways, such as:

1. any maintenance task.
2. any combination of maintenance tasks.
3. any maintenance event.

8.3.3.27 Utilising the flexibility afforded by the “any maintenance” interpretation an organisation may choose one or more of the following systems of release to service:

1. Several CRS are issued, each one of them covering a different single maintenance task.
2. Several CRS are issued, each one of them covering a different group of maintenance tasks.
3. A single CRS is issued covering all the maintenance included in a maintenance event.

8.3.3.28 The organisation must ensure that the CRS issued to the CAMO clearly identifies what maintenance is complete. If there is any incomplete maintenance, the CRS must clearly identify it in the CA records system and the corresponding limitations (if any). In each of the above cases, it is important to note that there is no change in the accountabilities of the individual authorised Certifying Staff in signing the CRS.

Who can issue a CRS in Line Maintenance?

8.3.3.29 Only appropriately authorised category A, B1 and/or B2 MAML holders can issue a CRS in Line Maintenance. The scope and responsibility of each license category is provided below.

Limited Certification Authorisation

8.3.3.30 By way of exception to paragraph 8.3.3.29, and in accordance with 145.A.30(j) 4, in unforeseen cases where the aircraft is grounded or operating away from a Main Operating Base, and where no appropriate certifying staff are available, the maintenance organisation may issue a limited certification authorisation to the aircraft commander on the basis of the flight crew licence subject to being satisfied the aircraft commander can accomplish the specified task to the required standard. These provisions shall be detailed in a MOE procedure.

One off Certification Authorisation

8.3.3.31 In unforeseen cases, where an aircraft is grounded at a location other than the main base where no appropriate certifying staff are available, the maintenance organisation may issue a one-off certification authorisation in accordance with 145.A.30(j)5.

Category A licence

8.3.3.32 The category A licence permits the authorised MAML holder, in a Line Maintenance environment only, to issue CRS for work that the licence holder has personally performed (‘sign off’) and within the scope of their certification authorisation.

8.3.3.33 A category A licence does not permit the authorised MAML holder to issue a CRS for the work of others, only for their own maintenance. While other personnel may be present and directed

Superseded

by the authorised A MAML holder in providing assistance during the performance of the maintenance task, the category A MAML holder may not undertake a supervisory role.

Category B licence

8.3.3.34 The category B1/B2 licence permits the authorised MAML holder to issue CRS, within the scope of their license and certification authorisation on maintenance that has been 'signed off' by themselves or other authorised personnel, within the scope of their license and certification authorisation.

Category C licence

8.3.3.35 The category C licence permits the authorised MAML holder to issue a CRS following Base Maintenance on aircraft carried out by a DASR 145 AMO. By definition, the DASR permits an authorised category C MAML holder to issue a single CRS for all maintenance activities pertaining to the aircraft during a single Base Maintenance visit.

8.3.3.36 Noting the complexity and the volume of the maintenance being carried out during a Base Maintenance activity, it is difficult for the authorised category C MAML holder to be across all tasks, to the extent required, to issue a CRS. For this reason, the authorised category C MAML holder may use Support Staff to enable the CRS to be issued.

8.3.3.37 The authorised category C MAML holder is accountable to ensure that all required maintenance that has been ordered, has been carried out properly, that there are no non-compliances which are known to endanger flight safety and any outstanding or incomplete maintenance has been identified and the CAMO notified before issuance of the CRS.

Support Staff

8.3.3.38 Support Staff are authorised B1 and B2 MAML holders. The role of Support Staff during Base Maintenance is to conduct, within the scope of their MAML and authorisation, activities such that it can be communicated to the authorised category C MAML holder that:

1. the maintenance has been performed properly;
2. that any defects found during the course of maintenance are recorded in the CA records; and
3. that any outstanding or incomplete maintenance is identified and recorded in the CA records.

8.3.3.39 In essence, Support Staff are oversighting and managing allocated maintenance tasks within Base Maintenance in support of the authorised category C MAML holder. Subsequently, the DASR 145 MO must have a mechanism in place and articulated in the MOE WRT how Support Staff communicate to the category C MAML holder when the CRS can be issued.

8.3.3.40 An authorised category C MAML holder may not require Support Staff if they also hold the required B1/B2 license scope and subsequent authorisation with regard to the Base Maintenance being performed. The authorised category C MAML holder in this instance can issue the CRS without the use of additional Support Staff. The procedures with respect to an authorised category C MAML holder acting as their own support staff must be articulated in the MOE.

Summary of Maintenance Authorisations

Superseded

8.3.3.41 The following figure summarises the different types of authorisations an organisation will require and the scope of work against which they may authorise their staff. It is the DASR 145 that performs and certifies maintenance requested by the DASR M.

Type of Authorisation	Line Maintenance		Base Maintenance		Component Maintenance	
	Sign Off*	CRS	Sign Off*	CRS	Sign Off*	CRS* See note 1
Technician (non MAML holder)	✓		✓		✓	✓
Non Type Rated B1/B2 MAML Holder	✓		✓		✓	✓
Type Rated B1/B2 MAML Holder	✓	✓	✓	Support Staff Does not issue CRS **See note 2**	✓	✓
A MAML Holder	✓	✓ Task Authorised **See note 3**	✓		✓	✓
C MAML Holder	✓	When Exercising B MAML	✓	✓	✓	✓
Foreign Trained Technician	✓		✓		✓	✓

* Denotes No MAML Required therefore all trained technicians may be authorised to perform maintenance and Sign Off. Authorisation QT&E requirements to issue a CRS in Component Maintenance is determined by the AMO
Note 1: Component CRS may be issued through ARC (Form 1) or via process detailed in the MOE
Note 2: This is not a certification activity. Type Rated B1/B2 Technician may be authorised to confirm tasks carried out to the required standard (i.e.: attest) for maintenance personally conducted or conducted by other technicians, to the scope of their B MAML
Note 3: May be Task Authorised to the scope of the A MAML for maintenance personally conducted

Figure 1 Summary of Maintenance Authorisations

8.3.4 Acceptance of Aircraft Components

Introduction

8.3.4.1 This chapter provides additional guidance on what constitutes a DASR Form 1 or recognised equivalent and outlines how DASR 145 Approved Maintenance Organisations (AMOs) should assess the suitability of component documentation to ensure such components are eligible to be fitted to Defence registered, type-certified products.

8.3.4.2 The Defence Aviation Safety Regulations (DASR) require Approved Maintenance Organisations (AMOs) to ensure the airworthiness[8] of components and materials prior to fitment to Defence registered, type-certified products. To fulfil this requirement, the AMO must ensure that components are accompanied by appropriate documentation attesting to the legitimacy of the component's maintenance or production history. This is underpinned by the regulatory requirement for the AMO to obtain a DASR Form 1 or equivalent documentation prior to fitment of such components.

8.3.4.3 This chapter relates to the acceptance of new and used aircraft components, which are listed by the appropriate design organisation as eligible for installation in/on a product and included in the design data approved by the Authority[9]. The term components broadly covers any product (other than complete aircraft), part or appliance that is, or is intended by its manufacturer to be, a part of or used in operating an aircraft in flight, or is installed in or attached to a product. This may include any self-contained part, combination of parts, assembly, subassemblies or units, which perform a distinctive function necessary to the operation of the airframe, engine, or propeller, or may include any other instrument, mechanism, equipment, apparatus, software or accessory, including communications equipment.

Superseded

8.3.4.4 Although alternate artefacts can be consumed by a DASR 145 Approved Maintenance Organisation (AMO), DASA requires the relevant CAMO to seek approval for, and manage, the ongoing validity of alternate artefacts for their respective platforms. Further detail on alternate artefacts can be found in Chapter 8.2.3 – Alternate Artefacts.

Products, parts and appliances

8.3.4.5 To align with the European Military Airworthiness Requirements (EMAR), the DASR has replaced the term Aeronautical Product with separate definitions for products, parts and appliances. The term 'components' in this document will be used interchangeably with products (other than complete aircraft), parts and appliances for simplicity.

Acceptance of components

8.3.4.5 The AMO is responsible for ensuring the 'eligibility for fitment' of components to type-certified products prior to installation[10].

Eligibility for fitment

8.3.4.6 A component is eligible to be fitted to a type-certified product, or another part or appliance if:

1. the fitting of the component is permitted by the approved design[11] for the product, part or appliance of the higher assembly;
2. the component is in a serviceable condition for safe operation; and
3. the component has been appropriately released or returned to service[12].

8.3.4.7 The AMO should have procedures for the acceptance of components and material, to ensure that the supplied components and material are in satisfactory condition and eligible for fitment. Furthermore, the AMO is responsible for ascertaining the traceability of components and material to their original or authorised source, including the maintenance or production and supplier source, where applicable. Therefore, it is the responsibility of the installer to request the appropriate documentation which establishes the airworthiness status and traceability of components and materials.

8.3.4.8 In determining whether a component is eligible for fitment, the AMO should conduct the following:

1. a physical inspection of components and/or material (including a check for any obvious physical damage and verification that part numbers, serial numbers, lot and/or batch numbers, etc. match the accompanying documentation; and
2. a review of accompanying documentation and data, which should be acceptable IAW DASR 145.A.42.

8.3.4.9 Particular caution should be exercised when the origin of components and materials cannot be established or when the origin is in doubt.

8.3.4.10 The flowcharts provided at Appendix 1 and Appendix 2 illustrate the process for determining the eligibility for fitment of new and used aircraft components, respectively, to type-certified products, or other parts and appliances.

Superseded

Acceptance of Aircraft Components

What is an Authorised Release Certificate?

8.3.4.11 An Authorised Release Certificate (ARC) is a document issued by an entity that has the applicable privilege and attests that a new or used component has been produced or maintained IAW the approved design data/standard, modification standard or applicable maintenance data[13].

8.3.4.12 An acceptable ARC is either:

1. DASR Form 1, or equivalent (refer DASA recognition website); or
2. an 'alternate artefact' accepted by DASA.

8.3.4.13 An acceptable ARC must show traceability back to a recognised CAA/MAA. In general, an Authorised Release Certificate must provide evidence of (where applicable):

1. the name and address of the issuing organisation;
2. the name of the recognised CAA/MAA;
3. evidence that the issuing organisation is working within the recognised authority's system (e.g. organisation approval reference);
4. details of the component(s): description, part number, serial number(s) and/or batch number, as applicable;
5. for used service-life-limited components, complete traceability to the component's service history;
6. a clear indication of the current airworthiness status (serviceability) of the component at the date of issue;
7. a release statement made by a suitably authorised person within the production or maintenance organisation;
8. the name, signature (or electronic equivalent) and approval number (where applicable) of the person making the release statement;
9. for components released from maintenance, a statement that the maintenance was carried out in accordance with the recognised authority's regulation/policy; and
10. for components released from production, a statement that the component(s) was manufactured in conformity with approved data.

8.3.4.14 The ARC does not constitute authority to install the item on a particular product or component, but provides evidence that assists the AMO in determining the item's eligibility for fitment. Furthermore, an ARC cannot be used for the release of complete aircraft.

8.3.4.15 The ARC serves as the official certificate for components from the manufacturer/AMO to users. It should therefore be used for the transfer of components between different airworthiness systems or AMOs. A delivery or shipping note does not constitute an ARC.

8.3.4.16 It should also be noted that a mixture of new and used items is not permitted on the same ARC. Likewise, a mixture of items certified in conformity with 'approved data' and to 'non-approved data' is not permitted on the same certificate.

Superseded

When is an Authorised Release Certificate required?

8.3.4.17 An ARC is necessary for the release to service of either new or used components. The certification of new components is performed IAW DASR 21.A.307, whereas the certification of maintenance on used components is performed IAW DASR 145.A.50.

8.3.4.18 A component is eligible for fitment to a type-certified product when the component is in a condition for safe operation (i.e. serviceable) and accompanied by an ARC. An ARC helps the AMO to determine the airworthiness approval status for components and therefore eligibility for fitment.

8.3.4.19 **Release of new components following production**[14]**.** The component manufacturer is responsible for producing the ARC following the production of a new component. The purpose of the Authorised Released Certificate for new components is to certify that the item has been manufactured in conformity to approved design data and marked in accordance with DASR 21, Subpart Q. An ARC is required for components produced under:

1. type-certificate or supplemental type-certificate and changes thereof;
2. Production Organisational Approval;
3. Parts Manufacturing Approval (PMA) / European Part Approval (EPA)[15]; or
4. AUSMTSO authorisation.

8.3.4.20 Such components will normally be listed within the OEM furnished Illustrated Parts Catalogue (IPC) or Illustrated Parts Breakdown (IPB).

8.3.4.21 **Release of used components following maintenance**[16]**.** The purpose of the ARC for used components is to release components to service after off-aircraft maintenance. The ARC is issued by the AMO and must be within their scope of approval

8.3.4.22 Issuing an ARC following maintenance is an attestation that all maintenance is complete (except for deferred defects agreed to by the CAMO), and there are no non-compliances which are known to endanger flight safety. Any incomplete maintenance ordered/tasked should be clearly stated in the ARC when such non-compliances (i.e. deferred maintenance) are within the approved aircraft limitations.

8.3.4.23 Only personnel authorised by the DASR 145 may issue a DASR Form 1 Authorised Release Certificate following off-aircraft maintenance. Where component maintenance is subcontracted to another maintenance organisation[17], the ARC may be issued either at the:

1. non-DASR 145 contractor/tasked maintenance organisation[18]; or
2. AMO facility by staff holding a certification authorisation, as appropriate[19] .

8.3.4.24 Further, for used components that are service life-limited the ARC shall contain, or be accompanied by, an updated maintenance status with reference to this status in Block 12 of the certificate. In addition to configuration data (modifications, repairs, ADs and SBs), the status should contain information on the utilisation, particularly accumulated service life in relation to component life-limits.

When is an Authorised Release Certificate not required?

Superseded

8.3.4.25 An ARC is not always required after component production or maintenance. However, documented evidence of conformity to approved design or certified material specification must be obtained prior to fitment to a type-certified product. Such evidence must be traceable back to the organisation that manufactured or maintained the component.

New Components.

8.3.4.26 **Specific equipment.** Components which have been incorporated into the type design as specific equipment[20] and therefore have been shown not to adversely affect the airworthiness of the aircraft and not subject to recognised airworthiness standards[21] do not require an ARC. The CAMO should provide installation instructions that authorise the component's return to service requirements. Examples of specific equipment may include commercial-off-the-shelf (COTS) 'industry supply' equipment. This may include Commercial Parts such as cabin reading light bulbs, curtain rings, sink valves, etc.

8.3.4.27 **Standard Parts.** Standard Parts must be supplied with a CoC referring to the specified standard, the manufacturer and supplier source, the batch/lot number and, if applicable, the shelf life (including expiration date) and storage conditions. Standard Parts are specified within the manufacturer's IPC/IPB or maintenance data. Examples of Standard Parts include, but are not limited to, those conforming to National Aerospace Standard (NAS), Air Force/Navy (AN) Aeronautical Standard, Society of Automotive Engineers (SAE), Aerospace Standard (AS), Military Standard (MS), etc.

8.3.4.28 A part is no longer considered a Standard Part if it is used in a critical application that imposes qualification or quality control requirements beyond the published standard specification. In such a case, the OEM should allocate its own part number reference, and these parts would require an ARC.

8.3.4.29 **Materials.** Both raw and consumable materials, used in the fabrication, maintenance, servicing or operation of an aircraft or component, may be accepted without an ARC[22]. Such materials are required to meet the specification detailed in the approved design, and have appropriate traceability.

Used Components.

8.3.4.30 **Restricted Parts manufactured by the AMO.** Where a maintenance organisation has been granted approval by the Authority to fabricate a restricted range of parts to be used by that maintenance organisation in the course of overhaul, maintenance, modifications or repair within its own facility, such parts do not qualify for certification via an ARC[23].

8.3.4.31 **Unserviceable Parts.** An ARC should not be issued for any unserviceable components, except where such items are undergoing a series of maintenance processes at multiple AMOs. In this case, the receiving AMO requires an ARC to accept the component prior to subsequent maintenance.

8.3.4.32 **In-house release.** An ARC may not be required in the case where an AMO maintains a component for its own use and there is an approved alternative in-house release document as described in the AMO's MOE.

8.3.4.33 **Aircraft on Ground – other than at Main Operating Base (MOB).** When an aircraft is grounded at a location other than the MOB due to the non-availability of a component with an appropriate release certificate, it is permissible to temporarily fit a component with an alternative release certificate, subject to CAMO approval. The component must be removed at a time specified

Superseded

by the CAMO, unless the appropriate release certificate has been subsequently obtained, prior to removal of the component.

What do I do with a completed Authorised Release Certificate?

8.3.4.34 The completed ARC becomes part of the technical record for the component to which it relates, and eventually will become part of the technical record of the higher assembly or product on which that component is installed. The certificate is therefore subject to all applicable regulatory requirements related to maintenance and technical records .

When are components not eligible for fitment?

8.3.4.35 A component is not eligible for fitment on a type-certified product where it is known or suspected to have any of the following:

1. Discrepancy between the component's identifying markings (as required by DASR 21 subpart Q) and its accompanying documentation;
2. Non-conformances between the component's physical characteristics and its approved design data/specification or applicable maintenance data (i.e. unacceptable or questionable quality);
3. Damage (due to packaging, etc.) or unserviceability;
4. Absence of or incomplete or inappropriate release documentation to determine the airworthiness status or eligibility for fitment; or
5. Unknown, suspect or unverified origin of the component (i.e. has not or may not have been manufactured or maintained by an approved source).

8.3.5 – Flexibility Provisions for Maintenance Organisations

Introduction

8.3.5.1 This chapter provides guidance on the application of DASR GR.80 Flexibility provisions within the specific context of maintenance organisations. To meet an operational need, there may be circumstances where the authorisation of non-MAML staff in certifying or support staff roles is necessary. These circumstances also extend to where it is not practical for foreign-trained personnel to obtain a MAML in the time available (e.g. short-term secondment).

8.3.5.2 Currently, the scope of guidance provided is related to the authorisation of non-MAML staff as certifying and support staff for on-aircraft maintenance.

DASR GR.80 Flexibility provisions

8.3.5.3 **Provisions.** DASR GR.80 *Flexibility provisions* includes two different avenues to enable regulated entities to deviate from the requirements of applicable DASR. These provisions are available subject to an operational need, where compliance with applicable DASR would impact the ability to meet operational objectives. The two avenues are:

1. **Achieve an equivalent level of protection under GR.80(b).** DASA may approve the deviation using the applicable DASR as the safety standard against which the deviation is assessed and approved.

Superseded

2. **Equivalent level of protection not demonstrated, but supported by the application of sound risk management, under GR.80(c).** DASA may *allow* the deviation but cannot approve it due to the absence of any established safety standard against which to approve.

8.3.5.4 **Second-order effects.** The use of DASR GR.80 provisions, including GR.80(b) which requires an equivalent level of protection, has the potential to create unintended second-order safety impacts due to the interlinked nature of the DASR (a system of systems). In each instance, the regulated entity seeking to apply these flexibility provisions should identify and address any such impacts.

8.3.5.5 **Increased safety risk.** The application of GR.80 flexibility provisions by service providers, such as maintenance organisations, may result in increased Aviation Safety risk for the relevant Military Air Operator (MAO). Affected MAOs must apply additional due diligence to activities utilising the flexibility provision for the period in which that flexibility provision is in effect, commensurate with the residual risk level. Additionally, GR.80 application does not absolve the organisation of its obligation to continue to comply with all other applicable DASR. Where GR.80 flexibility provisions have been appropriately applied, DASA will not issue a finding for non-compliance against specific DASR clauses covered by the provision.

8.3.5.6 **Remediation.** Any flexibility provision should only be continue to be in place while:

1. the operational need continues to exist; and
2. compliance with relevant DASR would continue to impact operational objectives.

8.3.5.7 **Application to DASA.** DASA expects that proposed implementation of flexibility provisions to be detailed within, or referenced by, draft amendments to the MO exposition submitted under a DASR Form 2 Application for DASR 145 and DASR M Subpart G Approval.

8.3.5.8 **Application by Defence Industry**. Defence Industry organisations may only enact DASR GR.80 provisions through their relevant Military Air Operator (MAO) as the Risk Management Authority. In the event that a MAO's operational need requires a Defence Industry MO to exercise flexibility provisions, Defence Industry would support the MAO through provision of technical considerations and controls.

Use of flexibility provisions to authorise certifying and support Staff

8.3.5.9 **Background.** As discussed in chapter 8.3.3, the DASR requires[24] that certifying staff and support staff for on-aircraft maintenance hold an appropriate MAML. DASA MAMLs are issued when an applicant provides to DASA the relevant evidence, from a DASR 147 Maintenance Training Organisation (MTO) or recognised equivalent, that basic knowledge, basic experience and applicable type training requirements have been met. Gaps in basic knowledge result in MAML exclusions – mostly aircraft system based (e.g. propulsion systems, electrical systems) – and preclude a MAML holder from issuing a CRS or acting as support staff on the excluded aircraft systems.

8.3.5.10 **Granting of MAMLs to foreign-trained personnel.** Provisions within the DASR 147 enable foreign-trained maintenance personnel to obtain a MAML by undergoing an equivalency assessment where time permits. This assessment is conducted by an approved or recognised 147 MTO and will consider knowledge and experience as well as relevant type training.

8.3.5.11 **DASA assurance of procedures and outcomes.** DASA will conduct independent safety assurance differently for DASR GR.80(b) and GR.80(c), commensurate with the level of risk exposure. However, DASA assurance for both DASR GR.80(b and GR.80(c) involves the prior assessment of the

Superseded

procedure used to authorise non-MAML staff in certifying or support staff roles. Where uncertainty exists as to the procedure's applicability or suitability in a particular instance, the DASR 145 MO (through the CAMO, on behalf of the MAO), should seek advice from DASA.

8.3.5.12 Common guidance. The maintenance organisation may choose to utilise a single procedure to address both GR.80(b) and GR.80(c) scenarios. However, the organisation must make it clear how it will meet the different aviation safety performance outcomes. In both scenarios, where practicable, the procedure should require DASA 145 MOs to seek assistance from the ADF DASR 147 MTO to assess training deficiencies and inform decisions.

DASR GR.80(b) equivalent level of protection

8.3.5.13 An application to use the GR.80(b) equivalent level of protection provision must articulate how the procedure to authorise non-MAML staff in certifying or support staff roles will provide an equivalent level of protection to that which would otherwise be attained through compliance with the relevant DASR. If DASA agrees that an equivalent level of protection is achieved through the procedural outcome, DASA will approve the exception from the DASR. DASA will apply assurance to the ongoing application of the procedure(s) through routine oversight unless the DASR 145 MO, through the CAMO (on behalf of the MAO), requests DASA independent assurance prior to the issue of an individual authorisation.

8.3.5.14 An application to DASA for approval of the GR.80(b) equivalent level of protection flexibility provision should describe a method for implementing risk controls equivalent to those inherent in a DASA MAML (e.g. categorisation, exclusions and type ratings). The procedure should require assessment of individual competency, through knowledge and experience considerations, via:

1. an approved foreign nation/service comparison process; or
2. suitable evidence against each relevant module of DASR 66 Appendix I I and relevant chapters of DASR 66 Appendix III, to the appropriate training level, for the scope of the authorisation to be given.

8.3.5.15 Utilisation of DASR GR.80(b) is likely to be complex and time-consuming, requiring detailed analysis that may not be suitable to support agile operations.

DASR GR.80(c) risk management

8.3.5.16 For DASR GR.80(c), the procedure to authorise non-MAML staff in certifying or support staff roles must demonstrate that a credible and defensible level of military aviation safety performance will be maintained through sound management of aviation safety risks arising through the deviation from applicable DASR. DASA will not approve a GR.80(c) procedure but will allow its use subject to the requirement that all instances of the organisation applying the procedure are reported to DASA at the first practical opportunity. The DASA assurance role provides an independent assessment of the credibility and defensibility of the risk-based decision that is made by the organisation.

8.3.5.17 Any application to DASA to implement a GR.80(c) *risk management* approach should address the following:

1. The seven-step risk management guidance provided in Annex A and the format and means in which it will be submitted to DASA.
2. The necessary interfaces to the MAO such that any Decisions to Proceed are appropriately documented.

Superseded

3. Where operational needs allow for prior assurance by DASA, the relevant DASA desk officer should be provided with the output of the procedure, to review prior to enactment.

4. Where operational needs do not allow for prior assurance by DASA, the procedure for authorising non-MAML certifying or support staff may still be enacted by the DASR 145 AMO (through the MAO). Retrospective DASA assurance will be applied where an ongoing operational need supports continued application of the flexibility provision.

Annex:

(a) Contextualised guidance for seven-step risk management

8.4.1 Introduction and Background

Introduction

8.4.1.1 This chapter provides additional guidance on the Military Aircraft Maintenance Licence (MAML), and for those individuals applying for a "personnel authorisation[25]" under DASR 66, how to comply with DASR 66 requirements.

8.4.1.2 DASR 66 establishes the regulations required to be met by Aircraft Maintenance Training Organisations (AMTO), responsible for either Basic or Type Training, to be eligible for a DASR Military Aircraft Maintenance Licence (MAML).

8.4.1.3 For the purpose of this chapter additional guidance does not include information already presented at Volume 2, but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3. Further information regarding DASR 147 is located within Volume 3, chapter 8.5.

Background

8.4.1.4 During the DASR 66/147 transition, DASA provided a number of interim arrangements which allowed the current workforce to apply for DASR 66 MAMLs, including acceptance of existing Military Aircraft Type Rating training until the DASR were fully implemented.

8.4.1.5 The DASR 66.A.70 conversion provisions were based on the Australian National Competency Training and Assessment framework. These provisions were applied to staff who held valid certifying qualifications prior to the date of these regulations being introduced.

8.4.1.6 All DASA MAMLs are based on objective evidence of an individual's Qualification, Training and Experience (QTE), against the criteria in Appendix I to DASR 66 Basic Knowledge Requirements. DASA has mapped the EMAR syllabus (Appendix I to DASR 66) to associated Australian nationally adopted Competency Based Training and Assessment Units of Competency (UoC), qualifications and non-vocational education and training (VET) service specific training. This mapping resulted in providing a DASA Category A1, A3, B1.1, B1.3 or B2 MAML, with or without exclusions and inclusions.

Superseded

8.4.1.7 The Defence Airworthiness Safety Regulations (DASR) 66 - Military Aircraft Maintenance Licencing provides Defence personnel who hold a MAML the privilege to issue Certificate of Release to Service (CRS). This regulation is based on the European Military Airworthiness Requirements Part 66 (EMAR Pt 66), but adapted to suit the Australian military maintenance environment.

8.4.1.8 DASR 66 identifies the skills and knowledge requirements for each licence category (refer MAML Categories below) by syllabi. DASA have mapped initial trade training and technical, promotion-related courses (eg Aviation Technician Supervisor Course, LSATT, CPL SUBJ 4 etc) against these syllabi.

8.4.1.9 The MAML is an attestation the holder has met the DASR 66 knowledge and experience requirements, but does not entitle the holder to issue an aircraft CRS until they are authorised within a DASR 145 Maintenance Organisation (MO) to exercise these privileges.

8.4.2 MAML Categories, Limitations and Extensions

DASR 66.A.3 - MAML Categories

8.4.2.1 There are four basic licence categories:

1. The Category A licence is a non-type rated licence for minor scheduled and unscheduled maintenance permitted within Line Maintenance (relevant tasks will be detailed in the relevant DASR 145 MOE). The privileges of a Category A licence are not applicable to Base Maintenance.

2. Category B1 - permits certification privileges for scheduled and unscheduled airframe, engine, structures, mechanical systems and electrical maintenance for more complex Line Maintenance activity. The B1 MAML also permits minor avionics maintenance (eg 'black box' changes, where no specialised support equipment is required). The B1 MAML allows for authorisations as support staff within Base Maintenance.

3. Category B2 - permits certification privileges for scheduled and unscheduled complex avionics and electrical Line Maintenance activities and allows the holder to act as B2 support staff within Base Maintenance.

   Note: The Category B1 and B2 licences are aircraft type-rated licences and permit the holder to certify the release to service only of aircraft types that are endorsed as ratings on their licence.

4. Category C - is required for personnel who issue the CRS following Base Maintenance.

   Note: The Category C licence is an aircraft type-rated licence and permits the holder to issue the CRS of an aircraft following Base Maintenance only. GM to DASR 66.A.20(a) para 3 provides more detail.

DASR 66.A.50 – Limitations and DASR 66.A.52 – Extensions

8.4.2.2 All MAMLs are managed in accordance with the DASA 66 MAML Exclusion Inclusion & Endorsement Manual, available on the DASA Website.

Superseded

8.4.2.3 The DASA 66 MAML Exclusion, Inclusion & Endorsements Manual outlines the required competency details and provides general guidance that reflects DASR 66.A.20 privileges against the S1000D system of standard numbering to specify particular Systems and Sub-systems.

8.4.2.4 Exclusions (Limitations) introduced on a MAML are omissions from an individual's certification privileges, indicating that the licence holder shall not issue a CRS in

8.4.2.5 Line Maintenance or act as B1 or B2 support staff in Base Maintenance if maintenance related to that exclusion has occurred.

8.4.2.6 Inclusions (Extensions) introduced on a MAML are additional privileges to an individual's certification privileges, indicating that the licence holder may issue a CRS or act as B1 or B2 support staff if maintenance related to that Inclusion. Noting that additional military specific systems Inclusions can be achieved through completion of all required competencies & a type course (where appropriate) which incorporates S1000D Air-vehicle system basic knowledge requirements into the type syllabus.

8.4.2.7 The S1000D is a numerical technical classification of all the systems and sub systems on an aircraft, which is largely used in aircraft engineering and maintenance, and helps to standardise data across aircraft manufacturers and programs to facilitate improved maintenance and logistics.

8.4.3 MAML Applications

DASR 66.A. 10 - Application

8.4.3.1 Refer to DASPMAN Volume 3, Chapter 5.3 – Annex W – MAML for details.

Foreign Licence Applications

8.4.3.2 Military Aviation Authority/National Aviation Authority's (MAA/NAA) have differing training requirements for aircraft maintenance personnel based upon their sovereign regulatory maintenance framework. Therefore, there may be considerable differences in each country's licence privileges, regulations, assessment methods/framework and specific guidelines; resulting in gaps and difficulties to enable direct conversion of a foreign MAA/NAA issued licence to a DASA MAML.

8.4.3.3 Australia has nationally adopted competency-based training and assessment in lieu of EASA/ EMAR basic knowledge syllabus and examinations, which results in attainment of Units of Competency (UoC), which in turn lead to Aeroskills qualifications.

8.4.3.4 DASA has mapped these Aeroskills Mechanical and Avionics UoC against DASR 66 syllabi requirements to provide either a Category A, B1.1, B1.3 or B2 MAML, with/without exclusions and inclusions.

8.4.3.5 To enable Non-Australian competencies/qualifications to be used to apply for a MAML, a 147 Maintenance Training Organisation (MTO) RPL assessment must be performed using objective evidence to provide an individual with an RPL report clearly outlining the required theory and practical training requirements that have been met.

Aging Qualifications

8.4.3.6 All MAML applications will need to meet the following requirements:

Superseded

1. Any grandfathering formally recognised and utilised for a MAML assessment during the transitional period will be honoured and no further action is required by the individual;

2. IAW DASR 66.A.25 any training courses and examinations shall be passed within 10 years prior to the application for:

   i. a MAML; or

   ii. an addition of a category or subcategory to a MAML; or

   iii. the removal/addition of a DASA exclusion/inclusion to a MAML.

3. Qualifications 10 years or older now come into question, as not meeting the requirements of 66.A.25(b). Any of these qualifications provided as evidence for a MAML application (initial or update), will generally not be accepted unless they have been assessed and converted against DASR 66.A.25 Basic knowledge requirements by a DASA/CASA approved 147 Organisation;

4. DASA acknowledges that there may be individual unique circumstances where aging qualifications could be considered in more detail – specifically where the time and effort required for conversion to contemporary standards, by a DASA/CASA approved 147 Organisation, may not be reasonable. To support this, where aging qualifications (>10yr) are used as evidence for a MAML application (initial or update), the applicant must provide detailed justification (with supporting evidence) on why the aging qualification should be considered. This should include relevant work history for the applicant (including objective evidence of previous maintenance authorisations) and detail any factors that support the acceptance of aging qualifications without conversion. MAML applications, with aging qualifications, will be rejected if no supporting justification is provided.

5. Where there is any doubt or ambiguity regarding the requirements for a MAML, contact DASA at dasa.dcadasr66@defence.gov.au, and provide detailed evidence for DASA's consideration

8.4.4 MAML Basic Knowledge and Experience Requirements

DASR 66.A.25 – Basic Knowledge Requirements

8.4.4.1 A MAML applicant must have a demonstrated level of knowledge relevant to the MAML privileges to be granted, and in order to obtain a Category A (Line Maintenance only), B (Line & Base Maintenance) or C (Base Maintenance only) MAML. An applicant requires "Basic Knowledge" in the appropriate subject modules IAW Appendix I toDASR 66.

DASR 66.A.30 – Basic Experience Requirement

8.4.4.2 In addition to Basic Knowledge requirements (DASR 66.A.25), a MAML applicant must also have a demonstrated level of Basic Experience of the requested licence category (DASR 66.A.30). An applicant requires:

1. The practical experience must be gained in the real environment of military aircraft maintenance;

Superseded

2. Initial employment training (IET) delivered to trainees of all three ADF Services provides the minimum practical training detailed in Appendix I to DASR 66. Therefore, maintenance personnel who have completed their IET are eligible for a category A licence after six months of practical training, following completion of specific aircraft task training in accordance with DASR AMC 66.A.20(b), and having achieved syllabus Module 10 requirements.

8.4.4.3 Experience shall be acquired within 10 years preceding the initial category or subcategory.

DASR 66.A.40 - Continued validity of the MAML

8.4.4.4 All MAMLs are perpetual and will remain valid unless suspended, surrendered or revoked.

8.4.4.5 DASA has a process that allows it to assess breaches or suspected breaches of the conditions that a MAML was issued and take appropriate action. Contact DASA at DASA.DCA DASR66 for more information.

8.4.5 MAML Military Aircraft Type Rating Endorsements

DASR 66.A.45 - Military Aircraft Type Rating

8.4.5.1 In order to enact the privileges of a DASR 66 Category B (Line and Base Maintenance) MAML, MAML holders must have a specific Military Aircraft Type Rating (MATR) endorsement and be authorised by the DASA 145 nominated person (generally the Quality Manager) to operate within their approved quality system. In order to obtain a type rating, an applicant requires:

1. Type Training (Theory & Practical) (DASR 66.A.45): and
2. On the Job Training (OJT) for first Type Rating (AMC 66.A.45)

Military Aircraft Type Ratings Guidance

8.4.5.2 Refer to Chapter 8.5.8 – Military Aircraft Type Ratings for further details.

Expectations

8.4.5.3 All MATR applications must confirm that any OJT requirements are completed IAW Appendix III to DASR 66.

8.4.5.4 All MATR type training courses must be started and completed within the 3 years preceding application for the MATR.

8.4.5.5 The “Basic Training Course” requirements stated in 66.A.30 and 147.A.200 must be met before individuals are eligible for the relevant category MAML.

8.4.5.6 OJT requirements stated in Appendix III to DASR 66 must be met for first MATR in licence subcategory. Evidence of completion must be provided with the MAML endorsement application.

8.4.5.7 DASA may accept practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 – Northrop Grumman for applications for P-8A Poseidon or E-7A Wedgetail.

Superseded

8.4.6 MAML Suspension or Revocation

8.4.6.1 On receipt of notification of fraudulent or unsafe behaviour by a MAML holder, DASA will assess the information to determine what action, if any, is required.

Notice to Show Cause

8.4.6.2 Should DASA determine that a suspension or revocation of a MAML be warranted, then a Notice to Show Cause (NTSC) will be issued to the MAML holder. For procedural fairness, the affected MAML holder will be provided the reasons and evidence supporting the decision to issue a NTSC. The NTSC provides the MAML holder the opportunity to respond to the proposed suspension or revocation of their MAML.

8.4.6.3 The response to the NTSC will be assessed by DASA to determine if:

1. No action required; or
2. MAML will be suspended; or
3. MAML will be revoked.

MAML Suspension or Revocation

8.4.6.4 DASA will notify the MAML holder, and the organisation for which the MAML holder held the authorisation, of the suspension or revocation of the MAML. DASA also publishes a list of suspended MAML on the Military Aircraft Maintenance Licencing page on the DASA website.

Review of Suspension or Revocation

8.4.6.5 The organisation for which the MAML holder held the authorisation, can request DASA to review the decision. The request for review should include the results of any internal investigation and any other relevant information to support the request for a review.

8.5 Aircraft Maintenance Training Organisations

8.5.1 Introduction and Background

Introduction

8.5.1.1 This chapter provides additional guidance on the Defence Airworthiness Safety Regulations DASR 147 – Aircraft Maintenance Training Organisations (AMTO), to assist those organisations applying for a DASR 147 approval on how to comply with DASR 147 requirements.

8.5.1.2 DASR 147 establishes the regulations required by an AMTO responsible for either Basic or Type Training of DASR 66 Engineers and Aircraft Maintenance Technicians to be eligible for a Military Aircraft Maintenance Licence (MAML).

8.5.1.3 For the purpose of this chapter additional guidance does not include information already presented at Volume 2, but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3

Superseded

Requirements for Aircraft Maintenance Training Organisation

8.5.1.4 The Defence Aviation Safety Regulations (DASR) requires individual DASR 147 Maintenance Training Organisations (MTOs) to define their maintenance training activities in their Maintenance Training Organisation Exposition (MTOE). The scope of maintenance training of basic knowledge and/ or Military Aircraft Type Rating (MATR) training should be in accordance with the MTO's policy and procedures defined in the MTOE.

Background

8.5.1.5 The Defence Aviation Safety Authority (DASA) and Headquarters Air Force Training Group (HQAFTG) have agreed that the primary framework to meet the DASR 147 requirements for the training of ADF personnel is through the creation of a single Air Domain MTO.

8.5.1.6 The single Air Domain MTO will:

1. leverage existing Joint and Single Service Individual Education and Training governance arrangements to provide an efficient and standardised governance approach for Australian Defence Organisation (ADO) aviation maintenance training.
2. align with the Defence Registered Training Organisation (DRTO) framework to enable standardisation against benchmarked Australian Skills Quality Authority (ASQA) standards.
3. provide a single point of accountability for aviation maintenance training, which will provide better holistic oversight that safety outcomes are being achieved.
4. provide the simplest path to the provision of recognition of Defence Maintenance Training by civil regulators and foreign militaries.

8.5.1.7 Commercial organisations that deliver aircraft maintenance training, either initial technical training (basic training) or Military Aircraft Type Training to meet DASR 66 requirements will be recognised by DASA if they:

1. already have a Part 147 Approval issued by a DASA- recognised Civil Aviation Authority (CAA)/ Military Aviation Authority (MAA); or
2. are included within the Air Domain MTO; or
3. are issued a discrete DASR 147 Approval, where they provide aviation maintenance training to DASR 145 organisation(s), but do not train ADF personnel.

8.5.1.8 The Air Domain MTO includes military aircraft type training courses delivered by Army Aviation Training Centre (AAvnTC), the Navy Training Authority – Aviation (TA-AVN) and the Air Force – Force Element Groups (FEGs). Basic aviation knowledge training delivered by RAAF School of Technical Training (STT) is also included under the Air Domain MTO.

Application to become an MTO

8.5.1.9 Refer to DASPMAN Volume 3, Chapter 5.3 – Annex I – MTO for detailed guidance on the application process.

Superseded

8.5.2 Facility and Equipment Requirements

8.5.2.1 This regulatory provision outlines the facility requirements for a DASR 147 Aircraft Maintenance Training Organisation (AMTO) and contains several sub-sections, which detail the requirements that AMTOs must meet in terms of facilities, equipment and resources.

Facility Standards

8.5.2.2 AMTOs are to provide adequate facilities, equipment and tools to conduct training. AMTOs must ensure that their facilities meet the appropriate standards for classroom space, simulator training areas and other areas necessary for conducive aviation maintenance training. Additionally, AMTOs must have facilities for storage of maintenance tools, equipment and parts.

Workshop Standards

8.5.2.3 Workshops must be equipped with tools, equipment and materials necessary to perform the practical tasks required by the relevant training courses. AMTOs must have appropriate facilities for the storage, testing and calibration of equipment used in the maintenance of the aircraft.

Training Equipment

8.5.2.4 Training equipment must be maintained and calibrated to ensure that it is safe and effective for use in training. AMTOs must ensure that they have the appropriate equipment for training in various aspects of aircraft maintenance including aircraft systems, avionics, structures and powerplant maintenance.

Library Facilities

8.5.2.5 AMTOs are to provide access to relevant aviation related reference materials, manuals and other resources necessary for aviation maintenance training. AMTOs must ensure that their libraries are up to date and have a wide range of materials that are relevant to the training courses they offer.

Computer Facilities

8.5.2.6 AMTOs are to have computer facilities that provide access to relevant aviation related software, databases and other tools necessary for effective aviation maintenance training. AMTOs must ensure that their computer facilities have up to date software and hardware as well as high-speed internet connections.

8.5.3 Personnel Requirements

Personnel Requirements

8.5.3.1 This section specifies the personnel requirements for management personnel employed by DASR 147 AMTOs. The organisation must have sufficient management personnel to ensure the effective management of its operations. The management personnel must be qualified, experienced and possess the necessary skills to oversee the organisation's activities and ensure compliance with all relevant regulations and standards. This includes an Accountable Manager who has overall accountability for the organisation's compliance with DASR regulations and will appoint other necessary resources to accomplish training commitments. The regulation includes requirements for

Superseded

different types of personnel, including management personnel, technical personnel, quality personnel, training personnel, and support personnel.

Records of Instructors, Examiners, Assessors and Invigilators

8.5.3.2 DASR 147.A.110 requires approved maintenance training organisations (AMTOs) in Australia to maintain records of instructors, examiners, and assessors. The records must contain specific details about the personnel including:

1. **Personal Details:** Personal details of the instructor, examiner, or assessor, including their full name, date of birth, and contact information.
2. **Qualifications:** Details of the instructors, examiners, or assessor's qualifications, including the type of qualification, the date it was obtained, and the organisation that issued it.
3. **Experience:** Details of the instructors, examiners, or assessor's experience, including the type of experience, the duration of experience, and the organisation where the experience was gained.
4. **Training:** Details of the training received by the instructor, examiner, or assessor, including the type of training, the duration of training, and the organisation that provided the training.
5. **Authorisations:** Details of any authorisations held by the instructor, examiner, or assessor, including the type of authorisation and scope, the date it was issued, and the organisation that issued it.
6. **Currency:** Details of the instructors, examiners, or assessors currency, including the type of currency, the date it was last achieved, and the date it is due to expire.
7. **Performance:** Details of the instructor's, examiner's or assessor's performance, including any relevant feedback or reviews and professional development plan.
8. **Relevant Training Material:** Details of any relevant training material that the instructor, examiner, or assessor has access to or uses in the performance of their duties.
9. **Verification of Competence:** Details of any verification of competence conducted on the instructor, examiner, or assessor, including the type of verification, the date it was conducted, and the organisation that conducted it.
10. **Compliance:** Details of the instructor's, examiners, or assessor's compliance with all relevant regulations and standards.

8.5.3.3 AMTOs can ensure that their personnel are qualified, competent, and authorised to perform their duties, and comply with all relevant regulations and standards.

Key Personnel Requirements

8.5.3.4 The qualification and experience of the instructors, knowledge examiners, practical assessors and invigilators are fundamental to ensuring the quality of a training course – only appropriately qualified personnel should be appointed to carry out training and examinations. In addition to the published Acceptable Means of Compliance (AMC) and Guidance Material (GM) to DASR 147.A.105(f), the following information provides additional guidance on the knowledge and

Superseded

skills that are expected of authorising instructors, knowledge examiners, practical assessors and invigilators employed by a DASR 147 Maintenance Training Organisation (MTO).

Instructors

8.5.3.5 A nominated person who will deliver a DASR 66 module or unit of competency (DASR 66 appendix I), a DASR 66 element (DASR 66 appendix III), or part thereof either of these. The instructor is not necessarily the person involved in drafting of the course material (content, duration, etc.), however they should be involved in the continued development of the lessons themselves (creation of the instructor notes, slides, sequencing, etc.).

8.5.3.6 Instructors should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO.
2. Pedagogic – should know how to organise a lesson and how to efficiently deliver a course that clearly highlights the fundamental points. They should also be able to adapt when communicating to a particular audience including with pre-existing knowledge/experience.
3. Able to promote the appropriate attitude towards regulation and procedures; in particular the strict adherence to approved maintenance practices and quality standards through the lens of their own experience in a regulated aviation environment.
4. Familiar and proficient with the tools and training techniques used by the training organisation to deliver lessons.
5. Appropriately experienced in the aircraft maintenance environment.
6. Able to demonstrate good knowledge, complimented with communication skills in the English language.
7. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.
8. Able to demonstrate good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directives, Service Bulletin, Maintenance Programme, etc.).
9. In receipt of continuous training in the company's procedures and DASRs.

Knowledge Examiners

8.5.3.7 A nominated person who will determine the level of theoretical knowledge of the trainees on a particular module, unit of competency, element, or part thereof. The function may include the drafting and/or the selection of questions (Multi-Choice Questions and Essays), the evaluation of the correctness of answers (except when correct answers are pre-determined) and the final judgement regarding the level of knowledge demonstrated by the trainee.

8.5.3.8 Persons solely supervising an exam session are not considered as examiners but are considered as support staff invigilators and, in this context, are not subject to knowledge and

Superseded

experience requirements, but need to be trained to the examination procedure described in the MTOE.

8.5.3.9 Knowledge examiners should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO, including the examination standards required by DASR 66.
2. Able to demonstrate a responsible attitude to the conduct of examinations, so that the highest integrity is ensured.
3. Trained in contemporary examination techniques and able to conduct an examination in such a way that the true abilities of the candidate are demonstrated.
4. Able to remain neutral at all times and behave in a manner that will not influence or prejudice the final result of the examination, for example by providing undue assistance or clarification to a candidate.
5. Familiar and proficient with the tools or the examination techniques used by the training organisation to perform the exams.
6. Appropriately experienced in the aircraft maintenance environment.
7. Able to demonstrate good knowledge, complimented with communication skills in the English language.
8. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.
9. Able to demonstrate good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directive, Service Bulletin, Maintenance Programme, etc.).
10. In receipt of continuous training in company's procedures and DASRs.

Practical Assessors

8.5.3.10 A nominated person who will determine the level of practical knowledge/practical skills of the trainees on a particular module, element, or part thereof. The function may include the drafting and/or the selection of practical tasks, the performance oversight and assessment of the practical activities. Practical assessors should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO.
2. Experienced and show solid judgement regarding the abilities of the assessed trainees – the assessor should have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks in compliance with current regulation, approved procedures, maintenance practices, etc.
3. Trained to contemporary assessment techniques. The assessor should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated.

Superseded

4. Familiar and proficient with the tools or the techniques used by the training organisation to assess the practical abilities of trainees (maintenance simulators, mock up, etc.).

5. Appropriately experienced in the aircraft maintenance environment.

6. Able to demonstrate good knowledge, complimented with communication skills in the English language.

7. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.

8. Able to demonstrate a good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directive, Service Bulletin, Maintenance Programme, etc.).

9. In receipt of continuous training in company's procedures and DASRs.

10. Able to act safely, apply safety precautions and prevent dangerous situations.

11. Able to demonstrate knowledge and understanding of areas requiring special emphasis or novelty (areas peculiar to the aircraft type, domains not covered by DASR-66 Appendix, practical training elements that cannot be imparted through simulation devices, etc.).

12. Able to demonstrate an understanding of the aircraft systems interaction.

13. Able to navigate, execute and obey the prescribed maintenance procedures.

Invigilators

8.5.3.11 A nominated person who will ensure the correct conduct of an examination in accordance with the examination procedures of the DASR 147 organisation. The invigilator is responsible for ensuring that examinations are conducted in accordance with the MTOE and Training Procedures and operates under the direction, responsibility and delegation of the Training Manager. The organisation can nominate permanent exam invigilators who should then be listed in MTOE Part 1 and qualified in accordance with Training Procedures.

8.5.3.12 Training organisations often delegate the invigilation of an examination to staff not listed as an examiner for the particular subject. These "invigilators" do not need to be qualified to the same extent as an examiner, and in particular, they do not need to demonstrate specialty knowledge, as long as their duty is strictly limited to the conduct of the examination itself.

8.5.3.13 Invigilators should however be trained to the organisation's examination procedures with a specific emphasis on the exam's integrity aspects and on the handling of cheating or misconduct cases. Such staff should be listed by the organisation with records of their training kept in the individual's personnel file.

Assessment and acceptance of staff

8.5.3.14 Assessment and acceptance of instructors, examiners and assessors should be performed, and documented by the approved training organisation in accordance with dedicated procedure described in the MTOE. Appropriate staff in the maintenance training organisation should physically interview proposed candidates in order to ensure their competency. Once completed, detailed result of this assessment, including any supporting documents (diplomas, DASR 66 licence, etc.) should be

Superseded

filed in accordance with MTOE procedure. The staff should be listed in MTOE with intended scope of instruction, examination or assessment.

Continued qualification

8.5.3.15 The qualification criteria and experience requirements only address the initial acceptance of instructor, examiners and assessors. The training organisation should develop and document a program in MTOE to ensure the continued competence of these staff.

8.5.4 Instructional Equipment Requirements

8.5.4.1 DASR 147.A.115 requires approved maintenance training organisations (AMTOs) to ensure that they have appropriate instructional equipment available to support their training activities. Here are some important points that must be considered when meeting this regulation:

1. **Type of Equipment:** The equipment must be appropriate for the type of training being delivered. This includes a wide range of equipment such as applicable aircraft, training aids, simulators, and computer-based training tools.
2. **Condition:** The equipment must be in good working order, and any faults or defects must be promptly rectified.
3. **Calibration:** The equipment must be calibrated as required, and records of calibration must be maintained.
4. **Availability**: The equipment must be readily available for use when required, and there must be sufficient equipment available to support the number of students being trained.
5. **Security:** The equipment must be stored securely when not in use, and access to the equipment must be controlled to prevent damage or misuse.
6. **Maintenance:** The equipment must be regularly maintained, and records of maintenance activities must be maintained.
7. **Training Material**: The equipment must be used in conjunction with appropriate training material to support effective learning.
8. **Compliance:** The equipment must comply with all relevant regulations and standards.
9. **Training for Equipment Use:** Instructors and trainers must be trained in the correct use of the equipment and any associated software or training materials.
10. **Upgrades and Replacements:** Equipment should be upgraded or replaced as necessary to ensure that it remains effective and meets current training requirements.

Aircraft Maintenance Training Aids

8.5.4.2 These are physical devices used to simulate or replicate various components or systems of an aircraft. For example, a training aid may be used to teach students how to inspect and troubleshoot an engine. Important points to consider for training aids:

1. The training aid must accurately represent the aircraft component or system being taught.

Superseded

2. The training aid should be durable and long-lasting.

3. The training aid should be kept clean and well-maintained.

8.5.4.3 **Computer-Based Training Tools:** These are software applications or programs that are used to deliver training material to students. For example, a computer-based training tool may be used to teach students how to use a maintenance management system. Important points to consider for computer-based training tools:

1. The software should be up-to-date and compatible with the AMTO's computer hardware.

2. The software should be easy to use and navigate.

3. The AMTO should have a system for monitoring and tracking student progress.

8.5.4.4 **Simulator Devices:** These are devices that replicate real-world situations or scenarios to provide hands-on training to students. For example, a simulator may be used to teach students how to perform a maintenance task on an aircraft. Important points to consider for simulator devices:

1. The simulator should accurately represent the real-world situation or scenario being taught.

2. The simulator should be well-maintained and regularly calibrated.

3. The AMTO should have a system for monitoring and tracking student progress.

8.5.4.5 **Training Videos and Audio Recordings:** These are pre-recorded videos or audio recordings that are used to deliver training material to students. For example, a training video may be used to teach students about safety procedures.

8.5.4.6 Important points to consider for training videos and audio recordings:

1. The video or audio recording should be up-to-date and relevant to the training being provided.

2. The AMTO should have a system for monitoring and tracking student progress.

3. The AMTO should ensure that the video or audio recording is of high quality and easy to understand.

8.5.5 Maintenance Training Material

8.5.5.1 DASR 147.A.120 requires approved maintenance training organisations (AMTOs) to develop and use maintenance training material that is appropriate for the type and level of training being delivered. DASR 66 specifies requirements for both basic and type course training material. Here are some important points to consider for each Basic course training material:

1. The training material used for basic courses must cover a broad range of topics and must be suitable for entry-level students. The following are some important points to consider when developing or using training material for basic courses:

    i. The training material must cover the theoretical and practical aspects of the aircraft, system, or component being taught.

Superseded

ii. The training material must be easy to understand and follow.

iii. The training material must include practical exercises that reinforce theoretical knowledge.

iv. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.

v. The training material must be appropriate for the level of experience and education of the students being trained.

Type Course Training Material

8.5.5.2 The training material used for type courses must cover the specific make and model of the aircraft, system, or component being taught. The following are some important points to consider when developing or using training material for type courses:

1. The training material must cover all relevant aspects of the aircraft, system, or component, including maintenance, inspection, troubleshooting, and repair.
2. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.
3. The training material must be appropriate for the level of experience and education of the students being trained.

8.5.5.3 Some additional important points to consider when developing or using maintenance training material include:

1. The training material must be structured in a logical and organized manner.
2. The training material must be consistent with the relevant regulations and standards.
3. The training material must be presented in a manner that is engaging and interesting for students.
4. The AMTO must have a system for tracking and monitoring the use of training material, including the progress and performance of students.

8.5.5.4 By meeting the requirements of DASR 147.A.120, AMTOs can ensure that they are providing high-quality maintenance training material that is appropriate for the level and type of training being delivered. This can help to ensure that students receive the knowledge and skills they need to perform maintenance tasks safely and effectively.

8.5.6 Examinations

8.5.6.1 DASR 147.A.135 specifies the requirements for conducting examinations for aircraft maintenance training organisations (AMTOs) to ensure that their students have the necessary knowledge and skills to perform their maintenance duties effectively and safely. Here are some key points regarding the examination requirements:

Examination Development

Superseded

8.5.6.2 The AMTO should develop examination questions that are aligned with the training objectives and outcomes. The questions should be designed to test the knowledge and skills that the student has acquired during the training program. The AMTO should also ensure that the examination questions are reviewed and approved by qualified personnel.

Examination Administration

8.5.6.3 The AMTO should have procedures in place for administering examinations. This includes ensuring that students are aware of the examination format, rules and regulations, and any special instructions that apply. The AMTO should also ensure that the examination environment is conducive to learning and that the examination is conducted in a fair and unbiased manner.

Examination Security

8.5.6.4 The AMTO should have procedures in place for ensuring the security of all the question, examinations and databanks. Particular attention should be made to the storage and transportation of the examination between venues and whilst onsite. Care must be taken to ensure the examination questions are secure at all times. Electronic means of storage may be utilised where available, providing that suitable security arrangements are in place.

Examination Grading

8.5.6.5 The AMTO should have procedures in place for grading and evaluating examination results. The grading procedures should be fair, consistent, and transparent, and should be based on established criteria. The AMTO should also ensure that examination results are communicated to students in a timely manner and that students have access to feedback on their performance.

Examination Records

8.5.6.6 The AMTO should maintain records of examination results, including the student's performance and any relevant feedback. These records should be kept in a secure location and retained for a specified period of time in accordance with regulatory requirements (e.g. Annex A to AMC 147.A.125)

Examination Review

8.5.6.7 The AMTO should have procedures in place for reviewing and evaluating examination results to identify any areas where improvements can be made. This includes analysing trends in examination results, identifying areas where students are struggling, and taking corrective actions to improve the effectiveness of the training program.

8.5.6.8 In summary, the examination requirements outlined in DASR 147.A.135 are designed to ensure that the AMTO's training program is effective and that students have the necessary knowledge and skills to perform their maintenance duties safely and effectively. By following these requirements, the AMTO can maintain a high standard of training and contribute to the overall safety of the aviation industry.

8.5.7 Training Procedures and Quality System

8.5.7.1 DASR 147.A.130 requires Aircraft Maintenance Training Organizations (AMTOs) to establish and maintain effective training procedures and a quality system to ensure that their training programs are of a high standard and meet the requirements of all applicable regulations and standards

Superseded

including DASRs. Some important points to be considered when developing or maintaining training procedures and a quality system are:

Training Procedures

8.5.7.2 The training procedures must include a description of the training program, including the objectives, scope, and content of the training. This should include the methods and materials used for training, the sequencing of the training, and the assessments used to measure the effectiveness of the training.

Courseware

8.5.7.3 The AMTO should have a system in place to develop, review, and update courseware, including lesson plans, training manuals, visual aids, and other materials used for training. The courseware should be reviewed and updated regularly to ensure that it remains relevant and effective.

Instructor Qualifications and Training

8.5.7.4 The AMTO should have procedures in place to ensure that their instructors are qualified and competent to deliver the training. This includes requirements for instructor qualifications and training, such as experience in the industry, knowledge of the subject matter, and teaching skills. The AMTO should also have a system in place to regularly assess the performance of their instructors and provide them with feedback / training as necessary.

Assessment Procedures

8.5.7.5 The AMTO should have a system in place to assess the effectiveness of their training, including the use of assessments and evaluations to measure the knowledge and skills of the students. The assessments should be designed to provide a fair and accurate measure of the student's performance, and be reviewed and updated regularly to ensure that they remain valid and reliable.

Quality System

8.5.7.6 The AMTO should have a quality system in place to ensure that their training program meets the requirements of DASRs and any other applicable regulations and standards. This includes procedures for monitoring and evaluating the effectiveness of the training by identifying, correcting and preventing recurrence of any deficiencies and continuously improving the training program.

8.5.7.7 Some additional important points to consider when developing or maintaining training procedures and a quality system include:

1. The AMTO should ensure that all training is conducted in a safe and secure environment, and that appropriate safety procedures are followed at all times.
2. The AMTO should ensure that their training programs are accessible to all students and meet their needs.
3. The AMTO should ensure that all training is conducted in accordance with relevant laws and regulations including those related to privacy and data protection.
4. The AMTO should ensure that all training is conducted in a professional and ethical manner, and that all students are treated fairly and with respect.

Superseded

Quality Policy

8.5.7.8 The AMTO should have a quality policy that outlines the organisation's commitment to quality and its goals for maintaining a high standard of training. The policy should be communicated to all staff and stakeholders, and reviewed and updated regularly.

Quality Objectives

8.5.7.9 The AMTO should establish quality objectives that are measurable and aligned with the goals of the organisation. The objectives should be reviewed and updated regularly, and progress towards meeting the objectives should be monitored.

Document Control

8.5.7.10 The AMTO should have a system in place to manage and control documents related to training procedures and the quality system. This includes procedures for document creation, control, review, approval, distribution and revision.

Record Keeping

8.5.7.11 The AMTO should maintain records related to the training programs and the quality system, including records of student performance, instructor qualifications, audit results, corrective actions taken, and other relevant information.

Records of Students

8.5.7.12 DASR 147.A.125 requires approved maintenance training organisations (AMTOs) to maintain accurate and complete records of their students. These records must include a variety of information to demonstrate that the student has successfully completed the required training and has the necessary knowledge and skills to perform maintenance tasks safely and effectively. Here are some important points to consider when developing or maintaining student records:

1. Student Identification: The record must include the student's full name, date of birth, contact information, and any relevant identification numbers or codes.
2. Training History: The record must include a detailed history of the student's training, including the courses they have completed, the date of completion, and the grade they received. This information should also include any remedial training or retesting that was required.
3. Assessment Records: The record must include documentation of any assessments or examinations the student has completed, including the results and any feedback or comments provided by the examiner.
4. Attendance and Absences: The record must include information on the student's attendance and any absences from training, including the reason for the absence and any make-up training that was required.
5. Certification: The record must include information on any certifications the student has received as a result of their training, including the type of certification, the date it was issued, and any restrictions or limitations.
6. Other Relevant Information: The record should also include any other relevant information about the student, such as their prior education or experience in the field

Superseded

of maintenance, any disciplinary actions taken, or any other notable achievements or accomplishments.

7. Some additional important points to consider when developing or maintaining student records include:

   i. The record must be maintained in a secure and confidential manner to protect the privacy of the student.

   ii. The record must be accurate, complete, and up-to-date at all times.

   iii. The record must be available for review by relevant authorities, such as regulatory agencies or potential employers.

   iv. The AMTO must have a system in place to ensure that student records are regularly reviewed and updated as necessary.

8.5.7.13 By meeting the requirements of DASR 147.A.125, AMTOs can ensure that they are maintaining accurate and complete records of their students, which can help to demonstrate that the students have received the necessary training and are qualified to perform maintenance tasks safely and effectively.

Corrective and Preventive Actions

8.5.7.14 The AMTO should have a system in place to identify and address non-conformities or areas where the procedures and system can be improved. This includes procedures for taking corrective and preventive actions to avoid recurrence including causal or root cause analysis, tracking and monitoring the effectiveness of the actions taken, and documenting the results.

Management Review

8.5.7.15 The AMTO should conduct regular management reviews of the training procedures and quality system to ensure that they are effective and meeting the goals of the organisation. The management review should include a review of audit results, quality objectives, corrective and preventive actions, and other relevant information.

Audit Procedures

8.5.7.16 Auditing is an important part of ensuring that the training procedures and quality system of the AMTO are effective and meeting the requirements of the applicable regulations. Audits should be conducted by an independent auditor, who can be an internal auditor or an external auditor.

Internal Auditing

8.5.7.17 The AMTO should conduct internal audits of their training procedures and quality system on a regular basis to ensure that all aspects of DASR 147 compliance are checked at least once in every 12 months and may be carried out as one complete single exercise or subdivided over a 12-month period in accordance with a scheduled plan. The purpose of internal audits is to identify any non-conformities or areas where the procedures and system can be improved. The results of the internal audits should be documented and corrective actions should be taken to address any non-conformities.

External Auditing

Superseded

8.5.7.19 The AMTO should also undergo external audits by an independent auditor, who is not part of the AMTO organisation. The purpose of external audits is to ensure that the training procedures and quality system of the AMTO are in compliance with the requirements of the regulation. The results of the external audits should be documented, and any corrective and preventive actions that need to be taken should be identified and addressed.

8.5.7.20 By meeting the requirements of DASR 147.A.130, AMTOs can ensure that their training programs are of a high standard and meet the requirements of the regulation, which can help to ensure the safety and effectiveness of maintenance operations in the aviation industry.

8.5.8 Military Aircraft Type Ratings

Introduction

8.5.8.1 Military Aircraft Type Rating Training consists of theory and examination, practical and assessment, plus On-the-Job Training (OJT) – see DASR 66.A.45(c) – for first aircraft in licence category/subcategory. Any subsequent Military Aircraft Type Rating (MATR) within the same category/sub-category require both theory and practical elements but will only require further OJT if stipulated by DASA during the approval of the course.

Note: A minimum of only theory and examination is required for the Category C Military Aircraft Maintenance Licence (MAML) rating (AMC 66.A.45).

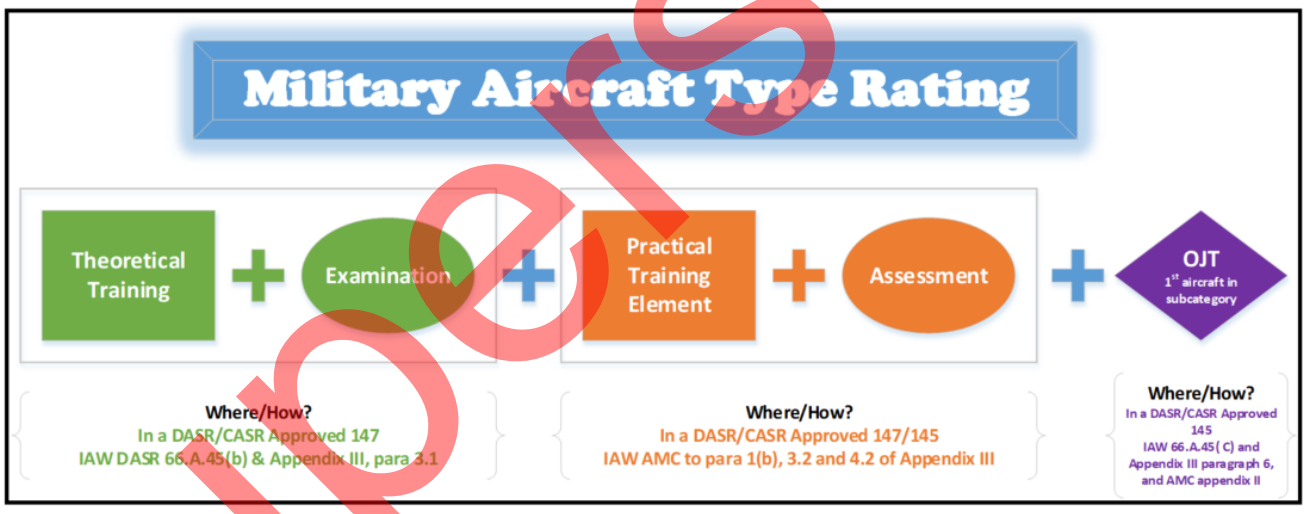

Figure 1: Military Aircraft Type Rating (MATR) - Required Elements

Privileges

8.5.8.2 In order to be entitled to exercise certification privileges for B and C categories on a specific aircraft type, the holder of a MAML shall have their MAML endorsed with the relevant Military Aircraft Type Ratings.

ADF Course Design and Development

Superseded

8.5.8.3 To ensure consistency across all ADF courses, the design and development of courses, including the course curriculum, should follow the System Approach to Defence Learning (SADL) – see SADL Website.

MATR Course – Initial Approval / Change Management

8.5.8.4 In order to facilitate approval by the authority, the following relevant DASR Forms are to be completed and submitted as appropriate:

1. DASR Form 12 - Application for DASR 147 Initial-Changes of Approval. The DASR Form 12 is the official DASA form to apply for a DASR 147 Maintenance Training Organisation approval. This form is considered part of an application pack and should be submitted with the appropriate evidence as detailed within the form to support the application.

2. DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval. The DASR Form 12A is to accompany the DASR Form 12 when the application is for an initial course approval. For an update to an existing approved course, only the completed Form 12A and associated evidence documents are required for submission.

8.5.8.5 As a minimum standard, the following documents must be submitted as evidence for MATR courseware approval:

1. Training Needs Analysis (TNA) or equivalent as accepted by DASA
2. Completed DASR 66 Appendix III MATR Courseware Assessment Matrix
3. MATR Theory Element (Learning Management Plan)
4. MATR Practical Element (Practical Training Logbooks)
5. On-The-Job-Training (OJT) logbook.

DASA Notification Requirements

8.5.8.6 Changes to MATR Courses shall be defined as either a Major or Minor Change.

8.5.8.7 A Major Change is any amendment, alteration or change to a MATR Course that is not accurately categorised as a Minor Change within the relevant Maintenance Training Organisation (MTO) Exposition procedure. A DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval must be submitted and approved prior to any Major Change to a MATR Course.

8.5.8.8 A Minor Change is any amendment, alteration or change to a MATR Course that does not affect the DASR related approval. Minor Changes may be acceptable to DASA without prior approval by the Authority; contingent to endorsement by the relevant MTO QMS that no adverse material effect is posed to safety, quality of training or the knowledge, skills and attitudes of course graduates, course learning outcomes or location.

8.5.8.9 An internally reportable process for approval of Minor Changes to MATR Courseware must be included within the relevant MTO Exposition/Annex; containing either a specific predefined listing of all actions, or defining statement considered by the MTO to fall within the scope of a 'Minor Change'.

8.5.8.10 Subject to the endorsement of the MTO QMS, listed actions could include (but are not limited to):

Superseded

1. Grammatical and typographic changes

2. Changes that incorporate updates from the relevant platform specific technical publications (e.g. updated maintenance procedures, configuration changes etc.)

3. Changes of content (provided the learning outcomes are not affected).

Theoretical Element of the Military Aircraft Type Rating Training

8.5.8.11 The theoretical element of the Type Course shall provide the person with detailed theoretical knowledge of the applicable systems, structure, operations, maintenance, repair, and troubleshooting of the aircraft type according to the approved maintenance data, including:

1. The appropriate use of manuals and approved procedures, including any relevant inspections and limitations;

2. How to perform system, power-plant and component functional checks as specified in the maintenance manual;

3. Related information for the purpose of making decisions in respect of fault diagnosis and rectification within the scope of the maintenance manual;

4. Describing procedures for replacement of components unique to the aircraft.

8.5.8.12 Theory training shall be conducted by an appropriately approved DASA 147 MTO or an organisation recognised by DASA.

8.5.8.13 In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA.

8.5.8.14 Theory training shall have been started and completed within the 3 years preceding the application for a MATR endorsement.

8.5.8.15 The minimum pass mark for the theoretical exam is 75%.

8.5.8.16 The theoretical type training shall describe how the type training is delivered (i.e. classrooms, training equipment, instructors qualifications, TNA etc.) meeting the requirements of DASR 66 and 147, as appropriate.

8.5.8.17 The course content and duration shall be demonstrated by:

1. a detailed curriculum showing the levels for each chapter of the type training, which should be assessed for equivalence to Appendix III to DASR 66 for the relevant certifying staff category; and

2. verifying that both content and duration are justified through a comprehensive TNA (or equivalent as accepted by DASA).

8.5.8.18 Evidence is required for the following elements:

1. the teaching methods and instructional equipment;

2. the material and documentation provided to the student;

3. the qualification of instructors, examiners;

Superseded

4. the documentation and records provided to the student to justify the satisfactory completion of the training course and related assessment.

Note: For further information about these elements, refer to the MTO exposition.

Practical Element of the Military Aircraft Type Rating Training

8.5.8.19 Practical training is a structured training activity that consolidates the knowledge gained during the theoretical phase of type training and as such, may be performed after or integrated within the theory training. Practical training should:

1. Address the different parts of the aircraft and its associated engines, which are representative of the structure, the systems/components installed and the cabin.
2. Include the use of technical manuals, maintenance procedures and the operational interfaces with the aircraft (e.g. FMC, electronic flight bag, etc.)
3. Include common maintenance and ground handling activities.
4. Cover both type specific and generic safety elements of the aircraft's maintenance.
5. Develop the student's competence in performing safe maintenance, prior to the practical assessment.

8.5.8.20 The purpose of practical training is not to include all the maintenance tasks associated with a particular type, but a representative sample of them that will allow the student to acquire the required knowledge, attitude and skills to safely carry out maintenance on that type.

8.5.8.21 The practical element of the MATR Training can be performed concurrently with the OJT element if both are performed on the same military aircraft type and in a real maintenance environment.

8.5.8.22 Practical training may be performed either following or integrated with the theoretical elements however, it should not be performed before theoretical training.

8.5.8.23 Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.24 Table 1 summarises the MATR Training requirements contained in DASR 66.A.45, and Appendix III to DASR 66.

Military Aircraft Type Rating Training requirements		
Aircraft Group	**B1/B2 MAML**	**C MAML**
All military aircraft are considered to be complex motor-powered aircraft	**Military Aircraft Type Rating Training:** Theory + examination Practical + assessment PLUS OJT (for first aircraft in licence category/subcategory. For subsequent Military Aircraft Type Rating within the same category/sub-category, further OJT only if required by DASA)	**Military Aircraft Type Rating Training:** Theory + examination Note: In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA

Table 1: Military Aircraft Type Rating Training requirements

Superseded

8.5.8.25 IAW AMC to Para 3.2 of Appendix III to DASR 66 - "The practical training may include instruction in a classroom or in simulators, but part of the practical training should be conducted in a real maintenance, or manufacturer, environment." It would be acceptable to complete practical training in a classroom or in simulators, if the practical training could be effectively delivered in this environment.

1. Practical training conducted in a real maintenance environment implies practical training on live aircraft or high fidelity maintenance training aids that are representative of the live aircraft. Practical training in a real maintenance environment should always be conducted on the highest fidelity training device reasonably available and include the use of maintenance data and specialist tooling.

2. Practical training should always be conducted in a real maintenance environment, where it is:

    i. the only reasonable method due to the complexity of the task, or

    ii. the only method available to enable familiarity with component location/ identification, or

    iii. the only method available to demonstrate the use of special equipment / tools.

8.5.8.26 Para 3.2 g. of Appendix III to DASR 66 states “The objective of practical training is to gain the required competence in performing safe maintenance, inspections and routine work…”. In the context of practical elements of the military aircraft type training, competence to perform safe maintenance, inspections and routine work does not require the actual performance of the maintenance (e.g. it is acceptable to use a live aircraft as a training aid without physical removal / installation of components). Practical training could be a visit to / walk around of an aircraft in the maintenance environment, identifying specialised tooling / equipment used on the aircraft, process walkthroughs for removal / installations tasks, and scenario based activities for troubleshooting. Practical training should also ensure students are knowledgeable in the use of technical literature, documentation, specialised tooling and test equipment.

8.5.8.27 Selected tasks should consist of a group of representative maintenance tasks drawn from the type training and examination curriculum, at the indicated level and shall cover all the relevant chapters described in the table contained in paragraph 3.2 of Appendix III to DASR 66.

8.5.8.28 The task curriculum must:

1. Be distributed in order to cover all applicable S1000D chapters.

2. Include all of the task categories (LOC, FOT, SGH, R/I, MEL, TS - Refer table 2 below) and may include others deemed appropriate to the type (e.g. ‘INS’pection, ‘ADJ’ustment).

3. Include an appropriate number of tasks in each task category for the aircraft type’s training requirements to be met.

4. Be sufficient to cover at least 50% of the crossed tasks in Appendix III to DASR 66 para 3.2. (Refer to “How should the 50% of tasks required for practical training be selected?” below).

Note: for further information on the S100D Specification refer to the following links on the DASA website. S1000D - International specification for technical publications.

Superseded

8.5.8.29 The duration of the practical training should ensure that the content of training required by paragraph 3.2 of Appendix III to DASR 66 is completed.

8.5.8.30 A record of the tasks completed should be entered into a logbook which should be designed such that each task or group of tasks may be countersigned by the designated assessor. The logbook format and its use should be clearly defined.

8.5.8.31 The practical element (for power-plant and avionics systems, armaments, escape systems and other relevant military-specific systems) of the MATR Training may be subcontracted by the approved DASA 147 organisation under its quality system according to the provisions of DASR 147.A.145(d)3 and the corresponding Guidance Material.

How should the 50% of tasks required for practical training be selected?

8.5.8.32 When selecting the tasks, the usage of a filtering method based on the criteria similar to that described in AMC to paragraph 3.1(d) of Appendix III to DASR 66, point 5f) is recommended.

8.5.8.33 The selection of 50% of tasks cannot be selected according to the glossary only (e.g. LOC, FOT, SGH, R/I, etc.):

1. Paragraph 3.2 of Appendix III to DASR 666 states that 'the tasks selected shall be representative of the aircraft and systems both in complexity and diversity'. In addition, the practical training should particularly address the tasks which cannot be explained by theoretical training only. While relatively simple tasks may be included, other more complex tasks shall also be incorporated and completed as appropriate to the aircraft type.

2. Guidelines on complex / simple tasks (taken from CASA AMC/GM Part 66, V7.4 of December 2024) are as follows:

   i. Complex tasks may have the following attributes:
   - involve several comprehensive steps to perform
   - have multiple decision points in order to complete
   - may use specialised test equipment
   - often requires more than one person to perform
   - have direct impact on flight safety

   ii. Simple tasks may have the following attributes:
   - does not use specialised test equipment
   - can be completed by a single person
   - does not require any in-depth skill/knowledge
   - does not involve decision steps (no troubleshooting)
   - may involve an on-board maintenance system BITE check to determine serviceability

3. How each task is selected (LOC, SGH, etc.), should be based upon the potential gains for the students' competency or its impact on safety. Availability should not be a

Superseded

reason to omit a pertinent task and consideration should be made to include a 'real maintenance environment' to complete an important or critical learning objective.

4. All pertinent sub-tasks, associated with the safe completion of each main task, such as Isolating mechanical/electrical systems, opening/closing CBs, locking flight controls, etc., should be included and the applicable aircraft maintenance manuals used.

5. Regarding the way to read the table in paragraph 3.2, each line aims to cover each of the main systems so that no line relevant to the particular aircraft type should be omitted in the selection. Inside each line applicable to the aircraft type, half or more of the crosses can be selected. From a learning point of view, selecting 2 simple tasks as LOC and SGH would not be "representative", while selecting LOC and TS, for example, would be much more appropriate of the aircraft and systems both in complexity and diversity.

6. The intent of the following tables are to provide a compliance report demonstrating that the practical type training meets the standard required by Appendix III to DASR 666. In particular, the tables shall indicate the percentage of tasks effectively performed against the tasks contained in the Appendix III to DASR 66 which are applicable to the aircraft type.

8.5.8.34 The following tables have been developed as a guide for assessment of MATR practical courseware elements. These tables are included in the MATR courseware assessment which can be found at the following link - DASR 66 Appendix III MATR Courseware Assessment Matrix. This assessment matrix should be completed by the MTO delivering the MATR practical type training in order to enable approval of courseware by the authority.

Percentage by Task Type

Type of task	Number of tasks applicable to the A/C type	Total number of tasks selected	Percentage (%) effectively performed against applicable tasks (should be at least 50% of the applicable tasks)
LOC			
FOT			
SGH			
R/I			
MEL			
TS			

Table 2 – Practical Task Training Requirements (By Task Type)

Superseded

Glossary of the table: LOC: Location; FOT: Functional/Operational Test; SGH: Service and Ground Handling; R/I: Removal/Installation; MEL: Minimum Equipment List; TS: Trouble-Shooting.

Percentage by Chapter

Chapter	Number of Practical Requirements for Each Chapter	Total number of Practical Elements Included Within Courseware	Percentage (%) included against applicable Chapter (should be at least 50% of the applicable practical requiorements within each Chapter)
05 Time limits / maintenance checks			
06 Dimensions/Areas (MTOM, etc.)			
.....			
99 Electronic Warfare			

Table 3 - Practical Task Training Requirements (By Chapter)

Practical Training Logbook

8.5.8.35 A Military Aircraft Type specific Practical Training Logbook (PTL) must be developed by a DASA 147 MTO, completed by the student and a certified true copy retained by the MTO delivering the training. It will record the training activities carried out during the practical training course and the subsequent assessment of trainee competence.

8.5.8.36 The PTL shall list all of the applicable S1000D systems, as specified within Appendix III to DASR 66, Section 3.2.

8.5.8.37 After the practical element of the MATR Training has been completed, an assessment must be performed, which must comply with the following:

1. The assessment shall be performed by designated assessors appropriately qualified (AMC to Appendix III).
2. The assessment shall evaluate the knowledge and demonstrated understanding of the trainee.

8.5.8.38 The PTL should include:

1. Trainee attendance sheet.
2. Course and Instructor’s details.
3. S1000D system number and title.
4. Aircraft Maintenance Manual or work-pack reference for each training task.
5. A list and detailed description of the training tasks.

Superseded

6. Each task must have a method of denoting the training technique (Synthetic, Aircraft registration, Classroom, etc.).

7. Task type (R/I, LOC, SGH etc.).

8. Date of each individual task completion.

9. Instructor signatures or stamps.

10. Spare entries for documenting additional/replacement “ad hoc” training tasks.

Note: Additional/replacement tasks must be of relevance to those they replace, be of benefit to the training objective and only replace planned tasks in exceptional circumstances.

8.5.8.39 EASA provide Practical type training logbook examples for both B1 and B2 PTL that can be used for guidance.

Practical Instructors and Assessors

8.5.8.40 In the majority of cases, the Practical instructor will be the same as that used for the Theory phase of the type training. They are a logical choice, as they possess an in-depth knowledge of the aircraft’s systems and will have developed an understanding of each student’s specific academic requirements.

8.5.8.41 Using the same instructor for both the Theory and Practical phases will often suit the business model of many organisations. In some cases, however, especially where a DASA 147 / DASA 145 affiliation exists, the organisation may choose to utilise experienced MAML holders / technicians, as appropirate, from their own maintenance workforce to deliver the Practical training.

8.5.8.42 These individuals must be given suitable training on the organisational processes involved, particularly the use of the Practical training record. It is recommended that they attended a train the trainer course, whether delivered by an external or internal source, which should specifically target the training techniques required for Practical training and set the organisation’s bench mark for the conduct of this training. They should be familiar with the tools or the techniques used by the training organisation to assess the competence of the practical abilities of trainees (maintenance simulators, mock up and etc.).

8.5.8.43 They should be experienced and show solid judgement regarding the abilities of the assessed trainees, they must have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks IAW current regulation, utilising approved procedures, maintenance practices etc. They should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated to maintain the system.

8.5.8.44 Workforce sourced Instructors will be qualified and managed by the DASA 147 organisation. Refer to DASR 147.A.105 for details.

8.5.8.45 They must be included in the list Instructional staff (point 1.5 of the MTOE) and be subject to the same Instructor records and update training requirements as the directly employed Instructors.

8.5.8.46 Practical assessments may be conducted by either the Practical Instructor or a dedicated assessor, who has undergone a similar training and qualification process to that detailed above.

8.5.8.47 Upon completion of the PTL, it must be reviewed, assessed and approved by the relevant DASA 147 in its entirety.

Superseded

OJT Element of the Military Aircraft Type Rating

8.5.8.48 OJT is required for the initial type rating being sought in each licence category or sub-category:

8.5.8.49 For example; If a B1.1/B2 MAML is endorsed with the P-8A type in the B1.1 category and the MAML holder wishes to add the P-8A in the B2 category, he/she will have to complete B2 related OJT representative of that aircraft and its systems.

8.5.8.50 If the same B1.1 MAML holder adds the B1.3 category to their MAML, and wishes to add their first helicopter type, he/she must complete OJT representative of that first helicopter type. Any subsequent MATR within the same category/sub-category will only require further OJT if stipulated by DASA during the approval of the course.

8.5.8.51 A DASA 145 maintenance organisation appropriately approved for the maintenance of the particular aircraft type can conduct OJT for that type rating:

1. The OJT content shall be approved by DASA (Appendix III to DASR 66, sec. 6) and supported by a detailed curriculum showing its content and recorded within detailed worksheets/logbook;
2. OJT tasks shall be signed off by the student and countersigned by a 'designated supervisor';
3. Final assessment of OJT is mandatory and shall be performed by a 'designated assessor';
4. It can be carried out in an approved DASA 145 maintenance organisation with a Category A rating (maintenance on aircraft) and the procedures for OJT should be included in the exposition (MOE chapter 3.15 "OJT procedure") approved by DASA.
5. Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.52 The OJT should include a sufficient number of tasks that are carried out under 'one to one' supervision (i.e. one supervisor dedicated to one trainee) and should involve actual work task performance on aircraft/components, covering line and/or base maintenance tasks.

8.5.8.53 AMC to Appendix II to DASR 66 contains a list of tasks, from which a representative sample appropriate to the type and licence (sub-) category applied for, should be extracted and approved by the MAA. The OJT should cover at least 50% of this approved extracted list.

8.5.8.54 Up to 50% of the required OJT may be undertaken before the aircraft theoretical MATR Training starts, noting that:

1. the ADF Initial Employment Training (IET) workplace journals are the primary means of meeting the practical requirements for the Defence Registered Training Organisation issuance of selected MEA Unit of Competency;
2. portions of these workplace journals may also be utilised as a means of meeting the requirements of OJT, as long as they are completed in a DASA 145, and on the

Superseded

platform/components which the individual is completing their Type Rating training (Appendix III to DASR 66, para 6).

8.5.8.55 If these journal tasks are not carried out on the aircraft type (or its components) required for their subcategory, then these tasks cannot be constituted as OJT.

8.5.8.56 As a minimum, the OJT procedure should describe the following elements:

1. Content of the OJT: the list of tasks that should be performed during the OJT or a list of generic tasks and the process how to develop a list of particular tasks out of this list of generic tasks,
2. Qualifications of the assessor and supervisors performing the OJT,
3. OJT logbook/worksheets format and content,
4. OJT compliance report format and content,
5. Production planning for the implementation of OJT (how to plan the tasks),
6. Supervision process and the assessment process, what to do if the assessment is not positive,
7. Safe release to service of the aircraft after OJT,
8. OJT Log Book final assessment process and associated forms:
    i. An OJT Logbook assessment is carried out on an OJT Logbook to ensure that all required tasks have been carried out and certified for in accordance with the OJT Logbook assessment procedure.
    ii. MTOE procedure and associated documents should contain a procedure for the final assessment of an OJT Logbook and who it is completed as well as any associated forms needed and who is qualified to carry out such assessment.

Note: AMC to Section 6. of Appendix III to DASR-66 should be used when defining the content of the procedure.

Practical Assessment Vs On the Job Training (OJT) for Military Aircraft Type Ratings

8.5.8.57 The objective of OJT is to gain the required competence and experience in performing safe, effective and efficient maintenance. The practical assessment addresses the practical portion of any type training, whereas the OJT assessment addresses the additional hands-on experience necessary in a true maintenance environment as part of the first type rating in a (sub)category, as illustrated by the table below:

Superseded

Practical Assessment Vs On the Job Training		
	Practical Assessment	**OJT Assessment** ***For the purpose of DASR 66.A.45(c)***
What/Who is assessed	Candidates following practical element of Military Aircraft Type Ratings training.	Completeness of OJT
	Reference: 66.A.45 (a)(b); Appendix III, 4.2.; AMC Appendix III	Reference: 66.A.45 (c); Appendix III, section 6; AMC to Section 6 of Appendix III
Function of assessor:	To perform the final evaluation of the knowledge, skills and attitude of the trainee following the practical element of the type training	To conduct the final assessment of the completed OJT, whereas the candidate's competence is indirectly justified.
	Reference: Appendix III 4.2.; AMC Appendix III	Reference: Appendix III, 6.; AMC to Section 6 of Appendix III 8.
Organisation :	• DASA-147 • Approved maintenance environment (DASR-145, M.A. Subpart F with A rating, manufacturer) under the DASA-147 approval • Defined maintenance environment as described in the direct approved procedure by the competent authority	Always in a maintenance organisation approved under DASA-145 with an aircraft rating.
	Reference: Appendix III 1(b)	Reference: Appendix III 6.; AMC to Section 6 of Appendix III 1.
Objectives:	To evaluate if the candidate has gained the required competence in performing safe maintenance, inspections and routine work according to the aircraft documentation and other relevant instructions and tasks as appropriate for the type of aircraft.	To confirm the completion of the required diversity and quantity of OJT, based on the supervisor(s) reports and feedback. It is sufficient that the completion of individual OJT tasks is confirmed by the direct supervisor(s), without necessary being the direct evaluation of the assessor.
	Reference: Appendix III, 3.2.	Reference: AMC to Section 6 of Appendix III 7. & 8.
Type of assessment:	The assessment may be: • diagnostic (prior to a course), • formative • summative (partial or final evaluation) • performed task-by-task • performed as a group of tasks • partly executed on simulation devices • performed as a final assessment	• Continuous during OJT (confirmed by the direct supervisor) • Summative, as a final evaluation by a designated assessor of the completeness of the OJT (based on the supervisor(s) reports and feedback)
	Reference: AMC to DASR-66 Appendix III 2)	Reference: AMC to Section 6 of Appendix III to DASR-66
Qualification of the assessor:	The assessment shall be performed by designated assessors appropriately qualified. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Guidance about the qualification is given in AMC to DASR-66 Appendix III 3.)	The OJT shall be assessed by appropriately qualified and designated assessors. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Guidance about the qualification is given in AMC to DASR-66 Appendix III 3.)
	Reference: Appendix III 4.2.; AMC to DASR-66 Appendix III 3.	Reference: Appendix III 6.; AMC to DASR-66 Appendix III 3.
Procedure included in:	DASR 147 MTOE	DASR 145 MOE

Table 4 – Practical Assessment Vs On the Job Training

Practical DASR 147 MILITARY AIRCRAFT TYPE TRAINING LEVELS VS SERVICE LEARNING LEVELS

Superseded

The following table provides guidance on the correlation between the DASR Military Aircraft Type Training levels (TL), Air Force (MAFET) Learning Levels (LL), Army (ATI 1-3/20), SADL TLs and Navy LLs;

DASR		RAAF			ARA			SADL		RAN
TL	Description	LL	Definition	Description of graduate	LL	Definition	Assessment	TL	Description	
1	Graduate is: • Able to define descriptions and maintenance practices • Identify appropriate manuals and maintenance practices • Define layout of major systems • Define layout and characteristics of power plant • Identify special tooling and testing equipment	1	Training provides background knowledge only. It is familiarising in nature or is an introduction to further training.	The graduate has completed learning that either has no clear links to identified workplace requirements or supports underpinning knowledge, skills or range of variables.	1	**Low** - Unable to perform, little to no experience.	Skill and Knowledge are not assessed, but confirmation of learning may occur during training	1	Trained, but not against a prescribed standard.	Navy do not use Training Levels.
N/A		2	Trained to a level below that required for successful assessment against identified workplace requirements, without further training and/or practice.	The graduate has limited knowledge and has performed components of, but not the complete task, during training.	2	**Basic** - Limited in ability or knowledge, needs significant help from others.	Skill and Knowledge are assessed against a restricted set of performance criteria	2	Partially trained against a prescribed standard.	
2	Graduate is able to: • Understand theoretical fundamentals • Apply knowledge in a practical manner • Recall safety precautions • Describe systems and aircraft handling • Identify locations of principal components • Explain normal functioning of major systems • Perform procedures for servicing • Demonstrate proficiency in interpreting crew reports and reporting systems and determine airworthiness • Demonstrate the use, interpretation and application of appropriate documentation	3	Trained to the level to achieve the identified workplace requirement, but unable to be assessed in the context of the training environment. Subsequent experience and assessment using the prescribed workplace requirements or UoC is needed in the workplace environment.	The graduate is trained and ready for assessment against the identified workplace requirements or UoC. The graduate will be aware of common problems in standard workplace contexts but will likely encounter new situations with limited confidence.	3	**Demonstrable** - Able to perform at basic level, has some experience, needs help from time to time.	Skill and Knowledge are to be formally assessed against a set of defined performance criteria.	3	Fully trained and ready for assessment against prescribed standard.	
3	Graduate is able to: • Demonstrate theoretical knowledge of systems, structures and their relationship with other systems. Provide detailed descriptions and interpret results applying corrective action where appropriate • Perform checks as specified in maintenance manuals • Demonstrate use, interpretation and application of appropriate documentation • Correlate information for the purpose of decision making • Describe procedures for replacement of components	4	Trained to the level required to achieve the workplace requirements, without the need for further workplace training or practice. Assessment, using the prescribed workplace requirements or UoC, is completed in training environment.	The graduate is trained and assessed, and can be employed effectively on the job. The graduate will be able to cope with common problems in standard workplace contexts and will encounter new situations with moderate confidence.	4	**Advanced** - Capable and experienced, demonstrated proficiency, able to work independently with little help.	Skill and Knowledge are assured under defined employment conditions	4	Trained and assessed competent against the prescribed standard.	
N/A		5	Training reflects outcomes related to values and/or feelings prescribed for the workplace.	The graduate has chosen a certain course of personal action, as prescribed for the workplace.	5	**Expert** - Fully capable and experienced, sought for help by others, needs no assistance to complete tasks, ability to train and lead others, seen as SME.	Skill and Knowledge are internalised by practice and reflection and expressed as autonomous professionalism	N/A

Superseded

8.5. Aircraft Maintenance Training Organisations

8.1 Introduction

8.1.1 This chapter is intended to provide additional guidance on continuing airworthiness regulations to supplement the DASR (DASP Manual Volume 2). This chapter provides additional guidance on aviation safety outcomes that may incorporate compliance with multiple regulations.

8.1.2 The sub-chapters within this chapter are associated with Continuing Airworthiness Management, Maintenance Organisations, Maintenance Licencing and Maintenance Training Organisations. These sub-chapters will also reference, where appropriate, other chapters and sub-chapters within DASP Manual Volume 3 for common aviation safety elements (e.g. occurrence reporting). Other DASP content relevant to continuing airworthiness will also be referenced where possible.

8.1.3 This chapter will contain information that has historically been communicated via Factsheets, Advisory Circulars (ACs) and Frequently Asked Questions (FAQs). In some instances, these historical methods of communicating guidance will remain – particularly for guidance that has a limited period of applicability or when inclusion in DASP Manual Volume 3 is not an intuitive way to communicate specific information. Use of separate Factsheets, enduring ACs and FAQs will be the exception, with the intent that DASP Manual Volume 3 to be the central repository for continuing airworthiness guidance outside of DASR.

8.1.4 The content in this chapter will evolve as the need for additional guidance is identified, with new content and/or new sub-chapters being added over time to support optimal capability outcomes. Accordingly, DASA welcomes any suggestions for future continuing airworthiness guidance noting that awareness training is available via the DASA website.

8.2 Continuing Airworthiness

8.2.1 Continuing Airworthiness Management

Introduction

8.2.1.1 The following chapters provide additional guidance on DASR M regulations – they cover activities such as Deferment of Defects, Acceptance of Components and Aircraft Maintenance Programs.

8.2.1.2 The Continuing Airworthiness Management Organisation (CAMO) should be principally located within the aircraft's operational organisation, although the majority of DASR M functions may be outsourced/assigned to other organisations or service providers.

8.2.1.3 Continuing airworthiness management regulation is summarised in the requirements of DASR M.A.101 as 'This [DASR M] establishes the measures to be taken to ensure that [continuing] airworthiness is maintained, including maintenance. It also specifies the conditions to be met by organisations involved in such continuing airworthiness management'.

Superseded

8.2.1.4 Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including other chapters of DASP Manual Volume 3.

DASR M - Continuing Airworthiness Management

8.2.1.5 CAMOs are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided. The scope of continuing airworthiness management activities should be in accordance with the Operating Organisation's policy and procedures defined in the Continuing Airworthiness Management Exposition (CAME). The CAME is approved by DASA and sets out the procedures, means and methods of how the CAMO intends to comply with the requirements of DASR M. A list of key management positions will be listed in the CAME. The CAME also includes all functions and privileges required to ensure the aircraft are maintained in an airworthy condition, the issue of Military Airworthiness Review Certificates (MARC), and/or changes to the Aircraft Maintenance Programme (AMP). Additional Information on gaining DASA approval to become a CAMO can be found in Chapter 5.3 Annex H –CAMO.

8.2.1.6 CAMOs are responsible for ensuring that maintenance of aircraft is performed by an organisation approved by DASA or another organisation acceptable to DASA. A maintenance organisation is acceptable to DASA if its services are accessed in accordance with the terms of a recognition certificate.

8.2.1.7 Recognition certificates may enable a CAMO to fulfil the aircraft Certificate of Release to Service (CRS) requirement using a maintenance organisation not approved by DASA. These provisions are applicable where DASA has recognised another airworthiness authority in the area of aircraft maintenance. Chapter 6.5, Recognition of Other Aviation Safety Authorities, provides further guidance on the application of recognition.

8.2.1.8 Recognised systems may include an artefact equivalent to an aircraft CRS; however, maintenance organisations may be prevented from issuing a native artefact against a Defence-registered aircraft by legal or policy constraints. Instead, the CAMO should request an artefact that meets the requirements set out in DASR M.A.801.

Airworthiness Directives

8.2.1.9 Airworthiness Directives (ADs) mandate actions to be performed on an aircraft to restore an acceptable level of safety. Furthermore it is mandatory that CAMOs comply with any AD applicable to its aircraft, guidance on Airworthiness Directives can be found in Section 7.4.3 – Airworthiness Directives.

Data for modifications and repairs

8.2.1.10 DASR M.A.304(d) provides for the consumption of data already approved within a recognised airworthiness framework. A CAMO may consume data for repairs and 'minor' modifications when the data is produced by an organisation accepted by DASA. An organisation is accepted by DASA if its design products are being accessed in accordance with the terms of a recognition certificate and a suitable procedure. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. The suitability assessment will consider, among other things, the effect of the design classification and its compatibility with the ADF Configuration, Role and Environment (CRE). Additional guidance can be found in Section 7.2.4 – Repair Designs.

Superseded

Aircraft continuing airworthiness record system

8.2.1.11 An Authorised Release Certificate is necessary for the release to service of either new or used components. It is a document issued by an entity that has the applicable privilege and attests that a new or used component has been produced or maintained in accordance with the approved design data/standard, modification standard or applicable maintenance data. Additional guidance on tracking status of service life-limited components and other usage data for aircraft structures and propulsion systems can be found in Chapter 6.6.4.

Airworthiness review staff

8.2.1.12 Airworthiness review entails a full documented review of the aircraft records and a physical survey of the aircraft. Airworthiness Review Staff are authorised by the CAMO and accepted by DASA to perform Airworthiness Reviews on aircraft which are listed on the CAMO approval certificate.

8.2.2 Operation of an Aircraft with a known Defect

Introduction

8.2.2.1 This chapter provides direction on what constitutes a Defect, how Defence aircraft can operate with a known defect and who can authorise an aircraft to operate with a known Defect.

Background

8.2.2.2 To meet the demands of operational availability, where it is not reasonably practicable to rectify defects, deferment of defects may be considered. The regulations provide Operators the flexibility to defer defects once assessed. The mechanism used should ensure due consideration is given to the impact to capability and safety. Organisations should ultimately prioritise, to the maximum practicable extent, rectifying defects prior to operating an aircraft.

What Constitutes a Defects?

8.2.2.3 A defect is an imperfection that impairs the structure, composition, or system of a product part or appliance or exceedance of operational limitations in the Instructions for Continuing Airworthiness (ICA).

Defect Management

8.2.2.4 Defects can be identified during operations or during the conduct of maintenance. However, regardless of how a defect is identified the CAMO must ensure that all defects discovered or reported are managed appropriately until rectified by a DASR 145 AMO. Annex A outlines the process for defect deferment.

8.2.2.5 Where a defect cannot be rectified before the next flight due to operational requirements, lack of spares or unavailability of maintenance services the CAMO may IAW a DASA approved procedure described at AMC M.A.301(a)(2) choose to defer the defect until it is reasonably practicable to rectify.

Deferment Options

Superseded

8.2.2.6 Deferment of MEL/CDL allowable defects can be accomplished by a DASR 145 AMO or Operator in compliance with the relevant aircraft technical log procedures. MEL/CDL allowable defects are subject to acceptance by the aircraft commander.

8.2.2.7 Where a MEL/CDL does not exist and there is credible data available, IAW GM M.A.301(a)(2), a determination can be made as to the impact to airworthiness for the aircraft. AMC M.A.301(a)(2) allows the CAMO to defer such a defect IAW a procedure documented in the CAME and approved by the MAA.

8.2.2.8 The procedure must ensure:

1. Airworthiness[1] is maintained, using only credible data, in the defect deferment determination;
    i. Within the context of Airworthiness, 'without significant hazard' is considered to mean that no credible hazard exists that would impact airworthiness.
    ii. A non-credible hazard is a defect that is considered so implausible as to its affect on Airworthiness that it does not need to be accounted for. To manifest into an Issue would require a series of exceptional failures or conditions to happen simultaneously making it impractical to consider for a given operational period.
2. potential hazards arising from the cumulative effect of any combination of defects and restrictions/limitations on the same aircraft are considered as to the impact on airworthiness;
3. deferred defects are documented in the continuing airworthiness record system, including the deferment period and any associated limitations/restrictions as described at M.A.306(a);
4. any conditions, limitations or restrictions are clearly identified and visible to aircrew;
5. monitoring on a continuous basis, defects occurring in flight and defects found during maintenance, highlighting any defects that are repetitive;
    i. Where repetitive defects are identified the CAMO may develop a list of pre-assessed defects that have been documented with consideration to the requirements of the DASA approved procedure. However, the accountability remains on the authorised person approving the defect to ensure the context in which the credible data used to assess the defect and the aircraft condition remains appropriate for the specific pre-assessed defect application.
    ii. In each instance of a pre-assessed defect MTCH engagement should be sought. This will allow consideration of inclusion of the repetitive defect in the relevant platform MEL/CDL or review of existing ICA for possible improvements.
6. Persons who determine whether a defect affects Airworthiness are competent and authorised to defer defects.

8.2.2.9 The procedure should also address how ongoing analysis of the effectiveness of the CAMO's defect control system is carried out.

Superseded

8.2.2.10 If the defect does not allow the aircraft to remain airworthy the Operator may seek to use the following for ongoing operations:

1. Military Permit to Fly, or
2. Command Clearance.

8.2.2.11 Where the CAMO has contracted/tasked the day-to-day control of aircraft technical log deferred defects to another Organisation or the DASR 145 has identified a defect in the course of maintenance that entity may defer that defect IAW M.A.306 (a) subject the following:

1. The defect has been assessed using maintenance data defined in DASR 145.A.45, by appropriately authorised certifying staff IAW DASR 145.A.48 (c), as not a Hazard to flight safety;
    i. Authorised certifying staff may only use maintenance data, as defined through DASR 145.A.45 in making an Endangerment to Flight Safety Assessment (EFSA). The authorised certifying staff may only consider the consequence of failure to determine if a defect hazards flight safety.
    ii. If available maintenance data is insufficient to enable a data driven assessment to identify if the defect either does or does not hazard flight safety the DASR 145 should seek additional maintenance data from the CAMO. If further maintenance data is not available or a definitive assessment cannot be made then the defect is to be processed as if it does hazard flight safety.
    iii. Where a defect does hazard flight safety this does not preclude the CAMO from operating the aircraft. However, the CAMO must establish, for the context of the intended aircraft operation, through the procedure described under 8.2.2.1 that the aircraft remains airworthy with the defect deferred.
2. potential hazards arising from the cumulative effect of any combination of defects and restrictions/limitations has been considered as to the impact on the Flight Safety Assessment; and
3. CAMO has been notified as described under DASR 145.A.48 (c) of the defect and agrees to its deferment.

8.2.2.12 Where a CAMO does not agree to the deferment of a defect they are to task a DASR 145 MO as described under DASR M.A.201(g) to rectify the defect.

Annex:

8.2.3 Alternate Artefacts

Introduction

8.2.3.1 This chapter provides additional guidance on acceptance of components – specifically the acceptance of alternate documentation, where components are not supplied with a DASA Form 1 or equivalent recognised document.

8.2.3.2 The introduction of DASRs brought with it a change to the information requirements accompanying components to be consumed on ADF aircraft. DASRs require that components be supplied with a DASA Form 1, or recognised equivalent, that declares the airworthiness of a component.

8.2.3.3 This chapter relates to the acceptance of new and used aircraft components, which are listed by the appropriate design organisation as eligible for installation in/on a product and included in the design data approved by the Authority[1]. The term components broadly covers any product (other than complete aircraft), part or appliance that is, or is intended by its manufacturer to be, a part of or used in operating an aircraft in flight, or is installed in or attached to a product. This may include any self-contained part, combination of parts, assembly, subassemblies or units, which perform a distinctive function necessary to the operation of the airframe, engine, or propeller, or may include any other instrument, mechanism, equipment, apparatus, software or accessory, including communications equipment.

8.2.3.4 Although alternate artefacts are consumed by a DASR 145 Approved Maintenance Organisation (AMO), DASA requires the relevant CAMO to seek approval for and manage the ongoing validity of alternate artefacts for their respective platforms. Further detail on alternate artefacts can be found in Chapter 8.3.4 – Acceptance of Aircraft Components

What constitutes an 'alternate artefact' accepted by DASA?

8.2.3.5 DASA may agree that an AMO may consume an alternate artefact other than a DASA Form 1, or recognised equivalent Authorised Release Certificate, that is produced by an organisation accepted by DASA. A CAMO can seek approval of an Alternate Artefact from DASA using DASR Form 155 – Application for Acceptance of Alternate Artefact. AMC to DASR M.A.201(g) and M.A.802(c) provide detail on when an alternate artefact would be acceptable. Chapter 8.3.4 – Acceptance of Aircraft Components provides further detail.

Consumption of United States (US) Department of Defence (DoD) products

8.2.3.6 There has been confusion with consumption of US DoD supplied products where associated documentation, such as DD Form 250, does not meet the requirements of a DASA Form 1 or recognised equivalent. The DASR provide a path for the regulated community to accommodate the consumption of products where the product supplied does not meet the requirements of a DASA Form 1. This is:

1. AMOs and CAMOs comply with DASR 145.A.42 and DASR M.A.201 (g) (e.g. via direct recognition or DASR Form 155 Application for Acceptance of Alternate Artefact).
2. Where (a) above is not reasonably practicable, CAMOs can develop a procedure within their exposition to demonstrate to DASA how these products can be consumed whilst maintaining an equivalent level of protection. DASA will then assess this procedure against the requirements of DASR GR.80(b), and if appropriate, approve the procedure for use.
3. Where (a) is not reasonably practicable, and an equivalent level of protection cannot be ensured (b), CAMOs can develop a procedure within their exposition to demonstrate to DASA how these components will be consumed; accompanied by a demonstration that the resultant risks are appropriately managed by the applicable MAO. DASA will then assess this procedure against the requirements of DASR GR.80(c), and if appropriate, allow the use of the procedure.

Superseded

8.2.4 Aircraft Maintenance Programme

Introduction

8.2.4.1 This chapter provides guidance on Aircraft Maintenance Programmes (AMPs) and Reliability Programmes (RPs).

Aircraft Maintenance Programme (AMP)

8.2.4.2 DASR M.A.302(a) requires that maintenance of each aircraft shall be organised in accordance with an AMP. The AMP encompasses the actual maintenance programme in its entirety. An AMP provides the scheduled maintenance tasks, their associated maintenance procedures and standard maintenance practices that are applied to the maintenance of an aircraft. The RP, which continually reviews the applicability of the AMP to the aircraft and operator, is also considered a part of the AMP.

8.2.4.3 Guidance on the application and approval of AMPs can be found in Chapter 5.3 Annex T – AMP with additional guidance in Chapter 6.6.4 (particularly guidance on how integrity programs can support the development and ongoing validity of the AMP).

Extension of promulgated maintenance interval

8.2.4.4 If a contracted/tasked maintenance organisation advises the CAMO that the maintenance cannot be carried out by the required timeframe and requests an extension of the promulgated maintenance interval, the CAMO when processing the request for an extension, has the following options available:

1. where the packaged/promulgated interval is less than the engineering justified interval, extend the interval up to a maximum of the engineering interval;
2. extend the task interval using the CAMO's indirect approval procedure, if suitably privileged, either once-off or permanently,
3. request DASR 21J design support for the requested interval extension; or
4. utilise the Command Clearance process to operate the aircraft IAW DASR M.A.301(a)(2) .

8.2.4.5 **Extending the Packaged Interval.** Interval flexibility may exist between a maintenance task's packaged/promulgated interval and its engineering/design interval in the AMP. The task may be packaged at a lesser interval maintenance efficiency due to tasks required in the same area or aligning maintenance to be conducted in blocks. If this is the case, and provided the CAMO has the underlying analysis that identifies the engineering interval and the reasons why the task was packaged at a lesser interval, the CAMO may authorise an extension to the packaged interval up to a maximum of the recorded engineering interval.

8.2.4.6 **Extend the AMP Task Interval.** If the AMP task interval has been reached, the CAMO may have sufficient data to extend the AMP task interval either once off, for a defined period, or permanently. To amend the AMP the CAMO must have the privilege from the MAA and sufficient scope as agreed in the indirect approval procedure. Note: where a task's interval has been extended permanently, the task may still be packaged as desired (not exceeding the extended interval).

Superseded

8.2.4.7 **Request DASR 21J Design Support.** If the two options at para 8.2.4.4a and b above are not applicable, the CAMO may request DASR 21J design support to either extend the interval once off, for a defined period, or permanently.

8.2.4.8 **Utilise the Command Clearance process.** DASR M.A.301(a)(2) contains provisions for the Operating Organisation to deviate from the Initial / Continued / Continuing regulations.

8.2.4.9 For servicings with multiple tasks, the decision on extending the interval and the method used will be dependent on the individual circumstances of each task within the servicing. A combination of paragraphs 8.2.4.4a to d may be necessary.

8.2.4.10 Note, that extending a maintenance task beyond its promulgated interval may reduce the preventive effect of the task by increasing the risk of exposure to the failure consequences of the failure mode being addressed. Extension of maintenance could adversely affect the operational capability and/or safety of the aircraft. Also, the percentage by which the interval is extended does not universally reflect the increase in risk in exposure to the failure consequences of the failure mode(s) the task is addressing. The increase in risk with the extension of a task's interval needs to be assessed individually based on the underlying Reliability Centered Maintenance (RCM) analysis that justified the existing interval and the context in which the interval extension is being asked.

8.2.5 Airworthiness Review

Introduction

8.2.5.1 This chapter provides guidance on Airworthiness Reviews (AWRs) to supplement the AMC M.A.710(a)

Airworthiness Review

8.2.5.2 During airworthiness review of an aircraft, the airworthiness review staff must examine continuing airworthiness records for the aircraft and perform a physical survey of the aircraft to determine whether the aircraft continues to comply with the airworthiness requirements as set out in DASR M.A.710(a) and DASR M.A710(b).

8.2.5.3 For many aircraft, the quantity of records that must be examined and the level of examination required will be extensive. It is anticipated that the airworthiness review staff will be assisted by other employees of the CAMO and/or appropriately experienced personnel in this regard. This does not prevent other personnel from assisting to retrieve records, compile information and prepare reports etc. for the examination by the airworthiness review staff. However, it is up to the airworthiness review staff carrying out the airworthiness review to be satisfied with the source, authenticity and accuracy of the information made available to them.

8.2.5.4 The airworthiness review staff are expected to have a level of understanding of the continuing airworthiness records system for the aircraft that allows them to carry out the review without error.

8.2.5.5 **Rectification of defects.** AWR staff shall examine the aircraft's continuing airworthiness record system to determine if any defects need rectification before flight. Defects that require rectification before flight must be rectified before the issue of an airworthiness review certificate.

Superseded

8.2.5.6 **Deferred defects.** AWR staff shall examine the existing deferred defects as recorded in the aircraft's continuing airworthiness record system to determine whether deferral of rectification has been carried out.

8.2.5.7 **Airworthiness Directives (AD).** AWR staff shall examine the records containing compliance with ADs to determine whether actions required by each AD that applies to the aircraft, product, parts or appliances fitted to the aircraft have been complied with. An examination of documents that substantiate each AD has been complied with should verify that information kept is correct. Examples of documents that may substantiate an AD has been complied with, includes:

1. maintenance records for maintenance carried out on the aircraft;
2. copies of authorised release certificates for product, parts or appliances; and
3. log books for products such as engines and propellers.

8.2.5.8 For a product, parts or appliances, the document that substantiates compliance with the AD should relate to the product that is identified in the records by part number and serial number.

8.2.5.9 Where an AD requires compliance with requirements contained in another document such as a service bulletin (SB), a record of compliance with the service bulletin would be acceptable as evidence of compliance with the AD.

8.2.5.10 **Modifications.** AWR staff shall examine the records of modifications kept to determine whether there is a DASR 21 (see DASR M.A.304—Data for modifications and repairs) approval for each design of the modification. For the purpose of this paragraph, a modification includes a repair that involves change to the approved design of the aircraft.

8.2.5.11 **Life Limited Components**. AWR staff should examine the records of life-limited components kept to determine whether part number, serial number, has correctly identified each life-limited part and whether the life limit has been exceeded for any of the parts.

8.2.5.12 In addition, documents that have been used to substantiate remaining life at installation shall be checked to verify that information kept for life-limited components is correct. Examples of such substantiating documents include:

1. maintenance records for installation of the parts;
2. authorised release certificates for the parts; and
3. life limited component history/log card.

8.2.5.13 **Weight and Balance.** AWR staff shall examine the record of the aircraft's weight and balance kept to determine if it is consistent with all the changes made to the weight and balance since the last weighing of the aircraft. All changes made to the weight and balance should be substantiated by documents such as a modification approval and an equipment list for the aircraft.

8.2.5.14 **Aircraft Configuration.** AWR staff shall examine the aircraft's continuing airworthiness records to determine whether the aircraft's configuration as recorded complies with the specification in the military type certificate data sheet (TCDS) for the aircraft, engine and propeller.

8.2.5.15 **Findings.** All findings discovered during an airworthiness review should be documented and managed in accordance with the CAMO's quality management system / safety management system, consistent with requirements of M.A.905.

Superseded

8.2.6 Master Minimum Equipment List (MMEL) and Minimum Equipment List (MEL)

Introduction

8.2.6.1 This chapter provides guidance on Master Minimum Equipment List (MMEL) and Minimum Equipment List (MEL) development and approval.

Background

8.2.6.2 Under certain conditions the required level of safety can be maintained with specific aircraft components being unserviceable, for a limited period of time, until repairs can be made. Many aircraft also have equipment installed that is not required for safe operation under certain operating conditions (e.g. aircraft with multiple VHF radios can operate with single radio if operations do not require the use of the systems associated). Equipment, such as entertainment systems, galley equipment, mission equipment or systems, may have no impact of flight safety.

8.2.6.3 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment, based on the aircraft type certification. An MEL consists of an approved list of the specific unserviceable equipment for a particular aircraft by serial and registration mark, based on the MMEL and the Operator's Configuration, Role and operating Environment (CRE).

8.2.6.4 An MEL can be used as the first step in a defect management process in accordance with procedures developed by the CAMO and approved by the DASA to meet the requirements of DASR M.A.301 (a) 2, for the deferral of defects.

8.2.6.5 Useful background information when developing a MEL can be found in:

1. CASA CAAP 37-1(5) - Minimum Equipment Lists (MEL)
2. EASA Rules for Master Minimum Equipment List (CS-MMEL)

DASA Regulatory Basis

8.2.6.6 DASR GM 21.A.15(a) - Application for a Military Type Certificate may include the MMEL as Operational Suitability Data (OSD) that may be approved as part of Type Certification and form part of the Military Type Certificate (MTC) .

8.2.6.7 DASR M.A.301 Continuing airworthiness tasks, refers to MEL and Configuration Deviation List (CDL) for use in the deferment of defect rectification.

8.2.6.8 DASR AO Gen.05 Management of OIP, ORO.05 Conduct of Flying Operations and ORO.30 Flight Authorisation support discharging flight operations requirements referred to in this chapter.

Configuration Deviation List

8.2.6.9 A Configuration Deviation List (CDL) is a listing of regulator-approved non-structural external parts that may be missing but the aircraft remains airworthy. A CDL provides options to dispatch an aircraft for flight when listed parts may be missing, provided the necessary performance corrections are adhered to (including limits or restrictions if required and specified rectification periods). Refer DASR M.A.301(a)2 and associated AMC/GM.

Superseded

8.2.6.10 CDLs are part of the certified type for any civil derivative aircraft (certified by the European Aviation Safety Agency (EASA) or the Federal Aviation Administration (FAA)). Within the ADF context, as part of Military Type Certification, the CDLs are presented as part of the Aircraft Flight Manual (AFM) for approval during Type Certification. Usually, they are contained in a standalone section of the AFM. The AFM is approved as part of Military Type Certification (DASR 21 Subpart B) and changes would be approved under (DASR 21 Subpart D).

8.2.6.11 The CDL should not be confused with the Minimum Equipment List (MEL). While the MEL describes the limitations of aircraft operation in case of a system being inoperative or having malfunctioned (e.g. transponder failure), the CDL deals with situations where external parts of an aircraft are missing (e.g. fairings, aerodynamic seals or panels).

MMEL

What is a MMEL?

8.2.6.12 A MMEL is a document created specifically to permit the continued operation of an aircraft type (e.g. C-130J-30) with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL does not take into account the operating circumstances of individual operators of that type. The MMEL cannot, in itself, be regarded as providing operational permission. It can, however, be the basis for the development of an individual Operator's MEL.

MMEL Characteristics

8.2.6.13 **Aircraft Type.** MMEL relief for a particular item may be unique to a specific aircraft type. Therefore, MMEL relief for an item for one aircraft type may not be the same as the relief allowed for the same item found in another aircraft type.

8.2.6.14 **Items required by an Airworthiness Directive (AD) are prohibited.** An MMEL will not include items that an AD requires to be operative, unless the AD specifically allows them.

8.2.6.15 **Variable Number of Items Required for Dispatch.** A MMEL may depict a variable number of items required for dispatch based on various makes and models of the same series aircraft. The MMEL must clearly articulate which makes and models each MMEL item is applicable to.

8.2.6.16 **Multiple Versions of the Same Item.** A MMEL may contain multiple versions of particular items (e.g., very high frequency (VHF) communications systems and fire extinguishers) that are installed on different models or series of the aircraft covered by the MMEL. The MMEL must clearly articulate which versions each MMEL item is applicable to.

8.2.6.17 **Repair Categories.** A MMEL will contain a repair category for each item. Each repair category allows for a certain amount of time until repairs must be accomplished.

8.2.6.18 **Prohibited Items.** A MMEL will not include items of the aircraft that are required for basic flight (wings, flaps, rudder, etc.), nor will it include instruments and equipment required for specific operations.

MEL

What is a MEL?

Superseded

8.2.6.19 A MEL is a document created specifically to manage the continued operation of an aircraft with unserviceable equipment consisting of an approved list of the specific unserviceable equipment for a particular make and model of aircraft by serial/production number and registration mark (e.g. C-130J-30, 5440, A97-440) as applicable. Its use is authorised by accepting the associated application procedures contained in an operator's Continuing Airworthiness Management Exposition (CAME) and/or operations manual, or other appropriately documented procedures.

MEL Transferability

8.2.6.20 An approved MEL for an aircraft is a non-transferable document, i.e. if the MAO of the aircraft changes, then a new approval for the MEL is required even if the aircraft retains the same registration mark.

8.2.6.21 If an aircraft moves from one Military Air Operator Certificate (MAOC) holder to another, the new MAOC holder cannot automatically use the approved MEL for the aircraft. The new MAOC holder will be authorised by DASA only if they have acceptable associated application procedures contained in their CAME and/or operations manual and have assessed the operator's CRE.

Use of the MMEL/MEL

MMEL/MEL Considerations for Use

8.2.6.22 The MMEL/MEL is an alleviating document. Its purpose is not to encourage the operation of aircraft with unserviceable equipment. It is never desirable that aircraft continue operations with unserviceable equipment. Such operations are permitted only as a result of careful analysis of each item to ensure that the required level of safety is maintained. A fundamental consideration in permitting the operation of aircraft with unserviceable equipment is that the continued operation of an aircraft in this condition is to be eliminated or otherwise minimised so far as reasonably practicable (SFARP).

Invoking the MEL

8.2.6.23 The Aircraft Captain or appropriately licenced and authorised Military Aircraft Maintenance Licence (MAML) holder invokes the MEL on behalf of the CAMO. It is the decision of the Aircraft Captain to accept the aircraft for flight with unserviceable systems or equipment listed in the MEL. The overriding principle is that, notwithstanding the provision of an approved MEL, a MAML holder should not release an aircraft for flight, and the Aircraft Captain should not accept an aircraft for flight, if it is considered unsafe for a particular flight.

8.2.6.24 A MAO may authorise Aircraft Captains to invoke MEL items through provisions in the Operations Manual. Where an Aircraft Captain is not authorised to invoke a MEL item the Aircraft Captain is to refer to local procedures for actions required to invoke the MEL item.

Developing a MMEL

MMEL Development Options

8.2.6.25 **Existing CAA/MAA MMEL as part of Operational Suitability Data (OSD).** As part of the introduction of a new type to Defence the initial certification package may contain a MMEL that has

Superseded

been developed by the OEM as part of the OEM state of design certification process. This MMEL document can be submitted as OSD, as part of the Australian MTC certification package and be assessed for approval as the DASA approved MMEL. Similarly, for an existing type with no DASA approved MMEL, an existing Civil Aviation Authority (CAA) / Military Aviation Authority (MAA) approved MMEL may be submitted for approval as a change to the type certificate.

8.2.6.26 In both cases above, foreign CAA/MAA approval of a MMEL does not constitute automatic approval under DASRs. DASA issues its own sovereign Military Type Certificates (MTC) for each aircraft type and does not 'accept' foreign civil or military TCs. Therefore, in order for a MMEL to be approved under DASRs it must be approved under the initial issue of, or as a change to, the DASA issued MTC and be included on the DASA issued Type Certificate Data Sheet (TCDS).

8.2.6.27 **MEL submitted in lieu of MMEL.** If the operator has access to an existing, or has developed, a MEL for the type, for which no MMEL exists, the operator may submit the MEL through the Military Type Certificate Holder (MTCH), for assessment as a MMEL. If the MEL is submitted, DASA will consider it a MMEL submission and assess it as such. It may then be used as the basis for acceptance as a MEL.

8.2.6.28 **Development of a new MMEL.** A MTCH may elect to submit a new MMEL to DASA for approval. DASA does not stipulate any specific format and/or contents of a MMEL. However, the Certification Programme must propose an appropriate Certification Basis that the MMEL will comply to, and that may include content and format requirements. Establishing the Certification Basis early and following the associated format will avoid delays in assessment and approval of the MMEL.

8.2.6.29 **Suitable Certification Specifications.** The Certification Programme should be submitted to DASA, proposing a Certification Basis for the MMEL. The following two certification specifications will likely be suitable for development of MMELs:

1. EASA CS-MMEL. CS-MMEL is the Certification Specification (CS) mandated by EASA for MMEL development and is likely to provide an acceptable basis for MMEL approval for Defence aircraft.

2. FAA FOEB process. FAA policy for MMEL approval is through the Flight Operational Evaluation Board process. MMEL document templates, guidance on specific systems, general format requirements, and guidance on justification requirements are available on the FAA FSIMS website. (Reference ICAO Manual – MMEL/MEL5 and Flight Standards Information Management System).

8.2.6.30 Alternate Certification Bases may be proposed in the Certification Programme but will require further justification.

MMEL development process

8.2.6.31 As the MMEL forms part of the Military Type Certificate, any MMEL change is to be classified IAW the guidance in DASR 21.A.91. On initial issue of the MMEL or identification of a MMEL change as Major, the Major Change to Type Certificate process as per DASR 21 subpart D applies. Minor changes to MMELs are to be processed IAW DASR 21.A.95. This process is depicted at Appendix 2.

8.2.6.32 **MMEL Change Classification Criteria.** The following guidance for classification of MMEL changes elaborates upon the generic classification advice in GM to DASR 21.A.91.

8.2.6.33 Conditions requiring classification of a MMEL change as Major:

Superseded

1. Where the change requires an adjustment of the MMEL certification basis;

2. Where the applicant proposes changes to the Means of Compliance (MoC) with the requirements for the MMEL certification basis (i.e. MMEL safety assessment methodology);

3. Where the extent of substantiation data and the degree to which the substantiation data has to be assessed and evaluated is considerable, in particular but not only when:

   i. The substantiation data involving review of failure conditions that are classified as hazardous or catastrophic has to be evaluated;

   ii. The assessment of the failure effects (including next worst failure/event effects) on crew workload and the applicable crew procedures has to be evaluated; or

   iii. The capability of the aircraft to perform types of operation (e.g. Defence Long Range Operations (DLRO), Instrument Flight Rules (IFR)) under MMEL is extended.

8.2.6.34 Conditions where the MMEL change can be considered Minor:

1. Modifications to an item/s when:

   i. The change is only to the applicability of an item for configuration management purposes;

   ii. The change is the removal of an item;

   iii. The change is an increase in the number of items required for dispatch; and

   iv. The change is a reduction in the rectification interval of an item.

2. Addition of a new item when:

   i. It is considered as non-safety related IAW FAA MEL Requirements for 14 CFR Parts 91 Subpart K (Part 91K), 121, 125, 125 LODA, 129, and 135 Operations CS-MMEL GM2 MMEL.110; or

   ii. It is indicated as eligible for minor change classification in FAA MEL Requirements for 14 CFR Parts 91 Subpart K (Part 91K), 121, 125, 125 LODA, 129, and 135 Operations, GM1 CS MMEL.145.

8.2.6.35 **Justification and development of supporting data.** Items must be justified for inclusion in the MMEL against the agreed certification basis. Any risk associated with inclusion of items is to be eliminated or minimised to the level inherent in the applicable design standards. Alternate methodologies for justification of changes must be presented to the Authority during the Certification Programme agreement (CP) process.

8.2.6.36 If the conditions and limitations applied against a MMEL item are assessed as insufficient to fully eliminate the associated risk, or an Equivalent Safety argument cannot be made that the risk meets the level of safety inherent in the applicable design standards in the aircraft Type Certification Basis (TCB), the MMEL item is NOT to be included in the MMEL.

8.2.6.37 Operational endorsement should be sought from the MAO (e.g. Hazard Tracking Authority or Standards Officer (STANDO) for any operational conditions or limitations identified against MMEL

Superseded

items. The MTCH in developing the MMEL considers the operational conditions/limitations of the aircraft against the type certification. The MMEL operational procedures are not specific to an individual Operator's Configuration Role and operating Environment (CRE).

8.2.6.38 **Relief from Development of Compliance Demonstration Evidence.** Relief from the requirement to develop compliance demonstration evidence can be sought on an item by item basis for MMELs. The requirements for leveraging prior certification from another CAA/MAA as per AMC to DASR 21.A.20 still apply when relief is applied in this manner.

MMEL approval process

8.2.6.39 Initial Type Certification

1. The applicant for initial DASA MTC would submit the MMEL as part of the application package.

8.2.6.40 MMEL for an aircraft with an existing DASA MTC

1. An MTCH submitting a MMEL for DASA approval must do so in accordance with the Change to Type Design process as described in DASR 21
2. Refer to Appendix 2: for the process flow to seek DASA approval of a MMEL.

Developing a MEL

Developing a MEL using an existing/relevant MMEL

8.2.6.41 DASA do not stipulate any specific format and/or contents of a MEL. Using an international recognised format could avoid delays in assessing the MEL. In the development of an MEL, DASA recommends that the MEL be developed in accordance with international standards as referenced in the Certification Programme from the MMEL (detailed above).

8.2.6.42 The MEL should be developed from the latest issue of the applicable MMEL on an item-by-item basis and keeping in view the relevant regulatory requirements.

8.2.6.43 If an operator chooses to add items that are not found in the MMEL (due to its particular type of operation) an assessment of those items must be carried out. This assessment is required to ensure that these items do not affect the design standards or safe operation of the aircraft and are not in conflict with the flight manual and any DASR requirements. Refer to the International standards as referenced in the Certification Programme from the MMEL for guidance on how to assess the criteria for these items.

8.2.6.44 In general, a MEL should be as, or more, restrictive than the applicable MMEL for the type of aircraft. If a certain item(s) of the applicant's MEL is less restrictive than the applicable MMEL, DASA will require an extensive qualitative and/or quantitative analysis to substantiate the proposed departure from the MMEL.

MEL Development with no MMEL

8.2.6.45 If a platform has no MMEL or MEL available from the manufacturer or other CAA/MAA and the operator wants to utilise the flexibility that a MEL affords, the Operator may choose to engage the MTCH to develop a MMEL from previously available deferment options.

Superseded

8.2.6.46 The MMEL should be developed in accordance with the guidance provided earlier in this chapter.

8.2.6.47 Once the MMEL is approved by DASA the operator can seek approval of the MMEL for use as an MEL from DASA.

MEL approval process

8.2.6.48 An Operator submitting a MEL for approval must provide DASA with:

1. A minute of application from the CAMO requesting approval of the MEL;
2. Digital access to a copy of the proposed MEL;
3. All OIP created for use of the MEL; and
4. If the MEL has no associated DASA approved MMEL, the MEL must be submitted for approval as a MMEL.

8.2.6.49 A MEL may cover more than one aircraft of the same type. However, all differences in the equipment/systems installed, if any, should be clearly identified by the aircraft registration mark.

8.2.6.50 Refer to Appendix 1: for the DASA process flow of MMEL/MEL approval.

Application for amendment to the MEL

8.2.6.51 Amendments to MELs are either mandatory or voluntary, depending upon the particular circumstances. Mandatory amendment of a MEL is required either:

1. When the applicable MMEL is amended so as to become more restrictive; or
2. When required by DASA in light of in-service experience.

8.2.6.52 Voluntary amendment of a MEL may be carried out when either:

1. The MMEL is amended so as to become less restrictive; or
2. As required by the operator, provided the proposed change is no less restrictive than the MMEL; or
3. Regulatory changes occur.

8.2.6.53 An application for amendment to an approved MEL, together with appropriate substantiation, should be forwarded to DASA.

MMEL/MEL Development Considerations

Operations and maintenance procedures

8.2.6.54 The objective of operations ((O)) and maintenance ((M)) procedures is to provide everyone using the document with clear and concise directions on how they are to proceed in case of unserviceability. The (O) and (M) procedures form part of the approved MEL.

8.2.6.55 **(O) Procedures:** Where the (O) symbol appears in the MMEL, an operations procedure must be developed that provides clear direction to the flight crew. These procedures may be included in the MEL. Where they are not included in the MEL, they must be available to the aircrew in another

Superseded

document that is always available to the aircrew (i.e. an operations manual or in an approved electronic form). In these cases, the MEL shall refer to a section of the appropriate document(s).

8.2.6.56 **(M) Procedures:** The MMEL may identify items that require a maintenance procedure. If this is the case, the operator must ensure that relevant (M) procedures have been developed for the MEL. These procedures must provide clear direction to the maintenance personnel.

Procedures for the use and guidance of flight crews and maintenance personnel

8.2.6.57 The operator must establish procedures for the use and guidance of flight crews and maintenance personnel, in relation to the MEL. These procedures must agree with those in the operator's CAME, Aircraft Maintenance Program (AMP), operations manual, and other operating documents. These procedures should include, but are not limited to, procedures for:

1. Deferring rectification action or invoking MEL item(s) for unserviceable equipment;
2. Placarding requirements as per the MEL;
3. Ensuring that a dispatched aircraft with an invoked MEL item(s) complies with the limits and conditions of the MEL;
4. Ensuring that existing deferred defects / MPTF / Command Clearances do not impact invoking of MEL provisions;
5. Controlling categorised repair intervals; and
6. The training of organisations personnel who are responsible for compliance with MEL procedures.

8.2.6.58 Procedures for invoking MEL items are normally contained in the operator's CAME, operations manual or an alternative document. Prior to issuing a MEL approval, DASA will ensure that the MEL references these procedures in the CAME, operations manual or similar document, if not already included in the MEL. If no procedures for the invoking of MEL items exist within the operator's organisation, then DASA will, in addition to vetting the MEL, require amendment to the CAME/MOE and/or operations manual.

8.2.6.59 A placarding procedure should be established and set out in the CAME/MOE and operations manual or, at least, within the approved MEL document.

8.2.6.60 When invoking a MEL item, the person responsible must:

1. Identify, in the aircraft technical log or appropriate document/maintenance information system, that this action has occurred;
2. Identify the item with its MEL number; and
3. Ensure that an unserviceable label is placed in an appropriate location (where applicable).

8.2.6.61 A procedure documenting the above requirement in the appropriate operator's documentation is acceptable for compliance purposes.

Repair intervals

8.2.6.62 Each item of a MEL must be repaired within the specified repair interval. These intervals are set to limit the maximum time an aircraft may fly with an unserviceable item(s) of equipment, and

Superseded

are designated Category 'A, B, C or D'. The definition of repair intervals should align with the selected certification basis for the MMEL as defined at para 8.2.6.29.

8.2.6.63 The operator must establish procedures whereby the maintenance support periodically reviews the deferred items. This is done to ensure that any accumulation of deferred items neither conflict each other nor present an unacceptable increase in crew workload. Notwithstanding the categorisation of item repair intervals, it should be the aim of each MEL document holder to ensure that unserviceable items are repaired as quickly as possible.

Repair interval extension

8.2.6.64 Each operator's MEL management program needs to contain procedures for controlling extensions to item repair intervals. Procedures must include the limitations of each extension and the method by which the operator approves an extension.

MEL training program

Training Requirement

8.2.6.65 The operator should as part of the introduction of a process for the use of a MEL develop a MEL training program for maintenance personnel and flight crew, which should be in place prior to an operator commencing operations with a MEL. The operator, when required, should conduct recurrent training, or put in place a controlled method to alert staff to any changes in MEL procedures. This will ensure company personnel remain current with those procedures.

Maintenance Personnel Training

8.2.6.66 The training for maintenance personnel should include those sections of the CAME procedures dealing with:

1. The use of, and compliance with, the MEL;
2. Placarding of unserviceable equipment;
3. Return to service of an aircraft;
4. Dispatching an aircraft; and
5. Any other MEL related procedures.

Flight Crew Training

8.2.6.67 The flight crew training should include, but not be limited to, the following:

1. The purpose and use of a MEL;
2. Instruction on operator's procedures for the use and guidance of flight crew;
3. The process and procedures required for supervision and flight authorisation; and
4. The Aircraft Captain's responsibility with respect to the above procedures.

Superseded

8.3.1 Requirements for Maintenance Organisations

Introduction

8.3.1.1 This section provides additional information and guidance to DASR 145 Approval Holder Organisations and those organisations that are applying for approval under DASR 145. Further guidance on applying for a Maintenance Organisation approval can be found in Section 5 Annex G – AMO.

8.3.1.2 For information on maintenance service providers that are approved though other means (i.e. not DASR 145 approval), refer to Chapter 6.5, Recognition of other Aviation Safety Authorities and to Chapter 8.2, Continuing Airworthiness Management.

8.3.1.3 This chapter does not include information already presented at Volume 2 (DASRs), but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3.

DASR 145 – Requirements for Maintenance Organisations

8.3.1.4 The Defence Aviation Safety Regulations (DASR) requires individual DASR 145 Approved Maintenance Organisations (AMOs) to define their own line and base maintenance activities in their Maintenance Organisation Exposition (MOE).The scope of maintenance of aircraft and components activities should be in accordance with the Maintenance Organisation's policy and procedures defined in the MOE.

Acceptance of components

8.3.1.5 The AMO must ensure that components are accompanied by appropriate documentation attesting to the legitimacy of the component's maintenance or production history. This is underpinned by the regulatory requirement for the AMO to obtain a DASR Form 1 or equivalent documentation prior to fitment of such components. Where an unserviceable or unsalvageable component is the subject of an occurrence report, the DASR 145 organisation should quarantine the component until the investigation has determined that the component is not required to be retained for further examination Additional information can be found in Chapter 8.3.4 – Acceptance of Components.

Certification of maintenance

8.3.1.6 Maintenance carried out on an aircraft, its systems and its components must be certified at completion and prior to its return to service. The instrument used to achieve this outcome is the Certificate of Release to Service (CRS) that must be issued at the completion of maintenance and before the next flight. Additional guidance for Certification of maintenance can be found in Chapter 8.3.3 - Certification of maintenance.

8.3.2 Performance of Maintenance

Introduction

Superseded

8.3.2.1 This chapter provides additional guidance on the performance of maintenance including guidance on line and base maintenance, and specialist maintenance qualifications.

8.3.2.2 Not all maintenance personnel in a DASA 145 MO need to be authorised as certifying and/ or support staff. Acting as certifying or support staff is intrinsically a hands-off activity (in contrast to the performance of maintenance being physical hands-on aircraft maintenance). DASA 145 MO personnel perform maintenance under a Task Sign-Off (TSO) authorisation. On-aircraft TSO is overseen, managed and later certified (issue of CRS) by authorised certifying staff.

8.3.2.3 Except for a few speciality areas (e.g. composite repairs), DASA does not prescribe knowledge / experience standards for the performance of maintenance. On-aircraft TSO provides an attestation that the maintenance task has been carried out to the required standard.

8.3.2.4 A DASA 145 MO has flexibility to determine their own Qualification, Training and Experience (QTE) requirements when assessing and authorising personnel to perform the vast majority of maintenance (less some specialist qualifications where DASA will specify acceptable means of compliance). It is up to a DASA 145 MO to determine the scope that maintenance personnel can be authorised to perform, and may also mandate the level of supervision maintenance personnel require – noting supervision can be performed by authorised persons who are not necessarily certifying staff – see GM2 DASR 145.A.35(e). Maintenance personnel do not need to hold a MAML, of any category, to be authorised to perform maintenance.

8.3.2.5 DASA oversight of DASA 145 MOs, in the context of foreign trained maintenance personnel employed to perform maintenance, will focus on the procedure that identifies knowledge and experience requirements, to determine the authorised scope of maintenance and supervision required.

8.3.2.6 For information on maintenance service providers that are approved though other means (i.e. not DASR 145 approved), refer Chapter 6.5, Recognition of other Aviation Safety Authorities and Chapter 8.2, Continuing Airworthiness Management.

8.3.2.7 For information on the performance of maintenance relates to the certification of maintenance, see Chapter 8.3.3 – Certification of Maintenance.

Line and Base Maintenance

Background

8.3.2.8 The Defence Aviation Safety Regulations (DASR) requires individual DASR 145 Approved Maintenance Organisations (AMOs) to define their own line and base maintenance activities in their Maintenance Organisation Exposition (MOE). Feedback from the regulated community indicates that there is insufficient DASR guidance on what types of activities constitute line and base maintenance. This chapter describes types of maintenance activities constituting line and base maintenance and describes the intended outcomes in relation to line and base maintenance as interpreted by DASA.

8.3.2.9 The DASR Glossary of Terms describes line and base maintenance as:

1. **Line Maintenance:** Carried out before flight to ensure that the aircraft is fit for the intended flight.

2. **Base Maintenance:** Maintenance tasks falling outside the criteria for line Maintenance.

Superseded

8.3.2.10 A more detailed definition of aircraft line maintenance is provided in AMC 145.A.20, together with a list of activities which “may” be considered as line maintenance. The word “may” is used because it is not possible to establish a provision giving a strict demarcation between line and base maintenance, having general applicability to all cases.

8.3.2.11 To assist civil MOs, the European Aviation Safety Agency (EASA) has developed an EASA 145 User Guide chapter on ‘Privileges and limitations of line maintenance’. This guide provides detailed guidance on what constitutes line and base maintenance. This Annex is has been developed based on the EASA User Guide to provide an EASA aligned approach to guide DASR 145 MOs in defining line and base maintenance.

Organisation responsibilities

8.3.2.12 The maintenance organisation should ensure prior to any intended maintenance event that the activity can be carried out under its line maintenance scope of approval (refer to AMC 145.A.20) and does not fall under paragraph 14 ‘Examples of maintenance activities considered to be base maintenance’ of this Chapter.

8.3.2.13 This assessment may not need to take place each time, but be based on already established MOE procedures (i.e. the fact that a daily check is a line maintenance task is obvious and does not need to be assessed each time).

8.3.2.14 Even if this assessment confirms that the activity is line maintenance, the maintenance organisation should also verify if this activity requires other means than the ones already in use at a line maintenance location.

When to assess the maintenance activity

8.3.2.15 The maintenance organisation`s assessment to decide if any maintenance event falls within the definition of line or base maintenance, may be needed in two different situations:

1. for an initial/change of approval, when evaluating the scope of work the maintenance organisation is applying for (refer paragraph 11); or
2. for an already approved maintenance organisation, when evaluating if maintenance requested by the customer (e.g. a new Service Bulletin (SB), defect rectification or work package requested by the customer, etc.) falls within the approved line maintenance scope of work.

Assessment of the intended scope of work (initial/change of approval)

8.3.2.16 It is the responsibility of the maintenance organisation to demonstrate to DASA that the intended scope of work may be carried out in a line maintenance environment, under its line maintenance scope of approval. The main criterion for this assessment is to consider the level of maintenance to be carried out under the line maintenance scope of approval, where the following general criteria apply:

1. **Trouble shooting, Defect Rectification.** Those unscheduled tasks required for the daily operation of an Aircraft and not falling under ‘Examples of maintenance activities considered to be base maintenance’;
2. **Minor scheduled line maintenance.** Those scheduled tasks not exceeding the weekly check as specified in the Aircraft Maintenance Program (AMP);

Superseded

3. **Scheduled checks.** Those scheduled tasks which exceed the weekly check (or equivalent as determined by the Authority). In this case, the organisation needs to analyse each of the routine tasks intended to be included in the line maintenance scope of work and identify a clear limit. This assessment needs to be performed using the Type Certificate Holder (TCH) data such as the manufacturer's Maintenance Planning Document (MPD), and/or the operator's AMP. The outcome of this exercise is to identify the intended limitation of the line maintenance scope of approval, in terms of scheduled maintenance checks. In particular, the following is expected:

4. Depending on the AMP logic (i.e. MSG 2, MSG 3, etc) a clear limitation to the line maintenance scope of work may be normally expressed in one of the following ways:

   i. "up to and excluding X check" (i.e. X= R1, R2, etc) for a MPD, where letter checks are identified;

   ii. "up to and excluding "X FH / Y FC / Z calendar time", for a MPD, where progressive task intervals are defined in terms of FH/FC/calendar time (i.e. X=3000FH, Y=750 FC, Z=12 months, etc);

5. The identified limit, to be indicated in the MOE, should be such that all the related routine/scheduled tasks are excluding any of the tasks listed in 'Examples of maintenance activities considered to be base maintenance'

6. A "decision making process" (refer paragraph 12 for example) needs to be established in the MOE in order to assess

   i. (the need to access the hangar (even if the activity is permitted under a line maintenance scope of approval), considering in particular the type of aircraft, the maintenance event type/complexity, the environmental and weather conditions;

   ii. any work order / work package received from the customer operator to ensure it may be fully performed under a line maintenance scope of approval, taking into account additional works to the original work package that may be added, leading out to the line maintenance scope of work, such as:

   – addition of previously deferred maintenance tasks; or

   – defects raising from the routine tasks (these defects are not known in advance, however, the related risk in terms of number and level of defects needs to be taken into account and estimated in advance).

8.3.2.17 **Example of 'decision making process'.** A R1 maintenance check on the Boeing Business Jet (BBJ) aircraft type is normally considered "line maintenance" when the routine tasks are assessed as per the manufacturer MPD/operator AMP. Therefore a maintenance organisation may be approved to perform this check under a line maintenance scope of work. However, a work order to perform the "R1 check", where the customer operator would request the performance of works in addition to the "R1" routine tasks, such as the addition of Airworthiness Directives (ADs), SBs, deferred tasks, will need to be carefully assessed by the maintenance organisation with the use of the "decision making process".

8.3.2.18 This type of maintenance check may easily fall within the examples given in Paragraph 14 'Examples of maintenance activities considered to be base maintenance' having the result to be considered as base maintenance and being outside the maintenance organisation scope of work. In such a case, the outcome of the "decision making process", may be for example:

Superseded

1. The impossibility to accept such work order from the operating organisation, being outside the scope of work of the maintenance organisation; or

2. to agree with the operating organisation a revised work order, to remove the works which have been identified as base maintenance tasks (e.g. removal of a SB which was requiring extensive disassembly and modification of flight controls, etc.).

Examples of maintenance activities considered to be base maintenance

8.3.2.19 When any of the following tasks are required to be carried out (regardless if contained in a scheduled maintenance check or arising from a defect rectification/AOG situation), a base maintenance scope of approval is needed:

1. High number of different type of tasks to be carried out, even if taken singularly those tasks may still fall under the definition of line maintenance (i.e. a combination of routine task cards, non-routine task cards issued following defects discovered during the check, out of phase tasks, deferred items from previous maintenance, minor repairs, minor modifications, component replacement, etc). Such cases require base maintenance production planning support and/or a base maintenance release to service process (category C Certifying Staff supported by B1/B2 support staff) in order to ensure that all the maintenance ordered has been carried out before issuing the CRS;

2. Replacement of any major component where the related maintenance procedures address the need of a hangar environment requiring special ground support equipment and/or structured production planning and/or complex and lengthy maintenance, such as for example a full landing gear replacement, simultaneous replacement of two engines, etc;

3. Any scheduled maintenance task (i.e. routine task from the AMP) which requires extensive disassembly of the aircraft and/or extensive in depth inspection;

4. Major repairs and/or major modifications;

5. Trouble shooting and/or defect rectification requiring special ground support usually relevant to base maintenance (e.g. special equipment, structured production planning, complex and lengthy maintenance);

6. A scheduled maintenance event, which in the planning phase has been already identified as significant in terms of duration and/or man-hours (i.e. an aircraft down time above 72 hours or four shifts, whichever is less);

7. A work package requiring a complex team composition in terms of high number and categories (avionic, structure, cabin, NDT qualification and skills, etc) of staff involved per shift; or

8. The management of the event by B1 and B2 support staff and the release by a C certifying staff.

8.3.2.20 For AMOs that do not hold a base maintenance approval, the AMO remains responsible to ensure that even if each individual work order constitutes a line maintenance activity, a maintenance event cumulating several of these work orders remains within the AMO's line maintenance scope of approval.

Assessment of maintenance task by an already approved maintenance organisation

Superseded

8.3.2.21 For AMOs that do not hold a base maintenance approval, the AMO remains responsible to assess if any maintenance requested by the operating organisation falls within the approved line maintenance scope of work. This assessment is expected to be performed based on the "decision making process" described above.

Specialist Task Qualifications

8.3.2.22 **Introduction.** DASR 145.A.30(f) relates to MO personnel who carry out Non-Destructive Testing (NDT) and other specialised tasks such as composite repair and welding. Definitions pertaining to the scope of DASR 145.A.30(f) are as follows:

1. Particular non-destructive test means any one or more of the following; Penetrant Testing (PT), Magnetic Testing (MT), Eddy current Testing (ET), Ultrasonic Testing (UT), Radiographic Testing (RT), Thermographic Testing (TT) and Shearographic Testing (ST) methods (refer GM 21.A.30(f)). Boroscoping and other techniques such as manual tap testing are non-destructive inspections rather than non-destructive testing (refer AMC 145.A.30(f)).

2. For the purposes of DASR 145.A.30(f), DASA should be consulted to confirm the complexity and associated training requirements of composite repairs for each platform. The complexity and training requirements for non-specialised composite repairs should be detailed in the DASR 145 MOE.

8.3.2.23 DASR 145.A.30(f) requires that the MO must ensure that personnel who carry out NDT and other specialised tasks are appropriately qualified in accordance with recognised standards. The following paragraphs provide guidance on the standards recognised by DASA and other aspects of personnel training and certification.

8.3.2.24 It should be noted that the training standards required to perform specialist tasks might exceed the training standards to certify this maintenance. For example a licence persons with no structural repair exclusions could certify for a complex composite repair but may not be qualified to perform the maintenance. In this case the certifying staff may require separate specialist supervision in order to very the maintenance has been performed properly.

Qualification of Personnel for Non-Destructive Testing (NDT)

8.3.2.25 **Recognised NDT Qualification Standards.** DASA recognises the following standards for qualification of personnel who carry out and/or control NDT of aircraft structures and/or components (refer DASR 145.A.30(f)):

1. European Standard EN4179 - Qualification and Approval of Personnel for Non-destructive Testing is the primary NDT standard recognised by DASA

2. NAS410 – NAS Certification & Qualification of Non-Destructive Testing Personnel is also recognised by DASA.

8.3.2.26 NAS410 is the only NDT qualification standard DASA recognises as being equivalent to EN4179. Organisations that wish to use an alternative NDT personnel qualification system should apply to DASA with a proposed Alternate Means of Compliance (AltMoC). Note that Australian Standard AS3669 and ATA Spec 105 have been assessed as non-equivalent to EN4179 (refer GM 145.A.30(f)) and will not be approved as AltMoC by DASA.

8.3.2.27 **NDT Personnel Training and Certification.** The appointed NDT Responsible Level 3 (RL3) for each DASR 145 MO is responsible for establishing a training and certification system which

Superseded

supports awarding of task authorisations to NDT personnel working within the DASR 145 MO. This training and certification system should be established in line with EN4179. In cases where the minimum training and experience hour requirements stipulated in EN4179 Section 6 do not align with Defence's requirements, a competency based training program can instead be used, provided the course program is approved by DASA. Refer to GM 145.A.30(f).

8.3.2.28 For details of the approach to NDT training and certification implemented in support of ADF DASR 145 MOs, refer to Volume 3 Section 4.2.3.

8.3.2.29 **Appointment of NDT Responsible Level 3.** AMC 145.A.30 stipulates that the NDT RL3 for a DASR 145 organisation is a nominated management position, and is accepted by DASA through a DASR Form 4 application. Each DASR 145 organisation should only have one appointed NDT RL3. The DASR Form 4 requires applicants to submit details and supporting documentation of relevant qualifications and experience. Specific to NDT RL3 applications:

1. Applicants are requested to provide a copy of all personnel certification records that DASR 145 organisations are required to retain under EN4179 Para 8.2 to demonstrate they meet the EN4179 requirements to be certified as a Level 3.

2. If the applicant holds certifications in multiple methods, only evidence from one NDT method is required. The employer is to ensure that certification records for all other methods are retained, as required by EN4179 Para 8.2.

Note: that DASA may request evidence of ongoing EN4179 compliance for NDT RL3s in the course of oversight and enforcement activities.

8.3.2.30 DASA does not require the involvement of the Australian National Aerospace NDT Board (NANDTB) in the certification of Level 3 staff. DASA will not request or rely on NANDTB recognition when assessing NDT RL3 Form 4 applications.

8.3.2.31 For questions about NDT RL3 Form 4 application evidence please email: dasa.dca@defence.gov.au

8.3.2.32 Responsibility for appointment of NDT RL3 personnel is as follows:

1. ADF DASR 145 MOs: the Directorate of Aviation Engineering (DAVENG), as Defence's Structural Integrity Centre of Expertise[3], performs the Defence NDT RL3 function (refer to Section 4.2.3 for further details).

2. Non-ADF DASR 145 MOs (i.e. contractor organisations): are responsible for appointing their own NDT RL3 personnel.

8.3.2.33 Notwithstanding the fact that Level 3 personnel may be qualified via EN4179 to establish and authorise methods, techniques, etc., this does not permit such personnel to deviate from the methods and techniques published in the Instructions for Continuing Airworthiness (ICA)[4] unless the ICA expressly permits such deviations (refer AMC 145.A.30(f)). Although it is recommended that Level 3 personnel have a role in NDT ICA deviations or changes (refer DASP Manual Volume 3 Section 7.2.5), NDT ICA deviations or changes must be approved in accordance with DASR 21.

Qualification of Personnel for Composite Repairs

8.3.2.34 **Recognised composite repair qualification standards.** Some types of composite structure repair are considered a specialised task and therefore personnel conducting those types of composite repairs require appropriate qualification in accordance with an officially recognised standard. DASA

Superseded

recognises SAE AIR4938 - Composite and Bonded Structure Technician Specialist Training Document for qualification of personnel who carry out composite repairs (refer AMC1 145.A.30(f)).

8.3.2.35 SAE AIR4938 Revision C includes requirements for both initial training and on-going certification. Superseded revisions of SAE AIR4938 do not include the requirements for ongoing certification, and also omit the training curriculum for bolted composite repairs. Superseded revisions of SAE AIR4938 should not be used without approval from DASA.

8.3.2.36 Organisations that seek to use an alternative to SAE AIR4938 for the qualification of composite repair personnel to conduct specialised composite repairs should apply to DASA with a proposed AltMoC. Organisations should note MEA405 is considered an introductory composites course only. DASA does not recognise MEA405 Cert IV AME Structures as a suitable equivalent to SAE AIR4938 for the conduct of specialised complex composite repairs. The complexity of composite repairs, and associated training requirements will vary for each platform. When suitable controls can be identified to ensure ongoing airworthiness a lower standard than SAE AIR4938 may be recognised as suitable for specific circumstances. Such controls could include:

1. type of structure being repaired
2. type or complexity of composite repair being conducted
3. specific nature of training undertaken
4. experience of personnel
5. supervision requirements
6. OEM or aircraft type specific training

8.3.2.37 Applications to DASA to officially recognise alternate qualification standards should demonstrate that the alternate standard:

1. provides an equivalent level of training to SAE AIR 4938; or
2. is suitable in the context of the specific MO and the scope of the maintenance activities to be performed. In such cases, the application should clearly state the scope of the activities being performed, how the training is suitable for that scope, and the means by which the scope is to be controlled.

8.3.2.38 **Composite repair Personnel Training.** Prior to authorising staff to perform composite repairs, the DASR 145 MO should ensure the staff are trained and qualified in accordance with appropriate standards, SAE AIR49385 or approved AltMOC, for specialised composite repairs. Composite repair training and certification procedures for specialised and non-specialised composite repairs should be specified in the MOE.

8.3.2.39 DASR 145 MOs can utilise any training course that demonstrates compliance to the standard. Note that DASA-DAVENG, as Defence's Structural Integrity Centre of Expertise, conducts the certification (initial and re-certification) for all ADF DASR 145 MO staff who perform composite repairs (refer to DASP Manual Volume 3 Section 4.2.3 for further details).

8.3.2.40 DASR 145 MOs are responsible for establishing training and authorisation systems to ensure that personnel who conduct composite repairs are appropriately qualified. Further guidance for ADF and non-ADF DASR 145 MOs is as follows:

Superseded

1. ADF DASR 145 MOs: The MO should verify that technicians hold a valid PMKeyS proficiency (refer DASP Manual Volume 3 Section 4.2.3) for composite repair prior to authorising them to conduct composite repairs within an ADF DASR 145 MO. MO authorisations should only remain valid for the validity period of the applicable PMKeyS proficiency.

2. Non-ADF DASR 145 MOs: The MO should document their certification/re-certification process in their MOE. The standard does not impose specific requirements on who can conduct certification.

Qualification of Personnel for Aircraft Welding

8.3.2.41 The following paragraphs are applicable to DASR 145 MOs that perform aircraft welding repairs.

8.3.2.42 Welding is used in the repair of critical and non-critical airframe and engine components within Defence. As a specialist task, personnel conducting welding operations must be appropriately qualified in accordance with officially recognised standards.

8.3.2.43 CASA Civil Aviation Advisory Publication (CAAP) 33-1 (1) Aircraft manual welding: Approvals and qualifications provides information on how to apply for the initial issue or renewal of an aircraft welding authority under Civil Aviation Regulations. DASA has determined that a CASA welding authority, granted in accordance with CAAP 33-1 (1), is an appropriate qualification for Defence purposes.

8.3.2.44 **DASR Requirement.** DASR 145 MO that perform aircraft welding repairs must comply with DASR 145.A.30(f), which requires "Personnel who carry out any other specialised task shall be appropriately qualified in accordance with officially recognised Standards."

8.3.2.45 **Acceptable Means of Compliance.** DASA considers a CASA welding authority, granted in accordance with CAAP 33-1 (1), is an appropriate qualification in accordance with DASR 145.A.30(f).

8.3.2.46 Organisations choosing to utilise welders qualified in accordance with CAAP 33-1 (1) must:

1. Ensure technicians hold a valid Civil Aviation Safety Authority (CASA) issued aircraft welding authority prior to task authorisation.

2. Ensure technicians are only authorised to carry out those types of welding processes that are specified in the welding authority document.

3. Ensure MO authorisations only remain valid for the validity period of the CASA-issued welding authority (i.e. renewal is required every 2 years IAW CAAP 33-1 (1)).

Aircraft Welding Questions and Answers

8.3.2.47 **Q:** What does a DASR 145 MO need so that it can use welders with a CASA welding authority?

8.3.2.48 **A:** The DASR 145 is required to:

1. Identify the scope of welding repairs that it requires (that is included in its overall maintenance scope).

2. Update the DASR 145 MO Orders, Instructions and Publications (i.e. MOE and any other associated documentation), to show compliance to DASR 145.A.30(f) and

Superseded

implement the required management framework. The aircraft welding repair training and qualification requirements should be specified in the MOE.

3. Authorise technicians who have obtained CASA welding authority

4. Ensure that authorised staff maintain their competency and CASA welding authority currency.

8.3.2.49 **Q:** How does a person achieve CASA welding authority?

8.3.2.50 **A:** CAAP 33-1 (1) details the framework that CASA applies to provide a welding authority, which is granted to applicants that have:

1. Successfully completed a relevant Australian Quality Training Framework recognised course; and

2. Passed the welding testing set out in the CASA Welding Syllabus.

8.3.2.51 Additional training may be required dependent on the specific work scope required by the DASR 145 MO. CASA will confirm any specific training requirements during the application for the welding authority.

8.3.2.52 DASR 145 MOs are responsible for organising CAAP 33-1(1) compliant renewal assessments for their personnel when required. There are a number of commercial organisations who employ CASA-authorised aircraft welding assessors (queries should be addressed to Contact us | Civil Aviation Safety Authority

8.3.2.53 CASA charge a fee to apply for the initial issue and for renewal of a welding authority. Applicants will also require a CASA Aviation Reference Number (ARN) prior to applying for a welding authority.

8.3.2.54 **Q:** Do welders require renewal of their CASA welding authority?

8.3.2.55 **A:** Yes. CAAP 33-1(1) requires a two yearly renewal in order to remain current. DASR 145.A.30(f) requirement that "Personnel who carry out any other specialised task shall be appropriately qualified in accordance with officially recognised Standards" requires a current CASA authorisation.

8.3.2.56 **Q.** Who covers the cost of gaining a CASA welding authority and renewal?

8.3.2.57 **A:** For:

1. Defence Maintenance Organisations, initial authority for ASTTECHs is covered within the Welder Aircraft Course at RAAFSTT, all subsequent renewal costs are to be supported though unit, or parent command funding.

2. Contractor Maintenance Organisations, refer to arrangements detailed in your contract.

8.3.2.58 **Q:** Can a non-welder supervise the conduct of a renewal welding assessment?

8.3.2.59 **A:** No. CASA requires that a CASA-authorised assessor supervise the conduct of welding examinations, and DASA has adopted this position.

8.3.2.60 **Q:** Can an organisation authorise welders with a different qualifications (in lieu a CASA welding authority)?

Superseded

8.3.2.61 **A:** Yes. DASR 145 MOs who wish to use an alternative qualification to that stipulated in AMC1 145.A.30(f) should seek approval from DASA (as AltMoC).

8.3.2.62 For further information refer to the following:

1. For issues relating to the use of CASA welding authority within the DASR context please contact the DASA Desk Officer assigned to your organisation or email dasa.dca@defence.gov.au.

2. For queries related to gaining and maintaining CASA welding authority and the application of CAAP 33-1 (1), refer Contact us | Civil Aviation Safety Authority

8.3.3 Certification of Maintenance

Introduction

8.3.3.1 This chapter provides guidance in relation to the Certificate of Release to Service (CRS) process for aircraft maintenance. The document aims to consolidate the applicable requirements from different sections of the DASR and describes the intended outcomes in relation to Sign-off & subsequent CRS at the completion of maintenance.

Background

8.3.3.2 Maintenance carried out on an aircraft, its systems and its components must be certified at completion and prior to its return to service. The instrument used to achieve this outcome is the CRS which must be issued before flight at the completion of maintenance. The CRS should contain as a minimum (AMC 145.A.50(b)):

1. Basic details of the maintenance that was carried out;

2. Date such maintenance was completed;

3. Identity of the organisation and person issuing the CRS; and

4. Limitations to airworthiness or operations, if there are any.

8.3.3.3 The requirements for CRS reside across multiple regulation subsections (DASR M and DASR 145) that collaboratively inform the regulated community of DASA's requirement. This chapter summarises the applicable requirements for CRS to assist the community in meeting the DASR.

Certification of Maintenance Responsibilities

Continuing Airworthiness Management Organisation responsibilities

8.3.3.4 CAMO responsibilities are described in detail within DASR M and include:

1. the CAMO is responsible for all activities aimed to determine the airworthiness status of the aircraft and to appropriately plan and coordinate maintenance.

2. ensuring that all maintenance requirements (Airworthiness Directives (AD), Aircraft Maintenance Program (AMP) requirements, defect rectification, etc...) are complied with and released by a DASR 145 Maintenance Organisation (DASR 145 MO) (or equivalent (M.A 708(b)).

Superseded

3. the CAMO is responsible for planning and ordering all required maintenance and for ensuring that all ordered maintenance conducted by the DASR 145 MO or equivalent is complete and has a CRS. The CAME must explain how this is achieved.

DASR 145 Maintenance Organisation responsibilities

8.3.3.5 The DASR 145 MO (or equivalent) responsibilities are described in detail in DASR 145 and include:

1. the development of 'certification of maintenance' procedures that ensures all maintenance actions have been properly coordinated and the CRS is issued within a reasonable timeframe after the actual performance of the tasks;
2. issuing a CRS following maintenance; and
3. the CRS issued has to be recorded in the Continuing Airworthiness (CA) record system. This information shall be available to the aircraft captain (refer to DASR M.A.306 and AMC DASR M.A.306(a), who is ultimately responsible for accepting the aircraft before a flight takes place.

DASR 145 maintenance personnel responsibilities

8.3.3.6 The completion of maintenance requires two actions. They are:

1. a 'sign-off'; and
2. a CRS.

8.3.3.7 These two actions may be performed by a singular person or group of people dependent upon maintenance complexity, qualifications and authorisations.

Maintenance Authorisation

8.3.3.8 A person can only be authorised when they have met all the organisation's applicable qualification requirements, and only for the scope of work applicable to that qualification detailed in the DASR 145 Maintenance Organisation Exposition (MOE). A person can carry out maintenance and sign-off tasks that they have performed for a particular maintenance activity, and also be a support or certifying staff for another. As an example, a person may be authorised to sign-off on an aircraft type, and certifying and/or support staff on a different aircraft type.

8.3.3.9 DASR 145.A.35 (i) requires the maintenance organisation to nominate an individual[6] responsible on behalf of the maintenance organisation for issuing certification authorisations to certifying staff.

Sign-off Authorisation.

8.3.3.10 This is exercised by a competent (IAW AMC1 145.A.30(e)) and appropriately authorised person, that the maintenance has been completed to the standard required in accordance maintenance data specified in DASR 145.A.45.

8.3.3.11 AMC 145.A.65(b)(3)3 states that, in order to prevent omissions, every task or group of tasks should be signed-off by authorised personnel after its completion. It also states that a sign-off relates to one step in the maintenance process and is different from a 'release to service' (CRS). Importantly,

Superseded

a sign-off is a statement by the competent person performing or supervising the work, that the task or group of tasks has been correctly performed.

8.3.3.12 Furthermore, this AMC states that work by 'unauthorised personnel' (temporary staff, trainee/apprentice) must be witnessed by the authorised person before they sign-off. This means the authorised person signing off the task is responsible for the task.

8.3.3.13 IAW AMC1 145.A.30(e) personnel performing the sign-off, "shall be able to carry out tasks to any standard specified in the maintenance data, and will notify supervisors of mistakes requiring rectification to re-establish required maintenance standards".

8.3.3.14 Nevertheless, holding a sign off authorisation doesn't mean that the authorised person can sign off all tasks. It means that they can sign off tasks within the scope of their authorisation, depending on the qualifications, training and experience held, and in accordance with a procedure described in the MOE. Sign-off authorisation does not need to be restricted to singular tasks where the technician is required to/has demonstrated a degree of competence for that task. In contrast, the technician shall demonstrate competence in performing or supervising work applicable to their training and qualifications.

8.3.3.15 Further details related to task completion and sign-off can be found in Chapter 8.3.2 – Performance of Maintenance.

Certificate of Release to Service

8.3.3.16 In executing the obligations of DASR 145.A.50(a) the organisation must have procedures in place that ensure:

1. the individual issuing the CRS is appropriately authorised to do so;
2. the individual issuing the CRS has ensured the maintenance has been carried out correctly using appropriate procedures IAW DASR 145.A.45(b); and
3. as a result of the maintenance conducted there are no defects which are known to 'endanger flight safety'.

8.3.3.17 A CRS is an attestation made by Certifying Staff by way of a certification signature after the completion of maintenance within their authorisation scope. The certification signature creates a 'certificate' and thus accountability, signifying that the maintenance or group of maintenance activities can be released to service. In Line maintenance the holder of a category A, B1 or B2 MAML may issue a CRS within the scope of their MAML and authorisation. In Base Maintenance the holder of a category C MAML is required to issue the CRS after the completion maintenance within the scope of their MAML and authorisation. Issue of a CRS in Component Maintenance can be done by appropriately authorised certifying staff, in this instance the individual does not need to hold a MAML.

8.3.3.18 There are two elements that need to be fulfilled by the authorised Certifying Staff before the issuance of a CRS is possible:

1. **Ensure.** Verify through oversight and management to ensure that the maintenance has been properly carried out; and
2. **Assessment.** Ensuring that no non-compliances which are known to exist that could 'endanger flight safety'

Superseded

How do Certifying Staff "ensure that the maintenance ordered/tasked has been properly carried out"?

8.3.3.19 *Verification through the supervision of the maintenance task.* Certifying Staff ensure that maintenance has been properly carried out by ensuring maintenance has been conducted in accordance with procedures detailed in the MOE and through the correct use of maintenance data as specified in DASR 145.A.45.

8.3.3.20 This statement does not necessarily mean that authorised Certifying Staff have to personally perform or supervise[7] the whole process of every task, rather it is expected that Certifying Staff will (non-exhaustive list):

1. make sure that personnel assigned to perform the maintenance are authorised to sign-off the work for the appropriate scope of their authorisation;
2. coordinate the different tasks associated with the maintenance being performed; and
3. be available to support personnel in case of any mistakes or unexpected difficulties.

8.3.3.21 Authorised Certifying Staff are responsible to determine the amount of involvement they require in order to be satisfied that the maintenance can be issued a CRS. Subsequently, the DASR 145 MO cannot limit Certifying Staff in terms of what level of supervision they put in place for the maintenance task. The DASR 145 MO may however set a minimum requirement.

How do Certifying Staff, "make an assessment that there are no non-compliances which are known to endanger flight safety"?

8.3.3.22 This is achieved by a cognitive process that assesses whether an endangerment to flight safety exists as defined within AMC1 DASR 145.A.50(a) against the physical outcomes of maintenance ordered by the CAMO. It does not require the DASR 145 MO to find or become responsible for hidden defects which are not expected to be discovered during the ordered maintenance. Defect assessments, including those endangering flight safety, must be clearly identified in the CA records system along with any corresponding limitations (if any) for further CAMO consideration.

Considerations for when the aircraft is left in a non-airworthy condition

8.3.3.23 In circumstances where after performing the maintenance ordered by the CAMO, the aircraft is left in a non-airworthy configuration, a CRS can still be issued for the maintenance that has been completed. The CRS can be issued as long as the incomplete maintenance or known defects are properly identified in the CA records system and communicated to the CAMO. For example, where the DASR 145 MO removes an engine for preservation (without installing a new one), or where the organisation performs an NDT inspection and identifies a crack outside limits.

8.3.3.24 The circumstances mentioned above (including defects affecting flight safety discovered during maintenance), can be properly addressed by using the provisions contained in DASR 145.A.50(c) and (e).

8.3.3.25 It is important to appreciate that a CRS does not mean that the aircraft is airworthy and ready for flight. A CRS is issued by the DASA 145 MO for the maintenance performed; the CAMO is accountable for ensuring that all CA requirements are met for the aircraft to undertake its assigned mission before releasing to the Operator.

When is a CRS issued?

Superseded

8.3.3.26 IAW DASR 145.A.50(b) “A certificate of release to service shall be issued before flight at the completion of any maintenance”. Subsequently, “any maintenance” can be interpreted in multiple ways, such as:

1. any maintenance task.
2. any combination of maintenance tasks.
3. any maintenance event.

8.3.3.27 Utilising the flexibility afforded by the “any maintenance” interpretation an organisation may choose one or more of the following systems of release to service:

1. Several CRS are issued, each one of them covering a different single maintenance task.
2. Several CRS are issued, each one of them covering a different group of maintenance tasks.
3. A single CRS is issued covering all the maintenance included in a maintenance event.

8.3.3.28 The organisation must ensure that the CRS issued to the CAMO clearly identifies what maintenance is complete. If there is any incomplete maintenance, the CRS must clearly identify it in the CA records system and the corresponding limitations (if any). In each of the above cases, it is important to note that there is no change in the accountabilities of the individual authorised Certifying Staff in signing the CRS.

Who can issue a CRS in Line Maintenance?

8.3.3.29 Only appropriately authorised category A, B1 and/or B2 MAML holders can issue a CRS in Line Maintenance. The scope and responsibility of each license category is provided below.

Limited Certification Authorisation

8.3.3.30 By way of exception to paragraph 8.3.3.29, and in accordance with 145.A.30(j) 4, in unforeseen cases where the aircraft is grounded or operating away from a Main Operating Base, and where no appropriate certifying staff are available, the maintenance organisation may issue a limited certification authorisation to the aircraft commander on the basis of the flight crew licence subject to being satisfied the aircraft commander can accomplish the specified task to the required standard. These provisions shall be detailed in a MOE procedure.

One off Certification Authorisation

8.3.3.31 In unforeseen cases, where an aircraft is grounded at a location other than the main base where no appropriate certifying staff are available, the maintenance organisation may issue a one-off certification authorisation in accordance with 145.A.30(j)5.

Category A licence

8.3.3.32 The category A licence permits the authorised MAML holder, in a Line Maintenance environment only, to issue CRS for work that the licence holder has personally performed (‘sign off’) and within the scope of their certification authorisation.

8.3.3.33 A category A licence does not permit the authorised MAML holder to issue a CRS for the work of others, only for their own maintenance. While other personnel may be present and directed

Superseded

by the authorised A MAML holder in providing assistance during the performance of the maintenance task, the category A MAML holder may not undertake a supervisory role.

Category B licence

8.3.3.34 The category B1/B2 licence permits the authorised MAML holder to issue CRS, within the scope of their license and certification authorisation on maintenance that has been 'signed off' by themselves or other authorised personnel, within the scope of their license and certification authorisation.

Category C licence

8.3.3.35 The category C licence permits the authorised MAML holder to issue a CRS following Base Maintenance on aircraft carried out by a DASR 145 AMO. By definition, the DASR permits an authorised category C MAML holder to issue a single CRS for all maintenance activities pertaining to the aircraft during a single Base Maintenance visit.

8.3.3.36 Noting the complexity and the volume of the maintenance being carried out during a Base Maintenance activity, it is difficult for the authorised category C MAML holder to be across all tasks, to the extent required, to issue a CRS. For this reason, the authorised category C MAML holder may use Support Staff to enable the CRS to be issued.

8.3.3.37 The authorised category C MAML holder is accountable to ensure that all required maintenance that has been ordered, has been carried out properly, that there are no non-compliances which are known to endanger flight safety and any outstanding or incomplete maintenance has been identified and the CAMO notified before issuance of the CRS.

Support Staff

8.3.3.38 Support Staff are authorised B1 and B2 MAML holders. The role of Support Staff during Base Maintenance is to conduct, within the scope of their MAML and authorisation, activities such that it can be communicated to the authorised category C MAML holder that:

1. the maintenance has been performed properly;
2. that any defects found during the course of maintenance are recorded in the CA records; and
3. that any outstanding or incomplete maintenance is identified and recorded in the CA records.

8.3.3.39 In essence, Support Staff are oversighting and managing allocated maintenance tasks within Base Maintenance in support of the authorised category C MAML holder. Subsequently, the DASR 145 MO must have a mechanism in place and articulated in the MOE WRT how Support Staff communicate to the category C MAML holder when the CRS can be issued.

8.3.3.40 An authorised category C MAML holder may not require Support Staff if they also hold the required B1/B2 license scope and subsequent authorisation with regard to the Base Maintenance being performed. The authorised category C MAML holder in this instance can issue the CRS without the use of additional Support Staff. The procedures with respect to an authorised category C MAML holder acting as their own support staff must be articulated in the MOE.

Summary of Maintenance Authorisations

Superseded

8.3.3.41 The following figure summarises the different types of authorisations an organisation will require and the scope of work against which they may authorise their staff. It is the DASR 145 that performs and certifies maintenance requested by the DASR M.

Type of Authorisation	Line Maintenance		Base Maintenance		Component Maintenance	
	Sign Off*	CRS	Sign Off*	CRS	Sign Off*	CRS* See note 1
Technician (non MAML holder)	✓		✓		✓	✓
Non Type Rated B1/B2 MAML Holder	✓		✓		✓	✓
Type Rated B1/B2 MAML Holder	✓	✓	✓	Support Staff Does not issue CRS **See note 2**	✓	✓
A MAML Holder	✓	✓ Task Authorised **See note 3**	✓		✓	✓
C MAML Holder	✓	When Exercising B MAML	✓	✓	✓	✓
Foreign Trained Technician	✓		✓		✓	✓

* Denotes No MAML Required therefore all trained technicians may be authorised to perform maintenance and Sign Off. Authorisation QT&E requirements to issue a CRS in Component Maintenance is determined by the AMO
Note 1: Component CRS may be issued through ARC (Form 1) or via process detailed in the MOE
Note 2: This is not a certification activity. Type Rated B1/B2 Technician may be authorised to confirm tasks carried out to the required standard (i.e.: attest) for maintenance personally conducted or conducted by other technicians, to the scope of their B MAML
Note 3: May be Task Authorised to the scope of the A MAML for maintenance personally conducted

Figure 1 Summary of Maintenance Authorisations

8.3.4 Acceptance of Aircraft Components

Introduction

8.3.4.1 This chapter provides additional guidance on what constitutes a DASR Form 1 or recognised equivalent and outlines how DASR 145 Approved Maintenance Organisations (AMOs) should assess the suitability of component documentation to ensure such components are eligible to be fitted to Defence registered, type-certified products.

8.3.4.2 The Defence Aviation Safety Regulations (DASR) require Approved Maintenance Organisations (AMOs) to ensure the airworthiness[8] of components and materials prior to fitment to Defence registered, type-certified products. To fulfil this requirement, the AMO must ensure that components are accompanied by appropriate documentation attesting to the legitimacy of the component's maintenance or production history. This is underpinned by the regulatory requirement for the AMO to obtain a DASR Form 1 or equivalent documentation prior to fitment of such components.

8.3.4.3 This chapter relates to the acceptance of new and used aircraft components, which are listed by the appropriate design organisation as eligible for installation in/on a product and included in the design data approved by the Authority[9]. The term components broadly covers any product (other than complete aircraft), part or appliance that is, or is intended by its manufacturer to be, a part of or used in operating an aircraft in flight, or is installed in or attached to a product. This may include any self-contained part, combination of parts, assembly, subassemblies or units, which perform a distinctive function necessary to the operation of the airframe, engine, or propeller, or may include any other instrument, mechanism, equipment, apparatus, software or accessory, including communications equipment.

Superseded

8.3.4.4 Although alternate artefacts can be consumed by a DASR 145 Approved Maintenance Organisation (AMO), DASA requires the relevant CAMO to seek approval for, and manage, the ongoing validity of alternate artefacts for their respective platforms. Further detail on alternate artefacts can be found in Chapter 8.2.3 – Alternate Artefacts.

Products, parts and appliances

8.3.4.5 To align with the European Military Airworthiness Requirements (EMAR), the DASR has replaced the term Aeronautical Product with separate definitions for products, parts and appliances. The term 'components' in this document will be used interchangeably with products (other than complete aircraft), parts and appliances for simplicity.

Acceptance of components

8.3.4.5 The AMO is responsible for ensuring the 'eligibility for fitment' of components to type-certified products prior to installation[10].

Eligibility for fitment

8.3.4.6 A component is eligible to be fitted to a type-certified product, or another part or appliance if:

1. the fitting of the component is permitted by the approved design[11] for the product, part or appliance of the higher assembly;
2. the component is in a serviceable condition for safe operation; and
3. the component has been appropriately released or returned to service[12].

8.3.4.7 The AMO should have procedures for the acceptance of components and material, to ensure that the supplied components and material are in satisfactory condition and eligible for fitment. Furthermore, the AMO is responsible for ascertaining the traceability of components and material to their original or authorised source, including the maintenance or production and supplier source, where applicable. Therefore, it is the responsibility of the installer to request the appropriate documentation which establishes the airworthiness status and traceability of components and materials.

8.3.4.8 In determining whether a component is eligible for fitment, the AMO should conduct the following:

1. a physical inspection of components and/or material (including a check for any obvious physical damage and verification that part numbers, serial numbers, lot and/or batch numbers, etc. match the accompanying documentation; and
2. a review of accompanying documentation and data, which should be acceptable IAW DASR 145.A.42.

8.3.4.9 Particular caution should be exercised when the origin of components and materials cannot be established or when the origin is in doubt.

8.3.4.10 The flowcharts provided at Appendix 1 and Appendix 2 illustrate the process for determining the eligibility for fitment of new and used aircraft components, respectively, to type-certified products, or other parts and appliances.

Superseded

Acceptance of Aircraft Components

What is an Authorised Release Certificate?

8.3.4.11 An Authorised Release Certificate (ARC) is a document issued by an entity that has the applicable privilege and attests that a new or used component has been produced or maintained IAW the approved design data/standard, modification standard or applicable maintenance data[13].

8.3.4.12 An acceptable ARC is either:

1. DASR Form 1, or equivalent (refer DASA recognition website); or
2. an 'alternate artefact' accepted by DASA.

8.3.4.13 An acceptable ARC must show traceability back to a recognised CAA/MAA. In general, an Authorised Release Certificate must provide evidence of (where applicable):

1. the name and address of the issuing organisation;
2. the name of the recognised CAA/MAA;
3. evidence that the issuing organisation is working within the recognised authority's system (e.g. organisation approval reference);
4. details of the component(s): description, part number, serial number(s) and/or batch number, as applicable;
5. for used service-life-limited components, complete traceability to the component's service history;
6. a clear indication of the current airworthiness status (serviceability) of the component at the date of issue;
7. a release statement made by a suitably authorised person within the production or maintenance organisation;
8. the name, signature (or electronic equivalent) and approval number (where applicable) of the person making the release statement;
9. for components released from maintenance, a statement that the maintenance was carried out in accordance with the recognised authority's regulation/policy; and
10. for components released from production, a statement that the component(s) was manufactured in conformity with approved data.

8.3.4.14 The ARC does not constitute authority to install the item on a particular product or component, but provides evidence that assists the AMO in determining the item's eligibility for fitment. Furthermore, an ARC cannot be used for the release of complete aircraft.

8.3.4.15 The ARC serves as the official certificate for components from the manufacturer/AMO to users. It should therefore be used for the transfer of components between different airworthiness systems or AMOs. A delivery or shipping note does not constitute an ARC.

8.3.4.16 It should also be noted that a mixture of new and used items is not permitted on the same ARC. Likewise, a mixture of items certified in conformity with 'approved data' and to 'non-approved data' is not permitted on the same certificate.

Superseded

When is an Authorised Release Certificate required?

8.3.4.17 An ARC is necessary for the release to service of either new or used components. The certification of new components is performed IAW DASR 21.A.307, whereas the certification of maintenance on used components is performed IAW DASR 145.A.50.

8.3.4.18 A component is eligible for fitment to a type-certified product when the component is in a condition for safe operation (i.e. serviceable) and accompanied by an ARC. An ARC helps the AMO to determine the airworthiness approval status for components and therefore eligibility for fitment.

8.3.4.19 **Release of new components following production**[14]**.** The component manufacturer is responsible for producing the ARC following the production of a new component. The purpose of the Authorised Released Certificate for new components is to certify that the item has been manufactured in conformity to approved design data and marked in accordance with DASR 21, Subpart Q. An ARC is required for components produced under:

1. type-certificate or supplemental type-certificate and changes thereof;
2. Production Organisational Approval;
3. Parts Manufacturing Approval (PMA) / European Part Approval (EPA)[15]; or
4. AUSMTSO authorisation.

8.3.4.20 Such components will normally be listed within the OEM furnished Illustrated Parts Catalogue (IPC) or Illustrated Parts Breakdown (IPB).

8.3.4.21 **Release of used components following maintenance**[16]**.** The purpose of the ARC for used components is to release components to service after off-aircraft maintenance. The ARC is issued by the AMO and must be within their scope of approval

8.3.4.22 Issuing an ARC following maintenance is an attestation that all maintenance is complete (except for deferred defects agreed to by the CAMO), and there are no non-compliances which are known to endanger flight safety. Any incomplete maintenance ordered/tasked should be clearly stated in the ARC when such non-compliances (i.e. deferred maintenance) are within the approved aircraft limitations.

8.3.4.23 Only personnel authorised by the DASR 145 may issue a DASR Form 1 Authorised Release Certificate following off-aircraft maintenance. Where component maintenance is subcontracted to another maintenance organisation[17], the ARC may be issued either at the:

1. non-DASR 145 contractor/tasked maintenance organisation[18]; or
2. AMO facility by staff holding a certification authorisation, as appropriate[19] .

8.3.4.24 Further, for used components that are service life-limited the ARC shall contain, or be accompanied by, an updated maintenance status with reference to this status in Block 12 of the certificate. In addition to configuration data (modifications, repairs, ADs and SBs), the status should contain information on the utilisation, particularly accumulated service life in relation to component life-limits.

When is an Authorised Release Certificate not required?

Superseded

8.3.4.25 An ARC is not always required after component production or maintenance. However, documented evidence of conformity to approved design or certified material specification must be obtained prior to fitment to a type-certified product. Such evidence must be traceable back to the organisation that manufactured or maintained the component.

New Components.

8.3.4.26 **Specific equipment.** Components which have been incorporated into the type design as specific equipment[20] and therefore have been shown not to adversely affect the airworthiness of the aircraft and not subject to recognised airworthiness standards[21] do not require an ARC. The CAMO should provide installation instructions that authorise the component's return to service requirements. Examples of specific equipment may include commercial-off-the-shelf (COTS) 'industry supply' equipment. This may include Commercial Parts such as cabin reading light bulbs, curtain rings, sink valves, etc.

8.3.4.27 **Standard Parts.** Standard Parts must be supplied with a CoC referring to the specified standard, the manufacturer and supplier source, the batch/lot number and, if applicable, the shelf life (including expiration date) and storage conditions. Standard Parts are specified within the manufacturer's IPC/IPB or maintenance data. Examples of Standard Parts include, but are not limited to, those conforming to National Aerospace Standard (NAS), Air Force/Navy (AN) Aeronautical Standard, Society of Automotive Engineers (SAE), Aerospace Standard (AS), Military Standard (MS), etc.

8.3.4.28 A part is no longer considered a Standard Part if it is used in a critical application that imposes qualification or quality control requirements beyond the published standard specification. In such a case, the OEM should allocate its own part number reference, and these parts would require an ARC.

8.3.4.29 **Materials.** Both raw and consumable materials, used in the fabrication, maintenance, servicing or operation of an aircraft or component, may be accepted without an ARC[22]. Such materials are required to meet the specification detailed in the approved design, and have appropriate traceability.

Used Components.

8.3.4.30 **Restricted Parts manufactured by the AMO.** Where a maintenance organisation has been granted approval by the Authority to fabricate a restricted range of parts to be used by that maintenance organisation in the course of overhaul, maintenance, modifications or repair within its own facility, such parts do not qualify for certification via an ARC[23].

8.3.4.31 **Unserviceable Parts.** An ARC should not be issued for any unserviceable components, except where such items are undergoing a series of maintenance processes at multiple AMOs. In this case, the receiving AMO requires an ARC to accept the component prior to subsequent maintenance.

8.3.4.32 **In-house release.** An ARC may not be required in the case where an AMO maintains a component for its own use and there is an approved alternative in-house release document as described in the AMO's MOE.

8.3.4.33 **Aircraft on Ground – other than at Main Operating Base (MOB).** When an aircraft is grounded at a location other than the MOB due to the non-availability of a component with an appropriate release certificate, it is permissible to temporarily fit a component with an alternative release certificate, subject to CAMO approval. The component must be removed at a time specified

Superseded

by the CAMO, unless the appropriate release certificate has been subsequently obtained, prior to removal of the component.

What do I do with a completed Authorised Release Certificate?

8.3.4.34 The completed ARC becomes part of the technical record for the component to which it relates, and eventually will become part of the technical record of the higher assembly or product on which that component is installed. The certificate is therefore subject to all applicable regulatory requirements related to maintenance and technical records .

When are components not eligible for fitment?

8.3.4.35 A component is not eligible for fitment on a type-certified product where it is known or suspected to have any of the following:

1. Discrepancy between the component's identifying markings (as required by DASR 21 subpart Q) and its accompanying documentation;
2. Non-conformances between the component's physical characteristics and its approved design data/specification or applicable maintenance data (i.e. unacceptable or questionable quality);
3. Damage (due to packaging, etc.) or unserviceability;
4. Absence of or incomplete or inappropriate release documentation to determine the airworthiness status or eligibility for fitment; or
5. Unknown, suspect or unverified origin of the component (i.e. has not or may not have been manufactured or maintained by an approved source).

8.3.5 – Flexibility Provisions for Maintenance Organisations

Introduction

8.3.5.1 This chapter provides guidance on the application of DASR GR.80 Flexibility provisions within the specific context of maintenance organisations. To meet an operational need, there may be circumstances where the authorisation of non-MAML staff in certifying or support staff roles is necessary. These circumstances also extend to where it is not practical for foreign-trained personnel to obtain a MAML in the time available (e.g. short-term secondment).

8.3.5.2 Currently, the scope of guidance provided is related to the authorisation of non-MAML staff as certifying and support staff for on-aircraft maintenance.

DASR GR.80 Flexibility provisions

8.3.5.3 **Provisions.** DASR GR.80 *Flexibility provisions* includes two different avenues to enable regulated entities to deviate from the requirements of applicable DASR. These provisions are available subject to an operational need, where compliance with applicable DASR would impact the ability to meet operational objectives. The two avenues are:

1. **Achieve an equivalent level of protection under GR.80(b).** DASA may approve the deviation using the applicable DASR as the safety standard against which the deviation is assessed and approved.

Superseded

2. **Equivalent level of protection not demonstrated, but supported by the application of sound risk management, under GR.80(c).** DASA may *allow* the deviation but cannot approve it due to the absence of any established safety standard against which to approve.

8.3.5.4 **Second-order effects.** The use of DASR GR.80 provisions, including GR.80(b) which requires an equivalent level of protection, has the potential to create unintended second-order safety impacts due to the interlinked nature of the DASR (a system of systems). In each instance, the regulated entity seeking to apply these flexibility provisions should identify and address any such impacts.

8.3.5.5 **Increased safety risk.** The application of GR.80 flexibility provisions by service providers, such as maintenance organisations, may result in increased Aviation Safety risk for the relevant Military Air Operator (MAO). Affected MAOs must apply additional due diligence to activities utilising the flexibility provision for the period in which that flexibility provision is in effect, commensurate with the residual risk level. Additionally, GR.80 application does not absolve the organisation of its obligation to continue to comply with all other applicable DASR. Where GR.80 flexibility provisions have been appropriately applied, DASA will not issue a finding for non-compliance against specific DASR clauses covered by the provision.

8.3.5.6 **Remediation.** Any flexibility provision should only be continue to be in place while:

1. the operational need continues to exist; and
2. compliance with relevant DASR would continue to impact operational objectives.

8.3.5.7 **Application to DASA.** DASA expects that proposed implementation of flexibility provisions to be detailed within, or referenced by, draft amendments to the MO exposition submitted under a DASR Form 2 Application for DASR 145 and DASR M Subpart G Approval.

8.3.5.8 **Application by Defence Industry**. Defence Industry organisations may only enact DASR GR.80 provisions through their relevant Military Air Operator (MAO) as the Risk Management Authority. In the event that a MAO's operational need requires a Defence Industry MO to exercise flexibility provisions, Defence Industry would support the MAO through provision of technical considerations and controls.

Use of flexibility provisions to authorise certifying and support Staff

8.3.5.9 **Background.** As discussed in chapter 8.3.3, the DASR requires[24] that certifying staff and support staff for on-aircraft maintenance hold an appropriate MAML. DASA MAMLs are issued when an applicant provides to DASA the relevant evidence, from a DASR 147 Maintenance Training Organisation (MTO) or recognised equivalent, that basic knowledge, basic experience and applicable type training requirements have been met. Gaps in basic knowledge result in MAML exclusions – mostly aircraft system based (e.g. propulsion systems, electrical systems) – and preclude a MAML holder from issuing a CRS or acting as support staff on the excluded aircraft systems.

8.3.5.10 **Granting of MAMLs to foreign-trained personnel.** Provisions within the DASR 147 enable foreign-trained maintenance personnel to obtain a MAML by undergoing an equivalency assessment where time permits. This assessment is conducted by an approved or recognised 147 MTO and will consider knowledge and experience as well as relevant type training.

8.3.5.11 **DASA assurance of procedures and outcomes.** DASA will conduct independent safety assurance differently for DASR GR.80(b) and GR.80(c), commensurate with the level of risk exposure. However, DASA assurance for both DASR GR.80(b and GR.80(c) involves the prior assessment of the

Superseded

procedure used to authorise non-MAML staff in certifying or support staff roles. Where uncertainty exists as to the procedure's applicability or suitability in a particular instance, the DASR 145 MO (through the CAMO, on behalf of the MAO), should seek advice from DASA.

8.3.5.12 Common guidance. The maintenance organisation may choose to utilise a single procedure to address both GR.80(b) and GR.80(c) scenarios. However, the organisation must make it clear how it will meet the different aviation safety performance outcomes. In both scenarios, where practicable, the procedure should require DASA 145 MOs to seek assistance from the ADF DASR 147 MTO to assess training deficiencies and inform decisions.

DASR GR.80(b) equivalent level of protection

8.3.5.13 An application to use the GR.80(b) equivalent level of protection provision must articulate how the procedure to authorise non-MAML staff in certifying or support staff roles will provide an equivalent level of protection to that which would otherwise be attained through compliance with the relevant DASR. If DASA agrees that an equivalent level of protection is achieved through the procedural outcome, DASA will approve the exception from the DASR. DASA will apply assurance to the ongoing application of the procedure(s) through routine oversight unless the DASR 145 MO, through the CAMO (on behalf of the MAO), requests DASA independent assurance prior to the issue of an individual authorisation.

8.3.5.14 An application to DASA for approval of the GR.80(b) equivalent level of protection flexibility provision should describe a method for implementing risk controls equivalent to those inherent in a DASA MAML (e.g. categorisation, exclusions and type ratings). The procedure should require assessment of individual competency, through knowledge and experience considerations, via:

1. an approved foreign nation/service comparison process; or
2. suitable evidence against each relevant module of DASR 66 Appendix I I and relevant chapters of DASR 66 Appendix III, to the appropriate training level, for the scope of the authorisation to be given.

8.3.5.15 Utilisation of DASR GR.80(b) is likely to be complex and time-consuming, requiring detailed analysis that may not be suitable to support agile operations.

DASR GR.80(c) risk management

8.3.5.16 For DASR GR.80(c), the procedure to authorise non-MAML staff in certifying or support staff roles must demonstrate that a credible and defensible level of military aviation safety performance will be maintained through sound management of aviation safety risks arising through the deviation from applicable DASR. DASA will not approve a GR.80(c) procedure but will allow its use subject to the requirement that all instances of the organisation applying the procedure are reported to DASA at the first practical opportunity. The DASA assurance role provides an independent assessment of the credibility and defensibility of the risk-based decision that is made by the organisation.

8.3.5.17 Any application to DASA to implement a GR.80(c) *risk management* approach should address the following:

1. The seven-step risk management guidance provided in Annex A and the format and means in which it will be submitted to DASA.
2. The necessary interfaces to the MAO such that any Decisions to Proceed are appropriately documented.

Superseded

3. Where operational needs allow for prior assurance by DASA, the relevant DASA desk officer should be provided with the output of the procedure, to review prior to enactment.

4. Where operational needs do not allow for prior assurance by DASA, the procedure for authorising non-MAML certifying or support staff may still be enacted by the DASR 145 AMO (through the MAO). Retrospective DASA assurance will be applied where an ongoing operational need supports continued application of the flexibility provision.

Annex:

(a) Contextualised guidance for seven-step risk management

8.4.1 Introduction and Background

Introduction

8.4.1.1 This chapter provides additional guidance on the Military Aircraft Maintenance Licence (MAML), and for those individuals applying for a "personnel authorisation[25]" under DASR 66, how to comply with DASR 66 requirements.

8.4.1.2 DASR 66 establishes the regulations required to be met by Aircraft Maintenance Training Organisations (AMTO), responsible for either Basic or Type Training, to be eligible for a DASR Military Aircraft Maintenance Licence (MAML).

8.4.1.3 For the purpose of this chapter additional guidance does not include information already presented at Volume 2, but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3. Further information regarding DASR 147 is located within Volume 3, chapter 8.5.

Background

8.4.1.4 During the DASR 66/147 transition, DASA provided a number of interim arrangements which allowed the current workforce to apply for DASR 66 MAMLs, including acceptance of existing Military Aircraft Type Rating training until the DASR were fully implemented.

8.4.1.5 The DASR 66.A.70 conversion provisions were based on the Australian National Competency Training and Assessment framework. These provisions were applied to staff who held valid certifying qualifications prior to the date of these regulations being introduced.

8.4.1.6 All DASA MAMLs are based on objective evidence of an individual's Qualification, Training and Experience (QTE), against the criteria in Appendix I to DASR 66 Basic Knowledge Requirements. DASA has mapped the EMAR syllabus (Appendix I to DASR 66) to associated Australian nationally adopted Competency Based Training and Assessment Units of Competency (UoC), qualifications and non-vocational education and training (VET) service specific training. This mapping resulted in providing a DASA Category A1, A3, B1.1, B1.3 or B2 MAML, with or without exclusions and inclusions.

Superseded

8.4.1.7 The Defence Airworthiness Safety Regulations (DASR) 66 - Military Aircraft Maintenance Licencing provides Defence personnel who hold a MAML the privilege to issue Certificate of Release to Service (CRS). This regulation is based on the European Military Airworthiness Requirements Part 66 (EMAR Pt 66), but adapted to suit the Australian military maintenance environment.

8.4.1.8 DASR 66 identifies the skills and knowledge requirements for each licence category (refer MAML Categories below) by syllabi. DASA have mapped initial trade training and technical, promotion-related courses (eg Aviation Technician Supervisor Course, LSATT, CPL SUBJ 4 etc) against these syllabi.

8.4.1.9 The MAML is an attestation the holder has met the DASR 66 knowledge and experience requirements, but does not entitle the holder to issue an aircraft CRS until they are authorised within a DASR 145 Maintenance Organisation (MO) to exercise these privileges.

8.4.2 MAML Categories, Limitations and Extensions

DASR 66.A.3 - MAML Categories

8.4.2.1 There are four basic licence categories:

1. The Category A licence is a non-type rated licence for minor scheduled and unscheduled maintenance permitted within Line Maintenance (relevant tasks will be detailed in the relevant DASR 145 MOE). The privileges of a Category A licence are not applicable to Base Maintenance.

2. Category B1 - permits certification privileges for scheduled and unscheduled airframe, engine, structures, mechanical systems and electrical maintenance for more complex Line Maintenance activity. The B1 MAML also permits minor avionics maintenance (eg 'black box' changes, where no specialised support equipment is required). The B1 MAML allows for authorisations as support staff within Base Maintenance.

3. Category B2 - permits certification privileges for scheduled and unscheduled complex avionics and electrical Line Maintenance activities and allows the holder to act as B2 support staff within Base Maintenance.

   Note: The Category B1 and B2 licences are aircraft type-rated licences and permit the holder to certify the release to service only of aircraft types that are endorsed as ratings on their licence.

4. Category C - is required for personnel who issue the CRS following Base Maintenance.

   Note: The Category C licence is an aircraft type-rated licence and permits the holder to issue the CRS of an aircraft following Base Maintenance only. GM to DASR 66.A.20(a) para 3 provides more detail.

DASR 66.A.50 – Limitations and DASR 66.A.52 – Extensions

8.4.2.2 All MAMLs are managed in accordance with the DASA 66 MAML Exclusion Inclusion & Endorsement Manual, available on the DASA Website.

Superseded

8.4.2.3 The DASA 66 MAML Exclusion, Inclusion & Endorsements Manual outlines the required competency details and provides general guidance that reflects DASR 66.A.20 privileges against the S1000D system of standard numbering to specify particular Systems and Sub-systems.

8.4.2.4 Exclusions (Limitations) introduced on a MAML are omissions from an individual's certification privileges, indicating that the licence holder shall not issue a CRS in

8.4.2.5 Line Maintenance or act as B1 or B2 support staff in Base Maintenance if maintenance related to that exclusion has occurred.

8.4.2.6 Inclusions (Extensions) introduced on a MAML are additional privileges to an individual's certification privileges, indicating that the licence holder may issue a CRS or act as B1 or B2 support staff if maintenance related to that Inclusion. Noting that additional military specific systems Inclusions can be achieved through completion of all required competencies & a type course (where appropriate) which incorporates S1000D Air-vehicle system basic knowledge requirements into the type syllabus.

8.4.2.7 The S1000D is a numerical technical classification of all the systems and sub systems on an aircraft, which is largely used in aircraft engineering and maintenance, and helps to standardise data across aircraft manufacturers and programs to facilitate improved maintenance and logistics.

8.4.3 MAML Applications

DASR 66.A. 10 - Application

8.4.3.1 Refer to DASPMAN Volume 3, Chapter 5.3 – Annex W – MAML for details.

Foreign Licence Applications

8.4.3.2 Military Aviation Authority/National Aviation Authority's (MAA/NAA) have differing training requirements for aircraft maintenance personnel based upon their sovereign regulatory maintenance framework. Therefore, there may be considerable differences in each country's licence privileges, regulations, assessment methods/framework and specific guidelines; resulting in gaps and difficulties to enable direct conversion of a foreign MAA/NAA issued licence to a DASA MAML.

8.4.3.3 Australia has nationally adopted competency-based training and assessment in lieu of EASA/ EMAR basic knowledge syllabus and examinations, which results in attainment of Units of Competency (UoC), which in turn lead to Aeroskills qualifications.

8.4.3.4 DASA has mapped these Aeroskills Mechanical and Avionics UoC against DASR 66 syllabi requirements to provide either a Category A, B1.1, B1.3 or B2 MAML, with/without exclusions and inclusions.

8.4.3.5 To enable Non-Australian competencies/qualifications to be used to apply for a MAML, a 147 Maintenance Training Organisation (MTO) RPL assessment must be performed using objective evidence to provide an individual with an RPL report clearly outlining the required theory and practical training requirements that have been met.

Aging Qualifications

8.4.3.6 All MAML applications will need to meet the following requirements:

Superseded

1. Any grandfathering formally recognised and utilised for a MAML assessment during the transitional period will be honoured and no further action is required by the individual;

2. IAW DASR 66.A.25 any training courses and examinations shall be passed within 10 years prior to the application for:

   i. a MAML; or

   ii. an addition of a category or subcategory to a MAML; or

   iii. the removal/addition of a DASA exclusion/inclusion to a MAML.

3. Qualifications 10 years or older now come into question, as not meeting the requirements of 66.A.25(b). Any of these qualifications provided as evidence for a MAML application (initial or update), will generally not be accepted unless they have been assessed and converted against DASR 66.A.25 Basic knowledge requirements by a DASA/CASA approved 147 Organisation;

4. DASA acknowledges that there may be individual unique circumstances where aging qualifications could be considered in more detail – specifically where the time and effort required for conversion to contemporary standards, by a DASA/CASA approved 147 Organisation, may not be reasonable. To support this, where aging qualifications (>10yr) are used as evidence for a MAML application (initial or update), the applicant must provide detailed justification (with supporting evidence) on why the aging qualification should be considered. This should include relevant work history for the applicant (including objective evidence of previous maintenance authorisations) and detail any factors that support the acceptance of aging qualifications without conversion. MAML applications, with aging qualifications, will be rejected if no supporting justification is provided.

5. Where there is any doubt or ambiguity regarding the requirements for a MAML, contact DASA at dasa.dcadasr66@defence.gov.au, and provide detailed evidence for DASA's consideration

8.4.4 MAML Basic Knowledge and Experience Requirements

DASR 66.A.25 – Basic Knowledge Requirements

8.4.4.1 A MAML applicant must have a demonstrated level of knowledge relevant to the MAML privileges to be granted, and in order to obtain a Category A (Line Maintenance only), B (Line & Base Maintenance) or C (Base Maintenance only) MAML. An applicant requires "Basic Knowledge" in the appropriate subject modules IAW Appendix I toDASR 66.

DASR 66.A.30 – Basic Experience Requirement

8.4.4.2 In addition to Basic Knowledge requirements (DASR 66.A.25), a MAML applicant must also have a demonstrated level of Basic Experience of the requested licence category (DASR 66.A.30). An applicant requires:

1. The practical experience must be gained in the real environment of military aircraft maintenance;

Superseded

2. Initial employment training (IET) delivered to trainees of all three ADF Services provides the minimum practical training detailed in Appendix I to DASR 66. Therefore, maintenance personnel who have completed their IET are eligible for a category A licence after six months of practical training, following completion of specific aircraft task training in accordance with DASR AMC 66.A.20(b), and having achieved syllabus Module 10 requirements.

8.4.4.3 Experience shall be acquired within 10 years preceding the initial category or subcategory.

DASR 66.A.40 - Continued validity of the MAML

8.4.4.4 All MAMLs are perpetual and will remain valid unless suspended, surrendered or revoked.

8.4.4.5 DASA has a process that allows it to assess breaches or suspected breaches of the conditions that a MAML was issued and take appropriate action. Contact DASA at DASA.DCA DASR66 for more information.

8.4.5 MAML Military Aircraft Type Rating Endorsements

DASR 66.A.45 - Military Aircraft Type Rating

8.4.5.1 In order to enact the privileges of a DASR 66 Category B (Line and Base Maintenance) MAML, MAML holders must have a specific Military Aircraft Type Rating (MATR) endorsement and be authorised by the DASA 145 nominated person (generally the Quality Manager) to operate within their approved quality system. In order to obtain a type rating, an applicant requires:

1. Type Training (Theory & Practical) (DASR 66.A.45): and
2. On the Job Training (OJT) for first Type Rating (AMC 66.A.45)

Military Aircraft Type Ratings Guidance

8.4.5.2 Refer to Chapter 8.5.8 – Military Aircraft Type Ratings for further details.

Expectations

8.4.5.3 All MATR applications must confirm that any OJT requirements are completed IAW Appendix III to DASR 66.

8.4.5.4 All MATR type training courses must be started and completed within the 3 years preceding application for the MATR.

8.4.5.5 The “Basic Training Course” requirements stated in 66.A.30 and 147.A.200 must be met before individuals are eligible for the relevant category MAML.

8.4.5.6 OJT requirements stated in Appendix III to DASR 66 must be met for first MATR in licence subcategory. Evidence of completion must be provided with the MAML endorsement application.

8.4.5.7 DASA may accept practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 – Northrop Grumman for applications for P-8A Poseidon or E-7A Wedgetail.

Superseded

8.4.6 MAML Suspension or Revocation

8.4.6.1 On receipt of notification of fraudulent or unsafe behaviour by a MAML holder, DASA will assess the information to determine what action, if any, is required.

Notice to Show Cause

8.4.6.2 Should DASA determine that a suspension or revocation of a MAML be warranted, then a Notice to Show Cause (NTSC) will be issued to the MAML holder. For procedural fairness, the affected MAML holder will be provided the reasons and evidence supporting the decision to issue a NTSC. The NTSC provides the MAML holder the opportunity to respond to the proposed suspension or revocation of their MAML.

8.4.6.3 The response to the NTSC will be assessed by DASA to determine if:

1. No action required; or
2. MAML will be suspended; or
3. MAML will be revoked.

MAML Suspension or Revocation

8.4.6.4 DASA will notify the MAML holder, and the organisation for which the MAML holder held the authorisation, of the suspension or revocation of the MAML. DASA also publishes a list of suspended MAML on the Military Aircraft Maintenance Licencing page on the DASA website.

Review of Suspension or Revocation

8.4.6.5 The organisation for which the MAML holder held the authorisation, can request DASA to review the decision. The request for review should include the results of any internal investigation and any other relevant information to support the request for a review.

8.5 Aircraft Maintenance Training Organisations

8.5.1 Introduction and Background

Introduction

8.5.1.1 This chapter provides additional guidance on the Defence Airworthiness Safety Regulations DASR 147 – Aircraft Maintenance Training Organisations (AMTO), to assist those organisations applying for a DASR 147 approval on how to comply with DASR 147 requirements.

8.5.1.2 DASR 147 establishes the regulations required by an AMTO responsible for either Basic or Type Training of DASR 66 Engineers and Aircraft Maintenance Technicians to be eligible for a Military Aircraft Maintenance Licence (MAML).

8.5.1.3 For the purpose of this chapter additional guidance does not include information already presented at Volume 2, but represents additional guidance material. Referenced content relevant to, but not directly related to, continuing airworthiness will be found in other areas of the Defence Aviation Safety Program including in other chapters of DASP Manual Volume 3

Superseded

Requirements for Aircraft Maintenance Training Organisation

8.5.1.4 The Defence Aviation Safety Regulations (DASR) requires individual DASR 147 Maintenance Training Organisations (MTOs) to define their maintenance training activities in their Maintenance Training Organisation Exposition (MTOE). The scope of maintenance training of basic knowledge and/ or Military Aircraft Type Rating (MATR) training should be in accordance with the MTO's policy and procedures defined in the MTOE.

Background

8.5.1.5 The Defence Aviation Safety Authority (DASA) and Headquarters Air Force Training Group (HQAFTG) have agreed that the primary framework to meet the DASR 147 requirements for the training of ADF personnel is through the creation of a single Air Domain MTO.

8.5.1.6 The single Air Domain MTO will:

1. leverage existing Joint and Single Service Individual Education and Training governance arrangements to provide an efficient and standardised governance approach for Australian Defence Organisation (ADO) aviation maintenance training.
2. align with the Defence Registered Training Organisation (DRTO) framework to enable standardisation against benchmarked Australian Skills Quality Authority (ASQA) standards.
3. provide a single point of accountability for aviation maintenance training, which will provide better holistic oversight that safety outcomes are being achieved.
4. provide the simplest path to the provision of recognition of Defence Maintenance Training by civil regulators and foreign militaries.

8.5.1.7 Commercial organisations that deliver aircraft maintenance training, either initial technical training (basic training) or Military Aircraft Type Training to meet DASR 66 requirements will be recognised by DASA if they:

1. already have a Part 147 Approval issued by a DASA- recognised Civil Aviation Authority (CAA)/ Military Aviation Authority (MAA); or
2. are included within the Air Domain MTO; or
3. are issued a discrete DASR 147 Approval, where they provide aviation maintenance training to DASR 145 organisation(s), but do not train ADF personnel.

8.5.1.8 The Air Domain MTO includes military aircraft type training courses delivered by Army Aviation Training Centre (AAvnTC), the Navy Training Authority – Aviation (TA-AVN) and the Air Force – Force Element Groups (FEGs). Basic aviation knowledge training delivered by RAAF School of Technical Training (STT) is also included under the Air Domain MTO.

Application to become an MTO

8.5.1.9 Refer to DASPMAN Volume 3, Chapter 5.3 – Annex I – MTO for detailed guidance on the application process.

Superseded

8.5.2 Facility and Equipment Requirements

8.5.2.1 This regulatory provision outlines the facility requirements for a DASR 147 Aircraft Maintenance Training Organisation (AMTO) and contains several sub-sections, which detail the requirements that AMTOs must meet in terms of facilities, equipment and resources.

Facility Standards

8.5.2.2 AMTOs are to provide adequate facilities, equipment and tools to conduct training. AMTOs must ensure that their facilities meet the appropriate standards for classroom space, simulator training areas and other areas necessary for conducive aviation maintenance training. Additionally, AMTOs must have facilities for storage of maintenance tools, equipment and parts.

Workshop Standards

8.5.2.3 Workshops must be equipped with tools, equipment and materials necessary to perform the practical tasks required by the relevant training courses. AMTOs must have appropriate facilities for the storage, testing and calibration of equipment used in the maintenance of the aircraft.

Training Equipment

8.5.2.4 Training equipment must be maintained and calibrated to ensure that it is safe and effective for use in training. AMTOs must ensure that they have the appropriate equipment for training in various aspects of aircraft maintenance including aircraft systems, avionics, structures and powerplant maintenance.

Library Facilities

8.5.2.5 AMTOs are to provide access to relevant aviation related reference materials, manuals and other resources necessary for aviation maintenance training. AMTOs must ensure that their libraries are up to date and have a wide range of materials that are relevant to the training courses they offer.

Computer Facilities

8.5.2.6 AMTOs are to have computer facilities that provide access to relevant aviation related software, databases and other tools necessary for effective aviation maintenance training. AMTOs must ensure that their computer facilities have up to date software and hardware as well as high-speed internet connections.

8.5.3 Personnel Requirements

Personnel Requirements

8.5.3.1 This section specifies the personnel requirements for management personnel employed by DASR 147 AMTOs. The organisation must have sufficient management personnel to ensure the effective management of its operations. The management personnel must be qualified, experienced and possess the necessary skills to oversee the organisation's activities and ensure compliance with all relevant regulations and standards. This includes an Accountable Manager who has overall accountability for the organisation's compliance with DASR regulations and will appoint other necessary resources to accomplish training commitments. The regulation includes requirements for

Superseded

different types of personnel, including management personnel, technical personnel, quality personnel, training personnel, and support personnel.

Records of Instructors, Examiners, Assessors and Invigilators

8.5.3.2 DASR 147.A.110 requires approved maintenance training organisations (AMTOs) in Australia to maintain records of instructors, examiners, and assessors. The records must contain specific details about the personnel including:

1. **Personal Details:** Personal details of the instructor, examiner, or assessor, including their full name, date of birth, and contact information.
2. **Qualifications:** Details of the instructors, examiners, or assessor's qualifications, including the type of qualification, the date it was obtained, and the organisation that issued it.
3. **Experience:** Details of the instructors, examiners, or assessor's experience, including the type of experience, the duration of experience, and the organisation where the experience was gained.
4. **Training:** Details of the training received by the instructor, examiner, or assessor, including the type of training, the duration of training, and the organisation that provided the training.
5. **Authorisations:** Details of any authorisations held by the instructor, examiner, or assessor, including the type of authorisation and scope, the date it was issued, and the organisation that issued it.
6. **Currency:** Details of the instructors, examiners, or assessors currency, including the type of currency, the date it was last achieved, and the date it is due to expire.
7. **Performance:** Details of the instructor's, examiner's or assessor's performance, including any relevant feedback or reviews and professional development plan.
8. **Relevant Training Material:** Details of any relevant training material that the instructor, examiner, or assessor has access to or uses in the performance of their duties.
9. **Verification of Competence:** Details of any verification of competence conducted on the instructor, examiner, or assessor, including the type of verification, the date it was conducted, and the organisation that conducted it.
10. **Compliance:** Details of the instructor's, examiners, or assessor's compliance with all relevant regulations and standards.

8.5.3.3 AMTOs can ensure that their personnel are qualified, competent, and authorised to perform their duties, and comply with all relevant regulations and standards.

Key Personnel Requirements

8.5.3.4 The qualification and experience of the instructors, knowledge examiners, practical assessors and invigilators are fundamental to ensuring the quality of a training course – only appropriately qualified personnel should be appointed to carry out training and examinations. In addition to the published Acceptable Means of Compliance (AMC) and Guidance Material (GM) to DASR 147.A.105(f), the following information provides additional guidance on the knowledge and

Superseded

skills that are expected of authorising instructors, knowledge examiners, practical assessors and invigilators employed by a DASR 147 Maintenance Training Organisation (MTO).

Instructors

8.5.3.5 A nominated person who will deliver a DASR 66 module or unit of competency (DASR 66 appendix I), a DASR 66 element (DASR 66 appendix III), or part thereof either of these. The instructor is not necessarily the person involved in drafting of the course material (content, duration, etc.), however they should be involved in the continued development of the lessons themselves (creation of the instructor notes, slides, sequencing, etc.).

8.5.3.6 Instructors should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO.
2. Pedagogic – should know how to organise a lesson and how to efficiently deliver a course that clearly highlights the fundamental points. They should also be able to adapt when communicating to a particular audience including with pre-existing knowledge/experience.
3. Able to promote the appropriate attitude towards regulation and procedures; in particular the strict adherence to approved maintenance practices and quality standards through the lens of their own experience in a regulated aviation environment.
4. Familiar and proficient with the tools and training techniques used by the training organisation to deliver lessons.
5. Appropriately experienced in the aircraft maintenance environment.
6. Able to demonstrate good knowledge, complimented with communication skills in the English language.
7. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.
8. Able to demonstrate good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directives, Service Bulletin, Maintenance Programme, etc.).
9. In receipt of continuous training in the company's procedures and DASRs.

Knowledge Examiners

8.5.3.7 A nominated person who will determine the level of theoretical knowledge of the trainees on a particular module, unit of competency, element, or part thereof. The function may include the drafting and/or the selection of questions (Multi-Choice Questions and Essays), the evaluation of the correctness of answers (except when correct answers are pre-determined) and the final judgement regarding the level of knowledge demonstrated by the trainee.

8.5.3.8 Persons solely supervising an exam session are not considered as examiners but are considered as support staff invigilators and, in this context, are not subject to knowledge and

Superseded

experience requirements, but need to be trained to the examination procedure described in the MTOE.

8.5.3.9 Knowledge examiners should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO, including the examination standards required by DASR 66.
2. Able to demonstrate a responsible attitude to the conduct of examinations, so that the highest integrity is ensured.
3. Trained in contemporary examination techniques and able to conduct an examination in such a way that the true abilities of the candidate are demonstrated.
4. Able to remain neutral at all times and behave in a manner that will not influence or prejudice the final result of the examination, for example by providing undue assistance or clarification to a candidate.
5. Familiar and proficient with the tools or the examination techniques used by the training organisation to perform the exams.
6. Appropriately experienced in the aircraft maintenance environment.
7. Able to demonstrate good knowledge, complimented with communication skills in the English language.
8. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.
9. Able to demonstrate good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directive, Service Bulletin, Maintenance Programme, etc.).
10. In receipt of continuous training in company's procedures and DASRs.

Practical Assessors

8.5.3.10 A nominated person who will determine the level of practical knowledge/practical skills of the trainees on a particular module, element, or part thereof. The function may include the drafting and/or the selection of practical tasks, the performance oversight and assessment of the practical activities. Practical assessors should be:

1. Conversant with the DASR 66, 145 and 147 regulations, AMC, GM and specific procedures (MTOE, instructions, etc.) that are assigned to their scope of approval within a DASR 147 MTO.
2. Experienced and show solid judgement regarding the abilities of the assessed trainees – the assessor should have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks in compliance with current regulation, approved procedures, maintenance practices, etc.
3. Trained to contemporary assessment techniques. The assessor should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated.

Superseded

4. Familiar and proficient with the tools or the techniques used by the training organisation to assess the practical abilities of trainees (maintenance simulators, mock up, etc.).

5. Appropriately experienced in the aircraft maintenance environment.

6. Able to demonstrate good knowledge, complimented with communication skills in the English language.

7. Able to demonstrate a good understanding of the workplace environment, human performance and safety culture.

8. Able to demonstrate a good knowledge of technical publications (Aircraft Maintenance Manual, Component Maintenance Manual, Airworthiness Directive, Service Bulletin, Maintenance Programme, etc.).

9. In receipt of continuous training in company's procedures and DASRs.

10. Able to act safely, apply safety precautions and prevent dangerous situations.

11. Able to demonstrate knowledge and understanding of areas requiring special emphasis or novelty (areas peculiar to the aircraft type, domains not covered by DASR-66 Appendix, practical training elements that cannot be imparted through simulation devices, etc.).

12. Able to demonstrate an understanding of the aircraft systems interaction.

13. Able to navigate, execute and obey the prescribed maintenance procedures.

Invigilators

8.5.3.11 A nominated person who will ensure the correct conduct of an examination in accordance with the examination procedures of the DASR 147 organisation. The invigilator is responsible for ensuring that examinations are conducted in accordance with the MTOE and Training Procedures and operates under the direction, responsibility and delegation of the Training Manager. The organisation can nominate permanent exam invigilators who should then be listed in MTOE Part 1 and qualified in accordance with Training Procedures.

8.5.3.12 Training organisations often delegate the invigilation of an examination to staff not listed as an examiner for the particular subject. These "invigilators" do not need to be qualified to the same extent as an examiner, and in particular, they do not need to demonstrate specialty knowledge, as long as their duty is strictly limited to the conduct of the examination itself.

8.5.3.13 Invigilators should however be trained to the organisation's examination procedures with a specific emphasis on the exam's integrity aspects and on the handling of cheating or misconduct cases. Such staff should be listed by the organisation with records of their training kept in the individual's personnel file.

Assessment and acceptance of staff

8.5.3.14 Assessment and acceptance of instructors, examiners and assessors should be performed, and documented by the approved training organisation in accordance with dedicated procedure described in the MTOE. Appropriate staff in the maintenance training organisation should physically interview proposed candidates in order to ensure their competency. Once completed, detailed result of this assessment, including any supporting documents (diplomas, DASR 66 licence, etc.) should be

Superseded

filed in accordance with MTOE procedure. The staff should be listed in MTOE with intended scope of instruction, examination or assessment.

Continued qualification

8.5.3.15 The qualification criteria and experience requirements only address the initial acceptance of instructor, examiners and assessors. The training organisation should develop and document a program in MTOE to ensure the continued competence of these staff.

8.5.4 Instructional Equipment Requirements

8.5.4.1 DASR 147.A.115 requires approved maintenance training organisations (AMTOs) to ensure that they have appropriate instructional equipment available to support their training activities. Here are some important points that must be considered when meeting this regulation:

1. **Type of Equipment:** The equipment must be appropriate for the type of training being delivered. This includes a wide range of equipment such as applicable aircraft, training aids, simulators, and computer-based training tools.
2. **Condition:** The equipment must be in good working order, and any faults or defects must be promptly rectified.
3. **Calibration:** The equipment must be calibrated as required, and records of calibration must be maintained.
4. **Availability**: The equipment must be readily available for use when required, and there must be sufficient equipment available to support the number of students being trained.
5. **Security:** The equipment must be stored securely when not in use, and access to the equipment must be controlled to prevent damage or misuse.
6. **Maintenance:** The equipment must be regularly maintained, and records of maintenance activities must be maintained.
7. **Training Material**: The equipment must be used in conjunction with appropriate training material to support effective learning.
8. **Compliance:** The equipment must comply with all relevant regulations and standards.
9. **Training for Equipment Use:** Instructors and trainers must be trained in the correct use of the equipment and any associated software or training materials.
10. **Upgrades and Replacements:** Equipment should be upgraded or replaced as necessary to ensure that it remains effective and meets current training requirements.

Aircraft Maintenance Training Aids

8.5.4.2 These are physical devices used to simulate or replicate various components or systems of an aircraft. For example, a training aid may be used to teach students how to inspect and troubleshoot an engine. Important points to consider for training aids:

1. The training aid must accurately represent the aircraft component or system being taught.

Superseded

2. The training aid should be durable and long-lasting.

3. The training aid should be kept clean and well-maintained.

8.5.4.3 **Computer-Based Training Tools:** These are software applications or programs that are used to deliver training material to students. For example, a computer-based training tool may be used to teach students how to use a maintenance management system. Important points to consider for computer-based training tools:

1. The software should be up-to-date and compatible with the AMTO's computer hardware.

2. The software should be easy to use and navigate.

3. The AMTO should have a system for monitoring and tracking student progress.

8.5.4.4 **Simulator Devices:** These are devices that replicate real-world situations or scenarios to provide hands-on training to students. For example, a simulator may be used to teach students how to perform a maintenance task on an aircraft. Important points to consider for simulator devices:

1. The simulator should accurately represent the real-world situation or scenario being taught.

2. The simulator should be well-maintained and regularly calibrated.

3. The AMTO should have a system for monitoring and tracking student progress.

8.5.4.5 **Training Videos and Audio Recordings:** These are pre-recorded videos or audio recordings that are used to deliver training material to students. For example, a training video may be used to teach students about safety procedures.

8.5.4.6 Important points to consider for training videos and audio recordings:

1. The video or audio recording should be up-to-date and relevant to the training being provided.

2. The AMTO should have a system for monitoring and tracking student progress.

3. The AMTO should ensure that the video or audio recording is of high quality and easy to understand.

8.5.5 Maintenance Training Material

8.5.5.1 DASR 147.A.120 requires approved maintenance training organisations (AMTOs) to develop and use maintenance training material that is appropriate for the type and level of training being delivered. DASR 66 specifies requirements for both basic and type course training material. Here are some important points to consider for each Basic course training material:

1. The training material used for basic courses must cover a broad range of topics and must be suitable for entry-level students. The following are some important points to consider when developing or using training material for basic courses:

    i. The training material must cover the theoretical and practical aspects of the aircraft, system, or component being taught.

Superseded

ii. The training material must be easy to understand and follow.

iii. The training material must include practical exercises that reinforce theoretical knowledge.

iv. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.

v. The training material must be appropriate for the level of experience and education of the students being trained.

Type Course Training Material

8.5.5.2 The training material used for type courses must cover the specific make and model of the aircraft, system, or component being taught. The following are some important points to consider when developing or using training material for type courses:

1. The training material must cover all relevant aspects of the aircraft, system, or component, including maintenance, inspection, troubleshooting, and repair.
2. The training material must be regularly reviewed and updated to ensure that it remains relevant and accurate.
3. The training material must be appropriate for the level of experience and education of the students being trained.

8.5.5.3 Some additional important points to consider when developing or using maintenance training material include:

1. The training material must be structured in a logical and organized manner.
2. The training material must be consistent with the relevant regulations and standards.
3. The training material must be presented in a manner that is engaging and interesting for students.
4. The AMTO must have a system for tracking and monitoring the use of training material, including the progress and performance of students.

8.5.5.4 By meeting the requirements of DASR 147.A.120, AMTOs can ensure that they are providing high-quality maintenance training material that is appropriate for the level and type of training being delivered. This can help to ensure that students receive the knowledge and skills they need to perform maintenance tasks safely and effectively.

8.5.6 Examinations

8.5.6.1 DASR 147.A.135 specifies the requirements for conducting examinations for aircraft maintenance training organisations (AMTOs) to ensure that their students have the necessary knowledge and skills to perform their maintenance duties effectively and safely. Here are some key points regarding the examination requirements:

Examination Development

Superseded

8.5.6.2 The AMTO should develop examination questions that are aligned with the training objectives and outcomes. The questions should be designed to test the knowledge and skills that the student has acquired during the training program. The AMTO should also ensure that the examination questions are reviewed and approved by qualified personnel.

Examination Administration

8.5.6.3 The AMTO should have procedures in place for administering examinations. This includes ensuring that students are aware of the examination format, rules and regulations, and any special instructions that apply. The AMTO should also ensure that the examination environment is conducive to learning and that the examination is conducted in a fair and unbiased manner.

Examination Security

8.5.6.4 The AMTO should have procedures in place for ensuring the security of all the question, examinations and databanks. Particular attention should be made to the storage and transportation of the examination between venues and whilst onsite. Care must be taken to ensure the examination questions are secure at all times. Electronic means of storage may be utilised where available, providing that suitable security arrangements are in place.

Examination Grading

8.5.6.5 The AMTO should have procedures in place for grading and evaluating examination results. The grading procedures should be fair, consistent, and transparent, and should be based on established criteria. The AMTO should also ensure that examination results are communicated to students in a timely manner and that students have access to feedback on their performance.

Examination Records

8.5.6.6 The AMTO should maintain records of examination results, including the student's performance and any relevant feedback. These records should be kept in a secure location and retained for a specified period of time in accordance with regulatory requirements (e.g. Annex A to AMC 147.A.125)

Examination Review

8.5.6.7 The AMTO should have procedures in place for reviewing and evaluating examination results to identify any areas where improvements can be made. This includes analysing trends in examination results, identifying areas where students are struggling, and taking corrective actions to improve the effectiveness of the training program.

8.5.6.8 In summary, the examination requirements outlined in DASR 147.A.135 are designed to ensure that the AMTO's training program is effective and that students have the necessary knowledge and skills to perform their maintenance duties safely and effectively. By following these requirements, the AMTO can maintain a high standard of training and contribute to the overall safety of the aviation industry.

8.5.7 Training Procedures and Quality System

8.5.7.1 DASR 147.A.130 requires Aircraft Maintenance Training Organizations (AMTOs) to establish and maintain effective training procedures and a quality system to ensure that their training programs are of a high standard and meet the requirements of all applicable regulations and standards

Superseded

including DASRs. Some important points to be considered when developing or maintaining training procedures and a quality system are:

Training Procedures

8.5.7.2 The training procedures must include a description of the training program, including the objectives, scope, and content of the training. This should include the methods and materials used for training, the sequencing of the training, and the assessments used to measure the effectiveness of the training.

Courseware

8.5.7.3 The AMTO should have a system in place to develop, review, and update courseware, including lesson plans, training manuals, visual aids, and other materials used for training. The courseware should be reviewed and updated regularly to ensure that it remains relevant and effective.

Instructor Qualifications and Training

8.5.7.4 The AMTO should have procedures in place to ensure that their instructors are qualified and competent to deliver the training. This includes requirements for instructor qualifications and training, such as experience in the industry, knowledge of the subject matter, and teaching skills. The AMTO should also have a system in place to regularly assess the performance of their instructors and provide them with feedback / training as necessary.

Assessment Procedures

8.5.7.5 The AMTO should have a system in place to assess the effectiveness of their training, including the use of assessments and evaluations to measure the knowledge and skills of the students. The assessments should be designed to provide a fair and accurate measure of the student's performance, and be reviewed and updated regularly to ensure that they remain valid and reliable.

Quality System

8.5.7.6 The AMTO should have a quality system in place to ensure that their training program meets the requirements of DASRs and any other applicable regulations and standards. This includes procedures for monitoring and evaluating the effectiveness of the training by identifying, correcting and preventing recurrence of any deficiencies and continuously improving the training program.

8.5.7.7 Some additional important points to consider when developing or maintaining training procedures and a quality system include:

1. The AMTO should ensure that all training is conducted in a safe and secure environment, and that appropriate safety procedures are followed at all times.
2. The AMTO should ensure that their training programs are accessible to all students and meet their needs.
3. The AMTO should ensure that all training is conducted in accordance with relevant laws and regulations including those related to privacy and data protection.
4. The AMTO should ensure that all training is conducted in a professional and ethical manner, and that all students are treated fairly and with respect.

Superseded

Quality Policy

8.5.7.8 The AMTO should have a quality policy that outlines the organisation's commitment to quality and its goals for maintaining a high standard of training. The policy should be communicated to all staff and stakeholders, and reviewed and updated regularly.

Quality Objectives

8.5.7.9 The AMTO should establish quality objectives that are measurable and aligned with the goals of the organisation. The objectives should be reviewed and updated regularly, and progress towards meeting the objectives should be monitored.

Document Control

8.5.7.10 The AMTO should have a system in place to manage and control documents related to training procedures and the quality system. This includes procedures for document creation, control, review, approval, distribution and revision.

Record Keeping

8.5.7.11 The AMTO should maintain records related to the training programs and the quality system, including records of student performance, instructor qualifications, audit results, corrective actions taken, and other relevant information.

Records of Students

8.5.7.12 DASR 147.A.125 requires approved maintenance training organisations (AMTOs) to maintain accurate and complete records of their students. These records must include a variety of information to demonstrate that the student has successfully completed the required training and has the necessary knowledge and skills to perform maintenance tasks safely and effectively. Here are some important points to consider when developing or maintaining student records:

1. Student Identification: The record must include the student's full name, date of birth, contact information, and any relevant identification numbers or codes.
2. Training History: The record must include a detailed history of the student's training, including the courses they have completed, the date of completion, and the grade they received. This information should also include any remedial training or retesting that was required.
3. Assessment Records: The record must include documentation of any assessments or examinations the student has completed, including the results and any feedback or comments provided by the examiner.
4. Attendance and Absences: The record must include information on the student's attendance and any absences from training, including the reason for the absence and any make-up training that was required.
5. Certification: The record must include information on any certifications the student has received as a result of their training, including the type of certification, the date it was issued, and any restrictions or limitations.
6. Other Relevant Information: The record should also include any other relevant information about the student, such as their prior education or experience in the field

Superseded

of maintenance, any disciplinary actions taken, or any other notable achievements or accomplishments.

7. Some additional important points to consider when developing or maintaining student records include:

   i. The record must be maintained in a secure and confidential manner to protect the privacy of the student.

   ii. The record must be accurate, complete, and up-to-date at all times.

   iii. The record must be available for review by relevant authorities, such as regulatory agencies or potential employers.

   iv. The AMTO must have a system in place to ensure that student records are regularly reviewed and updated as necessary.

8.5.7.13 By meeting the requirements of DASR 147.A.125, AMTOs can ensure that they are maintaining accurate and complete records of their students, which can help to demonstrate that the students have received the necessary training and are qualified to perform maintenance tasks safely and effectively.

Corrective and Preventive Actions

8.5.7.14 The AMTO should have a system in place to identify and address non-conformities or areas where the procedures and system can be improved. This includes procedures for taking corrective and preventive actions to avoid recurrence including causal or root cause analysis, tracking and monitoring the effectiveness of the actions taken, and documenting the results.

Management Review

8.5.7.15 The AMTO should conduct regular management reviews of the training procedures and quality system to ensure that they are effective and meeting the goals of the organisation. The management review should include a review of audit results, quality objectives, corrective and preventive actions, and other relevant information.

Audit Procedures

8.5.7.16 Auditing is an important part of ensuring that the training procedures and quality system of the AMTO are effective and meeting the requirements of the applicable regulations. Audits should be conducted by an independent auditor, who can be an internal auditor or an external auditor.

Internal Auditing

8.5.7.17 The AMTO should conduct internal audits of their training procedures and quality system on a regular basis to ensure that all aspects of DASR 147 compliance are checked at least once in every 12 months and may be carried out as one complete single exercise or subdivided over a 12-month period in accordance with a scheduled plan. The purpose of internal audits is to identify any non-conformities or areas where the procedures and system can be improved. The results of the internal audits should be documented and corrective actions should be taken to address any non-conformities.

External Auditing

Superseded

8.5.7.19 The AMTO should also undergo external audits by an independent auditor, who is not part of the AMTO organisation. The purpose of external audits is to ensure that the training procedures and quality system of the AMTO are in compliance with the requirements of the regulation. The results of the external audits should be documented, and any corrective and preventive actions that need to be taken should be identified and addressed.

8.5.7.20 By meeting the requirements of DASR 147.A.130, AMTOs can ensure that their training programs are of a high standard and meet the requirements of the regulation, which can help to ensure the safety and effectiveness of maintenance operations in the aviation industry.

8.5.8 Military Aircraft Type Ratings

Introduction

8.5.8.1 Military Aircraft Type Rating Training consists of theory and examination, practical and assessment, plus On-the-Job Training (OJT) – see DASR 66.A.45(c) – for first aircraft in licence category/subcategory. Any subsequent Military Aircraft Type Rating (MATR) within the same category/sub-category require both theory and practical elements but will only require further OJT if stipulated by DASA during the approval of the course.

Note: A minimum of only theory and examination is required for the Category C Military Aircraft Maintenance Licence (MAML) rating (AMC 66.A.45).

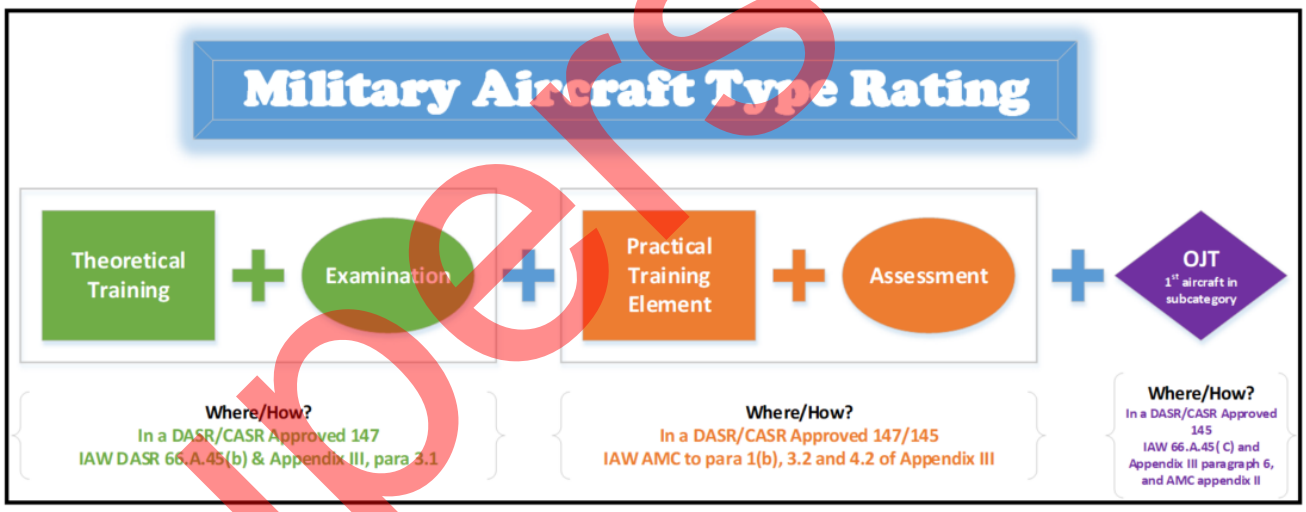

Figure 1: Military Aircraft Type Rating (MATR) - Required Elements

Privileges

8.5.8.2 In order to be entitled to exercise certification privileges for B and C categories on a specific aircraft type, the holder of a MAML shall have their MAML endorsed with the relevant Military Aircraft Type Ratings.

ADF Course Design and Development

Superseded

8.5.8.3 To ensure consistency across all ADF courses, the design and development of courses, including the course curriculum, should follow the System Approach to Defence Learning (SADL) – see SADL Website.

MATR Course – Initial Approval / Change Management

8.5.8.4 In order to facilitate approval by the authority, the following relevant DASR Forms are to be completed and submitted as appropriate:

1. DASR Form 12 - Application for DASR 147 Initial-Changes of Approval. The DASR Form 12 is the official DASA form to apply for a DASR 147 Maintenance Training Organisation approval. This form is considered part of an application pack and should be submitted with the appropriate evidence as detailed within the form to support the application.

2. DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval. The DASR Form 12A is to accompany the DASR Form 12 when the application is for an initial course approval. For an update to an existing approved course, only the completed Form 12A and associated evidence documents are required for submission.

8.5.8.5 As a minimum standard, the following documents must be submitted as evidence for MATR courseware approval:

1. Training Needs Analysis (TNA) or equivalent as accepted by DASA
2. Completed DASR 66 Appendix III MATR Courseware Assessment Matrix
3. MATR Theory Element (Learning Management Plan)
4. MATR Practical Element (Practical Training Logbooks)
5. On-The-Job-Training (OJT) logbook.

DASA Notification Requirements

8.5.8.6 Changes to MATR Courses shall be defined as either a Major or Minor Change.

8.5.8.7 A Major Change is any amendment, alteration or change to a MATR Course that is not accurately categorised as a Minor Change within the relevant Maintenance Training Organisation (MTO) Exposition procedure. A DASR Form 12A - Military Aircraft Type Rating Initial/Change Course Approval must be submitted and approved prior to any Major Change to a MATR Course.

8.5.8.8 A Minor Change is any amendment, alteration or change to a MATR Course that does not affect the DASR related approval. Minor Changes may be acceptable to DASA without prior approval by the Authority; contingent to endorsement by the relevant MTO QMS that no adverse material effect is posed to safety, quality of training or the knowledge, skills and attitudes of course graduates, course learning outcomes or location.

8.5.8.9 An internally reportable process for approval of Minor Changes to MATR Courseware must be included within the relevant MTO Exposition/Annex; containing either a specific predefined listing of all actions, or defining statement considered by the MTO to fall within the scope of a 'Minor Change'.

8.5.8.10 Subject to the endorsement of the MTO QMS, listed actions could include (but are not limited to):

Superseded

1. Grammatical and typographic changes

2. Changes that incorporate updates from the relevant platform specific technical publications (e.g. updated maintenance procedures, configuration changes etc.)

3. Changes of content (provided the learning outcomes are not affected).

Theoretical Element of the Military Aircraft Type Rating Training

8.5.8.11 The theoretical element of the Type Course shall provide the person with detailed theoretical knowledge of the applicable systems, structure, operations, maintenance, repair, and troubleshooting of the aircraft type according to the approved maintenance data, including:

1. The appropriate use of manuals and approved procedures, including any relevant inspections and limitations;

2. How to perform system, power-plant and component functional checks as specified in the maintenance manual;

3. Related information for the purpose of making decisions in respect of fault diagnosis and rectification within the scope of the maintenance manual;

4. Describing procedures for replacement of components unique to the aircraft.

8.5.8.12 Theory training shall be conducted by an appropriately approved DASA 147 MTO or an organisation recognised by DASA.

8.5.8.13 In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA.

8.5.8.14 Theory training shall have been started and completed within the 3 years preceding the application for a MATR endorsement.

8.5.8.15 The minimum pass mark for the theoretical exam is 75%.

8.5.8.16 The theoretical type training shall describe how the type training is delivered (i.e. classrooms, training equipment, instructors qualifications, TNA etc.) meeting the requirements of DASR 66 and 147, as appropriate.

8.5.8.17 The course content and duration shall be demonstrated by:

1. a detailed curriculum showing the levels for each chapter of the type training, which should be assessed for equivalence to Appendix III to DASR 66 for the relevant certifying staff category; and

2. verifying that both content and duration are justified through a comprehensive TNA (or equivalent as accepted by DASA).

8.5.8.18 Evidence is required for the following elements:

1. the teaching methods and instructional equipment;

2. the material and documentation provided to the student;

3. the qualification of instructors, examiners;

Superseded

4. the documentation and records provided to the student to justify the satisfactory completion of the training course and related assessment.

Note: For further information about these elements, refer to the MTO exposition.

Practical Element of the Military Aircraft Type Rating Training

8.5.8.19 Practical training is a structured training activity that consolidates the knowledge gained during the theoretical phase of type training and as such, may be performed after or integrated within the theory training. Practical training should:

1. Address the different parts of the aircraft and its associated engines, which are representative of the structure, the systems/components installed and the cabin.
2. Include the use of technical manuals, maintenance procedures and the operational interfaces with the aircraft (e.g. FMC, electronic flight bag, etc.)
3. Include common maintenance and ground handling activities.
4. Cover both type specific and generic safety elements of the aircraft's maintenance.
5. Develop the student's competence in performing safe maintenance, prior to the practical assessment.

8.5.8.20 The purpose of practical training is not to include all the maintenance tasks associated with a particular type, but a representative sample of them that will allow the student to acquire the required knowledge, attitude and skills to safely carry out maintenance on that type.

8.5.8.21 The practical element of the MATR Training can be performed concurrently with the OJT element if both are performed on the same military aircraft type and in a real maintenance environment.

8.5.8.22 Practical training may be performed either following or integrated with the theoretical elements however, it should not be performed before theoretical training.

8.5.8.23 Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.24 Table 1 summarises the MATR Training requirements contained in DASR 66.A.45, and Appendix III to DASR 66.

Military Aircraft Type Rating Training requirements		
Aircraft Group	**B1/B2 MAML**	**C MAML**
All military aircraft are considered to be complex motor-powered aircraft	**Military Aircraft Type Rating Training:** Theory + examination Practical + assessment PLUS OJT (for first aircraft in licence category/subcategory. For subsequent Military Aircraft Type Rating within the same category/sub-category, further OJT only if required by DASA)	**Military Aircraft Type Rating Training:** Theory + examination Note: In the case of a Category C person qualified by holding an academic degree as specified in DASR 66.A.30(a)(5), the first relevant aircraft type theoretical training shall be at the Category B1 or B2 level or at a level recognised by DASA

Table 1: Military Aircraft Type Rating Training requirements

Superseded

8.5.8.25 IAW AMC to Para 3.2 of Appendix III to DASR 66 - "The practical training may include instruction in a classroom or in simulators, but part of the practical training should be conducted in a real maintenance, or manufacturer, environment." It would be acceptable to complete practical training in a classroom or in simulators, if the practical training could be effectively delivered in this environment.

1. Practical training conducted in a real maintenance environment implies practical training on live aircraft or high fidelity maintenance training aids that are representative of the live aircraft. Practical training in a real maintenance environment should always be conducted on the highest fidelity training device reasonably available and include the use of maintenance data and specialist tooling.

2. Practical training should always be conducted in a real maintenance environment, where it is:

    i. the only reasonable method due to the complexity of the task, or

    ii. the only method available to enable familiarity with component location/ identification, or

    iii. the only method available to demonstrate the use of special equipment / tools.

8.5.8.26 Para 3.2 g. of Appendix III to DASR 66 states “The objective of practical training is to gain the required competence in performing safe maintenance, inspections and routine work…”. In the context of practical elements of the military aircraft type training, competence to perform safe maintenance, inspections and routine work does not require the actual performance of the maintenance (e.g. it is acceptable to use a live aircraft as a training aid without physical removal / installation of components). Practical training could be a visit to / walk around of an aircraft in the maintenance environment, identifying specialised tooling / equipment used on the aircraft, process walkthroughs for removal / installations tasks, and scenario based activities for troubleshooting. Practical training should also ensure students are knowledgeable in the use of technical literature, documentation, specialised tooling and test equipment.

8.5.8.27 Selected tasks should consist of a group of representative maintenance tasks drawn from the type training and examination curriculum, at the indicated level and shall cover all the relevant chapters described in the table contained in paragraph 3.2 of Appendix III to DASR 66.

8.5.8.28 The task curriculum must:

1. Be distributed in order to cover all applicable S1000D chapters.

2. Include all of the task categories (LOC, FOT, SGH, R/I, MEL, TS - Refer table 2 below) and may include others deemed appropriate to the type (e.g. ‘INS’pection, ‘ADJ’ustment).

3. Include an appropriate number of tasks in each task category for the aircraft type’s training requirements to be met.

4. Be sufficient to cover at least 50% of the crossed tasks in Appendix III to DASR 66 para 3.2. (Refer to “How should the 50% of tasks required for practical training be selected?” below).

Note: for further information on the S100D Specification refer to the following links on the DASA website. S1000D - International specification for technical publications.

Superseded

8.5.8.29 The duration of the practical training should ensure that the content of training required by paragraph 3.2 of Appendix III to DASR 66 is completed.

8.5.8.30 A record of the tasks completed should be entered into a logbook which should be designed such that each task or group of tasks may be countersigned by the designated assessor. The logbook format and its use should be clearly defined.

8.5.8.31 The practical element (for power-plant and avionics systems, armaments, escape systems and other relevant military-specific systems) of the MATR Training may be subcontracted by the approved DASA 147 organisation under its quality system according to the provisions of DASR 147.A.145(d)3 and the corresponding Guidance Material.

How should the 50% of tasks required for practical training be selected?

8.5.8.32 When selecting the tasks, the usage of a filtering method based on the criteria similar to that described in AMC to paragraph 3.1(d) of Appendix III to DASR 66, point 5f) is recommended.

8.5.8.33 The selection of 50% of tasks cannot be selected according to the glossary only (e.g. LOC, FOT, SGH, R/I, etc.):

1. Paragraph 3.2 of Appendix III to DASR 666 states that 'the tasks selected shall be representative of the aircraft and systems both in complexity and diversity'. In addition, the practical training should particularly address the tasks which cannot be explained by theoretical training only. While relatively simple tasks may be included, other more complex tasks shall also be incorporated and completed as appropriate to the aircraft type.

2. Guidelines on complex / simple tasks (taken from CASA AMC/GM Part 66, V7.4 of December 2024) are as follows:

   i. Complex tasks may have the following attributes:
   - involve several comprehensive steps to perform
   - have multiple decision points in order to complete
   - may use specialised test equipment
   - often requires more than one person to perform
   - have direct impact on flight safety

   ii. Simple tasks may have the following attributes:
   - does not use specialised test equipment
   - can be completed by a single person
   - does not require any in-depth skill/knowledge
   - does not involve decision steps (no troubleshooting)
   - may involve an on-board maintenance system BITE check to determine serviceability

3. How each task is selected (LOC, SGH, etc.), should be based upon the potential gains for the students' competency or its impact on safety. Availability should not be a

Superseded

reason to omit a pertinent task and consideration should be made to include a 'real maintenance environment' to complete an important or critical learning objective.

4. All pertinent sub-tasks, associated with the safe completion of each main task, such as Isolating mechanical/electrical systems, opening/closing CBs, locking flight controls, etc., should be included and the applicable aircraft maintenance manuals used.

5. Regarding the way to read the table in paragraph 3.2, each line aims to cover each of the main systems so that no line relevant to the particular aircraft type should be omitted in the selection. Inside each line applicable to the aircraft type, half or more of the crosses can be selected. From a learning point of view, selecting 2 simple tasks as LOC and SGH would not be "representative", while selecting LOC and TS, for example, would be much more appropriate of the aircraft and systems both in complexity and diversity.

6. The intent of the following tables are to provide a compliance report demonstrating that the practical type training meets the standard required by Appendix III to DASR 666. In particular, the tables shall indicate the percentage of tasks effectively performed against the tasks contained in the Appendix III to DASR 66 which are applicable to the aircraft type.

8.5.8.34 The following tables have been developed as a guide for assessment of MATR practical courseware elements. These tables are included in the MATR courseware assessment which can be found at the following link - DASR 66 Appendix III MATR Courseware Assessment Matrix. This assessment matrix should be completed by the MTO delivering the MATR practical type training in order to enable approval of courseware by the authority.

Percentage by Task Type

Type of task	Number of tasks applicable to the A/C type	Total number of tasks selected	Percentage (%) effectively performed against applicable tasks (should be at least 50% of the applicable tasks)
LOC			
FOT			
SGH			
R/I			
MEL			
TS			

Table 2 – Practical Task Training Requirements (By Task Type)

Superseded

Glossary of the table: LOC: Location; FOT: Functional/Operational Test; SGH: Service and Ground Handling; R/I: Removal/Installation; MEL: Minimum Equipment List; TS: Trouble-Shooting.

Percentage by Chapter

Chapter	Number of Practical Requirements for Each Chapter	Total number of Practical Elements Included Within Courseware	Percentage (%) included against applicable Chapter (should be at least 50% of the applicable practical requiorements within each Chapter)
05 Time limits / maintenance checks			
06 Dimensions/Areas (MTOM, etc.)			
.....			
99 Electronic Warfare			

Table 3 - Practical Task Training Requirements (By Chapter)

Practical Training Logbook

8.5.8.35 A Military Aircraft Type specific Practical Training Logbook (PTL) must be developed by a DASA 147 MTO, completed by the student and a certified true copy retained by the MTO delivering the training. It will record the training activities carried out during the practical training course and the subsequent assessment of trainee competence.

8.5.8.36 The PTL shall list all of the applicable S1000D systems, as specified within Appendix III to DASR 66, Section 3.2.

8.5.8.37 After the practical element of the MATR Training has been completed, an assessment must be performed, which must comply with the following:

1. The assessment shall be performed by designated assessors appropriately qualified (AMC to Appendix III).
2. The assessment shall evaluate the knowledge and demonstrated understanding of the trainee.

8.5.8.38 The PTL should include:

1. Trainee attendance sheet.
2. Course and Instructor’s details.
3. S1000D system number and title.
4. Aircraft Maintenance Manual or work-pack reference for each training task.
5. A list and detailed description of the training tasks.

Superseded

6. Each task must have a method of denoting the training technique (Synthetic, Aircraft registration, Classroom, etc.).

7. Task type (R/I, LOC, SGH etc.).

8. Date of each individual task completion.

9. Instructor signatures or stamps.

10. Spare entries for documenting additional/replacement “ad hoc” training tasks.

Note: Additional/replacement tasks must be of relevance to those they replace, be of benefit to the training objective and only replace planned tasks in exceptional circumstances.

8.5.8.39 EASA provide Practical type training logbook examples for both B1 and B2 PTL that can be used for guidance.

Practical Instructors and Assessors

8.5.8.40 In the majority of cases, the Practical instructor will be the same as that used for the Theory phase of the type training. They are a logical choice, as they possess an in-depth knowledge of the aircraft’s systems and will have developed an understanding of each student’s specific academic requirements.

8.5.8.41 Using the same instructor for both the Theory and Practical phases will often suit the business model of many organisations. In some cases, however, especially where a DASA 147 / DASA 145 affiliation exists, the organisation may choose to utilise experienced MAML holders / technicians, as appropirate, from their own maintenance workforce to deliver the Practical training.

8.5.8.42 These individuals must be given suitable training on the organisational processes involved, particularly the use of the Practical training record. It is recommended that they attended a train the trainer course, whether delivered by an external or internal source, which should specifically target the training techniques required for Practical training and set the organisation’s bench mark for the conduct of this training. They should be familiar with the tools or the techniques used by the training organisation to assess the competence of the practical abilities of trainees (maintenance simulators, mock up and etc.).

8.5.8.43 They should be experienced and show solid judgement regarding the abilities of the assessed trainees, they must have the required knowledge and experience of the task/s to be assessed. They should also be able to determine if the trainee accomplishes the tasks IAW current regulation, utilising approved procedures, maintenance practices etc. They should be fully aware of the aim of the assessment and conduct a practical assessment in such a way that the true abilities of the candidate are demonstrated to maintain the system.

8.5.8.44 Workforce sourced Instructors will be qualified and managed by the DASA 147 organisation. Refer to DASR 147.A.105 for details.

8.5.8.45 They must be included in the list Instructional staff (point 1.5 of the MTOE) and be subject to the same Instructor records and update training requirements as the directly employed Instructors.

8.5.8.46 Practical assessments may be conducted by either the Practical Instructor or a dedicated assessor, who has undergone a similar training and qualification process to that detailed above.

8.5.8.47 Upon completion of the PTL, it must be reviewed, assessed and approved by the relevant DASA 147 in its entirety.

Superseded

OJT Element of the Military Aircraft Type Rating

8.5.8.48 OJT is required for the initial type rating being sought in each licence category or sub-category:

8.5.8.49 For example; If a B1.1/B2 MAML is endorsed with the P-8A type in the B1.1 category and the MAML holder wishes to add the P-8A in the B2 category, he/she will have to complete B2 related OJT representative of that aircraft and its systems.

8.5.8.50 If the same B1.1 MAML holder adds the B1.3 category to their MAML, and wishes to add their first helicopter type, he/she must complete OJT representative of that first helicopter type. Any subsequent MATR within the same category/sub-category will only require further OJT if stipulated by DASA during the approval of the course.

8.5.8.51 A DASA 145 maintenance organisation appropriately approved for the maintenance of the particular aircraft type can conduct OJT for that type rating:

1. The OJT content shall be approved by DASA (Appendix III to DASR 66, sec. 6) and supported by a detailed curriculum showing its content and recorded within detailed worksheets/logbook;
2. OJT tasks shall be signed off by the student and countersigned by a 'designated supervisor';
3. Final assessment of OJT is mandatory and shall be performed by a 'designated assessor';
4. It can be carried out in an approved DASA 145 maintenance organisation with a Category A rating (maintenance on aircraft) and the procedures for OJT should be included in the exposition (MOE chapter 3.15 "OJT procedure") approved by DASA.
5. Where objective evidence can be provided; DASA may accept elements of practical and/or OJT experience gained on civil variants of state aircraft e.g. Boeing 737 for a P-8A Poseidon or E-7A Wedgetail MAML endorsement, provided the completed application also includes evidence of any additional 'differences training' for the Military type variant.

8.5.8.52 The OJT should include a sufficient number of tasks that are carried out under 'one to one' supervision (i.e. one supervisor dedicated to one trainee) and should involve actual work task performance on aircraft/components, covering line and/or base maintenance tasks.

8.5.8.53 AMC to Appendix II to DASR 66 contains a list of tasks, from which a representative sample appropriate to the type and licence (sub-) category applied for, should be extracted and approved by the MAA. The OJT should cover at least 50% of this approved extracted list.

8.5.8.54 Up to 50% of the required OJT may be undertaken before the aircraft theoretical MATR Training starts, noting that:

1. the ADF Initial Employment Training (IET) workplace journals are the primary means of meeting the practical requirements for the Defence Registered Training Organisation issuance of selected MEA Unit of Competency;
2. portions of these workplace journals may also be utilised as a means of meeting the requirements of OJT, as long as they are completed in a DASA 145, and on the

Superseded

platform/components which the individual is completing their Type Rating training (Appendix III to DASR 66, para 6).

8.5.8.55 If these journal tasks are not carried out on the aircraft type (or its components) required for their subcategory, then these tasks cannot be constituted as OJT.

8.5.8.56 As a minimum, the OJT procedure should describe the following elements:

1. Content of the OJT: the list of tasks that should be performed during the OJT or a list of generic tasks and the process how to develop a list of particular tasks out of this list of generic tasks,
2. Qualifications of the assessor and supervisors performing the OJT,
3. OJT logbook/worksheets format and content,
4. OJT compliance report format and content,
5. Production planning for the implementation of OJT (how to plan the tasks),
6. Supervision process and the assessment process, what to do if the assessment is not positive,
7. Safe release to service of the aircraft after OJT,
8. OJT Log Book final assessment process and associated forms:
    i. An OJT Logbook assessment is carried out on an OJT Logbook to ensure that all required tasks have been carried out and certified for in accordance with the OJT Logbook assessment procedure.
    ii. MTOE procedure and associated documents should contain a procedure for the final assessment of an OJT Logbook and who it is completed as well as any associated forms needed and who is qualified to carry out such assessment.

Note: AMC to Section 6. of Appendix III to DASR-66 should be used when defining the content of the procedure.

Practical Assessment Vs On the Job Training (OJT) for Military Aircraft Type Ratings

8.5.8.57 The objective of OJT is to gain the required competence and experience in performing safe, effective and efficient maintenance. The practical assessment addresses the practical portion of any type training, whereas the OJT assessment addresses the additional hands-on experience necessary in a true maintenance environment as part of the first type rating in a (sub)category, as illustrated by the table below:

Superseded

Practical Assessment Vs On the Job Training		
	Practical Assessment	**OJT Assessment** ***For the purpose of DASR 66.A.45(c)***
What/Who is assessed	Candidates following practical element of Military Aircraft Type Ratings training.	Completeness of OJT
	Reference: 66.A.45 (a)(b); Appendix III, 4.2.; AMC Appendix III	Reference: 66.A.45 (c); Appendix III, section 6; AMC to Section 6 of Appendix III
Function of assessor:	To perform the final evaluation of the knowledge, skills and attitude of the trainee following the practical element of the type training	To conduct the final assessment of the completed OJT, whereas the candidate's competence is indirectly justified.
	Reference: Appendix III 4.2.; AMC Appendix III	Reference: Appendix III, 6.; AMC to Section 6 of Appendix III 8.
Organisation :	• DASA-147 • Approved maintenance environment (DASR-145, M.A. Subpart F with A rating, manufacturer) under the DASA-147 approval • Defined maintenance environment as described in the direct approved procedure by the competent authority	Always in a maintenance organisation approved under DASA-145 with an aircraft rating.
	Reference: Appendix III 1(b)	Reference: Appendix III 6.; AMC to Section 6 of Appendix III 1.
Objectives:	To evaluate if the candidate has gained the required competence in performing safe maintenance, inspections and routine work according to the aircraft documentation and other relevant instructions and tasks as appropriate for the type of aircraft.	To confirm the completion of the required diversity and quantity of OJT, based on the supervisor(s) reports and feedback. It is sufficient that the completion of individual OJT tasks is confirmed by the direct supervisor(s), without necessary being the direct evaluation of the assessor.
	Reference: Appendix III, 3.2.	Reference: AMC to Section 6 of Appendix III 7. & 8.
Type of assessment:	The assessment may be: • diagnostic (prior to a course), • formative • summative (partial or final evaluation) • performed task-by-task • performed as a group of tasks • partly executed on simulation devices • performed as a final assessment	• Continuous during OJT (confirmed by the direct supervisor) • Summative, as a final evaluation by a designated assessor of the completeness of the OJT (based on the supervisor(s) reports and feedback)
	Reference: AMC to DASR-66 Appendix III 2)	Reference: AMC to Section 6 of Appendix III to DASR-66
Qualification of the assessor:	The assessment shall be performed by designated assessors appropriately qualified. It means that the assessors should demonstrate training and experience on the assessment process being undertaken and be authorised to do so by the organisation. Guidance about the qualification is given in AMC to DASR-66 Appendix III 3.)	The OJT shall be assessed by appropriately qualified and designated assessors. Table 4 – Practical Assessment Vs On the Job Training

Practical DASR 147 MILITARY AIRCRAFT TYPE TRAINING LEVELS VS SERVICE LEARNING LEVELS

The following table provides guidance on the correlation between the DASR Military Aircraft Type Training levels (TL), Air Force (MAFET) Learning Levels (LL), Army (ATI 1-3/20), SADL TLs and Navy LLs;

DASR		RAAF			ARA			SADL		RAN
TL	Description	LL	Definition	Description of graduate	LL	Definition	Assessment	TL	Description	
1	Graduate is: • Able to define descriptions and maintenance practices • Identify appropriate manuals and maintenance practices • Define layout of major systems • Define layout and characteristics of power plant • Identify special tooling and testing equipment	1	Training provides background knowledge only. It is familiarising in nature or is an introduction to further training.	The graduate has completed learning that either has no clear links to identified workplace requirements or supports underpinning knowledge, skills or range of variables.	1	**Low** - Unable to perform, little to no experience.	Skill and Knowledge are not assessed, but confirmation of learning may occur during training	1	Trained, but not against a prescribed standard.	Navy do not use Training Levels.
N/A		2	Trained to a level below that required for successful assessment against identified workplace requirements, without further training and/or practice.	The graduate has limited knowledge and has performed components of, but not the complete task, during training.	2	**Basic** - Limited in ability or knowledge, needs significant help from others.	Skill and Knowledge are assessed against a restricted set of performance criteria	2	Partially trained against a prescribed standard.	
2	Graduate is able to: • Understand theoretical fundamentals • Apply knowledge in a practical manner • Recall safety precautions • Describe systems and aircraft handling • Identify locations of principal components • Explain normal functioning of major systems • Perform procedures for servicing • Demonstrate proficiency in interpreting crew reports and reporting systems and determine airworthiness • Demonstrate the use, interpretation and application of appropriate documentation	3	Trained to the level to achieve the identified workplace requirement, but unable to be assessed in the context of the training environment. Subsequent experience and assessment using the prescribed workplace requirements or UoC is needed in the workplace environment.	The graduate is trained and ready for assessment against the identified workplace requirements or UoC. The graduate will be aware of common problems in standard workplace contexts but will likely encounter new situations with limited confidence.	3	**Demonstrable** - Able to perform at basic level, has some experience, needs help from time to time.	Skill and Knowledge are to be formally assessed against a set of defined performance criteria.	3	Fully trained and ready for assessment against prescribed standard.	
3	Graduate is able to: • Demonstrate theoretical knowledge of systems, structures and their relationship with other systems. Provide detailed descriptions and interpret results applying corrective action where appropriate • Perform checks as specified in maintenance manuals • Demonstrate use, interpretation and application of appropriate documentation • Correlate information for the purpose of decision making • Describe procedures for replacement of components	4	Trained to the level required to achieve the workplace requirements, without the need for further workplace training or practice. Assessment, using the prescribed workplace requirements or UoC, is completed in training environment.	The graduate is trained and assessed, and can be employed effectively on the job. The graduate will be able to cope with common problems in standard workplace contexts and will encounter new situations with moderate confidence.	4	**Advanced** - Capable and experienced, demonstrated proficiency, able to work independently with little help.	Skill and Knowledge are assured under defined employment conditions	4	Trained and assessed competent against the prescribed standard.	
N/A		5	Training reflects outcomes related to values and/or feelings prescribed for the workplace.	The graduate has chosen a certain course of personal action, as prescribed for the workplace.	5	**Expert** - Fully capable and experienced, sought for help by others, needs no assistance to complete tasks, ability to train and lead others, seen as SME.	Skill and Knowledge are internalised by practice and reflection and expressed as autonomous professionalism	N/A		

Table 5 - SADL Training Level Descriptions

Superseded

9. Flight Operations

9.1 Introduction

9.1.1 Flight Operations Regulations

9.1.1.1 The Flight Operations DASR provide amplification of Defence's obligations[1] under the WHS Act 2011 in the context of Defence flight operations. The regulations prescribe the accountabilities of the chain of command as they relate to Defence flight operations. For Military Air Operators (MAO), the regulations define management requirements. MAOs are obliged to implement a system of management to comply with applicable DASR and to ensure that their personnel conform to that system of management.

9.1.1.2 The Flight Operations DASR contain regulations for the safe conduct of flight operations by Defence aircraft, including UAS and aircraft operated on behalf of Defence. It includes requirements for training and qualification of all personnel involved in military flight operations.

9.1.1.3 **DASR Aircrew**. The purpose of DASR Aircrew is to assure that Defence aircrew are adequately trained and proficient for employment in a specific role. This includes regulation for the personnel and training aspects of Flying Instruction, Airborne Emergency Training, Crew Resource Management, Aviation Safety training and Flying Logbooks.

9.1.1.4 **DASR AO.Gen — Air Operations General**. DASR Air Operations (AO) General is applicable to all areas of air operations and includes requirements for Orders, Instructions and Publications (OIP) specific to air operations.

9.1.1.5 **DASR ARO – Authority Requirements for Air Operations**. The purpose of DASR ARO — Authority Requirements for Air Operations is to address a range of AO matters, including the following:

1. Statement of Operating Intent and Usage (SOIU), to inform decisions on whether an aircraft design remains safe for operations
2. The Defence Register
3. establishment of the Military Air Operator (MAO).

9.1.1.6 A MAO is the regulated organisation approved by DASA to conduct air operations. The senior member of a MAO is the Accountable Manager (AM), which is usually an O7 commander.

9.1.1.7 The majority of Defence flight operations are conducted under a Military Air Operator Certificate (MAOC) issued to a MAO. The MAO is usually a Force Element Group (FEG) or equivalent.

9.1.1.8 **DASR FSTD – Flight Simulation Training Devices.** The purpose of DASR FSTD — Flight Simulation Training Devices is to assure aviation operations augmented by a Flight Simulation Training Device (FSTD) are adequately controlled and managed. Approval of an FSTD is via an Installation Operating Permit (IOP).

9.1.1.9 **DASR FT – Flight Test.** The purpose of DASR FT — Flight Test is to assure that a MAO only undertakes those Flight Test activities it is capable of safely conducting, including that the tests are conducted under appropriate airworthiness controls using suitable personnel, processes and data. Flight Test is a subset of Defence Test and Evaluation (T&E). Flight Test activities involve, to varying

Superseded

extents, the operation of an aircraft outside of its existing type design certification. A MAO requires a specific privilege to be able to conduct Flight Test activities of this nature.

9.1.1.10 **DASR NDR – Non-Defence Registered Aircraft.** The purpose of DASR Non-Defence Registered Aircraft (NDRA) is to clarify Defence Aviation Safety Program (DASP) obligations of Defence when operating non Defence registered aircraft.

9.1.1.11 **DASR ORO – Organisation Requirements for Air Operations.** The purpose of DASR ORO Organisation Requirements for Air Operations is to assure Defence aircraft are operated with adequate controls to ensure safety of flight. They include the following:

1. Flight Operations—ensuring aircraft are operated in approved roles, with correct mission equipment, to approved procedures and instructions
2. Flying Management Systems
3. Appointment of Key Staff
4. Aircrew Competency System
5. Flight Authorisation System
6. Aeronautical Life Support Equipment
7. Aircraft Crewing (including Captaincy)
8. Oxygen Management (including Flight Crew and Supplemental Oxygen)
9. Authorised Electronic Equipment
10. Carriage of Personnel on Defence Aircraft
11. Use of Role Equipment
12. Flight Recorder(s) and Locating Equipment.

9.1.1.12 **DAS RoA – Rules of the Air.** The purpose of DASR RoA — Rules of the Air is to assure that the rules stipulated within Defence Aeronautical Information Publication (AIP), as they apply to Defence Aviation, are harmonised with ICAO and national civil practice wherever practical. The intent is that Defence Aviation will have due regard for the safety of navigation of civil aircraft.

9.1.1.13 **DASR SPA – Specific Purpose Approval.** The purpose of DASR SPA — Specific Purpose Approval is to assure that certain Defence Aviation activities are conducted safely. The scope of DASR SPA includes Command Clearances, Low Flying, Flypasts and Flying Displays, Defence Long Range Operations and Night Vision Imaging System operations.

9.1.1.14 **DASR UAS – Uncrewed Aircraft Systems.** The purpose of DASR UAS — Uncrewed Aircraft Systems is to assure the safe operation of UAS. The regulations account for the range of UAS complexity, design pedigree and mass through three different categories: [type] certified category UAS, specific category UAS and open category UAS.

9.1.2 Flight Operations Compliance

9.1.2.1 DASA approved aviation organisations implement DASR FLTOPS through a Command approved Flying Management System (FMS) that include:

Superseded

1. a framework of controls
2. approved orders, instructions and publications
3. the operation of crewed and uncrewed aircraft in approved roles, with correct mission equipment, by qualified and authorised individuals
4. a safety framework that supports compliance with statutory safety obligations and enables risk-based command decisions to deliver capability
5. a system to enable commanders to eliminate and minimise risks SFARP.

9.1.2.2 While the Defence Aviation Safety Framework (DASF) establishes a structure for the management of aviation safety within Defence, responsibility for ensuring the safe operation of aviation systems rests with the chain of command. In the assure/ensure balance, the responsibility to ensure compliance and conformance with the Flight Operations regulations lies largely with the Accountable Manager (AM) of the MAO, ACD Service Provider (ACDSP), or ABM Operator (ABMO). AMs are accountable for:

1. the creation and internal validation of local systems of management that are capable of effectively complying with the requirements of applicable DASR, to the defined scope and level contained in the Military Air Operator Certificate(MAOC), Operational Compliance Statement (OCS), Operations Specification (OpSpec), Air Cargo Service Provider Certificate (ACSPC) and Air Battle Management Operator Certificate (ABMOC)
2. liaison with DASA during development, implementation and application of the system of management, to ensure initial and ongoing compliance.

9.1.2.3 DASA, the MAO, ACDSP and ABMO have overlapping and complementary responsibilities in the Oversight and Enforcement, and Safety Investigation areas of the DASF. However, aviation safety is always a command responsibility. Commanders and managers are therefore accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

9.1.3 Command Clearances

9.1.3.1 The DASP contains flexibility provisions to assist commanders faced with compelling operational imperatives to make informed decisions regarding regulatory compliance. These provisions become particularly relevant in situations where commanders are expected to operate Defence aircraft at markedly higher levels of risk than normal[2], to achieve non-discretionary activities in support of Australia's national interests. Such decisions must be made at the appropriate command level to ensure that aviation safety risks are eliminated or otherwise minimised SFARFP.

9.1.3.2 In the FLTOPS regulations, Commanders may utilise DASR SPA.10 - Command Clearance (CC), to operate an aviation system outside the system's configuration, role, environment, limitation or condition within a risk based framework. Other flexibility provisions provided in Airworthiness DASR, such as the Military Permit to Fly (MPTF), and those under DASR GR.80 are discussed further in DASPMAN Volume 3, Section 6. However, before a MAO utilises a flexibility provision under the auspices of DASR GR.80, the application must be forwarded to, and approved by, the Authority.

Superseded

9.1.3.3 The Command Clearance process, available to MAOs under DASR SPA.10, differs from other flexibility provisions, in so far as it is not issued by the Authority, rather a commander at an appropriate level who can make the decision to proceed without further minimising risks commensurate with the clearance being granted. The Command Clearance process should not be used in the first instance to allow an aircraft to fly outside of its approved CRE. It should only be utilised when absolutely necessary to enable an aircraft to fly when the normal methods of ensuring airworthiness cannot be met and it must never be used for administrative convenience.

9.1.3.4 To summarise the process, when aircrew find a fault with their aircraft, a defect should be raised against the aircraft and then cleared, or deferred, by the appropriate maintenance organisation before returning to flight. An exception to this occurs when the defect is allowed under the aircraft's Minimum Equipment List (MEL) of allowable defects. In this case the aircrew may continue with their planned flight, giving due regard to the risks associated with the MEL item. If this process is not suitable or allowed under the DASR, then the MPTF process should be undertaken. Noting that the operational imperative influences the timeline for an MPTF, the captain may seek a Command Clearance through their chain of command.

9.1.3.5 The MAO should only process and approve a Command Clearance when considered with respect to the mission concerned, whether it is urgent or compelling, and the associated elevated level of risk that a Command Clearance would provide. As per all military aviation activities, the Command Clearance system requires appropriate risk consideration and the 7-Step Risk Management process must be followed. The Command Clearance system is there to enable a commander to fly aircraft outside of the approved CRE and as such, the granting of the clearance should not be made in haste or considered lightly.

9.1.3.6 For further information on Military Permits to Fly and Command Clearances see Chapter 5.3 and DASR SPA.10.

9.1.4 Historical context of Flight Operations Related Regulation

9.1.4.1 The Convention on International Civil Aviation (Chicago Convention 1944) set the basis for current civil aviation regulations and founded the International Civil Aviation Organisation (ICAO). Article 3 of the convention states:

> **This Convention shall be applicable only to civil aircraft, and shall not be applicable to state aircraft.**

9.1.4.2 In the Australian context, State Aircraft are defined as 'aircraft of any part of the Defence Force (including any aircraft that is commanded by a member of that Force in the course of duties as such a member); and aircraft used in the military, customs or police services of a foreign country'[3]. As Defence aircraft are included within this broad category, they are thereby exempt from all requirements contained within the civil aviation regulations.

9.1.4.3 To provide the directed level of aviation capability, Defence aviation platforms need to regularly use both domestic and international civil and military airspace. In doing so, military operators voluntarily adhere to ICAO flight procedures, including 'flying with due regard for the safety of navigation of civil aircraft', because militaries have a natural duty of care to all airspace users. Additionally, the Australian Government's National Aviation Policy White Paper notes that 'Defence, in collaboration with Airservices, is committed to improving civil and military aviation harmonisation, and to enhance better airspace access arrangements'. However, not all ICAO or civil aviation requirements are suited to military operations. Militaries therefore require bespoke regulatory

Superseded

systems to provide for operational capability and an equivalent level of safety. Hence, the tailored application of both civil and military requirements will ensure that Defence aircraft can continue to maximise their operational effectiveness.

9.1.5 MAO-AM Accountabilities and Responsibilities for Force Assigned Aircraft and Crew

9.1.5.1 **DASF and the spectrum of conflict.** The Defence Aviation Safety Framework (DASF) applies throughout the spectrum of conflict. While there are flexibility provisions, Joint Directive 21/2021 - *The Defence Aviation Safety Framework* contains no exceptions to the applicability of the DASF, in totality, during times of conflict.

9.1.5.2 **Accountability.** The DASF aligns accountability with control. Specifically [4]:

> *Commanders and managers are … accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.*

9.1.5.3 **TECHCON.** ADF Command and Control (C2) doctrine has a suitable means of control for MAO-AMs to exercise their accountability for force assigned aircraft and crew—Technical Advisory Control (TECHCON)[5] [6].

9.1.5.4 **Purpose.** The DASF provides amplification of Defence's safety obligations in the Defence Aviation Environment regarding the application of the:

1. *Work Health and Safety Act 2011*
2. *Work Health and Safety Regulations 2011*
3. various Codes of Practice made pursuant to the principal Act from time to time [7].

9.1.5.5 **Suitability.** The DASF is suitable for application across the spectrum of conflict. The DASF contains 'flexibility provisions to assist commanders faced with compelling operational imperatives.'[8] Notwithstanding, the DASF requires the application of flexibility provisions based on 'informed judgements … at the appropriate command level to ensure that aviation safety risks are eliminated or otherwise minimised so far as is reasonably practicable.'[9] This requirement drives the need for MAO-AMs to exercise TECHCON for force assigned aircraft—as the Joint Force Air Component Commander (JFACC) per se does not hold the knowledge, resources, structures or staff to support the risk management necessary to enact flexibility provisions[10].

9.1.5.6 **Division of duties between operational commanders and TECHCON authorities.** Note, for force assigned aircraft and crews, a court would likely find a MAO-AM (with TECHCON authority), and an operational commander (eg JFACC with operational command), have the same duty under s.16 WHS Act. However, the court would likely consider the capacity to influence and control, and thus discharge the duty by each commander will vary, depending on the factual circumstances of the situation.

9.1.5.7 **WHS Act applicability throughout the spectrum of conflict.** The WHS Act applies throughout the spectrum of conflict. Anecdotally, there is a common misconception that, the WHS Act does not apply during times of conflict. *The CDF declaration* makes clear that the obligations on

Superseded

'officers, workers and other persons' are largely unchanged between peace, warlike operations and non-warlike operations. Specifically:

1. *the CDF declaration* renders inapplicable to warlike operations or non-warlike operations only the sections of the WHS Act that deal with[11]:
   i. 'Duty to notify of notifiable incidents'
   ii. 'Duty to preserve incident sites'.

9.1.5.8 **MAO-AM accountabilities/responsibilities.** MAO-AM accountabilities and responsibilities are unchanged for force assigned aircraft and crew. The DASP Manual, consistent with Joint Directive 21/2021, places accountabilities and responsibilities on MAO-AM. While there are flexibility provisions, the DASP Manual contains no exceptions to the applicability of the DASP (including the DASR) to MAO-AM regarding force assigned aircraft and crew.

9.1.5.9 **ADF doctrine—C2 provisions to account for the relationship between MAO-AM and force assigned commanders.** ADF doctrine has established C2 provisions to account for the relationship between MAO-AM and force assigned commanders—specifically, TECHCON. TECHCON is 'the provision of specialist and technical advice by designated authorities for the management and operation of forces.[12],

9.1.5.10 By convention (and consistent with ADF-P-0 *Command*[13]) MAO-AMs retain TECHCON for force assigned aircraft and crew. ADF-P-0 Command specifies:

> *Capability managers exercise techcon through advice to the theatre commander for assigned forces ….*
>
> *… For an operational commander, techcon advice will relate to the employment of capabilities so that they are used within their operating parameters ….*

9.1.5.11 C2, as described in ADF-P-0 Command, provides an operational commander the necessary freedom to reject TECHCON advice, as follows:

> *Techcon advice may not be altered but may be rejected in part, or in total, by a commander in consideration of operational factors and within their span of command …*

9.1.5.12 DASF obligations on MAOs, considered against the ability of an operational commander to reject TECHCON advice, infer a number of tasks:

1. **on the MAO-AM[14]:**
   i. to be informed of the operational context in providing any TECHCON advice
   ii. to be available and responsive to operational commanders' requests for TECHCON advice
   iii. to *administer* Command Clearances[15] consistent with the operational commander's decisions regarding TECHCON advice -including any necessary risk management following an operational commander's decision to operate an aircraft outside its 'approved standards and limitations

   Note the obligation to 'administer' the Command Clearance should not be read as an obligation on the MAO-AM to replicate or endorse the 'decision to proceed' that the operational commander has already made. Rather, the

Superseded

obligation on the MAO-AM to administer the Command Clearance is a recognition that:

- A Command Clearance is the system for managing operation of an aviation system outside its 'approved standards and limitations'—across the spectrum of conflict.
- The MAO is resourced (ie has the staff, expertise and processes to conduct informed, capability specific, risk management) to risk manage the ongoing safe operation of the aircraft—and the JFACC is not.
- Operation of the aircraft following an exceedance of its 'approved standards and limitations' requires risk management—both immediate and ongoing[16].

2. **on the operational commander:**

   i. to provide the MAO-AM sufficient information to understand the operational context

   ii. to weigh the operational imperative against the impact on the capability in considering any TECHCON advice

   iii. to formally document the risk(s) they are accepting by setting aside the MAO-AM-provided TECHCON advice, to meet their operational imperative

   iv. to inform the MAO-AM of any circumstances in which the operational commander has rejected TECHCON advice - to enable the MAO-AM to administer a Command Clearance, and conduct any necessary risk management.

9.1.5.13 **Historical operational experience.** Historical RAAF C2 constructs were not suitable. The Jones-Bostock affair[17] in World War II is an example of a failure of C2 in dealing with the relationship between an operational commander and a TECHCON authority[18]. It illustrates the importance of both a suitable C2 structure, and constructive interpersonal relationships between the TECHCON authority and the operational commander.

9.1.5.14 **Recent operational history.** Recent operational history indicates that doctrinal C2 provisions are suitable. Recent operational experience evidences that:

1. TECHCON provides a suitable C2 arrangement between MAO-AMs and operational commanders
2. there are suitable personnel posted to MAO-AM and senior Air Operations Centre positions to support effective interpersonal relationships.

9.5 Defence Navigation Approvals

9.5.1 Introduction

9.5.1.1 The purpose of this chapter is to provide MAOs with guidance when seeking new (or updated) Defence navigation approvals, for Aircraft operations in airspace involving either:

Superseded

1. Performance Based Navigation (PBN)
2. Reduced Vertical Separation Minima (RVSM)
3. North Atlantic High-Level Airspace (NAT HLA).

9.5.1.2 A MAO must obtain DASA approval to conduct specified Defence navigation operations — DASR SPA.50 refers. MAOs require both:

1. a Military Type Certificate (MTC) (or design approval of changes to the MTC, under DASR Part 21) detailing the necessary equipment to support the Defence navigation approval
2. an updated Military Air Operator Certificate (MAOC) Operations Specification (OpSpec) to include a 'Specific Approval', under DASR SPA.50.

9.5.1.3 Approval to operate in PBN, RVSM or NAT HLA airspace requires demonstration that:

1. the aircraft is technically capable of conducting the requested operations (also known as 'aircraft eligibility')
2. the relevant DASR Part 21J organisation has implemented the continued airworthiness requirements for the required operations
3. the MAO has updated its Flying Management System (FMS) for the requested operations (including, for example, that appropriate training is in place, aircrew competence has been assessed, and associated OIP has been published).

9.5.1.4 The Defence navigation approvals that MAOs can request are the Defence equivalent of the civil navigation requirements defined by[19]:

1. CASA Civil Aviation Order (CAO) 20.91 – (Instructions and Directions for Performance Based Navigation) Instrument 2014
2. the CASA AC 91 series – Performance Based Navigation
3. Civil Aviation Safety Regulation (CASR) Part 91.655 – Reduced Vertical Separation Minima (RVSM) Airspace
4. ICAO NAT Doc 007 - North Atlantic Operations and Airspace Manual.

9.5.1.5 Relevant acronyms, abbreviations and additional reference can be found at Annex A.

9.5.2 Navigation Approvals - Background

9.5.2.1 PBN, RVSM and NAT HLA requirements form part of an internationally recognised framework of area-based navigation capabilities for Aircraft[20], based on the exploitation of:

1. the Global Navigation Satellite System (GNSS)
2. on-board Aircraft systems.

9.5.2.2 International Civil Aviation Organisation (ICAO) member nations commenced introducing these navigation requirements in 2001. For Australia, CASA CAO 20.18 mandated the installation of GNSS into all civil Instrument Flight Rules (IFR) Aircraft WEF 4 Feb 16. On that date, the Australian

Superseded

Back-up Navigation Network (BNN) was activated, resulting in approximately 200 (traditional) terrestrial navigation aids being withdrawn from service in Australia (approximately 50%). Therefore, from that date, Australia effectively became GNSS-based PBN and RVSM airspace.

9.5.2.3 While State Aircraft are not bound to the Civil Aviation Act 1988 (Cth), Defence aerospace platforms need to regularly use both domestic and international civil and military airspace for their Defence roles. The tailored application of PBN, RVSM and NAT HLA requirements in Defence Aircraft will ensure that Defence aviation assets can continue to maximise their operational effectiveness. Additionally, the Australian Government's Aviation White Paper—Towards 2050 noted that 'Defence, in collaboration with Air Services, is committed to improving civil and military aviation harmonisation, and to enhance better airspace access arrangements'[21].

9.5.2.4 **PBN operations.** PBN encompasses two lateral navigation specification suites:

1. Required Navigation Performance (RNP)
2. aRea NAVigation (RNAV).

9.5.2.5 The difference is that On-Board Performance Monitoring and Alerting (OBPMA) is required for RNP[22], but not for RNAV.

9.5.2.6 **RVSM operations.** RVSM applies to operations in airspace between Flight Level (FL) 290 and FL 410 inclusive, where a 1000 ft reduced vertical separation minimum is applied.

9.5.2.7 **NAT HLA operations.** NAT HLA operations apply in the North Atlantic, between FL 285 and FL 420 (inclusive), in the airspace linking Europe and North America. This is the busiest oceanic airspace in the world, with limited control and communications coverage. Successful Aircraft separation depends on applying the highest standards of horizontal and vertical navigation performance, and on aircrew operating discipline.

9.5.3 Navigation Approval—Education and Training Development Guidance

9.5.3.1 MAO education and self-training development guidance is available below. The guidance supports MAO development or acceptance of extant training materials that allow the qualification of aircrew for the navigation approvals requested.

1. PBN and RVSM Education and Training Guidance for Military Air Operators
2. Example PBN - RVSM Multiple Choice Aircrew Assessment Quizzes Operators
3. Example PBN - RVSM Quick Reference Handbook Operational Summary

9.5.4 Defence Navigation Approval[23] Process

9.5.4.1 DASR SPA.50 and its complementary DASR Form 1307 Application for Navigation Specification Approval, are based on CASA (ie ICAO) requirements. The form is used to:

1. assist MAOs manage their navigation approval requests, by listing required compliance evidence against PBN, RVSM and NAT HLA requirements
2. support complementary MAO risk management processes

Superseded

3. support MAO and DASA evidence review

4. support a complementary major change to the Type Certification Basis (TCB) where the Aircraft have not previously demonstrated meeting PBN, RVSM and NAT HLA requirements. [24] [25],

9.5.4.2 **Alternative demonstration of compliance.** As of 2023, CASA only specifically provides approvals for PBN RNP-AR operations. Other PBN specifications are automatically considered 'approved' if they are listed in relevant Aircraft OIP (including the AFM)—this is normal practice in civil aviation. However, most non-civil-derivative military platforms do not typically provide statements of compliance with PBN, RVSM and NAT HLA requirements in their OIP. In these military cases, DASA may accept compliance with civil standards through alternative means, by establishing equivalent performance. This involves either, or a combination of[26]:

1. demonstrating that equipment function and performance meets the intent of (but not strict compliance with) the relevant civil standard

2. demonstrating that the use of operational procedures can meet the same function, integrity and OBPMA performance requirements.

9.5.4.3 The most common reasons non-civil derivative military platforms have difficulty achieving compliance with PBN, RVSM and NAT HLA requirements are:

1. the absence of Technical Standard Order (TSO)-approved equipment

2. limited or no evidence of compliance with system functional, integrity or OBPMA performance requirements.

9.5.4.4 Early DASA engagement should be sought for demonstrations via equivalency— to seek assistance in defining the scope of compliance evidence required and likely timelines, and to confirm that a navigation approval is possible before the applicant commits significant resources. Where operational urgency applies, MAOs should consider temporarily applying for less precise[27] navigation approvals—which can be demonstrated more easily—while pursuing more precise navigation approvals in parallel over a less constrained timeframe.

9.5.5 DASR Form 1307 – Application for Navigation Specification Approvals

9.5.5.1 MAOs can request Defence navigational approvals using DASR Form 1307. Each approval is categorised as either 'core', 'non-core', 'supplemental', and 'other', as shown below.

9.5.5.2 **Core approvals.** Core approvals are simpler to process than non-core approvals, and include:

1. RNAV 1

2. RNAV 2

3. RNAV 5

4. RNP 1

5. RNP 2

6. RNP APCH, including:

Superseded

i. LNAV

ii. LNAV/VNAV

iii. LP

iv. LPV

9.5.5.3 **Non-Core approvals.** Non-core approvals require a more complex compliance process and evidence; and include those specifications that are detailed in other regulatory documents, but are administered in accordance with the nominal PBN approval process (ie RVSM)[28] Non-core approvals include:

1. RNAV 10 (RNP 10)
2. RNP 0.3 (Helicopter)
3. RNP 4
4. RNP AR (RNP AR APCH and RNP AR DP Operations may include One Engine Inoperative (OEI) procedures), including:
   i. RNP AR APCH
   ii. RNP AR DP
5. A-RNP
6. RVSM.

9.5.5.4 **Supplemental approvals.** Supplemental approvals either support another approval, provide an alternate means to support an approval, or provide supplemental navigational capabilities. However, they do not exist in isolation (ie they are complementary to selected core and non-core approvals). Supplemental approvals include:

1. APV / Baro-VNAV
2. Radius to Fix (RF)
3. Fixed Radius Transition (FRT)
4. Time of Arrival Control (TOAC)
5. use of suitable area navigation systems on conventional routes and procedures (both en route and terminal).

9.5.5.5 **Other approvals.** Other approvals are specific or location-based, and include:

1. NAT HLA.

9.5.5.6 A MAO may use the same DASR Form 1307 for multiple approvals. Note, some of the more precise Defence navigation approvals automatically include approval for less precise Defence navigation approvals—this is known as 'nesting'. For example, if DASA awards an approval for RNP 4, DASA will automatically consider approvals for RNP 5 and RNP 10.

Superseded

9.5.6 Applying for Navigation Approvals

9.5.6.1 To gain DASA navigation approval, the applicant must:

1. complete DASR Form 1307
2. submit the required evidence against the approval(s) selected.

9.5.6.2 MAOs should submit applications to DASA at least 90 days prior to the required navigation operations. This allows for the resolution of potential shortfalls against the requested approval(s) before the major change to the TCB and applicant OpSpec.

9.5.6.3 To provide a navigation approval, DASA assesses each approval's compliance evidence against three navigation approval component requirements. The three components are the same for each approval, but the level of detail differs dependent on the approval chosen. The three navigation component requirements are:

1. **Component 1**: Initial Airworthiness and Aircraft eligibility requirements.
2. **Component 2**: Continued Airworthiness requirements.
3. **Component 3**: Flight operations procedures and training requirements.

9.5.6.4 **DASR Form 1307 preparation.** Applicants must use DASR Form 1307 to support review of the evidence requirements of each navigation approval sought. In order of increasing complexity (ie time to process), application evidence options are:

1. The application is based upon an **existing** navigation approval (eg the Aircraft eligibility and continuing airworthiness requirements for the RNP 2 approval can be based on navigation approvals already held for either RNP 1, RNP APCH or RNP AR).
2. The application is based upon a **prior certification** against relevant navigation approval requirements[29].
3. The application is based upon **demonstration** that on-board equipment (and its installation) **meets** the navigation approval's functional, display, alerting and performance requirements[30].
4. The application is based upon **demonstration** that on-board equipment (and its installation), when supported by defined operational controls, **provides functional equivalence** to the approval's functional, display, alerting and performance requirements.
5. The application is based upon a **DASA-agreed alternate approach** to achieving **functional equivalence** to the approval's functional, display, alerting and performance requirements.

9.5.6.5 **Navigation approval evidence.** The following can assist MAOs in collating or generating the evidence required:

1. **For component 1 - Initial Airworthiness and Aircraft eligibility.** DASR Form 1307 uses question sets to guide applicants through the necessary evidence. MAOs may demonstrate Aircraft eligibility through any one of the following:

Superseded

i. the CAA/MAA-approved AFM confirms that the Aircraft **is capable** of undertaking the required operations, with a CRE assessment that either:

– confirms that there are no CRE differences that adversely impact the approval in the Defence operational context

– identifies CRE differences that adversely impact the approval in the Defence operational context, together with additional compliance demonstration evidence to address the differences

ii. the CAA/MAA confirms that the Aircraft **has been certified** for the required PBN, RVSM and NAT HLA operations, with a CRE assessment that either:

– confirms that there are no CRE differences that adversely impact the approval in the Defence operational context

– identifies CRE differences that adversely impact the approval in the Defence operational context, together with additional compliance demonstration evidence to address the differences

iii. a technical assessment of the design demonstrates compliance with the prescribed airworthiness requirements for the specified operations.

2. **For Component 2 - Continued Airworthiness.** DASR Form 1307 guides applicants through the evidence necessary to demonstrate that navigation system components will remain compliant with the approved Type Design[31] while in-Service, and that the navigation databases used will remain valid during operations.

3. **For Component 3 - Flight operations procedures and training.**

i. Flight operations procedures. DASR Form 1307 lists operations documentation requirements for each navigation approval, including[32]:

– operating policies to support selected operations under all normal and emergency conditions

– flight crew procedures and checklists for all navigation approvals for the Aircraft Type

– Minimum Equipment Lists (MELs, or their equivalent) for each navigation approval

– planning and management OIP (including for navigation database updates and validation, and mission planning procedures)

– OIP for the reporting and management of navigation database discrepancies and errant Aircraft behaviour observed during approved operations.

ii. **Flight operations training.** DASR Form 1307 lists both generic and specific Flight operations training requirements for each navigation approval, including:

– Flight crew training programs, competency assessments, currency, and training records

– maintenance staff training requirements.

Superseded

9.5.6.6 **Navigation approval evidence shortfall resolution.** Where DASR Form 1307 requirements cannot be met, the form supports DASA consultation and shortfall resolution. The applicant must demonstrate functional equivalence to published requirements. Shortfall resolution involves the:

1. DASA Desk Officer and applicant reviewing shortfalls and discussing possible pathways to demonstrating compliance
2. applicant proposing an appropriate alternative to compliance, that demonstrates functional equivalence, for example:
    i. prior alternative CAA/MAA certifications
    ii. operational or crew-based procedural additions that can demonstrate functional equivalence[33].
3. applicant providing evidence that demonstrates functional equivalence, such as[34]:
    i. flight test programs
    ii. operational human factors and workload assessments
    iii. LMPs
    iv. Aircraft Type Design System Safety Assessments
    v. Risk Management Plans and Mission Risk Profiles to define the additional controls required to be incorporated into OIP.

9.5.6.7 **DASR Form 1307 submission.** To finalise the MAO request, the applicant must submit the form and the corresponding evidence data pack, via a MAO request, to dasa-davnops.operationalreviews@defence.gov.au. The data pack should include a summary of the documents attached and a description of each document's purpose towards navigation approval requirement compliance.

9.5.6.8 When compliance is demonstrated, and the MTCH has updated the aircraft's TCB (through a DASA approved Major change to Type Design), DASA will add the navigation approval(s) to the OpSpec.

9.5.5.9 Table 1 provides MAOs with a checklist of the evidence required in data packs. Note, not all items are required for all navigation approvals. Additionally—in the case of non-core approvals; or where there is a requirement to demonstrate functional equivalence—this checklist is not exhaustive.

Submission Checklist Item
DASR Form 1307 • In original MS Excel Format
Initial Airworthiness and Aircraft Eligibility

Superseded

- Aircraft Airworthiness documents which provide evidence that the Aircraft is Type Certified for the requested operations (eg AFM and supplements, OEM service letters, Type Certificate Compliance Document).
- A description of the relevant Aircraft equipment required for the proposed navigation approvals, including a configuration list of components, and how the system meets applicable requirements.

Continued Airworthiness

- A description of the maintenance program used to ensure the continued Airworthiness of the Aircraft for the equipment required for the navigation approval. This need only address those circumstances where additional specific maintenance is required.
- Applicable Aircraft Maintenance Manuals for the relevant system/s.
- An equipment list for the navigation approvals requested (make, model & part—both hardware & software).
- Applicable extracts from the Minimum Equipment List (Airworthiness items) and applicable instructions that demonstrate identification and management of:
- any unserviceability that affects the conduct of any approved operation
- the systems that GNSS interfaces with, so that in the event of the GNSS being inoperative, the full impact of the failure can be determined
- The rationale for selection of specific MEL items as having an impact on safe operations, and any associated risk assessments.

Airworthiness - Digital Data

- A description of the method used to receive updates to (including the frequency of updates) and to ensure the validity of the airborne navigation database. This should address the validation of data provided externally and internally; and verification procedures for any internal change to the supplied data
    - **Note:** this should include coverage of all digital navigation data (including map and chart data used in Flight during the conduct of procedures, or for ground verification); and

Superseded

	data acquisition, manipulation, and management (to encompass all potential Defence Aircraft operations). • Evidence that the suppliers of the navigation database comply with the minimum integrity requirements of the most stringent approval requested.
Flight Operations Processes • Operational procedures (including normal and emergency) published in OIP. These procedures should include Flight planning, pre-flight, inflight and post-flight. • Procedures should include copies of, or extracts from, OIP covering: o operations manuals o the AFM o checklists o contingency procedures o QRH (or equivalent) o sections of the MEL applicable to the requested operations	
Training and Qualifications • A description of the proposed aircrew, maintenance and other applicable personnel and specialists' training for the requested operations; and associated competencies and currency requirements (including a copy of the LMP and associated artefacts[35]. • Copies of relevant training syllabi, training proficiency examination and assessment templates and currency assessment templates.	

Table 1 – MAO Navigation Approval Submission checklist

Superseded

9.1.1 Flight Operations Regulations

9.1.1.1 The Flight Operations DASR provide amplification of Defence's obligations[1] under the WHS Act 2011 in the context of Defence flight operations. The regulations prescribe the accountabilities of the chain of command as they relate to Defence flight operations. For Military Air Operators (MAO), the regulations define management requirements. MAOs are obliged to implement a system of management to comply with applicable DASR and to ensure that their personnel conform to that system of management.

9.1.1.2 The Flight Operations DASR contain regulations for the safe conduct of flight operations by Defence aircraft, including UAS and aircraft operated on behalf of Defence. It includes requirements for training and qualification of all personnel involved in military flight operations.

9.1.1.3 **DASR Aircrew**. The purpose of DASR Aircrew is to assure that Defence aircrew are adequately trained and proficient for employment in a specific role. This includes regulation for the personnel and training aspects of Flying Instruction, Airborne Emergency Training, Crew Resource Management, Aviation Safety training and Flying Logbooks.

9.1.1.4 **DASR AO.Gen — Air Operations General**. DASR Air Operations (AO) General is applicable to all areas of air operations and includes requirements for Orders, Instructions and Publications (OIP) specific to air operations.

9.1.1.5 **DASR ARO – Authority Requirements for Air Operations**. The purpose of DASR ARO — Authority Requirements for Air Operations is to address a range of AO matters, including the following:

1. Statement of Operating Intent and Usage (SOIU), to inform decisions on whether an aircraft design remains safe for operations
2. The Defence Register
3. establishment of the Military Air Operator (MAO).

9.1.1.6 A MAO is the regulated organisation approved by DASA to conduct air operations. The senior member of a MAO is the Accountable Manager (AM), which is usually an O7 commander.

9.1.1.7 The majority of Defence flight operations are conducted under a Military Air Operator Certificate (MAOC) issued to a MAO. The MAO is usually a Force Element Group (FEG) or equivalent.

9.1.1.8 **DASR FSTD – Flight Simulation Training Devices.** The purpose of DASR FSTD — Flight Simulation Training Devices is to assure aviation operations augmented by a Flight Simulation Training Device (FSTD) are adequately controlled and managed. Approval of an FSTD is via an Installation Operating Permit (IOP).

9.1.1.9 **DASR FT – Flight Test.** The purpose of DASR FT — Flight Test is to assure that a MAO only undertakes those Flight Test activities it is capable of safely conducting, including that the tests are

Superseded

conducted under appropriate airworthiness controls using suitable personnel, processes and data. Flight Test is a subset of Defence Test and Evaluation (T&E). Flight Test activities involve, to varying extents, the operation of an aircraft outside of its existing type design certification. A MAO requires a specific privilege to be able to conduct Flight Test activities of this nature.

9.1.1.10 **DASR NDR – Non-Defence Registered Aircraft.** The purpose of DASR Non-Defence Registered Aircraft (NDRA) is to clarify Defence Aviation Safety Program (DASP) obligations of Defence when operating non Defence registered aircraft.

9.1.1.11 **DASR ORO – Organisation Requirements for Air Operations.** The purpose of DASR ORO Organisation Requirements for Air Operations is to assure Defence aircraft are operated with adequate controls to ensure safety of flight. They include the following:

1. Flight Operations—ensuring aircraft are operated in approved roles, with correct mission equipment, to approved procedures and instructions
2. Flying Management Systems
3. Appointment of Key Staff
4. Aircrew Competency System
5. Flight Authorisation System
6. Aeronautical Life Support Equipment
7. Aircraft Crewing (including Captaincy)
8. Oxygen Management (including Flight Crew and Supplemental Oxygen)
9. Authorised Electronic Equipment
10. Carriage of Personnel on Defence Aircraft
11. Use of Role Equipment
12. Flight Recorder(s) and Locating Equipment.

9.1.1.12 **DAS RoA – Rules of the Air.** The purpose of DASR RoA — Rules of the Air is to assure that the rules stipulated within Defence Aeronautical Information Publication (AIP), as they apply to Defence Aviation, are harmonised with ICAO and national civil practice wherever practical. The intent is that Defence Aviation will have due regard for the safety of navigation of civil aircraft.

9.1.1.13 **DASR SPA – Specific Purpose Approval.** The purpose of DASR SPA — Specific Purpose Approval is to assure that certain Defence Aviation activities are conducted safely. The scope of DASR SPA includes Command Clearances, Low Flying, Flypasts and Flying Displays, Defence Long Range Operations and Night Vision Imaging System operations.

9.1.1.14 **DASR UAS – Uncrewed Aircraft Systems.** The purpose of DASR UAS — Uncrewed Aircraft Systems is to assure the safe operation of UAS. The regulations account for the range of UAS complexity, design pedigree and mass through three different categories: [type] certified category UAS, specific category UAS and open category UAS.

Superseded

9.1.2 Flight Operations Compliance

9.1.2.1 DASA approved aviation organisations implement DASR FLTOPS through a Command approved Flying Management System (FMS) that include:

1. a framework of controls
2. approved orders, instructions and publications
3. the operation of crewed and uncrewed aircraft in approved roles, with correct mission equipment, by qualified and authorised individuals
4. a safety framework that supports compliance with statutory safety obligations and enables risk-based command decisions to deliver capability
5. a system to enable commanders to eliminate and minimise risks SFARP.

9.1.2.2 While the Defence Aviation Safety Framework (DASF) establishes a structure for the management of aviation safety within Defence, responsibility for ensuring the safe operation of aviation systems rests with the chain of command. In the assure/ensure balance, the responsibility to ensure compliance and conformance with the Flight Operations regulations lies largely with the Accountable Manager (AM) of the MAO, ACD Service Provider (ACDSP), or ABM Operator (ABMO). AMs are accountable for:

1. the creation and internal validation of local systems of management that are capable of effectively complying with the requirements of applicable DASR, to the defined scope and level contained in the Military Air Operator Certificate(MAOC), Operational Compliance Statement (OCS), Operations Specification (OpSpec), Air Cargo Service Provider Certificate (ACSPC) and Air Battle Management Operator Certificate (ABMOC)
2. liaison with DASA during development, implementation and application of the system of management, to ensure initial and ongoing compliance.

9.1.2.3 DASA, the MAO, ACDSP and ABMO have overlapping and complementary responsibilities in the Oversight and Enforcement, and Safety Investigation areas of the DASF. However, aviation safety is always a command responsibility. Commanders and managers are therefore accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

9.1.3 Command Clearances

9.1.3.1 The DASP contains flexibility provisions to assist commanders faced with compelling operational imperatives to make informed decisions regarding regulatory compliance. These provisions become particularly relevant in situations where commanders are expected to operate Defence aircraft at markedly higher levels of risk than normal[2], to achieve non-discretionary activities in support of Australia's national interests. Such decisions must be made at the appropriate command level to ensure that aviation safety risks are eliminated or otherwise minimised SFARFP.

9.1.3.2 In the FLTOPS regulations, Commanders may utilise DASR SPA.10 - Command Clearance (CC), to operate an aviation system outside the system's configuration, role, environment, limitation

Superseded

or condition within a risk based framework. Other flexibility provisions provided in Airworthiness DASR, such as the Military Permit to Fly (MPTF), and those under DASR GR.80 are discussed further in DASPMAN Volume 3, Section 6. However, before a MAO utilises a flexibility provision under the auspices of DASR GR.80, the application must be forwarded to, and approved by, the Authority.

9.1.3.3 The Command Clearance process, available to MAOs under DASR SPA.10, differs from other flexibility provisions, in so far as it is not issued by the Authority, rather a commander at an appropriate level who can make the decision to proceed without further minimising risks commensurate with the clearance being granted. The Command Clearance process should not be used in the first instance to allow an aircraft to fly outside of its approved CRE. It should only be utilised when absolutely necessary to enable an aircraft to fly when the normal methods of ensuring airworthiness cannot be met and it must never be used for administrative convenience.

9.1.3.4 To summarise the process, when aircrew find a fault with their aircraft, a defect should be raised against the aircraft and then cleared, or deferred, by the appropriate maintenance organisation before returning to flight. An exception to this occurs when the defect is allowed under the aircraft's Minimum Equipment List (MEL) of allowable defects. In this case the aircrew may continue with their planned flight, giving due regard to the risks associated with the MEL item. If this process is not suitable or allowed under the DASR, then the MPTF process should be undertaken. Noting that the operational imperative influences the timeline for an MPTF, the captain may seek a Command Clearance through their chain of command.

9.1.3.5 The MAO should only process and approve a Command Clearance when considered with respect to the mission concerned, whether it is urgent or compelling, and the associated elevated level of risk that a Command Clearance would provide. As per all military aviation activities, the Command Clearance system requires appropriate risk consideration and the 7-Step Risk Management process must be followed. The Command Clearance system is there to enable a commander to fly aircraft outside of the approved CRE and as such, the granting of the clearance should not be made in haste or considered lightly.

9.1.3.6 For further information on Military Permits to Fly and Command Clearances see Chapter 5.3 and DASR SPA.10.

9.1.4 Historical context of Flight Operations Related Regulation

9.1.4.1 The Convention on International Civil Aviation (Chicago Convention 1944) set the basis for current civil aviation regulations and founded the International Civil Aviation Organisation (ICAO). Article 3 of the convention states:

> **This Convention shall be applicable only to civil aircraft, and shall not be applicable to state aircraft.**

9.1.4.2 In the Australian context, State Aircraft are defined as 'aircraft of any part of the Defence Force (including any aircraft that is commanded by a member of that Force in the course of duties as such a member); and aircraft used in the military, customs or police services of a foreign country'[3]. As Defence aircraft are included within this broad category, they are thereby exempt from all requirements contained within the civil aviation regulations.

9.1.4.3 To provide the directed level of aviation capability, Defence aviation platforms need to regularly use both domestic and international civil and military airspace. In doing so, military operators voluntarily adhere to ICAO flight procedures, including 'flying with due regard for the safety

Superseded

of navigation of civil aircraft', because militaries have a natural duty of care to all airspace users. Additionally, the Australian Government's National Aviation Policy White Paper notes that 'Defence, in collaboration with Airservices, is committed to improving civil and military aviation harmonisation, and to enhance better airspace access arrangements'. However, not all ICAO or civil aviation requirements are suited to military operations. Militaries therefore require bespoke regulatory systems to provide for operational capability and an equivalent level of safety. Hence, the tailored application of both civil and military requirements will ensure that Defence aircraft can continue to maximise their operational effectiveness.

9.1.5 MAO-AM Accountabilities and Responsibilities for Force Assigned Aircraft and Crew

9.1.5.1 **DASF and the spectrum of conflict.** The Defence Aviation Safety Framework (DASF) applies throughout the spectrum of conflict. While there are flexibility provisions, Joint Directive 21/2021 - *The Defence Aviation Safety Framework* contains no exceptions to the applicability of the DASF, in totality, during times of conflict.

9.1.5.2 **Accountability.** The DASF aligns accountability with control. Specifically [4]:

> *Commanders and managers are … accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.*

9.1.5.3 **TECHCON.** ADF Command and Control (C2) doctrine has a suitable means of control for MAO-AMs to exercise their accountability for force assigned aircraft and crew—Technical Advisory Control (TECHCON)[5] [6].

9.1.5.4 **Purpose.** The DASF provides amplification of Defence's safety obligations in the Defence Aviation Environment regarding the application of the:

1. *Work Health and Safety Act 2011*
2. *Work Health and Safety Regulations 2011*
3. various Codes of Practice made pursuant to the principal Act from time to time [7].

9.1.5.5 **Suitability.** The DASF is suitable for application across the spectrum of conflict. The DASF contains 'flexibility provisions to assist commanders faced with compelling operational imperatives.'[8] Notwithstanding, the DASF requires the application of flexibility provisions based on 'informed judgements … at the appropriate command level to ensure that aviation safety risks are eliminated or otherwise minimised so far as is reasonably practicable.'[9] This requirement drives the need for MAO-AMs to exercise TECHCON for force assigned aircraft—as the Joint Force Air Component Commander (JFACC) per se does not hold the knowledge, resources, structures or staff to support the risk management necessary to enact flexibility provisions[10].

9.1.5.6 **Division of duties between operational commanders and TECHCON authorities.** Note, for force assigned aircraft and crews, a court would likely find a MAO-AM (with TECHCON authority), and an operational commander (eg JFACC with operational command), have the same duty under s.16 WHS Act. However, the court would likely consider the capacity to influence and control, and thus

Superseded

discharge the duty by each commander will vary, depending on the factual circumstances of the situation.

9.1.5.7 **WHS Act applicability throughout the spectrum of conflict.** The WHS Act applies throughout the spectrum of conflict. Anecdotally, there is a common misconception that, the WHS Act does not apply during times of conflict. *The CDF declaration* makes clear that the obligations on 'officers, workers and other persons' are largely unchanged between peace, warlike operations and non-warlike operations. Specifically:

1. *the CDF declaration* renders inapplicable to warlike operations or non-warlike operations only the sections of the WHS Act that deal with[11]:
    i. 'Duty to notify of notifiable incidents'
    ii. 'Duty to preserve incident sites'.

9.1.5.8 **MAO-AM accountabilities/responsibilities.** MAO-AM accountabilities and responsibilities are unchanged for force assigned aircraft and crew. The DASP Manual, consistent with Joint Directive 21/2021, places accountabilities and responsibilities on MAO-AM. While there are flexibility provisions, the DASP Manual contains no exceptions to the applicability of the DASP (including the DASR) to MAO-AM regarding force assigned aircraft and crew.

9.1.5.9 **ADF doctrine—C2 provisions to account for the relationship between MAO-AM and force assigned commanders.** ADF doctrine has established C2 provisions to account for the relationship between MAO-AM and force assigned commanders—specifically, TECHCON. TECHCON is 'the provision of specialist and technical advice by designated authorities for the management and operation of forces.[12]'

9.1.5.10 By convention (and consistent with ADF-P-0 *Command*[13]) MAO-AMs retain TECHCON for force assigned aircraft and crew. ADF-P-0 Command specifies:

> *Capability managers exercise techcon through advice to the theatre commander for assigned forces ….*
>
> *… For an operational commander, techcon advice will relate to the employment of capabilities so that they are used within their operating parameters ….*

9.1.5.11 C2, as described in ADF-P-0 Command, provides an operational commander the necessary freedom to reject TECHCON advice, as follows:

> *Techcon advice may not be altered but may be rejected in part, or in total, by a commander in consideration of operational factors and within their span of command …*

9.1.5.12 DASF obligations on MAOs, considered against the ability of an operational commander to reject TECHCON advice, infer a number of tasks:

1. **on the MAO-AM[14]:**
    i. to be informed of the operational context in providing any TECHCON advice
    ii. to be available and responsive to operational commanders' requests for TECHCON advice

Superseded

iii. to *administer* Command Clearances[15] consistent with the operational commander's decisions regarding TECHCON advice -including any necessary risk management following an operational commander's decision to operate an aircraft outside its 'approved standards and limitations

Note the obligation to 'administer' the Command Clearance should not be read as an obligation on the MAO-AM to replicate or endorse the 'decision to proceed' that the operational commander has already made. Rather, the obligation on the MAO-AM to administer the Command Clearance is a recognition that:

- A Command Clearance is the system for managing operation of an aviation system outside its 'approved standards and limitations'—across the spectrum of conflict.
- The MAO is resourced (ie has the staff, expertise and processes to conduct informed, capability specific, risk management) to risk manage the ongoing safe operation of the aircraft—and the JFACC is not.
- Operation of the aircraft following an exceedance of its 'approved standards and limitations' requires risk management—both immediate and ongoing[16].

2. **on the operational commander:**

i. to provide the MAO-AM sufficient information to understand the operational context

ii. to weigh the operational imperative against the impact on the capability in considering any TECHCON advice

iii. to formally document the risk(s) they are accepting by setting aside the MAO-AM-provided TECHCON advice, to meet their operational imperative

iv. to inform the MAO-AM of any circumstances in which the operational commander has rejected TECHCON advice - to enable the MAO-AM to administer a Command Clearance, and conduct any necessary risk management.

9.1.5.13 **Historical operational experience.** Historical RAAF C2 constructs were not suitable. The Jones-Bostock affair[17] in World War II is an example of a failure of C2 in dealing with the relationship between an operational commander and a TECHCON authority[18]. It illustrates the importance of both a suitable C2 structure, and constructive interpersonal relationships between the TECHCON authority and the operational commander.

9.1.5.14 **Recent operational history.** Recent operational history indicates that doctrinal C2 provisions are suitable. Recent operational experience evidences that:

1. TECHCON provides a suitable C2 arrangement between MAO-AMs and operational commanders

2. there are suitable personnel posted to MAO-AM and senior Air Operations Centre positions to support effective interpersonal relationships.

Superseded

9.5.1 Introduction

9.5.1.1 The purpose of this chapter is to provide MAOs with guidance when seeking new (or updated) Defence navigation approvals, for Aircraft operations in airspace involving either:

1. Performance Based Navigation (PBN)
2. Reduced Vertical Separation Minima (RVSM)
3. North Atlantic High-Level Airspace (NAT HLA).

9.5.1.2 A MAO must obtain DASA approval to conduct specified Defence navigation operations—DASR SPA.50 refers. MAOs require both:

1. a Military Type Certificate (MTC) (or design approval of changes to the MTC, under DASR Part 21) detailing the necessary equipment to support the Defence navigation approval
2. an updated Military Air Operator Certificate (MAOC) Operations Specification (OpSpec) to include a 'Specific Approval', under DASR SPA.50.

9.5.1.3 Approval to operate in PBN, RVSM or NAT HLA airspace requires demonstration that:

1. the aircraft is technically capable of conducting the requested operations (also known as 'aircraft eligibility')
2. the relevant DASR Part 21J organisation has implemented the continued airworthiness requirements for the required operations
3. the MAO has updated its Flying Management System (FMS) for the requested operations (including, for example, that appropriate training is in place, aircrew competence has been assessed, and associated OIP has been published).

9.5.1.4 The Defence navigation approvals that MAOs can request are the Defence equivalent of the civil navigation requirements defined by[19]:

1. CASA Civil Aviation Order (CAO) 20.91 – (Instructions and Directions for Performance Based Navigation) Instrument 2014
2. the CASA AC 91 series – Performance Based Navigation
3. Civil Aviation Safety Regulation (CASR) Part 91.655 – Reduced Vertical Separation Minima (RVSM) Airspace
4. ICAO NAT Doc 007 - North Atlantic Operations and Airspace Manual.

9.5.1.5 Relevant acronyms, abbreviations and additional reference can be found at Annex A.

Superseded

9.5.2 Navigation Approvals - Background

9.5.2.1 PBN, RVSM and NAT HLA requirements form part of an internationally recognised framework of area-based navigation capabilities for Aircraft[20], based on the exploitation of:

1. the Global Navigation Satellite System (GNSS)
2. on-board Aircraft systems.

9.5.2.2 International Civil Aviation Organisation (ICAO) member nations commenced introducing these navigation requirements in 2001. For Australia, CASA CAO 20.18 mandated the installation of GNSS into all civil Instrument Flight Rules (IFR) Aircraft WEF 4 Feb 16. On that date, the Australian Back-up Navigation Network (BNN) was activated, resulting in approximately 200 (traditional) terrestrial navigation aids being withdrawn from service in Australia (approximately 50%). Therefore, from that date, Australia effectively became GNSS-based PBN and RVSM airspace.

9.5.2.3 While State Aircraft are not bound to the Civil Aviation Act 1988 (Cth), Defence aerospace platforms need to regularly use both domestic and international civil and military airspace for their Defence roles. The tailored application of PBN, RVSM and NAT HLA requirements in Defence Aircraft will ensure that Defence aviation assets can continue to maximise their operational effectiveness. Additionally, the Australian Government's Aviation White Paper—Towards 2050 noted that 'Defence, in collaboration with Air Services, is committed to improving civil and military aviation harmonisation, and to enhance better airspace access arrangements'[21].

9.5.2.4 **PBN operations.** PBN encompasses two lateral navigation specification suites:

1. Required Navigation Performance (RNP)
2. aRea NAVigation (RNAV).

9.5.2.5 The difference is that On-Board Performance Monitoring and Alerting (OBPMA) is required for RNP[22], but not for RNAV.

9.5.2.6 **RVSM operations.** RVSM applies to operations in airspace between Flight Level (FL) 290 and FL 410 inclusive, where a 1000 ft reduced vertical separation minimum is applied.

9.5.2.7 **NAT HLA operations.** NAT HLA operations apply in the North Atlantic, between FL 285 and FL 420 (inclusive), in the airspace linking Europe and North America. This is the busiest oceanic airspace in the world, with limited control and communications coverage. Successful Aircraft separation depends on applying the highest standards of horizontal and vertical navigation performance, and on aircrew operating discipline.

9.5.3 Navigation Approval—Education and Training Development Guidance

9.5.3.1 MAO education and self-training development guidance is available below. The guidance supports MAO development or acceptance of extant training materials that allow the qualification of aircrew for the navigation approvals requested.

1. PBN and RVSM Education and Training Guidance for Military Air Operators

Superseded

2. Example PBN - RVSM Multiple Choice Aircrew Assessment Quizzes Operators

3. Example PBN - RVSM Quick Reference Handbook Operational Summary

9.5.4 Defence Navigation Approval[23] Process

9.5.4.1 DASR SPA.50 and its complementary DASR Form 1307 Application for Navigation Specification Approval, are based on CASA (ie ICAO) requirements. The form is used to:

1. assist MAOs manage their navigation approval requests, by listing required compliance evidence against PBN, RVSM and NAT HLA requirements
2. support complementary MAO risk management processes
3. support MAO and DASA evidence review
4. support a complementary major change to the Type Certification Basis (TCB) where the Aircraft have not previously demonstrated meeting PBN, RVSM and NAT HLA requirements. [24] [25],

9.5.4.2 **Alternative demonstration of compliance.** As of 2023, CASA only specifically provides approvals for PBN RNP-AR operations. Other PBN specifications are automatically considered 'approved' if they are listed in relevant Aircraft OIP (including the AFM)—this is normal practice in civil aviation. However, most non-civil-derivative military platforms do not typically provide statements of compliance with PBN, RVSM and NAT HLA requirements in their OIP. In these military cases, DASA may accept compliance with civil standards through alternative means, by establishing equivalent performance. This involves either, or a combination of[26]:

1. demonstrating that equipment function and performance meets the intent of (but not strict compliance with) the relevant civil standard
2. demonstrating that the use of operational procedures can meet the same function, integrity and OBPMA performance requirements.

9.5.4.3 The most common reasons non-civil derivative military platforms have difficulty achieving compliance with PBN, RVSM and NAT HLA requirements are:

1. the absence of Technical Standard Order (TSO)-approved equipment
2. limited or no evidence of compliance with system functional, integrity or OBPMA performance requirements.

9.5.4.4 Early DASA engagement should be sought for demonstrations via equivalency— to seek assistance in defining the scope of compliance evidence required and likely timelines, and to confirm that a navigation approval is possible before the applicant commits significant resources. Where operational urgency applies, MAOs should consider temporarily applying for less precise[27] navigation approvals—which can be demonstrated more easily—while pursuing more precise navigation approvals in parallel over a less constrained timeframe.

Superseded

9.5.5 DASR Form 1307 – Application for Navigation Specification Approvals

9.5.5.1 MAOs can request Defence navigational approvals using DASR Form 1307. Each approval is categorised as either 'core', 'non-core', 'supplemental', and 'other', as shown below.

9.5.5.2 **Core approvals.** Core approvals are simpler to process than non-core approvals, and include:

1. RNAV 1
2. RNAV 2
3. RNAV 5
4. RNP 1
5. RNP 2
6. RNP APCH, including:
    i. LNAV
    ii. LNAV/VNAV
    iii. LP
    iv. LPV

9.5.5.3 **Non-Core approvals.** Non-core approvals require a more complex compliance process and evidence; and include those specifications that are detailed in other regulatory documents, but are administered in accordance with the nominal PBN approval process (ie RVSM)[28] Non-core approvals include:

1. RNAV 10 (RNP 10)
2. RNP 0.3 (Helicopter)
3. RNP 4
4. RNP AR (RNP AR APCH and RNP AR DP Operations may include One Engine Inoperative (OEI) procedures), including:
    i. RNP AR APCH
    ii. RNP AR DP
5. A-RNP
6. RVSM.

9.5.5.4 **Supplemental approvals.** Supplemental approvals either support another approval, provide an alternate means to support an approval, or provide supplemental navigational capabilities. However, they do not exist in isolation (ie they are complementary to selected core and non-core approvals). Supplemental approvals include:

1. APV / Baro-VNAV

Superseded

2. Radius to Fix (RF)

3. Fixed Radius Transition (FRT)

4. Time of Arrival Control (TOAC)

5. use of suitable area navigation systems on conventional routes and procedures (both en route and terminal).

9.5.5.5 **Other approvals.** Other approvals are specific or location-based, and include:

1. NAT HLA.

9.5.5.6 A MAO may use the same DASR Form 1307 for multiple approvals. Note, some of the more precise Defence navigation approvals automatically include approval for less precise Defence navigation approvals—this is known as 'nesting'. For example, if DASA awards an approval for RNP 4, DASA will automatically consider approvals for RNP 5 and RNP 10.

9.5.6 Applying for Navigation Approvals

9.5.6.1 To gain DASA navigation approval, the applicant must:

1. complete DASR Form 1307

2. submit the required evidence against the approval(s) selected.

9.5.6.2 MAOs should submit applications to DASA at least 90 days prior to the required navigation operations. This allows for the resolution of potential shortfalls against the requested approval(s) before the major change to the TCB and applicant OpSpec.

9.5.6.3 To provide a navigation approval, DASA assesses each approval's compliance evidence against three navigation approval component requirements. The three components are the same for each approval, but the level of detail differs dependent on the approval chosen. The three navigation component requirements are:

1. **Component 1**: Initial Airworthiness and Aircraft eligibility requirements.

2. **Component 2**: Continued Airworthiness requirements.

3. **Component 3**: Flight operations procedures and training requirements.

9.5.6.4 **DASR Form 1307 preparation.** Applicants must use DASR Form 1307 to support review of the evidence requirements of each navigation approval sought. In order of increasing complexity (ie time to process), application evidence options are:

1. The application is based upon an **existing** navigation approval (eg the Aircraft eligibility and continuing airworthiness requirements for the RNP 2 approval can be based on navigation approvals already held for either RNP 1, RNP APCH or RNP AR).

2. The application is based upon a **prior certification** against relevant navigation approval requirements[29].

Superseded

3. The application is based upon **demonstration** that on-board equipment (and its installation) **meets** the navigation approval's functional, display, alerting and performance requirements[30].

4. The application is based upon **demonstration** that on-board equipment (and its installation), when supported by defined operational controls, **provides functional equivalence** to the approval's functional, display, alerting and performance requirements.

5. The application is based upon a **DASA-agreed alternate approach** to achieving **functional equivalence** to the approval's functional, display, alerting and performance requirements.

9.5.6.5 **Navigation approval evidence.** The following can assist MAOs in collating or generating the evidence required:

1. **For component 1 - Initial Airworthiness and Aircraft eligibility.** DASR Form 1307 uses question sets to guide applicants through the necessary evidence. MAOs may demonstrate Aircraft eligibility through any one of the following:

   i. the CAA/MAA-approved AFM confirms that the Aircraft **is capable** of undertaking the required operations, with a CRE assessment that either:

      – confirms that there are no CRE differences that adversely impact the approval in the Defence operational context

      – identifies CRE differences that adversely impact the approval in the Defence operational context, together with additional compliance demonstration evidence to address the differences

   ii. the CAA/MAA confirms that the Aircraft **has been certified** for the required PBN, RVSM and NAT HLA operations, with a CRE assessment that either:

      – confirms that there are no CRE differences that adversely impact the approval in the Defence operational context

      – identifies CRE differences that adversely impact the approval in the Defence operational context, together with additional compliance demonstration evidence to address the differences

   iii. a technical assessment of the design demonstrates compliance with the prescribed airworthiness requirements for the specified operations.

2. **For Component 2 - Continued Airworthiness.** DASR Form 1307 guides applicants through the evidence necessary to demonstrate that navigation system components will remain compliant with the approved Type Design[31] while in-Service, and that the navigation databases used will remain valid during operations.

3. **For Component 3 - Flight operations procedures and training.**

   i. Flight operations procedures. DASR Form 1307 lists operations documentation requirements for each navigation approval, including[32]:

      – operating policies to support selected operations under all normal and emergency conditions

Superseded

- flight crew procedures and checklists for all navigation approvals for the Aircraft Type
- Minimum Equipment Lists (MELs, or their equivalent) for each navigation approval
- planning and management OIP (including for navigation database updates and validation, and mission planning procedures)
- OIP for the reporting and management of navigation database discrepancies and errant Aircraft behaviour observed during approved operations.

ii. **Flight operations training.** DASR Form 1307 lists both generic and specific Flight operations training requirements for each navigation approval, including:

- Flight crew training programs, competency assessments, currency, and training records
- maintenance staff training requirements.

9.5.6.6 **Navigation approval evidence shortfall resolution.** Where DASR Form 1307 requirements cannot be met, the form supports DASA consultation and shortfall resolution. The applicant must demonstrate functional equivalence to published requirements. Shortfall resolution involves the:

1. DASA Desk Officer and applicant reviewing shortfalls and discussing possible pathways to demonstrating compliance
2. applicant proposing an appropriate alternative to compliance, that demonstrates functional equivalence, for example:
   i. prior alternative CAA/MAA certifications
   ii. operational or crew-based procedural additions that can demonstrate functional equivalence[33].
3. applicant providing evidence that demonstrates functional equivalence, such as[34]:
   i. flight test programs
   ii. operational human factors and workload assessments
   iii. LMPs
   iv. Aircraft Type Design System Safety Assessments
   v. Risk Management Plans and Mission Risk Profiles to define the additional controls required to be incorporated into OIP.

9.5.6.7 **DASR Form 1307 submission.** To finalise the MAO request, the applicant must submit the form and the corresponding evidence data pack, via a MAO request, to dasa-davnops.operationalreviews@defence.gov.au. The data pack should include a summary of the documents attached and a description of each document's purpose towards navigation approval requirement compliance.

Superseded

9.5.6.8 When compliance is demonstrated, and the MTCH has updated the aircraft's TCB (through a DASA approved Major change to Type Design), DASA will add the navigation approval(s) to the OpSpec.

9.5.5.9 Table 1 provides MAOs with a checklist of the evidence required in data packs. Note, not all items are required for all navigation approvals. Additionally—in the case of non-core approvals; or where there is a requirement to demonstrate functional equivalence—this checklist is not exhaustive.

Submission Checklist Item
DASR Form 1307 • In original MS Excel Format
Initial Airworthiness and Aircraft Eligibility • Aircraft Airworthiness documents which provide evidence that the Aircraft is Type Certified for the requested operations (eg AFM and supplements, OEM service letters, Type Certificate Compliance Document). • A description of the relevant Aircraft equipment required for the proposed navigation approvals, including a configuration list of components, and how the system meets applicable requirements.
Continued Airworthiness • A description of the maintenance program used to ensure the continued Airworthiness of the Aircraft for the equipment required for the navigation approval. This need only address those circumstances where additional specific maintenance is required. • Applicable Aircraft Maintenance Manuals for the relevant system/s. • An equipment list for the navigation approvals requested (make, model & part—both hardware & software). • Applicable extracts from the Minimum Equipment List (Airworthiness items) and applicable instructions that demonstrate identification and management of:

Superseded

- any unserviceability that affects the conduct of any approved operation
- the systems that GNSS interfaces with, so that in the event of the GNSS being inoperative, the full impact of the failure can be determined
- The rationale for selection of specific MEL items as having an impact on safe operations, and any associated risk assessments.

Airworthiness - Digital Data

- A description of the method used to receive updates to (including the frequency of updates) and to ensure the validity of the airborne navigation database. This should address the validation of data provided externally and internally; and verification procedures for any internal change to the supplied data
    - **Note:** this should include coverage of all digital navigation data (including map and chart data used in Flight during the conduct of procedures, or for ground verification); and data acquisition, manipulation, and management (to encompass all potential Defence Aircraft operations).
- Evidence that the suppliers of the navigation database comply with the minimum integrity requirements of the most stringent approval requested.

Flight Operations Processes

- Operational procedures (including normal and emergency) published in OIP. These procedures should include Flight planning, pre-flight, inflight and post-flight.

- Procedures should include copies of, or extracts from, OIP covering:
    - operations manuals
    - the AFM
    - checklists
    - contingency procedures
    - QRH (or equivalent)
    - sections of the MEL applicable to the requested operations

Superseded

Training and Qualifications • A description of the proposed aircrew, maintenance and other applicable personnel and specialists' training for the requested operations; and associated competencies and currency requirements (including a copy of the LMP and associated artefacts[35]. • Copies of relevant training syllabi, training proficiency examination and assessment templates and currency assessment templates.

9.5 Defence Navigation Approvals

9.1 Introduction

9.1.1 Flight Operations Regulations

9.1.1.1 The Flight Operations DASR provide amplification of Defence's obligations[1] under the WHS Act 2011 in the context of Defence flight operations. The regulations prescribe the accountabilities of the chain of command as they relate to Defence flight operations. For Military Air Operators (MAO), the regulations define management requirements. MAOs are obliged to implement a system of management to comply with applicable DASR and to ensure that their personnel conform to that system of management.

9.1.1.2 The Flight Operations DASR contain regulations for the safe conduct of flight operations by Defence aircraft, including UAS and aircraft operated on behalf of Defence. It includes requirements for training and qualification of all personnel involved in military flight operations.

9.1.1.3 **DASR Aircrew**. The purpose of DASR Aircrew is to assure that Defence aircrew are adequately trained and proficient for employment in a specific role. This includes regulation for the personnel and training aspects of Flying Instruction, Airborne Emergency Training, Crew Resource Management, Aviation Safety training and Flying Logbooks.

9.1.1.4 **DASR AO.Gen — Air Operations General**. DASR Air Operations (AO) General is applicable to all areas of air operations and includes requirements for Orders, Instructions and Publications (OIP) specific to air operations.

9.1.1.5 **DASR ARO – Authority Requirements for Air Operations**. The purpose of DASR ARO — Authority Requirements for Air Operations is to address a range of AO matters, including the following:

1. Statement of Operating Intent and Usage (SOIU), to inform decisions on whether an aircraft design remains safe for operations
2. The Defence Register
3. establishment of the Military Air Operator (MAO).

9.1.1.6 A MAO is the regulated organisation approved by DASA to conduct air operations. The senior member of a MAO is the Accountable Manager (AM), which is usually an O7 commander.

9.1.1.7 The majority of Defence flight operations are conducted under a Military Air Operator Certificate (MAOC) issued to a MAO. The MAO is usually a Force Element Group (FEG) or equivalent.

9.1.1.8 **DASR FSTD – Flight Simulation Training Devices.** The purpose of DASR FSTD — Flight Simulation Training Devices is to assure aviation operations augmented by a Flight Simulation Training Device (FSTD) are adequately controlled and managed. Approval of an FSTD is via an Installation Operating Permit (IOP).

9.1.1.9 **DASR FT – Flight Test.** The purpose of DASR FT — Flight Test is to assure that a MAO only undertakes those Flight Test activities it is capable of safely conducting, including that the tests are

Superseded

conducted under appropriate airworthiness controls using suitable personnel, processes and data. Flight Test is a subset of Defence Test and Evaluation (T&E). Flight Test activities involve, to varying extents, the operation of an aircraft outside of its existing type design certification. A MAO requires a specific privilege to be able to conduct Flight Test activities of this nature.

9.1.1.10 **DASR NDR – Non-Defence Registered Aircraft.** The purpose of DASR Non-Defence Registered Aircraft (NDRA) is to clarify Defence Aviation Safety Program (DASP) obligations of Defence when operating non Defence registered aircraft.

9.1.1.11 **DASR ORO – Organisation Requirements for Air Operations.** The purpose of DASR ORO Organisation Requirements for Air Operations is to assure Defence aircraft are operated with adequate controls to ensure safety of flight. They include the following:

1. Flight Operations—ensuring aircraft are operated in approved roles, with correct mission equipment, to approved procedures and instructions
2. Flying Management Systems
3. Appointment of Key Staff
4. Aircrew Competency System
5. Flight Authorisation System
6. Aeronautical Life Support Equipment
7. Aircraft Crewing (including Captaincy)
8. Oxygen Management (including Flight Crew and Supplemental Oxygen)
9. Authorised Electronic Equipment
10. Carriage of Personnel on Defence Aircraft
11. Use of Role Equipment
12. Flight Recorder(s) and Locating Equipment.

9.1.1.12 **DAS RoA – Rules of the Air.** The purpose of DASR RoA — Rules of the Air is to assure that the rules stipulated within Defence Aeronautical Information Publication (AIP), as they apply to Defence Aviation, are harmonised with ICAO and national civil practice wherever practical. The intent is that Defence Aviation will have due regard for the safety of navigation of civil aircraft.

9.1.1.13 **DASR SPA – Specific Purpose Approval.** The purpose of DASR SPA — Specific Purpose Approval is to assure that certain Defence Aviation activities are conducted safely. The scope of DASR SPA includes Command Clearances, Low Flying, Flypasts and Flying Displays, Defence Long Range Operations and Night Vision Imaging System operations.

9.1.1.14 **DASR UAS – Uncrewed Aircraft Systems.** The purpose of DASR UAS — Uncrewed Aircraft Systems is to assure the safe operation of UAS. The regulations account for the range of UAS complexity, design pedigree and mass through three different categories: [type] certified category UAS, specific category UAS and open category UAS.

Superseded

9.1.2 Flight Operations Compliance

9.1.2.1 DASA approved aviation organisations implement DASR FLTOPS through a Command approved Flying Management System (FMS) that include:

1. a framework of controls
2. approved orders, instructions and publications
3. the operation of crewed and uncrewed aircraft in approved roles, with correct mission equipment, by qualified and authorised individuals
4. a safety framework that supports compliance with statutory safety obligations and enables risk-based command decisions to deliver capability
5. a system to enable commanders to eliminate and minimise risks SFARP.

9.1.2.2 While the Defence Aviation Safety Framework (DASF) establishes a structure for the management of aviation safety within Defence, responsibility for ensuring the safe operation of aviation systems rests with the chain of command. In the assure/ensure balance, the responsibility to ensure compliance and conformance with the Flight Operations regulations lies largely with the Accountable Manager (AM) of the MAO, ACD Service Provider (ACDSP), or ABM Operator (ABMO). AMs are accountable for:

1. the creation and internal validation of local systems of management that are capable of effectively complying with the requirements of applicable DASR, to the defined scope and level contained in the Military Air Operator Certificate(MAOC), Operational Compliance Statement (OCS), Operations Specification (OpSpec), Air Cargo Service Provider Certificate (ACSPC) and Air Battle Management Operator Certificate (ABMOC)
2. liaison with DASA during development, implementation and application of the system of management, to ensure initial and ongoing compliance.

9.1.2.3 DASA, the MAO, ACDSP and ABMO have overlapping and complementary responsibilities in the Oversight and Enforcement, and Safety Investigation areas of the DASF. However, aviation safety is always a command responsibility. Commanders and managers are therefore accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

9.1.3 Command Clearances

9.1.3.1 The DASP contains flexibility provisions to assist commanders faced with compelling operational imperatives to make informed decisions regarding regulatory compliance. These provisions become particularly relevant in situations where commanders are expected to operate Defence aircraft at markedly higher levels of risk than normal[2], to achieve non-discretionary activities in support of Australia's national interests. Such decisions must be made at the appropriate command level to ensure that aviation safety risks are eliminated or otherwise minimised SFARFP.

9.1.3.2 In the FLTOPS regulations, Commanders may utilise DASR SPA.10 - Command Clearance (CC), to operate an aviation system outside the system's configuration, role, environment, limitation

Superseded

or condition within a risk based framework. Other flexibility provisions provided in Airworthiness DASR, such as the Military Permit to Fly (MPTF), and those under DASR GR.80 are discussed further in DASPMAN Volume 3, Section 6. However, before a MAO utilises a flexibility provision under the auspices of DASR GR.80, the application must be forwarded to, and approved by, the Authority.

9.1.3.3 The Command Clearance process, available to MAOs under DASR SPA.10, differs from other flexibility provisions, in so far as it is not issued by the Authority, rather a commander at an appropriate level who can make the decision to proceed without further minimising risks commensurate with the clearance being granted. The Command Clearance process should not be used in the first instance to allow an aircraft to fly outside of its approved CRE. It should only be utilised when absolutely necessary to enable an aircraft to fly when the normal methods of ensuring airworthiness cannot be met and it must never be used for administrative convenience.

9.1.3.4 To summarise the process, when aircrew find a fault with their aircraft, a defect should be raised against the aircraft and then cleared, or deferred, by the appropriate maintenance organisation before returning to flight. An exception to this occurs when the defect is allowed under the aircraft's Minimum Equipment List (MEL) of allowable defects. In this case the aircrew may continue with their planned flight, giving due regard to the risks associated with the MEL item. If this process is not suitable or allowed under the DASR, then the MPTF process should be undertaken. Noting that the operational imperative influences the timeline for an MPTF, the captain may seek a Command Clearance through their chain of command.

9.1.3.5 The MAO should only process and approve a Command Clearance when considered with respect to the mission concerned, whether it is urgent or compelling, and the associated elevated level of risk that a Command Clearance would provide. As per all military aviation activities, the Command Clearance system requires appropriate risk consideration and the 7-Step Risk Management process must be followed. The Command Clearance system is there to enable a commander to fly aircraft outside of the approved CRE and as such, the granting of the clearance should not be made in haste or considered lightly.

9.1.3.6 For further information on Military Permits to Fly and Command Clearances see Chapter 5.3 and DASR SPA.10.

9.1.4 Historical context of Flight Operations Related Regulation

9.1.4.1 The Convention on International Civil Aviation (Chicago Convention 1944) set the basis for current civil aviation regulations and founded the International Civil Aviation Organisation (ICAO). Article 3 of the convention states:

> **This Convention shall be applicable only to civil aircraft, and shall not be applicable to state aircraft.**

9.1.4.2 In the Australian context, State Aircraft are defined as 'aircraft of any part of the Defence Force (including any aircraft that is commanded by a member of that Force in the course of duties as such a member); and aircraft used in the military, customs or police services of a foreign country'[3]. As Defence aircraft are included within this broad category, they are thereby exempt from all requirements contained within the civil aviation regulations.

9.1.4.3 To provide the directed level of aviation capability, Defence aviation platforms need to regularly use both domestic and international civil and military airspace. In doing so, military operators voluntarily adhere to ICAO flight procedures, including 'flying with due regard for the safety

Superseded

of navigation of civil aircraft', because militaries have a natural duty of care to all airspace users. Additionally, the Australian Government's National Aviation Policy White Paper notes that 'Defence, in collaboration with Airservices, is committed to improving civil and military aviation harmonisation, and to enhance better airspace access arrangements'. However, not all ICAO or civil aviation requirements are suited to military operations. Militaries therefore require bespoke regulatory systems to provide for operational capability and an equivalent level of safety. Hence, the tailored application of both civil and military requirements will ensure that Defence aircraft can continue to maximise their operational effectiveness.

9.1.5 MAO-AM Accountabilities and Responsibilities for Force Assigned Aircraft and Crew

9.1.5.1 **DASF and the spectrum of conflict.** The Defence Aviation Safety Framework (DASF) applies throughout the spectrum of conflict. While there are flexibility provisions, Joint Directive 21/2021 - *The Defence Aviation Safety Framework* contains no exceptions to the applicability of the DASF, in totality, during times of conflict.

9.1.5.2 **Accountability.** The DASF aligns accountability with control. Specifically [4]:

> *Commanders and managers are … accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.*

9.1.5.3 **TECHCON.** ADF Command and Control (C2) doctrine has a suitable means of control for MAO-AMs to exercise their accountability for force assigned aircraft and crew—Technical Advisory Control (TECHCON)[5] [6].

9.1.5.4 **Purpose.** The DASF provides amplification of Defence's safety obligations in the Defence Aviation Environment regarding the application of the:

1. *Work Health and Safety Act 2011*
2. *Work Health and Safety Regulations 2011*
3. various Codes of Practice made pursuant to the principal Act from time to time [7].

9.1.5.5 **Suitability.** The DASF is suitable for application across the spectrum of conflict. The DASF contains 'flexibility provisions to assist commanders faced with compelling operational imperatives.'[8] Notwithstanding, the DASF requires the application of flexibility provisions based on 'informed judgements … at the appropriate command level to ensure that aviation safety risks are eliminated or otherwise minimised so far as is reasonably practicable.'[9] This requirement drives the need for MAO-AMs to exercise TECHCON for force assigned aircraft—as the Joint Force Air Component Commander (JFACC) per se does not hold the knowledge, resources, structures or staff to support the risk management necessary to enact flexibility provisions[10].

9.1.5.6 **Division of duties between operational commanders and TECHCON authorities.** Note, for force assigned aircraft and crews, a court would likely find a MAO-AM (with TECHCON authority), and an operational commander (eg JFACC with operational command), have the same duty under s.16 WHS Act. However, the court would likely consider the capacity to influence and control, and thus

Superseded

discharge the duty by each commander will vary, depending on the factual circumstances of the situation.

9.1.5.7 **WHS Act applicability throughout the spectrum of conflict.** The WHS Act applies throughout the spectrum of conflict. Anecdotally, there is a common misconception that, the WHS Act does not apply during times of conflict. *The CDF declaration* makes clear that the obligations on 'officers, workers and other persons' are largely unchanged between peace, warlike operations and non-warlike operations. Specifically:

1. *the CDF declaration* renders inapplicable to warlike operations or non-warlike operations only the sections of the WHS Act that deal with[11]:
    i. 'Duty to notify of notifiable incidents'
    ii. 'Duty to preserve incident sites'.

9.1.5.8 **MAO-AM accountabilities/responsibilities.** MAO-AM accountabilities and responsibilities are unchanged for force assigned aircraft and crew. The DASP Manual, consistent with Joint Directive 21/2021, places accountabilities and responsibilities on MAO-AM. While there are flexibility provisions, the DASP Manual contains no exceptions to the applicability of the DASP (including the DASR) to MAO-AM regarding force assigned aircraft and crew.

9.1.5.9 **ADF doctrine—C2 provisions to account for the relationship between MAO-AM and force assigned commanders.** ADF doctrine has established C2 provisions to account for the relationship between MAO-AM and force assigned commanders—specifically, TECHCON. TECHCON is 'the provision of specialist and technical advice by designated authorities for the management and operation of forces.[12]'

9.1.5.10 By convention (and consistent with ADF-P-0 *Command*[13]) MAO-AMs retain TECHCON for force assigned aircraft and crew. ADF-P-0 Command specifies:

> *Capability managers exercise techcon through advice to the theatre commander for assigned forces ….*
>
> *… For an operational commander, techcon advice will relate to the employment of capabilities so that they are used within their operating parameters ….*

9.1.5.11 C2, as described in ADF-P-0 Command, provides an operational commander the necessary freedom to reject TECHCON advice, as follows:

> *Techcon advice may not be altered but may be rejected in part, or in total, by a commander in consideration of operational factors and within their span of command …*

9.1.5.12 DASF obligations on MAOs, considered against the ability of an operational commander to reject TECHCON advice, infer a number of tasks:

1. **on the MAO-AM[14]:**
    i. to be informed of the operational context in providing any TECHCON advice
    ii. to be available and responsive to operational commanders' requests for TECHCON advice

Superseded

iii. to *administer* Command Clearances[15] consistent with the operational commander's decisions regarding TECHCON advice -including any necessary risk management following an operational commander's decision to operate an aircraft outside its 'approved standards and limitations

Note the obligation to 'administer' the Command Clearance should not be read as an obligation on the MAO-AM to replicate or endorse the 'decision to proceed' that the operational commander has already made. Rather, the obligation on the MAO-AM to administer the Command Clearance is a recognition that:

- A Command Clearance is the system for managing operation of an aviation system outside its 'approved standards and limitations'—across the spectrum of conflict.
- The MAO is resourced (ie has the staff, expertise and processes to conduct informed, capability specific, risk management) to risk manage the ongoing safe operation of the aircraft—and the JFACC is not.
- Operation of the aircraft following an exceedance of its 'approved standards and limitations' requires risk management—both immediate and ongoing[16].

2. **on the operational commander:**

i. to provide the MAO-AM sufficient information to understand the operational context

ii. to weigh the operational imperative against the impact on the capability in considering any TECHCON advice

iii. to formally document the risk(s) they are accepting by setting aside the MAO-AM-provided TECHCON advice, to meet their operational imperative

iv. to inform the MAO-AM of any circumstances in which the operational commander has rejected TECHCON advice - to enable the MAO-AM to administer a Command Clearance, and conduct any necessary risk management.

9.1.5.13 **Historical operational experience.** Historical RAAF C2 constructs were not suitable. The Jones-Bostock affair[17] in World War II is an example of a failure of C2 in dealing with the relationship between an operational commander and a TECHCON authority[18]. It illustrates the importance of both a suitable C2 structure, and constructive interpersonal relationships between the TECHCON authority and the operational commander.

9.1.5.14 **Recent operational history.** Recent operational history indicates that doctrinal C2 provisions are suitable. Recent operational experience evidences that:

1. TECHCON provides a suitable C2 arrangement between MAO-AMs and operational commanders

2. there are suitable personnel posted to MAO-AM and senior Air Operations Centre positions to support effective interpersonal relationships.

Superseded

9.5.1 Introduction

9.5.1.1 The purpose of this chapter is to provide MAOs with guidance when seeking new (or updated) Defence navigation approvals, for Aircraft operations in airspace involving either:

1. Performance Based Navigation (PBN)
2. Reduced Vertical Separation Minima (RVSM)
3. North Atlantic High-Level Airspace (NAT HLA).

9.5.1.2 A MAO must obtain DASA approval to conduct specified Defence navigation operations—DASR SPA.50 refers. MAOs require both:

1. a Military Type Certificate (MTC) (or design approval of changes to the MTC, under DASR Part 21) detailing the necessary equipment to support the Defence navigation approval
2. an updated Military Air Operator Certificate (MAOC) Operations Specification (OpSpec) to include a 'Specific Approval', under DASR SPA.50.

9.5.1.3 Approval to operate in PBN, RVSM or NAT HLA airspace requires demonstration that:

1. the aircraft is technically capable of conducting the requested operations (also known as 'aircraft eligibility')
2. the relevant DASR Part 21J organisation has implemented the continued airworthiness requirements for the required operations
3. the MAO has updated its Flying Management System (FMS) for the requested operations (including, for example, that appropriate training is in place, aircrew competence has been assessed, and associated OIP has been published).

9.5.1.4 The Defence navigation approvals that MAOs can request are the Defence equivalent of the civil navigation requirements defined by[19]:

1. CASA Civil Aviation Order (CAO) 20.91 – (Instructions and Directions for Performance Based Navigation) Instrument 2014
2. the CASA AC 91 series – Performance Based Navigation
3. Civil Aviation Safety Regulation (CASR) Part 91.655 – Reduced Vertical Separation Minima (RVSM) Airspace
4. ICAO NAT Doc 007 - North Atlantic Operations and Airspace Manual.

9.5.1.5 Relevant acronyms, abbreviations and additional reference can be found at Annex A.

Superseded

9.5.2 Navigation Approvals - Background

9.5.2.1 PBN, RVSM and NAT HLA requirements form part of an internationally recognised framework of area-based navigation capabilities for Aircraft[20], based on the exploitation of:

1. the Global Navigation Satellite System (GNSS)
2. on-board Aircraft systems.

9.5.2.2 International Civil Aviation Organisation (ICAO) member nations commenced introducing these navigation requirements in 2001. For Australia, CASA CAO 20.18 mandated the installation of GNSS into all civil Instrument Flight Rules (IFR) Aircraft WEF 4 Feb 16. On that date, the Australian Back-up Navigation Network (BNN) was activated, resulting in approximately 200 (traditional) terrestrial navigation aids being withdrawn from service in Australia (approximately 50%). Therefore, from that date, Australia effectively became GNSS-based PBN and RVSM airspace.

9.5.2.3 While State Aircraft are not bound to the Civil Aviation Act 1988 (Cth), Defence aerospace platforms need to regularly use both domestic and international civil and military airspace for their Defence roles. The tailored application of PBN, RVSM and NAT HLA requirements in Defence Aircraft will ensure that Defence aviation assets can continue to maximise their operational effectiveness. Additionally, the Australian Government's Aviation White Paper—Towards 2050 noted that 'Defence, in collaboration with Air Services, is committed to improving civil and military aviation harmonisation, and to enhance better airspace access arrangements'[21].

9.5.2.4 **PBN operations.** PBN encompasses two lateral navigation specification suites:

1. Required Navigation Performance (RNP)
2. aRea NAVigation (RNAV).

9.5.2.5 The difference is that On-Board Performance Monitoring and Alerting (OBPMA) is required for RNP[22], but not for RNAV.

9.5.2.6 **RVSM operations.** RVSM applies to operations in airspace between Flight Level (FL) 290 and FL 410 inclusive, where a 1000 ft reduced vertical separation minimum is applied.

9.5.2.7 **NAT HLA operations.** NAT HLA operations apply in the North Atlantic, between FL 285 and FL 420 (inclusive), in the airspace linking Europe and North America. This is the busiest oceanic airspace in the world, with limited control and communications coverage. Successful Aircraft separation depends on applying the highest standards of horizontal and vertical navigation performance, and on aircrew operating discipline.

9.5.3 Navigation Approval—Education and Training Development Guidance

9.5.3.1 MAO education and self-training development guidance is available below. The guidance supports MAO development or acceptance of extant training materials that allow the qualification of aircrew for the navigation approvals requested.

1. PBN and RVSM Education and Training Guidance for Military Air Operators

Superseded

2. Example PBN - RVSM Multiple Choice Aircrew Assessment Quizzes Operators

3. Example PBN - RVSM Quick Reference Handbook Operational Summary

9.5.4 Defence Navigation Approval[23] Process

9.5.4.1 DASR SPA.50 and its complementary DASR Form 1307 Application for Navigation Specification Approval, are based on CASA (ie ICAO) requirements. The form is used to:

1. assist MAOs manage their navigation approval requests, by listing required compliance evidence against PBN, RVSM and NAT HLA requirements
2. support complementary MAO risk management processes
3. support MAO and DASA evidence review
4. support a complementary major change to the Type Certification Basis (TCB) where the Aircraft have not previously demonstrated meeting PBN, RVSM and NAT HLA requirements. [24] [25],

9.5.4.2 **Alternative demonstration of compliance.** As of 2023, CASA only specifically provides approvals for PBN RNP-AR operations. Other PBN specifications are automatically considered 'approved' if they are listed in relevant Aircraft OIP (including the AFM)—this is normal practice in civil aviation. However, most non-civil-derivative military platforms do not typically provide statements of compliance with PBN, RVSM and NAT HLA requirements in their OIP. In these military cases, DASA may accept compliance with civil standards through alternative means, by establishing equivalent performance. This involves either, or a combination of[26]:

1. demonstrating that equipment function and performance meets the intent of (but not strict compliance with) the relevant civil standard
2. demonstrating that the use of operational procedures can meet the same function, integrity and OBPMA performance requirements.

9.5.4.3 The most common reasons non-civil derivative military platforms have difficulty achieving compliance with PBN, RVSM and NAT HLA requirements are:

1. the absence of Technical Standard Order (TSO)-approved equipment
2. limited or no evidence of compliance with system functional, integrity or OBPMA performance requirements.

9.5.4.4 Early DASA engagement should be sought for demonstrations via equivalency— to seek assistance in defining the scope of compliance evidence required and likely timelines, and to confirm that a navigation approval is possible before the applicant commits significant resources. Where operational urgency applies, MAOs should consider temporarily applying for less precise[27] navigation approvals—which can be demonstrated more easily—while pursuing more precise navigation approvals in parallel over a less constrained timeframe.

Superseded

9.5.5 DASR Form 1307 – Application for Navigation Specification Approvals

9.5.5.1 MAOs can request Defence navigational approvals using DASR Form 1307. Each approval is categorised as either 'core', 'non-core', 'supplemental', and 'other', as shown below.

9.5.5.2 **Core approvals.** Core approvals are simpler to process than non-core approvals, and include:

1. RNAV 1
2. RNAV 2
3. RNAV 5
4. RNP 1
5. RNP 2
6. RNP APCH, including:
    i. LNAV
    ii. LNAV/VNAV
    iii. LP
    iv. LPV

9.5.5.3 **Non-Core approvals.** Non-core approvals require a more complex compliance process and evidence; and include those specifications that are detailed in other regulatory documents, but are administered in accordance with the nominal PBN approval process (ie RVSM)[28] Non-core approvals include:

1. RNAV 10 (RNP 10)
2. RNP 0.3 (Helicopter)
3. RNP 4
4. RNP AR (RNP AR APCH and RNP AR DP Operations may include One Engine Inoperative (OEI) procedures), including:
    i. RNP AR APCH
    ii. RNP AR DP
5. A-RNP
6. RVSM.

9.5.5.4 **Supplemental approvals.** Supplemental approvals either support another approval, provide an alternate means to support an approval, or provide supplemental navigational capabilities. However, they do not exist in isolation (ie they are complementary to selected core and non-core approvals). Supplemental approvals include:

1. APV / Baro-VNAV

Superseded

2. Radius to Fix (RF)

3. Fixed Radius Transition (FRT)

4. Time of Arrival Control (TOAC)

5. use of suitable area navigation systems on conventional routes and procedures (both en route and terminal).

9.5.5.5 **Other approvals.** Other approvals are specific or location-based, and include:

1. NAT HLA.

9.5.5.6 A MAO may use the same DASR Form 1307 for multiple approvals. Note, some of the more precise Defence navigation approvals automatically include approval for less precise Defence navigation approvals—this is known as 'nesting'. For example, if DASA awards an approval for RNP 4, DASA will automatically consider approvals for RNP 5 and RNP 10.

9.5.6 Applying for Navigation Approvals

9.5.6.1 To gain DASA navigation approval, the applicant must:

1. complete DASR Form 1307

2. submit the required evidence against the approval(s) selected.

9.5.6.2 MAOs should submit applications to DASA at least 90 days prior to the required navigation operations. This allows for the resolution of potential shortfalls against the requested approval(s) before the major change to the TCB and applicant OpSpec.

9.5.6.3 To provide a navigation approval, DASA assesses each approval's compliance evidence against three navigation approval component requirements. The three components are the same for each approval, but the level of detail differs dependent on the approval chosen. The three navigation component requirements are:

1. **Component 1**: Initial Airworthiness and Aircraft eligibility requirements.

2. **Component 2**: Continued Airworthiness requirements.

3. **Component 3**: Flight operations procedures and training requirements.

9.5.6.4 **DASR Form 1307 preparation.** Applicants must use DASR Form 1307 to support review of the evidence requirements of each navigation approval sought. In order of increasing complexity (ie time to process), application evidence options are:

1. The application is based upon an **existing** navigation approval (eg the Aircraft eligibility and continuing airworthiness requirements for the RNP 2 approval can be based on navigation approvals already held for either RNP 1, RNP APCH or RNP AR).

2. The application is based upon a **prior certification** against relevant navigation approval requirements[29].

Superseded

3. The application is based upon **demonstration** that on-board equipment (and its installation) **meets** the navigation approval's functional, display, alerting and performance requirements[30].

4. The application is based upon **demonstration** that on-board equipment (and its installation), when supported by defined operational controls, **provides functional equivalence** to the approval's functional, display, alerting and performance requirements.

5. The application is based upon a **DASA-agreed alternate approach** to achieving **functional equivalence** to the approval's functional, display, alerting and performance requirements.

9.5.6.5 **Navigation approval evidence.** The following can assist MAOs in collating or generating the evidence required:

1. **For component 1 - Initial Airworthiness and Aircraft eligibility.** DASR Form 1307 uses question sets to guide applicants through the necessary evidence. MAOs may demonstrate Aircraft eligibility through any one of the following:

   i. the CAA/MAA-approved AFM confirms that the Aircraft **is capable** of undertaking the required operations, with a CRE assessment that either:

      – confirms that there are no CRE differences that adversely impact the approval in the Defence operational context

      – identifies CRE differences that adversely impact the approval in the Defence operational context, together with additional compliance demonstration evidence to address the differences

   ii. the CAA/MAA confirms that the Aircraft **has been certified** for the required PBN, RVSM and NAT HLA operations, with a CRE assessment that either:

      – confirms that there are no CRE differences that adversely impact the approval in the Defence operational context

      – identifies CRE differences that adversely impact the approval in the Defence operational context, together with additional compliance demonstration evidence to address the differences

   iii. a technical assessment of the design demonstrates compliance with the prescribed airworthiness requirements for the specified operations.

2. **For Component 2 - Continued Airworthiness.** DASR Form 1307 guides applicants through the evidence necessary to demonstrate that navigation system components will remain compliant with the approved Type Design[31] while in-Service, and that the navigation databases used will remain valid during operations.

3. **For Component 3 - Flight operations procedures and training.**

   i. Flight operations procedures. DASR Form 1307 lists operations documentation requirements for each navigation approval, including[32]:

      – operating policies to support selected operations under all normal and emergency conditions

Superseded

- flight crew procedures and checklists for all navigation approvals for the Aircraft Type
- Minimum Equipment Lists (MELs, or their equivalent) for each navigation approval
- planning and management OIP (including for navigation database updates and validation, and mission planning procedures)
- OIP for the reporting and management of navigation database discrepancies and errant Aircraft behaviour observed during approved operations.

ii. **Flight operations training.** DASR Form 1307 lists both generic and specific Flight operations training requirements for each navigation approval, including:

- Flight crew training programs, competency assessments, currency, and training records
- maintenance staff training requirements.

9.5.6.6 **Navigation approval evidence shortfall resolution.** Where DASR Form 1307 requirements cannot be met, the form supports DASA consultation and shortfall resolution. The applicant must demonstrate functional equivalence to published requirements. Shortfall resolution involves the:

1. DASA Desk Officer and applicant reviewing shortfalls and discussing possible pathways to demonstrating compliance
2. applicant proposing an appropriate alternative to compliance, that demonstrates functional equivalence, for example:
   i. prior alternative CAA/MAA certifications
   ii. operational or crew-based procedural additions that can demonstrate functional equivalence[33].
3. applicant providing evidence that demonstrates functional equivalence, such as[34]:
   i. flight test programs
   ii. operational human factors and workload assessments
   iii. LMPs
   iv. Aircraft Type Design System Safety Assessments
   v. Risk Management Plans and Mission Risk Profiles to define the additional controls required to be incorporated into OIP.

9.5.6.7 **DASR Form 1307 submission.** To finalise the MAO request, the applicant must submit the form and the corresponding evidence data pack, via a MAO request, to dasa-davnops.operationalreviews@defence.gov.au. The data pack should include a summary of the documents attached and a description of each document's purpose towards navigation approval requirement compliance.

Superseded

9.5.6.8 When compliance is demonstrated, and the MTCH has updated the aircraft's TCB (through a DASA approved Major change to Type Design), DASA will add the navigation approval(s) to the OpSpec.

9.5.5.9 Table 1 provides MAOs with a checklist of the evidence required in data packs. Note, not all items are required for all navigation approvals. Additionally—in the case of non-core approvals; or where there is a requirement to demonstrate functional equivalence—this checklist is not exhaustive.

Submission Checklist Item
DASR Form 1307 • In original MS Excel Format
Initial Airworthiness and Aircraft Eligibility • Aircraft Airworthiness documents which provide evidence that the Aircraft is Type Certified for the requested operations (eg AFM and supplements, OEM service letters, Type Certificate Compliance Document). • A description of the relevant Aircraft equipment required for the proposed navigation approvals, including a configuration list of components, and how the system meets applicable requirements.
Continued Airworthiness • A description of the maintenance program used to ensure the continued Airworthiness of the Aircraft for the equipment required for the navigation approval. This need only address those circumstances where additional specific maintenance is required. • Applicable Aircraft Maintenance Manuals for the relevant system/s. • An equipment list for the navigation approvals requested (make, model & part—both hardware & software). • Applicable extracts from the Minimum Equipment List (Airworthiness items) and applicable instructions that demonstrate identification and management of:

Superseded

- any unserviceability that affects the conduct of any approved operation
- the systems that GNSS interfaces with, so that in the event of the GNSS being inoperative, the full impact of the failure can be determined
- The rationale for selection of specific MEL items as having an impact on safe operations, and any associated risk assessments.

Airworthiness - Digital Data

- A description of the method used to receive updates to (including the frequency of updates) and to ensure the validity of the airborne navigation database. This should address the validation of data provided externally and internally; and verification procedures for any internal change to the supplied data
    - **Note:** this should include coverage of all digital navigation data (including map and chart data used in Flight during the conduct of procedures, or for ground verification); and data acquisition, manipulation, and management (to encompass all potential Defence Aircraft operations).
- Evidence that the suppliers of the navigation database comply with the minimum integrity requirements of the most stringent approval requested.

Flight Operations Processes

- Operational procedures (including normal and emergency) published in OIP. These procedures should include Flight planning, pre-flight, inflight and post-flight.

- Procedures should include copies of, or extracts from, OIP covering:
    - operations manuals
    - the AFM
    - checklists
    - contingency procedures
    - QRH (or equivalent)
    - sections of the MEL applicable to the requested operations

Superseded

Training and Qualifications
• A description of the proposed aircrew, maintenance and other applicable personnel and specialists' training for the requested operations; and associated competencies and currency requirements (including a copy of the LMP and associated artefacts[35]. • Copies of relevant training syllabi, training proficiency examination and assessment templates and currency assessment templates.

Table 1 – MAO Navigation Approval Submission checklist

9.5.1 Introduction

Annex A - Relevant acronyms, abbreviations and additional references

A.1 Acronyms

Acronyms and abbreviations in this chapter and its supporting forms, which are in addition to those defined in the Defence Glossary and DASR Glossary, are listed below.

Superseded

Acronym	Description
APCH	Approach
AR	Authorisation Required
BARO	Barometric
B-RNAV	Basic RNAV
CAANZ	Civil Aviation Authority of New Zealand
CPDLC	Controller-Pilot Data Link Communications
(E)TSO	(European) Technical Standard Order
EUROCAE	European Organisation for Civil Aviation Equipment
FL	Flight Level
FMS	Flight Management System
FRT	Fixed Radius Transition
IRS	Inertial Reference System
LNAV	Lateral Navigation
LNAV / VNAV	Lateral Navigation with Vertical Navigation
LP	Localiser Performance
LPV	Localiser Performance with Vertical Guidance
MSO	Military Standard Order
NSE	Navigation System Error
PBN	Performance-based Navigation
PCL	Pocket Checklist (also see QRH)
P-RNAV	Precision Area Navigation
QRH	Quick Reference Handbook (also see PCL)
RAIM	Receiver Autonomous Integrity Monitor
RF	Radius to Fix (typically associated with APCH-AR)
RNAV	Area Navigation
RNP	Required Navigation Performance
RNP APCH	RNP Approach

Superseded

A.2 Definitions

Terms that have specific meaning within this chapter and its supporting documents have been replicated from reference material and are listed below.

Airspace

Area(s), route(s) or procedure(s) where: navigation performance requirements have been specified (PBN specifications) and aircraft must hold an authorisation or approval for the specified requirements (PBN specifications) in order to operate in the designated environment; or aircraft navigation equipment carriage , navigation system functional or performance requirements, or aircraft installation requirements have been specified in order for an aircraft to operate in the designated environment.

Aeronautical Radio Incorporated Specification (ARINC) 424 Path Terminator

Aeronautical Radio Incorporated Specification 424 format for coding airborne navigation databases.

Letter of Acceptance (LOA)

A letter issued by a regulatory authority to a data supplier that has demonstrated compliance with the requirements of RTCA DO-200A / EUROCAE ED-76 Standards for processing Aeronautical Data. A LOA may be a Type 1 LOA or a Type 2 LOA.

Performance-based Navigation

Area navigation based on performance requirements for aircraft operating along an Air Traffic Services (ATS) route, on an instrument approach procedure or in a designated airspace.

Receiver Autonomous Integrity Monitor

A form of Aircraft-Based Augmentation System (ABAS) whereby a GNSS receiver processor determines the integrity of the GNSS navigation signals using only GPS signals or GPS signals augmented with altitude (baro-aiding). This determination is achieved by a consistency check among redundant pseudo-range measurements. At least one additional satellite needs to be available with the correct geometry over and above that needed for the position estimation, for the receiver to perform the Receiver Autonomous Integrity Monitor (RAIM) function.

RNAV specification

A navigation specification based on area navigation that does not include the requirement for on-board performance monitoring and alerting, designated by the prefix RNAV (e.g. RNAV 5, RNAV 1).

RNP specification

Superseded

A navigation specification based on area navigation that includes the requirement for on-board performance monitoring and alerting, designated by the prefix RNP (e.g. RNP 4, RNP APCH).

Type 1 LOA

Provides recognition of a navigation data supplier's compliance with RTCA DO-200A / EUROCAE ED-76 Standards for Processing Aeronautical Data, with no identified compatibility with an aircraft system.

Type 2 LOA

Provides recognition of a navigation data supplier's compliance with RTCA DO-200A / EUROCAE ED-76 Standards for Processing Aeronautical Data, and identifies compatibility of delivered data with particular avionic systems that are identified in the LOA.

A.3 Supporting Documents

The following supporting documents may be relevant to MAOs seeking to implement the Defence Navigation requirements.

9.5.2 Navigation approvals - Background

9.1 Introduction

9.1.1 Flight Operations Regulations

9.1.1.1 The Flight Operations DASR provide amplification of Defence's obligations[1] under the WHS Act 2011 in the context of Defence flight operations. The regulations prescribe the accountabilities of the chain of command as they relate to Defence flight operations. For Military Air Operators (MAO), the regulations define management requirements. MAOs are obliged to implement a system of management to comply with applicable DASR and to ensure that their personnel conform to that system of management.

9.1.1.2 The Flight Operations DASR contain regulations for the safe conduct of flight operations by Defence aircraft, including UAS and aircraft operated on behalf of Defence. It includes requirements for training and qualification of all personnel involved in military flight operations.

9.1.1.3 **DASR Aircrew**. The purpose of DASR Aircrew is to assure that Defence aircrew are adequately trained and proficient for employment in a specific role. This includes regulation for the personnel and training aspects of Flying Instruction, Airborne Emergency Training, Crew Resource Management, Aviation Safety training and Flying Logbooks.

9.1.1.4 **DASR AO.Gen — Air Operations General**. DASR Air Operations (AO) General is applicable to all areas of air operations and includes requirements for Orders, Instructions and Publications (OIP) specific to air operations.

9.1.1.5 **DASR ARO – Authority Requirements for Air Operations**. The purpose of DASR ARO — Authority Requirements for Air Operations is to address a range of AO matters, including the following:

1. Statement of Operating Intent and Usage (SOIU), to inform decisions on whether an aircraft design remains safe for operations
2. The Defence Register
3. establishment of the Military Air Operator (MAO).

9.1.1.6 A MAO is the regulated organisation approved by DASA to conduct air operations. The senior member of a MAO is the Accountable Manager (AM), which is usually an O7 commander.

9.1.1.7 The majority of Defence flight operations are conducted under a Military Air Operator Certificate (MAOC) issued to a MAO. The MAO is usually a Force Element Group (FEG) or equivalent.

9.1.1.8 **DASR FSTD – Flight Simulation Training Devices.** The purpose of DASR FSTD — Flight Simulation Training Devices is to assure aviation operations augmented by a Flight Simulation Training Device (FSTD) are adequately controlled and managed. Approval of an FSTD is via an Installation Operating Permit (IOP).

9.1.1.9 **DASR FT – Flight Test.** The purpose of DASR FT — Flight Test is to assure that a MAO only undertakes those Flight Test activities it is capable of safely conducting, including that the tests are conducted under appropriate airworthiness controls using suitable personnel, processes and data.

Superseded

Flight Test is a subset of Defence Test and Evaluation (T&E). Flight Test activities involve, to varying extents, the operation of an aircraft outside of its existing type design certification. A MAO requires a specific privilege to be able to conduct Flight Test activities of this nature.

9.1.1.10 **DASR NDR – Non-Defence Registered Aircraft.** The purpose of DASR Non-Defence Registered Aircraft (NDRA) is to clarify Defence Aviation Safety Program (DASP) obligations of Defence when operating non Defence registered aircraft.

9.1.1.11 **DASR ORO – Organisation Requirements for Air Operations.** The purpose of DASR ORO Organisation Requirements for Air Operations is to assure Defence aircraft are operated with adequate controls to ensure safety of flight. They include the following:

1. Flight Operations—ensuring aircraft are operated in approved roles, with correct mission equipment, to approved procedures and instructions
2. Flying Management Systems
3. Appointment of Key Staff
4. Aircrew Competency System
5. Flight Authorisation System
6. Aeronautical Life Support Equipment
7. Aircraft Crewing (including Captaincy)
8. Oxygen Management (including Flight Crew and Supplemental Oxygen)
9. Authorised Electronic Equipment
10. Carriage of Personnel on Defence Aircraft
11. Use of Role Equipment
12. Flight Recorder(s) and Locating Equipment.

9.1.1.12 **DAS RoA – Rules of the Air.** The purpose of DASR RoA — Rules of the Air is to assure that the rules stipulated within Defence Aeronautical Information Publication (AIP), as they apply to Defence Aviation, are harmonised with ICAO and national civil practice wherever practical. The intent is that Defence Aviation will have due regard for the safety of navigation of civil aircraft.

9.1.1.13 **DASR SPA – Specific Purpose Approval.** The purpose of DASR SPA — Specific Purpose Approval is to assure that certain Defence Aviation activities are conducted safely. The scope of DASR SPA includes Command Clearances, Low Flying, Flypasts and Flying Displays, Defence Long Range Operations and Night Vision Imaging System operations.

9.1.1.14 **DASR UAS – Uncrewed Aircraft Systems.** The purpose of DASR UAS — Uncrewed Aircraft Systems is to assure the safe operation of UAS. The regulations account for the range of UAS complexity, design pedigree and mass through three different categories: [type] certified category UAS, specific category UAS and open category UAS.

Superseded

9.1.2 Flight Operations Compliance

9.1.2.1 DASA approved aviation organisations implement DASR FLTOPS through a Command approved Flying Management System (FMS) that include:

1. a framework of controls
2. approved orders, instructions and publications
3. the operation of crewed and uncrewed aircraft in approved roles, with correct mission equipment, by qualified and authorised individuals
4. a safety framework that supports compliance with statutory safety obligations and enables risk-based command decisions to deliver capability
5. a system to enable commanders to eliminate and minimise risks SFARP.

9.1.2.2 While the Defence Aviation Safety Framework (DASF) establishes a structure for the management of aviation safety within Defence, responsibility for ensuring the safe operation of aviation systems rests with the chain of command. In the assure/ensure balance, the responsibility to ensure compliance and conformance with the Flight Operations regulations lies largely with the Accountable Manager (AM) of the MAO, ACD Service Provider (ACDSP), or ABM Operator (ABMO). AMs are accountable for:

1. the creation and internal validation of local systems of management that are capable of effectively complying with the requirements of applicable DASR, to the defined scope and level contained in the Military Air Operator Certificate(MAOC), Operational Compliance Statement (OCS), Operations Specification (OpSpec), Air Cargo Service Provider Certificate (ACSPC) and Air Battle Management Operator Certificate (ABMOC)
2. liaison with DASA during development, implementation and application of the system of management, to ensure initial and ongoing compliance.

9.1.2.3 DASA, the MAO, ACDSP and ABMO have overlapping and complementary responsibilities in the Oversight and Enforcement, and Safety Investigation areas of the DASF. However, aviation safety is always a command responsibility. Commanders and managers are therefore accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

9.1.3 Command Clearances

9.1.3.1 The DASP contains flexibility provisions to assist commanders faced with compelling operational imperatives to make informed decisions regarding regulatory compliance. These provisions become particularly relevant in situations where commanders are expected to operate Defence aircraft at markedly higher levels of risk than normal[2], to achieve non-discretionary activities in support of Australia's national interests. Such decisions must be made at the appropriate command level to ensure that aviation safety risks are eliminated or otherwise minimised SFARFP.

9.1.3.2 In the FLTOPS regulations, Commanders may utilise DASR SPA.10 - Command Clearance (CC), to operate an aviation system outside the system's configuration, role, environment, limitation or condition within a risk based framework. Other flexibility provisions provided in Airworthiness DASR, such as the Military Permit to Fly (MPTF), and those under DASR GR.80 are discussed further

Superseded

in DASPMAN Volume 3, Section 6. However, before a MAO utilises a flexibility provision under the auspices of DASR GR.80, the application must be forwarded to, and approved by, the Authority.

9.1.3.3 The Command Clearance process, available to MAOs under DASR SPA.10, differs from other flexibility provisions, in so far as it is not issued by the Authority, rather a commander at an appropriate level who can make the decision to proceed without further minimising risks commensurate with the clearance being granted. The Command Clearance process should not be used in the first instance to allow an aircraft to fly outside of its approved CRE. It should only be utilised when absolutely necessary to enable an aircraft to fly when the normal methods of ensuring airworthiness cannot be met and it must never be used for administrative convenience.

9.1.3.4 To summarise the process, when aircrew find a fault with their aircraft, a defect should be raised against the aircraft and then cleared, or deferred, by the appropriate maintenance organisation before returning to flight. An exception to this occurs when the defect is allowed under the aircraft's Minimum Equipment List (MEL) of allowable defects. In this case the aircrew may continue with their planned flight, giving due regard to the risks associated with the MEL item. If this process is not suitable or allowed under the DASR, then the MPTF process should be undertaken. Noting that the operational imperative influences the timeline for an MPTF, the captain may seek a Command Clearance through their chain of command.

9.1.3.5 The MAO should only process and approve a Command Clearance when considered with respect to the mission concerned, whether it is urgent or compelling, and the associated elevated level of risk that a Command Clearance would provide. As per all military aviation activities, the Command Clearance system requires appropriate risk consideration and the 7-Step Risk Management process must be followed. The Command Clearance system is there to enable a commander to fly aircraft outside of the approved CRE and as such, the granting of the clearance should not be made in haste or considered lightly.

9.1.3.6 For further information on Military Permits to Fly and Command Clearances see Chapter 5.3 and DASR SPA.10.

9.1.4 Historical context of Flight Operations Related Regulation

9.1.4.1 The Convention on International Civil Aviation (Chicago Convention 1944) set the basis for current civil aviation regulations and founded the International Civil Aviation Organisation (ICAO). Article 3 of the convention states:

> **This Convention shall be applicable only to civil aircraft, and shall not be applicable to state aircraft.**

9.1.4.2 In the Australian context, State Aircraft are defined as 'aircraft of any part of the Defence Force (including any aircraft that is commanded by a member of that Force in the course of duties as such a member); and aircraft used in the military, customs or police services of a foreign country'[3]. As Defence aircraft are included within this broad category, they are thereby exempt from all requirements contained within the civil aviation regulations.

9.1.4.3 To provide the directed level of aviation capability, Defence aviation platforms need to regularly use both domestic and international civil and military airspace. In doing so, military operators voluntarily adhere to ICAO flight procedures, including 'flying with due regard for the safety of navigation of civil aircraft', because militaries have a natural duty of care to all airspace users. Additionally, the Australian Government's National Aviation Policy White Paper notes that 'Defence, in collaboration with Airservices, is committed to improving civil and military aviation harmonisation,

Superseded

and to enhance better airspace access arrangements'. However, not all ICAO or civil aviation requirements are suited to military operations. Militaries therefore require bespoke regulatory systems to provide for operational capability and an equivalent level of safety. Hence, the tailored application of both civil and military requirements will ensure that Defence aircraft can continue to maximise their operational effectiveness.

9.1.5 MAO-AM Accountabilities and Responsibilities for Force Assigned Aircraft and Crew

9.1.5.1 **DASF and the spectrum of conflict.** The Defence Aviation Safety Framework (DASF) applies throughout the spectrum of conflict. While there are flexibility provisions, Joint Directive 21/2021 - *The Defence Aviation Safety Framework* contains no exceptions to the applicability of the DASF, in totality, during times of conflict.

9.1.5.2 **Accountability.** The DASF aligns accountability with control. Specifically [4]:

> *Commanders and managers are … accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.*

9.1.5.3 **TECHCON.** ADF Command and Control (C2) doctrine has a suitable means of control for MAO-AMs to exercise their accountability for force assigned aircraft and crew—Technical Advisory Control (TECHCON)[5] [6].

9.1.5.4 **Purpose.** The DASF provides amplification of Defence's safety obligations in the Defence Aviation Environment regarding the application of the:

1. *Work Health and Safety Act 2011*
2. *Work Health and Safety Regulations 2011*
3. various Codes of Practice made pursuant to the principal Act from time to time [7].

9.1.5.5 **Suitability.** The DASF is suitable for application across the spectrum of conflict. The DASF contains 'flexibility provisions to assist commanders faced with compelling operational imperatives.'[8] Notwithstanding, the DASF requires the application of flexibility provisions based on 'informed judgements … at the appropriate command level to ensure that aviation safety risks are eliminated or otherwise minimised so far as is reasonably practicable.'[9] This requirement drives the need for MAO-AMs to exercise TECHCON for force assigned aircraft—as the Joint Force Air Component Commander (JFACC) per se does not hold the knowledge, resources, structures or staff to support the risk management necessary to enact flexibility provisions[10].

9.1.5.6 **Division of duties between operational commanders and TECHCON authorities.** Note, for force assigned aircraft and crews, a court would likely find a MAO-AM (with TECHCON authority), and an operational commander (eg JFACC with operational command), have the same duty under s.16 WHS Act. However, the court would likely consider the capacity to influence and control, and thus discharge the duty by each commander will vary, depending on the factual circumstances of the situation.

9.1.5.7 **WHS Act applicability throughout the spectrum of conflict.** The WHS Act applies throughout the spectrum of conflict. Anecdotally, there is a common misconception that, the WHS

Superseded

Act does not apply during times of conflict. *The CDF declaration* makes clear that the obligations on 'officers, workers and other persons' are largely unchanged between peace, warlike operations and non-warlike operations. Specifically:

1. *the CDF declaration* renders inapplicable to warlike operations or non-warlike operations only the sections of the WHS Act that deal with[11]:
    i. 'Duty to notify of notifiable incidents'
    ii. 'Duty to preserve incident sites'.

9.1.5.8 **MAO-AM accountabilities/responsibilities.** MAO-AM accountabilities and responsibilities are unchanged for force assigned aircraft and crew. The DASP Manual, consistent with Joint Directive 21/2021, places accountabilities and responsibilities on MAO-AM. While there are flexibility provisions, the DASP Manual contains no exceptions to the applicability of the DASP (including the DASR) to MAO-AM regarding force assigned aircraft and crew.

9.1.5.9 **ADF doctrine—C2 provisions to account for the relationship between MAO-AM and force assigned commanders.** ADF doctrine has established C2 provisions to account for the relationship between MAO-AM and force assigned commanders—specifically, TECHCON. TECHCON is 'the provision of specialist and technical advice by designated authorities for the management and operation of forces.[12],

9.1.5.10 By convention (and consistent with ADF-P-0 *Command*[13]) MAO-AMs retain TECHCON for force assigned aircraft and crew. ADF-P-0 Command specifies:

> *Capability managers exercise techcon through advice to the theatre commander for assigned forces ….*
>
> *… For an operational commander, techcon advice will relate to the employment of capabilities so that they are used within their operating parameters ….*

9.1.5.11 C2, as described in ADF-P-0 Command, provides an operational commander the necessary freedom to reject TECHCON advice, as follows:

> *Techcon advice may not be altered but may be rejected in part, or in total, by a commander in consideration of operational factors and within their span of command …*

9.1.5.12 DASF obligations on MAOs, considered against the ability of an operational commander to reject TECHCON advice, infer a number of tasks:

1. **on the MAO-AM[14]:**
    i. to be informed of the operational context in providing any TECHCON advice
    ii. to be available and responsive to operational commanders' requests for TECHCON advice
    iii. to *administer* Command Clearances[15] consistent with the operational commander's decisions regarding TECHCON advice -including any necessary risk management following an operational commander's decision to operate an aircraft outside its 'approved standards and limitations

Superseded

Note the obligation to 'administer' the Command Clearance should not be read as an obligation on the MAO-AM to replicate or endorse the 'decision to proceed' that the operational commander has already made. Rather, the obligation on the MAO-AM to administer the Command Clearance is a recognition that:

- A Command Clearance is the system for managing operation of an aviation system outside its 'approved standards and limitations'—across the spectrum of conflict.
- The MAO is resourced (ie has the staff, expertise and processes to conduct informed, capability specific, risk management) to risk manage the ongoing safe operation of the aircraft—and the JFACC is not.
- Operation of the aircraft following an exceedance of its 'approved standards and limitations' requires risk management—both immediate and ongoing[16].

2. **on the operational commander:**

   i. to provide the MAO-AM sufficient information to understand the operational context

   ii. to weigh the operational imperative against the impact on the capability in considering any TECHCON advice

   iii. to formally document the risk(s) they are accepting by setting aside the MAO-AM-provided TECHCON advice, to meet their operational imperative

   iv. to inform the MAO-AM of any circumstances in which the operational commander has rejected TECHCON advice - to enable the MAO-AM to administer a Command Clearance, and conduct any necessary risk management.

9.1.5.13 **Historical operational experience.** Historical RAAF C2 constructs were not suitable. The Jones-Bostock affair[17] in World War II is an example of a failure of C2 in dealing with the relationship between an operational commander and a TECHCON authority[18]. It illustrates the importance of both a suitable C2 structure, and constructive interpersonal relationships between the TECHCON authority and the operational commander.

9.1.5.14 **Recent operational history.** Recent operational history indicates that doctrinal C2 provisions are suitable. Recent operational experience evidences that:

1. TECHCON provides a suitable C2 arrangement between MAO-AMs and operational commanders
2. there are suitable personnel posted to MAO-AM and senior Air Operations Centre positions to support effective interpersonal relationships.

9.5 Defence Navigation Approvals

Superseded

9.5.1 Introduction

9.5.1.1 The purpose of this chapter is to provide MAOs with guidance when seeking new (or updated) Defence navigation approvals, for Aircraft operations in airspace involving either:

1. Performance Based Navigation (PBN)
2. Reduced Vertical Separation Minima (RVSM)
3. North Atlantic High-Level Airspace (NAT HLA).

9.5.1.2 A MAO must obtain DASA approval to conduct specified Defence navigation operations—DASR SPA.50 refers. MAOs require both:

1. a Military Type Certificate (MTC) (or design approval of changes to the MTC, under DASR Part 21) detailing the necessary equipment to support the Defence navigation approval
2. an updated Military Air Operator Certificate (MAOC) Operations Specification (OpSpec) to include a 'Specific Approval', under DASR SPA.50.

9.5.1.3 Approval to operate in PBN, RVSM or NAT HLA airspace requires demonstration that:

1. the aircraft is technically capable of conducting the requested operations (also known as 'aircraft eligibility')
2. the relevant DASR Part 21J organisation has implemented the continued airworthiness requirements for the required operations
3. the MAO has updated its Flying Management System (FMS) for the requested operations (including, for example, that appropriate training is in place, aircrew competence has been assessed, and associated OIP has been published).

9.5.1.4 The Defence navigation approvals that MAOs can request are the Defence equivalent of the civil navigation requirements defined by[19]:

1. CASA Civil Aviation Order (CAO) 20.91 – (Instructions and Directions for Performance Based Navigation) Instrument 2014
2. the CASA AC 91 series – Performance Based Navigation
3. Civil Aviation Safety Regulation (CASR) Part 91.655 – Reduced Vertical Separation Minima (RVSM) Airspace
4. ICAO NAT Doc 007 - North Atlantic Operations and Airspace Manual.

9.5.1.5 Relevant acronyms, abbreviations and additional reference can be found at Annex A.

9.5.2 Navigation Approvals - Background

9.5.2.1 PBN, RVSM and NAT HLA requirements form part of an internationally recognised framework of area-based navigation capabilities for Aircraft[20], based on the exploitation of:

1. the Global Navigation Satellite System (GNSS)

Superseded

2. on-board Aircraft systems.

9.5.2.2 International Civil Aviation Organisation (ICAO) member nations commenced introducing these navigation requirements in 2001. For Australia, CASA CAO 20.18 mandated the installation of GNSS into all civil Instrument Flight Rules (IFR) Aircraft WEF 4 Feb 16. On that date, the Australian Back-up Navigation Network (BNN) was activated, resulting in approximately 200 (traditional) terrestrial navigation aids being withdrawn from service in Australia (approximately 50%). Therefore, from that date, Australia effectively became GNSS-based PBN and RVSM airspace.

9.5.2.3 While State Aircraft are not bound to the Civil Aviation Act 1988 (Cth), Defence aerospace platforms need to regularly use both domestic and international civil and military airspace for their Defence roles. The tailored application of PBN, RVSM and NAT HLA requirements in Defence Aircraft will ensure that Defence aviation assets can continue to maximise their operational effectiveness. Additionally, the Australian Government's Aviation White Paper—Towards 2050 noted that 'Defence, in collaboration with Air Services, is committed to improving civil and military aviation harmonisation, and to enhance better airspace access arrangements'[21].

9.5.2.4 **PBN operations.** PBN encompasses two lateral navigation specification suites:

1. Required Navigation Performance (RNP)
2. aRea NAVigation (RNAV).

9.5.2.5 The difference is that On-Board Performance Monitoring and Alerting (OBPMA) is required for RNP[22], but not for RNAV.

9.5.2.6 **RVSM operations.** RVSM applies to operations in airspace between Flight Level (FL) 290 and FL 410 inclusive, where a 1000 ft reduced vertical separation minimum is applied.

9.5.2.7 **NAT HLA operations.** NAT HLA operations apply in the North Atlantic, between FL 285 and FL 420 (inclusive), in the airspace linking Europe and North America. This is the busiest oceanic airspace in the world, with limited control and communications coverage. Successful Aircraft separation depends on applying the highest standards of horizontal and vertical navigation performance, and on aircrew operating discipline.

9.5.3 Navigation Approval—Education and Training Development Guidance

9.5.3.1 MAO education and self-training development guidance is available below. The guidance supports MAO development or acceptance of extant training materials that allow the qualification of aircrew for the navigation approvals requested.

1. PBN and RVSM Education and Training Guidance for Military Air Operators
2. Example PBN - RVSM Multiple Choice Aircrew Assessment Quizzes Operators
3. Example PBN - RVSM Quick Reference Handbook Operational Summary

9.5.4 Defence Navigation Approval[23] Process

9.5.4.1 DASR SPA.50 and its complementary DASR Form 1307 Application for Navigation Specification Approval, are based on CASA (ie ICAO) requirements. The form is used to:

Superseded

1. assist MAOs manage their navigation approval requests, by listing required compliance evidence against PBN, RVSM and NAT HLA requirements
2. support complementary MAO risk management processes
3. support MAO and DASA evidence review
4. support a complementary major change to the Type Certification Basis (TCB) where the Aircraft have not previously demonstrated meeting PBN, RVSM and NAT HLA requirements. [24] [25],

9.5.4.2 **Alternative demonstration of compliance.** As of 2023, CASA only specifically provides approvals for PBN RNP-AR operations. Other PBN specifications are automatically considered 'approved' if they are listed in relevant Aircraft OIP (including the AFM)—this is normal practice in civil aviation. However, most non-civil-derivative military platforms do not typically provide statements of compliance with PBN, RVSM and NAT HLA requirements in their OIP. In these military cases, DASA may accept compliance with civil standards through alternative means, by establishing equivalent performance. This involves either, or a combination of[26]:

1. demonstrating that equipment function and performance meets the intent of (but not strict compliance with) the relevant civil standard
2. demonstrating that the use of operational procedures can meet the same function, integrity and OBPMA performance requirements.

9.5.4.3 The most common reasons non-civil derivative military platforms have difficulty achieving compliance with PBN, RVSM and NAT HLA requirements are:

1. the absence of Technical Standard Order (TSO)-approved equipment
2. limited or no evidence of compliance with system functional, integrity or OBPMA performance requirements.

9.5.4.4 Early DASA engagement should be sought for demonstrations via equivalency— to seek assistance in defining the scope of compliance evidence required and likely timelines, and to confirm that a navigation approval is possible before the applicant commits significant resources. Where operational urgency applies, MAOs should consider temporarily applying for less precise[27] navigation approvals—which can be demonstrated more easily—while pursuing more precise navigation approvals in parallel over a less constrained timeframe.

9.5.5 DASR Form 1307 – Application for Navigation Specification Approvals

9.5.5.1 MAOs can request Defence navigational approvals using DASR Form 1307. Each approval is categorised as either 'core', 'non-core', 'supplemental', and 'other', as shown below.

9.5.5.2 **Core approvals.** Core approvals are simpler to process than non-core approvals, and include:

1. RNAV 1
2. RNAV 2
3. RNAV 5
4. RNP 1

Superseded

5. RNP 2

6. RNP APCH, including:

   i. LNAV

   ii. LNAV/VNAV

   iii. LP

   iv. LPV

9.5.5.3 **Non-Core approvals.** Non-core approvals require a more complex compliance process and evidence; and include those specifications that are detailed in other regulatory documents, but are administered in accordance with the nominal PBN approval process (ie RVSM)[28] Non-core approvals include:

1. RNAV 10 (RNP 10)

2. RNP 0.3 (Helicopter)

3. RNP 4

4. RNP AR (RNP AR APCH and RNP AR DP Operations may include One Engine Inoperative (OEI) procedures), including:

   i. RNP AR APCH

   ii. RNP AR DP

5. A-RNP

6. RVSM.

9.5.5.4 **Supplemental approvals.** Supplemental approvals either support another approval, provide an alternate means to support an approval, or provide supplemental navigational capabilities. However, they do not exist in isolation (ie they are complementary to selected core and non-core approvals). Supplemental approvals include:

1. APV / Baro-VNAV

2. Radius to Fix (RF)

3. Fixed Radius Transition (FRT)

4. Time of Arrival Control (TOAC)

5. use of suitable area navigation systems on conventional routes and procedures (both en route and terminal).

9.5.5.5 **Other approvals.** Other approvals are specific or location-based, and include:

1. NAT HLA.

9.5.5.6 A MAO may use the same DASR Form 1307 for multiple approvals. Note, some of the more precise Defence navigation approvals automatically include approval for less precise Defence navigation approvals—this is known as 'nesting'. For example, if DASA awards an approval for RNP 4, DASA will automatically consider approvals for RNP 5 and RNP 10.

Superseded

9.5.6 Applying for Navigation Approvals

9.5.6.1 To gain DASA navigation approval, the applicant must:

1. complete DASR Form 1307
2. submit the required evidence against the approval(s) selected.

9.5.6.2 MAOs should submit applications to DASA at least 90 days prior to the required navigation operations. This allows for the resolution of potential shortfalls against the requested approval(s) before the major change to the TCB and applicant OpSpec.

9.5.6.3 To provide a navigation approval, DASA assesses each approval's compliance evidence against three navigation approval component requirements. The three components are the same for each approval, but the level of detail differs dependent on the approval chosen. The three navigation component requirements are:

1. **Component 1**: Initial Airworthiness and Aircraft eligibility requirements.
2. **Component 2**: Continued Airworthiness requirements.
3. **Component 3**: Flight operations procedures and training requirements.

9.5.6.4 **DASR Form 1307 preparation.** Applicants must use DASR Form 1307 to support review of the evidence requirements of each navigation approval sought. In order of increasing complexity (ie time to process), application evidence options are:

1. The application is based upon an **existing** navigation approval (eg the Aircraft eligibility and continuing airworthiness requirements for the RNP 2 approval can be based on navigation approvals already held for either RNP 1, RNP APCH or RNP AR).
2. The application is based upon a **prior certification** against relevant navigation approval requirements[29].
3. The application is based upon **demonstration** that on-board equipment (and its installation) **meets** the navigation approval's functional, display, alerting and performance requirements[30].
4. The application is based upon **demonstration** that on-board equipment (and its installation), when supported by defined operational controls, **provides functional equivalence** to the approval's functional, display, alerting and performance requirements.
5. The application is based upon a **DASA-agreed alternate approach** to achieving **functional equivalence** to the approval's functional, display, alerting and performance requirements.

9.5.6.5 **Navigation approval evidence.** The following can assist MAOs in collating or generating the evidence required:

1. **For component 1 - Initial Airworthiness and Aircraft eligibility.** DASR Form 1307 uses question sets to guide applicants through the necessary evidence. MAOs may demonstrate Aircraft eligibility through any one of the following:

Superseded

i. the CAA/MAA-approved AFM confirms that the Aircraft **is capable** of undertaking the required operations, with a CRE assessment that either:

– confirms that there are no CRE differences that adversely impact the approval in the Defence operational context

– identifies CRE differences that adversely impact the approval in the Defence operational context, together with additional compliance demonstration evidence to address the differences

ii. the CAA/MAA confirms that the Aircraft **has been certified** for the required PBN, RVSM and NAT HLA operations, with a CRE assessment that either:

– confirms that there are no CRE differences that adversely impact the approval in the Defence operational context

– identifies CRE differences that adversely impact the approval in the Defence operational context, together with additional compliance demonstration evidence to address the differences

iii. a technical assessment of the design demonstrates compliance with the prescribed airworthiness requirements for the specified operations.

2. **For Component 2 - Continued Airworthiness.** DASR Form 1307 guides applicants through the evidence necessary to demonstrate that navigation system components will remain compliant with the approved Type Design[31] while in-Service, and that the navigation databases used will remain valid during operations.

3. **For Component 3 - Flight operations procedures and training.**

i. Flight operations procedures. DASR Form 1307 lists operations documentation requirements for each navigation approval, including[32]:

– operating policies to support selected operations under all normal and emergency conditions

– flight crew procedures and checklists for all navigation approvals for the Aircraft Type

– Minimum Equipment Lists (MELs, or their equivalent) for each navigation approval

– planning and management OIP (including for navigation database updates and validation, and mission planning procedures)

– OIP for the reporting and management of navigation database discrepancies and errant Aircraft behaviour observed during approved operations.

ii. **Flight operations training.** DASR Form 1307 lists both generic and specific Flight operations training requirements for each navigation approval, including:

– Flight crew training programs, competency assessments, currency, and training records

– maintenance staff training requirements.

Superseded

9.5.6.6 **Navigation approval evidence shortfall resolution.** Where DASR Form 1307 requirements cannot be met, the form supports DASA consultation and shortfall resolution. The applicant must demonstrate functional equivalence to published requirements. Shortfall resolution involves the:

1. DASA Desk Officer and applicant reviewing shortfalls and discussing possible pathways to demonstrating compliance
2. applicant proposing an appropriate alternative to compliance, that demonstrates functional equivalence, for example:
    i. prior alternative CAA/MAA certifications
    ii. operational or crew-based procedural additions that can demonstrate functional equivalence[33].
3. applicant providing evidence that demonstrates functional equivalence, such as[34]:
    i. flight test programs
    ii. operational human factors and workload assessments
    iii. LMPs
    iv. Aircraft Type Design System Safety Assessments
    v. Risk Management Plans and Mission Risk Profiles to define the additional controls required to be incorporated into OIP.

9.5.6.7 **DASR Form 1307 submission.** To finalise the MAO request, the applicant must submit the form and the corresponding evidence data pack, via a MAO request, to dasa-davnops.operationalreviews@defence.gov.au. The data pack should include a summary of the documents attached and a description of each document's purpose towards navigation approval requirement compliance.

9.5.6.8 When compliance is demonstrated, and the MTCH has updated the aircraft's TCB (through a DASA approved Major change to Type Design), DASA will add the navigation approval(s) to the OpSpec.

9.5.5.9 Table 1 provides MAOs with a checklist of the evidence required in data packs. Note, not all items are required for all navigation approvals. Additionally—in the case of non-core approvals; or where there is a requirement to demonstrate functional equivalence—this checklist is not exhaustive.

Submission Checklist Item
DASR Form 1307 • In original MS Excel Format
Initial Airworthiness and Aircraft Eligibility

Superseded

- Aircraft Airworthiness documents which provide evidence that the Aircraft is Type Certified for the requested operations (eg AFM and supplements, OEM service letters, Type Certificate Compliance Document).
- A description of the relevant Aircraft equipment required for the proposed navigation approvals, including a configuration list of components, and how the system meets applicable requirements.

Continued Airworthiness

- A description of the maintenance program used to ensure the continued Airworthiness of the Aircraft for the equipment required for the navigation approval. This need only address those circumstances where additional specific maintenance is required.
- Applicable Aircraft Maintenance Manuals for the relevant system/s.
- An equipment list for the navigation approvals requested (make, model & part—both hardware & software).
- Applicable extracts from the Minimum Equipment List (Airworthiness items) and applicable instructions that demonstrate identification and management of:
- any unserviceability that affects the conduct of any approved operation
- the systems that GNSS interfaces with, so that in the event of the GNSS being inoperative, the full impact of the failure can be determined
- The rationale for selection of specific MEL items as having an impact on safe operations, and any associated risk assessments.

Airworthiness - Digital Data

- A description of the method used to receive updates to (including the frequency of updates) and to ensure the validity of the airborne navigation database. This should address the validation of data provided externally and internally; and verification procedures for any internal change to the supplied data
    - **Note:** this should include coverage of all digital navigation data (including map and chart data used in Flight during the conduct of procedures, or for ground verification); and

Superseded

	data acquisition, manipulation, and management (to encompass all potential Defence Aircraft operations). • Evidence that the suppliers of the navigation database comply with the minimum integrity requirements of the most stringent approval requested.
Flight Operations Processes • Operational procedures (including normal and emergency) published in OIP. These procedures should include Flight planning, pre-flight, inflight and post-flight. • Procedures should include copies of, or extracts from, OIP covering: o operations manuals o the AFM o checklists o contingency procedures o QRH (or equivalent) o sections of the MEL applicable to the requested operations	
Training and Qualifications • A description of the proposed aircrew, maintenance and other applicable personnel and specialists' training for the requested operations; and associated competencies and currency requirements (including a copy of the LMP and associated artefacts[35]. • Copies of relevant training syllabi, training proficiency examination and assessment templates and currency assessment templates.

10. Uncrewed Aircraft Systems

10.1 Introduction

10.1.1 Section 10 establishes provides guidance on the elements necessary to assure aviation safety of Uncrewed Aircraft Systems (UAS), with emphasis on the acquisition, management and operation of UAS.

10.2 Occurrence Reporting

10.2.1 Introduction

10.2.1.1 UAS are subject to aviation safety reporting tailored to their design, function, complexity and the level of skill required for their operation and maintenance based on their category of operation. This section provides the Authority defined minimum reporting requirements as referred to in DASR UAS.60.B.2. The full, open, timely and accurate reporting of UAS aviation safety events and issues allows Defence to respond and apply strategies to prevent future reoccurrence of such events and issues.

10.2.1.2 DASR UAS.60 introduces the terms 'aviation safety event' and 'aviation safety issue' to distinguish between failure of the aviation system while operating and higher-order organisational factors that could lead to a failure of the aviation system while operating.

10.2.1.3 This chapter describes occurrence-reporting requirements for UAS.

Definitions

10.2.1.4 The following definitions are pertinent to this chapter.

1. **Aviation Safety Event**[1]. Any event where an aviation system (including the human element) fails to perform in the expected manner and adversely affects, or could adversely affect, the safety or airworthiness of an aviation system or third party.
2. **Aviation Safety Issue**[2]. A characteristic of an organisation or a system that can reasonably be regarded as having the potential to adversely affect the safe operation of an aircraft, aviation-related equipment or products and services.
3. **Immediate Reporting.** Events that are Class A or Class B per Table 1-1 of the DASM.
4. **Routine Reporting.** Events that are Class C or Class D per Table 1-1 of the DASM.

Event Classification	Description
Class A	Personal Injury Level (PIL) of Fatal
Class B	PIL[3] of Serious Aircraft Damage Level (ADL) of Substantial Perceived Risk Level (PRL) of High or Very High

Superseded

Class C	PIL of Minor ADL of Moderate PRL of Medium
Class D	PIL of No Injury ADL of No Damage/Minor Damage PRL of Low or Very Low

Table 1: Event classifications

10.2.2 Aviation Safety Events and Issues

10.2.2.1 Some UAS may be considered attritable. However, an event or issue should be considered a UAS Safety Event or Issue if the event or issue results in degradation, or failure, of the risk controls upon which the operational authorisation or approval is based. Paragraphs 10.2.3.4 and 10.2.3.5 provide examples.

10.2.2.2 Figure 1 demonstrates a simple flow chart to aid in determining whether an event or issue is a candidate for reporting via the process provided in DASM

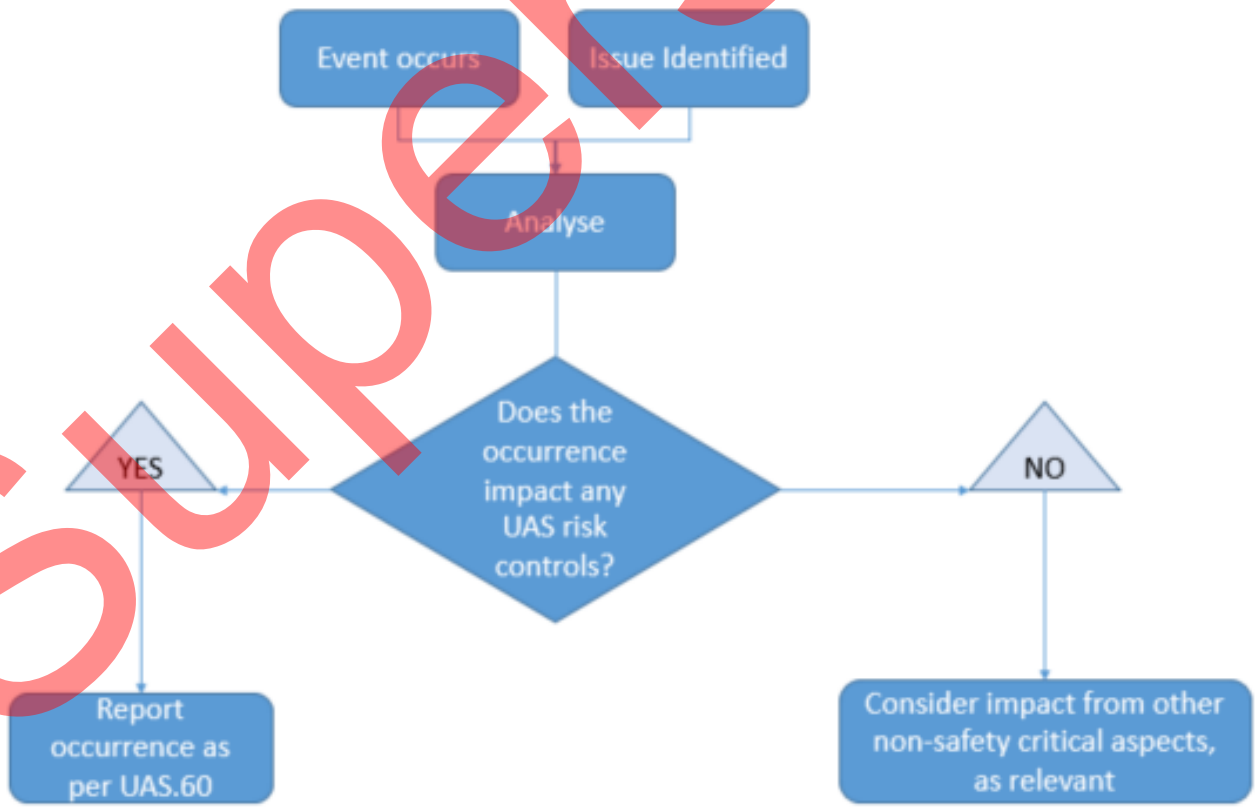

Figure 1: UAS Risk Control Impact

Superseded

UAS Aviation Safety Events

10.2.2.3 An aviation safety event is characterised by an event occurring that involves a safety-related portion of the UAS and/or supporting systems failing in some way. By definition, a 'safety-related' portion of the UAS is any aspect of the UAS that has some control or influence over risk controls or is directly involved in operational use of the UAS— upon which the UAS operational approval was issued. Failure of a safety-related portion of the UAS may directly result in a loss of control of the UAS; or exhibit, or could reasonably have been expected to, exhibit an unintended behaviour.

10.2.2.4 Aviation safety events for UAS are categorised into one or more of the following:

1. **Flight Operations events.** Flight operations events are those aviation safety events that degrade the performance of any of the approved risk controls that occurs during activities associated with flight.

2. **Maintenance events.** Maintenance events are those aviation safety events that degrade the performance of any of the approved risk controls during the conduct of maintenance activities. These safety events, at the time of identification, had not manifested during the conduct of flight operations.

3. **Other support systems events.** Other support systems events that degrade the performance of any of the approved risk controls involving systems or services that functionally and/or physically support the conduct of safe flying operations. These safety events, at the time of identification, had not manifested during the conduct of flight operations.

UAS Aviation Safety Issues

10.2.2.5 An aviation safety issue is an identified shortfall with any organisation supporting the operation of the UAS, which may influence the effectiveness of the organisation, as a risk control for safe operation. Given the organisational focus of safety issues, an aviation safety issue may include identified shortfalls in organisations that:

1. operate the UAS
2. provide maintenance services for the UAS
3. provide engineering services for the UAS
4. provide training services for the UAS
5. provide supporting systems for operation of the UAS; including navigation, communications or meteorological services amongst others.

10.2.3 What to Report

10.2.3.1 DASR Part UAS.60 states that the operator of a UAS must report any identified UAS aviation safety event and that the operator must report UAS aviation safety issues for Certified UAS. Further, it states that the Authority will define minimum reporting requirements for aviation issues through the UASOP approval process for Specific Type A UAS. For Specific Type B and Open Category UAS, there are no mandated reporting requirements. However, command should still consider reporting safety events listed in the examples below.

Superseded

10.2.3.2 The reporting of UAS aviation safety events must be in accordance with the Defence Aviation Safety Manual (DASM), specifically Part 2, Chapter 1. The DASM provides direction on how to report, event classification and expected timings.

Examples of Safety Events and Issues that 'a person authorising or operator of a UAS' must report

10.2.3.3 DASR Part UAS.60 (b).2 indicates the Authority will define the minimum reporting requirements for Specific Type A category UAS in the Authority promulgated UASOP.

10.2.3.4 The following lists capture a non-exhaustive list of UAS Aviation safety events and issues which must be reported via ASR in Sentinel and classified as per DASM Part 2, Section 1.22(b) and 1.23:

1. collision with crewed aircraft, ground or water based personnel, critical infrastructure.
2. near collision with crewed aircraft (including Near Mid-Air Collision (NMAC)[4]), ground or water based personnel, or critical infrastructure
3. breakdown of deconfliction with crewed aircraft,
4. personnel injury sustained directly arising from the conduct of the UAS operation
5. UAS departure from assigned area or operational approved airspace
6. any activation of the flight termination system (FTS) during flight operations (excluding during routine activations of the FTS; for example, during maintenance)
7. technical failures and malfunction within a Remote Pilot Station/Ground Control Station with impact on the flight operation safety.
8. for weaponised UAS, the inadvertent/irregular release or discharge of weapons (where the stores or equipment are configured as part of the UAS).

10.2.3.5 The following safety issues must be reported via an Operational Hazard report:

1. an implemented operational or technical risk control that was found to be less effective than expected
2. an identified discrepancy with RP training (including currency, qualification and ongoing management
3. RP fatigue
4. operations in weather conditions outside of operational limits
5. any identified communications breakdown or failure
6. any organisational failures that have the potential to lead to a UAS aviation safety event.

10.2.3.6 If any of the safety issues listed at item 10.2.3.5 resulted in, or could have reasonably endangered the safety of crewed aircraft, ground or water based personnel, or critical infrastructure, 'a person authorising or operator of a UAS' must report such as a UAS safety event.

11. Aerodromes

11.1 Aerodrome Regulation

11.1.1 DASR 139 Aerodromes Overview

11.1.1.1 To support safe aircraft operations at Defence aerodromes, the Defence Aviation Safety Authority (DASA) released the Defence Aviation Safety Regulations 139 – Aerodromes (DASR 139). These regulations require all Defence aerodromes to be classified as 'certified' or 'non-certified'. Where DASR 139 refers to the term 'aerodrome', it should be read to include:

1. airport
2. airfield
3. airbase
4. heliport (land based or shipborne).

11.1.1.2 DASR 139 deals with, *inter alia*, two key approvals:

1. Aerodrome Operator (AD OPR) Organisation approvals
2. Defence Certified Aerodrome approvals.

Classification of aerodromes (Certified/Non-Certified)

11.1.1.3 Defence aerodromes may be certified or non-certified. DASA's decision[1] to classify an aerodrome as a Certified Aerodrome is based on meeting one of the following four criteria[2]:

1. there is a terminal instrument flight procedure[3] (not including Airborne Radar Approach (ARA) per se) for the aerodrome[4]
2. there are regular civil commercial passenger operations at the aerodrome
3. there are frequent aircraft operations at the aerodrome[5]
4. Defence flight operations at the aerodrome are often inherently hazardous, beyond the scope of normal civilian operations—and the provision of a well-designed/ maintained aerodrome is a key safety risk control[6].

11.1.1.4 DASA developed these criteria through benchmarking certification criteria and information from the Civil Aviation Safety Authority, the European Union Aviation Safety Agency and the International Civil Aviation Organisation tailored to the context of Defence aviation operations at Defence aerodromes.

Guidance for Non-Certified Defence Aerodromes

11.1.1.5 Non-certified Defence aerodromes are not subject to DASR 139 requirements. However, a commander's obligations under the WHS Act 2011 still apply. The underlying principles in DASR 139 (and the Defence Aviation Safety Design Requirements Manual (DASDRM) Section 6 standards) provide guidance to the responsible commander[7] for operation of a non-certified aerodrome—in

Superseded

ensuring that the aerodrome equipment, systems and installations support safe aviation operations. There could also be more than one responsible commander[8] at any one time[9], depending on the operation of the aerodrome.

11.1.1.6 If the design or operating intent change throughout the life of a non-certified aerodrome, certification and assurance may be warranted under DASR 139. Those responsible for operating/ managing the aerodrome should contact DASA for guidance if such changes (eg major design changes) occur.

Certified Aerodromes

11.1.1.7 The AD OPR organisation must submit an application to DASA for an Aerodrome Certificate for those aerodromes requiring certification. The Aerodrome Certification process is in Chapter 5.3 Annex V.

11.1.1.8 On determining that the aerodrome and the aerodrome operations meet all DASR 139 requirements, DASA will issue an amendment to the AD OPR Certificate (AD OPRC) Operations Specification (OpSpec) — authorising the approved AD OPR to operate the aerodrome as a DASR 139 Certified Aerodrome. Chapter 5.3 Annex B details the process for updating the OpSpec.

Aerodrome Operator management systems and documentation

Aerodrome Operator organisational structure

11.1.1.9 An AD OPR is an organisation consisting of operational, maintenance and engineering personnel that:

1. forms part of a Force Element Group or equivalent force structure
2. must achieve the roles and responsibilities of DASR 139. (See Chapter 5.3 Annex B for the AD OPR approval process).

11.1.1.10 Due to the complexities of the organisations, facilities and locations associated with individual aerodromes, clear understanding and documentation of an organisational structure will enhance command's ability to achieve safe flight operations. The Services outsource to other Defence Groups, such as Security and Estate Group, Chief Information Officer Group and Capability Acquisition and Sustainment Group, to deliver aerodrome capability. Contractors are utilised extensively to complete tasks. This occurs at the AD OPR and base level.

1.1.1.11 DASR AMC 139.30.2.g requires the AD OPR to include an 'outline of relevant aerodrome management arrangements' in the AD OPR Compliance Statement. This outline should include aerodrome management arrangements with subordinates, subordinate organisations (eg wings/ units), supporting Defence groups, contractors and other organisations that support DASR 139 compliance. The AD OPR should include details of formal agreements which such organisations or individuals in the Compliance Statement.

11.1.1.12 At the base level, DASR AMC 139.50.2 requires the Aerodrome Manual to include the aerodrome's organisation and management structure, including agreements with civil operators. The description of organisation and management arrangements should include relationships with organisations that support the AD OPR's local team to achieve and maintain DASR 139 compliance. This should include any subcontractors from supporting organisations and details of formal agreements.

Superseded

Personnel competency

11.1.1.13 As the safe operation and maintenance of an aerodrome requires a large number of personnel working in a range of fields and disciplines, ensuring their competence is essential. To ensure AD OPR personnel meet the requirements of DASR AMC 139.100 (to obtain, complete and maintain effective competency), AD OPRs should define the training, qualifications and authorisations required for personnel undertaking a role in support of aerodrome operation. These may include training and assessment programs pertaining to airside awareness, aerodrome rescue and firefighting, operations, engineering and maintenance.

Aerodrome management systems and documentation

Aerodrome documentation

11.1.1.14 DASA requires evidence demonstrating suitable systems for the maintenance and operation of each aerodrome are in place. These artefacts are part of the Aerodrome Manual requirements. There are a number of systems, including the Quality Management System and Safety Management System, which the AD OPR may implement across the organisation or have aerodromes establish individually. Regardless, when applying to add a Certified Aerodrome to an AD OPRC OpSpec, the AD OPR must include details of the implemented organisational systems in the Aerodrome Manual.

11.1.1.15 DASA reviews these documents on receipt of an application for addition of a DASR 139 Certified Aerodrome to an AD OPRC OpSpec. These documents form part of the evidence supporting compliance with the regulation.

Aerodrome maintenance program

11.1.1.16 Failure to follow the aerodrome maintenance program may lead to DASA making a finding against the AD OPR approval, and can affect certification. Examples of arrangements (systems and procedures) used to enact the aerodrome maintenance program plan include:

1. repainting of markings – periodic repaint
2. electrical system works – continuity testing
3. periodic friction testing
4. obstacle surveys
5. aerodrome technical inspections
6. aerodrome serviceability inspections.

11.1.1.17 There is no requirement to submit an aerodrome maintenance program to DASA. However, the program should be available for DASA on request and may be reviewed as part of initial approval and oversight activities.

11.2 Aerodrome Certification

11.2.1 Aerodrome Certificate

Certification process and programs

Superseded

11.2.1.1 The Aerodrome Certificate is a certificate granted to an Aerodrome Operator (AD OPR) by DASA certifying that the aerodrome meets the technical specifications outlined in its certification basis. The Aerodrome Certificate addresses the requirements of DASR 139.80.

11.2.1.2 To achieve aerodrome certification, the following five primary activities must be undertaken:

1. define a DASA-agreed CB for the aerodrome
2. demonstrate that the aerodrome design and construction complies with the agreed CB
3. declare that the aerodrome design and construction complies with the agreed CB
4. implement arrangements to support continued aerodrome compliance with the CB
5. provide design information to support continuing safe operation of the aerodrome.

11.2.1.3 Each of these mandated activities (and other supporting aspects) form the basis of the certification process.

11.2.1.4 The following figure shows the aerodrome certification activities:

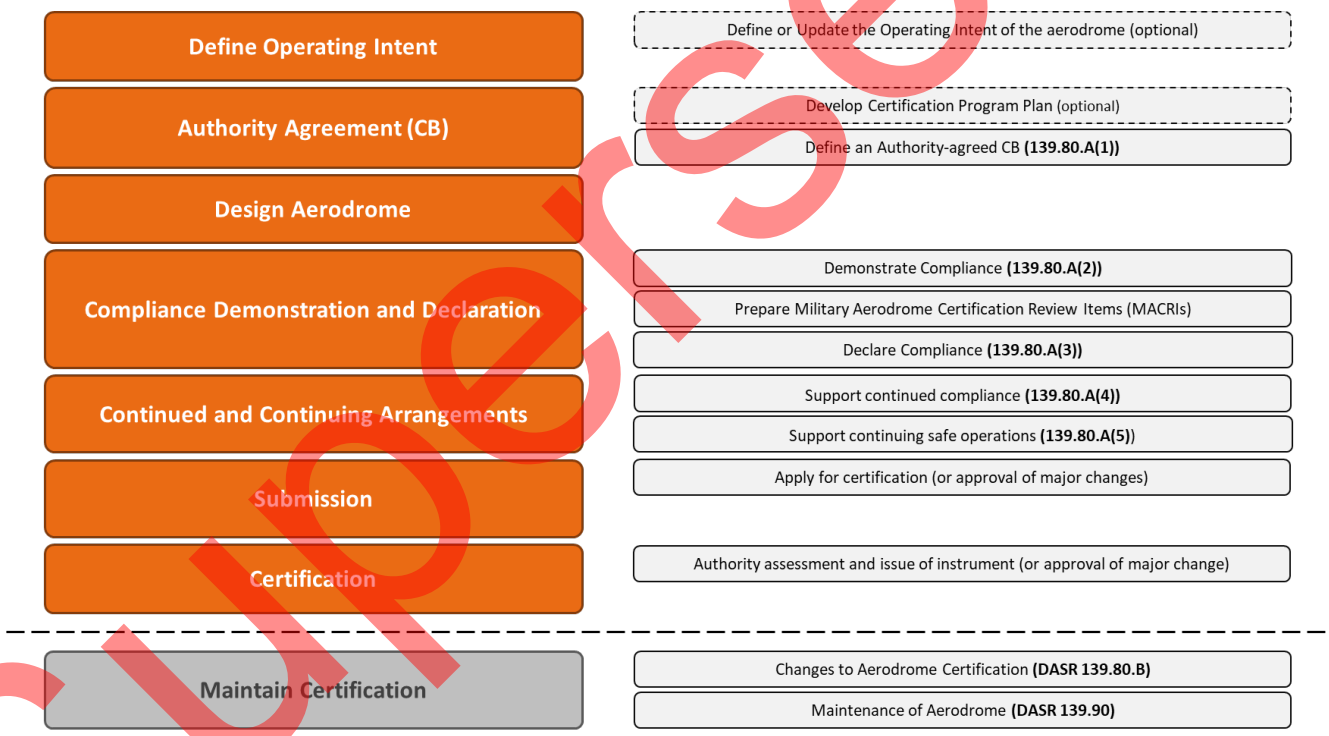

Figure 1: Aerodrome certification activities diagram

11.2.1.5 The certification program of work captures the operating intent; establishes the design requirements; designs, constructs and demonstrates compliance to the design requirements; establishes arrangements for continued compliance to the certification basis; and establishes arrangements for continuing safe operations at the aerodrome. The plan documenting this program of work is the Certification Program Plan (CPP), which will help align and coordinate all stakeholders involved in the aerodromes certification activity.

Develop a Certification Program

Superseded

11.2.1.6 Obtaining an Aerodrome Certificate requires the completion of the Certification Program (CP) conforming to DASR 139 requirements. A CPP is not mandated by the regulations, but a project should consider developing a CPP. A CPP will aid the process by gaining agreement with DASA, of the proposed approach to achieve certification. The plan then informs and aligns all stakeholders in an effort to increase efficiency in a complex process. Acquisition projects and complex changes should produce a detailed CP while a simplified CP may be acceptable for less complex changes.

11.2.1.7 DASA will review and endorse a CPP if found suitable to support the future application for a certificate. DASA will be available to support the applicant throughout the certification process and provide guidance and feedback where needed. This will reduce the likelihood of an application being incomplete at the time of submission.

11.2.1.8 The applicant should submit a mature draft of the document to the DASA aerodromes mailbox for comments and feedback. The Aerodrome and Heliport section in DASA and the applicant will discuss the content of the CPP until both parties are satisfied that the certification activities are appropriate and sufficiently detailed for the stage of the project. An applicant organisation may submit a signed CPP to DASA for endorsement.

Certification Basis

11.2.1.9 An Aerodrome's CB is an agreed set of requirements needed to support safe flight operations at the aerodrome. To receive an Aerodrome Certificate, the aerodrome must be compliant with the CB. The basis of a Defence Aerodrome CB is a set of standards, which are recognised, credible and defensible. The Authority identifies these recognised standards within Section 6 of the Defence Aviation Safety Design Requirements Manual (DASDRM) (For details on the DASDRM, refer to Annex A). The applicable requirements extracted from the DASDRM are tailored to take into account the operating intent of the aerodrome. The CB may also include any special detailed technical requirements that address unique issues beyond the scope of the design requirements contained in the DASDRM. A CB thus comprises of:

1. applicable design requirements prescribed in the relevant chapter of Section 6 of the DASDRM
2. any tailoring to the above design requirements to meet an aerodrome's operating intent
3. any additional technical requirements that are needed to address unique issues beyond the scope of design requirements in Section 6 of the DASDRM.

11.2.1.10 DASA has developed templates to support the creation of Certification Basis for land-based aerodromes intended primarily for use by fixed wing aircraft; land-based heliports, and shipborne heliports. These templates contain all the design requirements from Chapter 2, Chapter 3, and Chapter 4 of Section 6 of the DASDRM respectively that the applicant can use to develop a CB and track certification activities.

11.2.1.11 For shipborne heliports the CB will normally be established as part of the Projects Material Seaworthiness Requirement Set (MSRS) as defined in the N-Library. Notwithstanding the Seaworthiness system requirements, the subset of a Projects MSRS related to aerodrome certification (those requirements based on the DASDRM design requirements) – the shipborne heliport CB requires DASA agreement.

Operating intent informing the Certification Basis

Superseded

11.2.1.12 As the operations taking place at each Defence aerodrome are unique, not all the requirements contained in the DASDRM are applicable to every aerodrome. To help identify those requirements that are relevant and those requirements that are not, there is a clear need for an understanding of the operations taking place at an aerodrome. The achievement of the design, construction and certification of an aerodrome is unlikely without the understanding of the operations at the aerodrome. As such, a documented operating intent is critical to establishing a CB and gaining certification. A documented operating intent is also likely to help inform development of compliance demonstration programs and support on-going safe flight operations at the aerodrome.

11.2.1.13 A high-level description of the facilities and operations at an aerodrome are often captured in a Statement of Operating Intent (SOI) (or similar documents – similar documents may include the Statement of Operating Intent and Usage (SOIU) and the Operating and Support Intent (OSI)) for an aerodrome). While DASA does not mandate the development or update of a specific document for Defence aerodromes (such as a SOIU), it is important to have this information documented before commencing the development of the CB. The basis for tailoring DASDRM requirements is a documented operating intent, justifying the removal of different requirements that are not relevant to the aerodrome, or identifying and adding special technical requirements. The Certification Basis Templates provide the functionality to capture the justification of tailoring of the design requirement set.

Certification Basis tailoring

11.2.1.14 The provisional CB represents the 'target' aerodrome design and construction requirements (note – use of the term 'provisional CB' is simply because there may be additional tailoring identified as the design and production process develops). During design and construction of an aerodrome, it is unlikely that there will be compliance with all the design requirements of a provisional CB. These shortfalls require management to ensure elimination of any risks posed by the non-compliances or that they are otherwise minimised SFARP. Addressing these shortfalls will result in changes to the CB. These changes need to be done through the Military Aerodrome Certification Review Item (MACRI) where either alternate requirements are used which have been demonstrated to achieve an equivalent level of safety or limitations/treatments are applied to the CB requirement to eliminate or otherwise minimise risks SFARP to safe flight operations.

11.2.1.15 Tailoring of the CB must be based upon:

1. a safety argument that demonstrates an equivalent level of safety can be achieved through a tailored design requirement, or
2. detailed Safety Risk Management (SRM) (normally in the form of an Aerodrome Issue Paper (ADIP)) if compliance with the design requirement would adversely affect Defence capability, and risks to aviation safety can be eliminated or otherwise minimised SFARP through alternate means.

11.2.1.16 The Certification Basis Templates can be used to identify the tailoring that has occurred and reference all the supporting documentation.

11.2.1.17 DASA approves aerodrome CBs and any changes to an extant CB. Approval of the provisional CB for an aerodrome can be through a formal standalone approval of the CB or combined with approval of the CPP.

11.2.1.18 Approval for updates to a CB can be through a formal standalone process similar to that undertaken for a provisional CB or combined with the CPP for the change. For a change, the applicant only needs to identify the affected CB requirements for approval.

Superseded

11.2.1.19 DASA must approve all tailoring of the CB prior to the application of the aerodrome certificate.

Demonstrate compliance

11.2.1.20 Once the CB has been established, and the design and construction of an aerodrome commenced or completed, the applicant needs to demonstrate, through the production of evidence, that the design and construction of the aerodrome meets the agreed CB.

11.2.1.21 Compliance demonstration evidence must be available for inspection by the DASA (on a non-exhaustive basis) in order to provide independent assurance that the evidence is suitable, and that the evidence demonstrates compliance to the agreed CB requirements.

11.2.1.22 Compliance demonstration evidence is contained in compliance documents. It may consist of design data, test plans and reports, analyses, drawings, processes, material specifications, operating limitations, aerodrome manual and supplements, and maintenance program and supplements amongst others. The applicant is responsible for demonstrating compliance by the agreed means during the CP, and making the evidence available to DASA for inspection.

11.2.1.23 Generation of evidence is solely the responsibility of the applicant. All compliance documents must be independently checked by the applicant and signed as complete and accurate regardless of DASA's inspection requirements. The applicant shall compile a list of evidence produced to demonstrate compliance against each line item of the CB; and provide a formal declaration that the design and construction of the aerodrome entirely meets the requirements of the CB. The evidence can be captured in the DASA CB template tool or another applicant specified means. A 'User Guide – Certification Basis Template Guidance' provides information on how to use the CB template tool to capture the compliance demonstration evidence which can be obtained from DASA.

11.2.1.24 The process for the RANs Materiel Assurance, described in the N-Library, will normally be used to plan and complete compliance demonstration for shipborne heliports. However, the requirement to make all evidence that demonstrates compliance to the agreed CB available to DASA is still applicable.

11.2.1.25 Throughout the CP, DASA will inspect selected compliance evidence to the extent necessary to assure the safety of the design and construction of the aerodrome. DASA will review, on a non-exhaustive basis, any compliance evidence used to support the declaration of compliance to provide the independent assurance necessary to support the granting of an Aerodrome Certificate.

Management of non-compliances

11.2.1.26 During compliance demonstration activities and over the life of the aerodrome, shortfalls / non-compliances against the aerodrome CB design requirements may be identified. Non-compliances against the CB should be examined for impact to certification and safety of flight operations.

11.2.1.27 Where it is not reasonably practicable to change the aerodrome design OR where evidence cannot be generated to demonstrate compliance with a design requirement in the CB, the applicant should pursue approval for tailoring of the CB. Central to this tailoring process are the MACRI and the ADIP.

11.2.1.28 A MACRI is a document, which captures an applicant's proposal to modify an aerodromes CB design requirement, and DASA approval of the modification. There are two types of MACRI, an Equivalent Safety Finding (ESF) MACRI and an Exception MACRI. Development of a MACRI should only

Superseded

proceed if it is not reasonably practicable to eliminate the risks through engineering / design changes. For details on the MACRI process, refer to Factsheet – Military Aerodrome Certification Review Items.

11.2.1.29 ADIP are used when an applicant identifies an enduring design deficiency, which requires a risk treatment decision by Command. An ADIP usually underpins an Exception MACRI but may also be used to support an ESF MACRI. A safety argument should normally be used to support an ESF MACRI. However, if the Safety argument is complex and the controls contentious, an ADIP can be used to capture the argument and controls and gain operator agreement. Factsheet *Aerodrome Issue Paper* describes what constitutes an ADIP, and illustrates the process for raising and processing an ADIP, including the roles of the applicant / person evaluating the Non-compliance, and the roles of the DASA and Command.

11.2.1.30 By Approving an ADIP, DASA is providing assurance that the risk management is following the 7-Step SRM process and is defensible. By approving a MACRI, DASA approves the tailoring of the CB. Once approved by DASA, any tailoring of the CB requirements should be captured in the CB Template, or an applicant specified template, with the corresponding MACRI information. For details on how to use the template to capture this information, refer to the User Guide – Certification Basis Template which can be obtained from DASA.

11.2.1.31 DASA reviews all MACRIs and supporting ADIP and will provide approval if the DASA is assured a credible and defensible safety argument or application of the SRM has been completed. The approval provides agreement to the change in the CB requirement.

Declare compliance

11.2.1.32 When applying for certification of an Aerodrome under DASR 139.80, the applicant must make a declaration of compliance. The purpose of the declaration is to ensure the applicant organisation has considered and confirmed that compliance has been demonstrated to all CB requirements and no aspect is unsafe for use as intended. The applicant must identify a suitable person to make the declaration – usually the person responsible for design/manufacture/inspection of the aerodrome.

11.2.1.33 The person chosen to declare compliance must be a competent, qualified and authorised individual. Whilst DASA does not mandate whom is such a person, the applicant is to propose and justify why the nominated person is suitable. DASA does however have the expectation that the person making the declaration would be a senior engineer of an accountable organisation. This person does not have to be a part of the applicant's organisation; though this should be clearly identified in the Certification Program Plan.

11.2.1.34 When all Military Aerodrome Certification Review Items (MACRIs) have been approved and all compliance demonstration evidence has been developed and approved, the applicant is in a position to make a declaration that the design and construction of the aerodrome entirely meets the requirements of the CB. The declaration can be made as part of the application for an Aerodrome Certificate, for which a DASA form has been developed (see Forms area below), or via another means (which could be formally agreed in the CPP).

11.2.1.35 The declaration of compliance is made by the applicant organisation, with the applicant declaring that:

1. the Design meets the Certification Basis
2. the Construction meets the Design
3. all non-compliance issues are addressed through DASA approved MACRIs.

Superseded

11.2.1.36 Declaration of compliance can only be completed:

1. after DASA approval of all MACRIs
2. and after compliance has been shown against ALL requirements in the CB

11.2.1.37 An applicant can make their Declaration in the Aerodrome Certification application form (Application for Aerodrome Certificate). When submitting an application for an Aerodrome Certificate, the submission of the declaration of compliance must be accompanied with:

1. the Certification Check List (CCL) - to be made available and can be attached as an Annex to the application form
2. DASA must be given access to all compliance evidence referenced in the CCL
3. evidence of arrangements to support continued compliance with the CB
4. evidence of arrangements to manage design information for continuing safe operations.

11.2.1.38 Prior to completion of the declaration of compliance and all supporting documentation, the Applicant may choose to invite DASA to review completed compliance demonstration evidence and/or supporting documents.

11.2.1.39 The Applicant should be pro-active and engage with DASA as early as possible in the certification process to plan for early reviews of completed documents.

11.2.1.40 DASA will not review early draft versions, only mature drafts of documents.

11.2.1.41 The applicant can use the CB template, developed by the DASA, to keep track of compliance demonstration activities against each line item of the CB, including MACRI submissions and approvals. Evidence of arrangements to support continued compliance with the CB, and evidence of arrangements to manage design information for continuing safe operations can be referenced in this template. Once completed, the CCL sheet from the template can be attached as an annex to the Application form. While the use of this CB template is not mandatory, the information captured within a completed CCL needs to be made available to the DASA in an easily discernible manner. For details on how to use the CB template, refer to the User Guide – Certification Basis Template which can be obtained from DASA.

11.2.1.42 DASA will review the compliance declaration, including the personnel competency of the person making the declaration, as part of the aerodrome certification.

11.2.1.43 DASA may choose to inspect some, most or all of the compliance demonstration evidence provided by the applicant. The applicant has the responsibility to ensure all compliance evidence is available to DASA.

Establishing arrangements for continued compliance

11.2.1.44 Continued (Design) aerodrome compliance encompasses all tasks, to be carried-out to verify that the conditions under which an aerodrome certificate has been granted, continue to be fulfilled throughout its period of validity. Arrangements that enable continued aerodrome compliance are an integral part of aerodrome certification. DASA must be assured that the aerodrome will continue to comply with the aerodrome certification basis and that the safe design of the aerodrome will be retained through the service life of the Aerodrome to issue and maintain certification.

Superseded

11.2.1.45 Aerodromes can have a long service life, and changes are often made to the aerodrome design, construction and operation during that service life. Furthermore, the original design and/or construction of the aerodrome may include latent defects, not evident at the time of original certification. Arrangements to support continued aerodrome compliance with the aerodrome certification basis is essential. The following systems and procedures are a minimum to be implemented to support continued compliance:

1. A system to retain, and retention of all relevant design information, drawings and test reports; including inspection records for the aerodrome.

2. A system and procedures to capture and manage the configuration of the aerodrome design.

3. A system and processes to collect, investigate and analyse reports of and information related to failures, malfunctions, defects or other occurrences which might adversely affect safe operation of the aerodrome, and to implement corrective action if warranted.

11.2.1.46 For initial certification, the applicant is to establish and provide evidence of these systems and procedures. These arrangements will then be implemented and monitored by the AD OPR in service.

11.2.1.47 DASA will review, on a non-exhaustive basis, the information and procedures provided for continued aerodrome compliance arrangements amongst other things before issuing an aerodrome certificate. Furthermore, DASA may review any non-compliance, occurrences or design defects communicated by the applicant and/or the AD OPR for the potential to affect the certification status and whether the actions taken to maintain support to safe flight operations are credible and defensible.

11.2.1.48 A record of the documents and information that is provided for supporting continued safe operations can be captured in the Aerodrome Certification Basis Template. The template and guide for use of the template can be found on the DASA website.

Establishing arrangements for continuing safe operations

11.2.1.49 An Aerodrome Operator must ensure that, at any time in its operating life, an aerodrome condition supports safe flight operations. The design information that enables the AD OPR to execute the continuing function is an integral part of aerodrome certification. DASA must be assured that the AD OPR has sufficient information to ensure that the conditions for safe flight operation are met to issue and maintain certification. An applicant for aerodrome certification must provide (amongst other things) the design information and procedures in order to enable the AD OPR to ensure the continuing safe flight operations at the Aerodrome. The following information is the minimum required to be provided:

1. Documents that describe specific scheduled maintenance task and their frequency of completion

2. Descriptive data and instructions that enable inspections, processes and procedures necessary to keep the aerodrome in a condition for safe flight operation

11.2.1.50 The AD OPR will use this information to develop and conduct maintenance and inspection processes and procedures to ensure that the aerodrome is always in a condition to support safe flight operations.

Superseded

11.2.1.51 DASA will review, on a non-exhaustive basis, the information and procedures associated with continuing safe operation of the aerodrome before issuing an aerodrome certificate. Upon becoming aware of any non-compliance, the applicant and/or the AD OPR should bring this to the attention of DASA as it has the potential to affect the certification status.

Application for an Aerodrome Certificate

11.2.1.52 On completion of all compliance demonstration, including approval of all MACRIs, the applicant should start completing the application form for an Aerodrome Certificate. An application to DASA for an aerodrome certificate should use DASA Form – Application for Aerodrome Certificate. Submit the form, along with the supporting documentation, via the DASA Aerodromes Group Mailbox for approval.

11.2.1.53 Aerodrome Continued Compliance and Continuing Safe Operation are also integral parts of Aerodrome Initial Certification. For issue of an Aerodrome Certificate by the DASA, the applicant must (amongst other things) implement arrangements to support continued aerodrome compliance with the CB and provide design information to support the continuing safe operation of the Aerodrome. Before an application is made these aspects should be completed.

11.2.2 Arrangements for maintaining aerodrome certification

Aerodrome design changes

11.2.2.1 Any change to the design, construction or operations of an aerodrome, that has appreciable effect on the safety of flight operations or changes the aerodrome configuration so that it deviates from the DASA agreed CB, invalidates the aerodrome certificate and therefore, must be presented to DASA for re-certification. The purpose of the re-certification process is to assure that the aerodrome continues to be subject to engineering rigour and that the aerodrome remains in a condition that supports safe-flight operations over its service life.

11.2.2.2 Approval of all design changes follows the same principles of certification of a new aerodrome. For all changes, including changes to the Operating intent that affect the design, the certification basis of the change must be established, the means of compliance determined and compliance with the certification basis demonstrated and declared. Alteration of any design data covered by the Aerodrome Certificate and used for Aerodrome Continued Compliance or authorised data for completing Aerodrome continuing compliance also requires a design change approval.

11.2.2.3 Changes that have no appreciable effect on the safety of flight operations do not require presentation to DASA. Any change which changes the agreed CB requires DASA approval. The expectation is that an AD OPR will use professional judgement in determining whether a design change has an 'appreciable' effect on safety, and when in doubt should consult DASA. Determinations for these changes must be available and may be subject to DASA review during oversight activities. The AD OPR is expected to apply the same rigour / standard in implementing those design changes without an appreciable effect on safety of flight, as they would for those changes when they apply to DASA. That is, they should comprehensively complete all steps of the certification process, as applicable, without needing to submit the application to DASA.

11.2.2.4 DASA will agree to CP and approve CB requirements for those changes submitted to DASA, inspect selected compliance evidence, approve all tailoring of requirements and approve all applications for changes. The applicant is encouraged to consult the DASA if there is any doubt regarding whether a change requires re-certification.

Superseded

11.2.2.5 For any change, the applicant should discuss the content of the CP with DASA until both parties are satisfied, then submit a simplified CP to seek agreement from DASA.

11.2.2.6 An application for DASA's certification for an aerodrome is to be made by writing to DASA. The application should include reference to all information required to be developed by the CP. The Application for a change to the aerodrome certificate can be made using the Application for Aerodrome Certificate.

Annex:

(a) Aerodrome Design Requirements

Superseded

11.1.1 DASR 139 Aerodromes Overview

11.1.1.1 To support safe aircraft operations at Defence aerodromes, the Defence Aviation Safety Authority (DASA) released the Defence Aviation Safety Regulations 139 – Aerodromes (DASR 139). These regulations require all Defence aerodromes to be classified as 'certified' or 'non-certified'. Where DASR 139 refers to the term 'aerodrome', it should be read to include:

1. airport
2. airfield
3. airbase
4. heliport (land based or shipborne).

11.1.1.2 DASR 139 deals with, *inter alia*, two key approvals:

1. Aerodrome Operator (AD OPR) Organisation approvals
2. Defence Certified Aerodrome approvals.

Classification of aerodromes (Certified/Non-Certified)

11.1.1.3 Defence aerodromes may be certified or non-certified. DASA's decision[1] to classify an aerodrome as a Certified Aerodrome is based on meeting one of the following four criteria[2]:

1. there is a terminal instrument flight procedure[3] (not including Airborne Radar Approach (ARA) per se) for the aerodrome[4]
2. there are regular civil commercial passenger operations at the aerodrome
3. there are frequent aircraft operations at the aerodrome[5]
4. Defence flight operations at the aerodrome are often inherently hazardous, beyond the scope of normal civilian operations—and the provision of a well-designed/ maintained aerodrome is a key safety risk control[6].

11.1.1.4 DASA developed these criteria through benchmarking certification criteria and information from the Civil Aviation Safety Authority, the European Union Aviation Safety Agency and the International Civil Aviation Organisation tailored to the context of Defence aviation operations at Defence aerodromes.

Guidance for Non-Certified Defence Aerodromes

11.1.1.5 Non-certified Defence aerodromes are not subject to DASR 139 requirements. However, a commander's obligations under the WHS Act 2011 still apply. The underlying principles in DASR 139 (and the Defence Aviation Safety Design Requirements Manual (DASDRM) Section 6 standards)

Superseded

provide guidance to the responsible commander[7] for operation of a non-certified aerodrome—in ensuring that the aerodrome equipment, systems and installations support safe aviation operations.

There could also be more than one responsible commander[8] at any one time[9], depending on the operation of the aerodrome.

11.1.1.6 If the design or operating intent change throughout the life of a non-certified aerodrome, certification and assurance may be warranted under DASR 139. Those responsible for operating/ managing the aerodrome should contact DASA for guidance if such changes (eg major design changes) occur.

Certified Aerodromes

11.1.1.7 The AD OPR organisation must submit an application to DASA for an Aerodrome Certificate for those aerodromes requiring certification. The Aerodrome Certification process is in Chapter 5.3 Annex V.

11.1.1.8 On determining that the aerodrome and the aerodrome operations meet all DASR 139 requirements, DASA will issue an amendment to the AD OPR Certificate (AD OPRC) Operations Specification (OpSpec) — authorising the approved AD OPR to operate the aerodrome as a DASR 139 Certified Aerodrome. Chapter 5.3 Annex B details the process for updating the OpSpec.

Aerodrome Operator management systems and documentation

Aerodrome Operator organisational structure

11.1.1.9 An AD OPR is an organisation consisting of operational, maintenance and engineering personnel that:

1. forms part of a Force Element Group or equivalent force structure
2. must achieve the roles and responsibilities of DASR 139. (See Chapter 5.3 Annex B for the AD OPR approval process).

11.1.1.10 Due to the complexities of the organisations, facilities and locations associated with individual aerodromes, clear understanding and documentation of an organisational structure will enhance command's ability to achieve safe flight operations. The Services outsource to other Defence Groups, such as Security and Estate Group, Chief Information Officer Group and Capability Acquisition and Sustainment Group, to deliver aerodrome capability. Contractors are utilised extensively to complete tasks. This occurs at the AD OPR and base level.

1.1.1.11 DASR AMC 139.30.2.g requires the AD OPR to include an 'outline of relevant aerodrome management arrangements' in the AD OPR Compliance Statement. This outline should include aerodrome management arrangements with subordinates, subordinate organisations (eg wings/ units), supporting Defence groups, contractors and other organisations that support DASR 139 compliance. The AD OPR should include details of formal agreements which such organisations or individuals in the Compliance Statement.

11.1.1.12 At the base level, DASR AMC 139.50.2 requires the Aerodrome Manual to include the aerodrome's organisation and management structure, including agreements with civil operators. The description of organisation and management arrangements should include relationships with organisations that support the AD OPR's local team to achieve and maintain DASR 139 compliance.

Superseded

This should include any subcontractors from supporting organisations and details of formal agreements.

Personnel competency

11.1.1.13 As the safe operation and maintenance of an aerodrome requires a large number of personnel working in a range of fields and disciplines, ensuring their competence is essential. To ensure AD OPR personnel meet the requirements of DASR AMC 139.100 (to obtain, complete and maintain effective competency), AD OPRs should define the training, qualifications and authorisations required for personnel undertaking a role in support of aerodrome operation. These may include training and assessment programs pertaining to airside awareness, aerodrome rescue and firefighting, operations, engineering and maintenance.

Aerodrome management systems and documentation

Aerodrome documentation

11.1.1.14 DASA requires evidence demonstrating suitable systems for the maintenance and operation of each aerodrome are in place. These artefacts are part of the Aerodrome Manual requirements. There are a number of systems, including the Quality Management System and Safety Management System, which the AD OPR may implement across the organisation or have aerodromes establish individually. Regardless, when applying to add a Certified Aerodrome to an AD OPRC OpSpec, the AD OPR must include details of the implemented organisational systems in the Aerodrome Manual.

11.1.1.15 DASA reviews these documents on receipt of an application for addition of a DASR 139 Certified Aerodrome to an AD OPRC OpSpec. These documents form part of the evidence supporting compliance with the regulation.

Aerodrome maintenance program

11.1.1.16 Failure to follow the aerodrome maintenance program may lead to DASA making a finding against the AD OPR approval, and can affect certification. Examples of arrangements (systems and procedures) used to enact the aerodrome maintenance program plan include:

1. repainting of markings – periodic repaint
2. electrical system works – continuity testing
3. periodic friction testing
4. obstacle surveys
5. aerodrome technical inspections
6. aerodrome serviceability inspections.

11.1.1.17 There is no requirement to submit an aerodrome maintenance program to DASA. However, the program should be available for DASA on request and may be reviewed as part of initial approval and oversight activities.

Superseded

11.2.1 Aerodrome Certificate

Certification process and programs

11.2.1.1 The Aerodrome Certificate is a certificate granted to an Aerodrome Operator (AD OPR) by DASA certifying that the aerodrome meets the technical specifications outlined in its certification basis. The Aerodrome Certificate addresses the requirements of DASR 139.80.

11.2.1.2 To achieve aerodrome certification, the following five primary activities must be undertaken:

1. define a DASA-agreed CB for the aerodrome
2. demonstrate that the aerodrome design and construction complies with the agreed CB
3. declare that the aerodrome design and construction complies with the agreed CB
4. implement arrangements to support continued aerodrome compliance with the CB
5. provide design information to support continuing safe operation of the aerodrome.

11.2.1.3 Each of these mandated activities (and other supporting aspects) form the basis of the certification process.

11.2.1.4 The following figure shows the aerodrome certification activities:

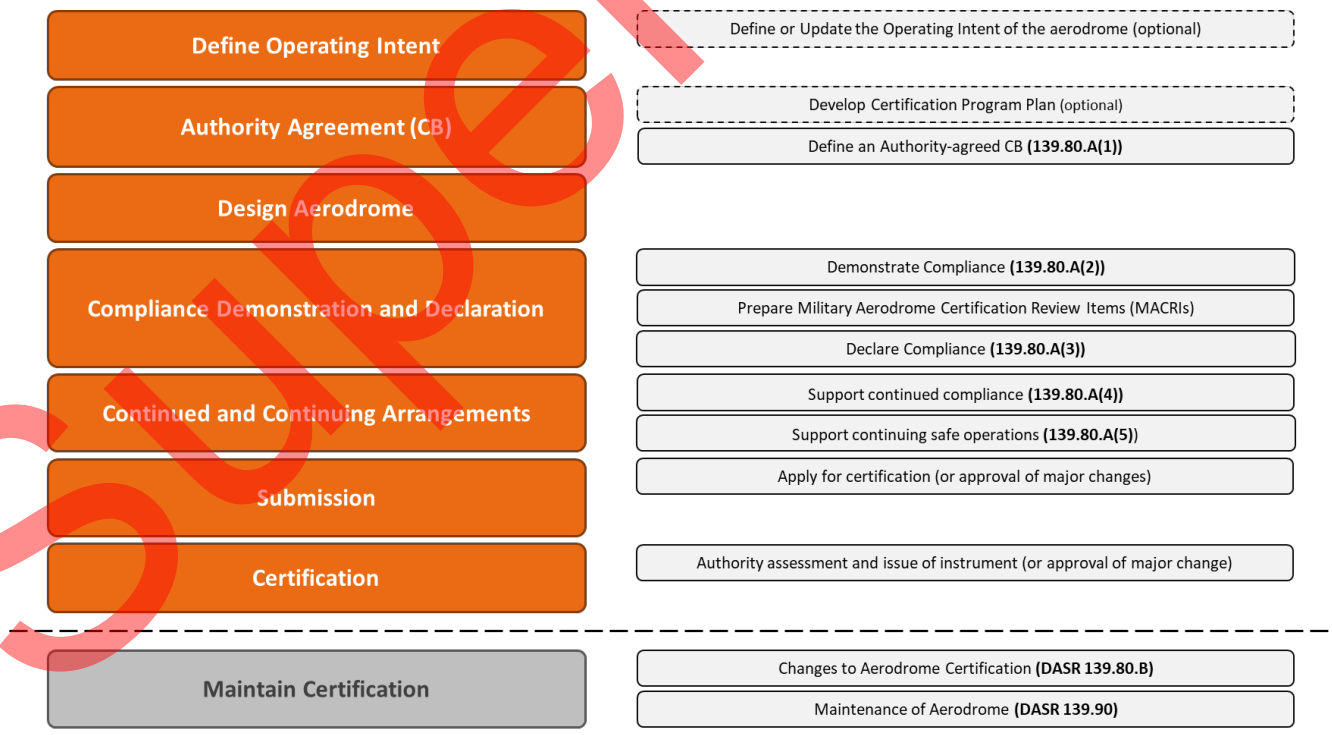

Figure 1: Aerodrome certification activities diagram

Superseded

11.2.1.5 The certification program of work captures the operating intent; establishes the design requirements; designs, constructs and demonstrates compliance to the design requirements; establishes arrangements for continued compliance to the certification basis; and establishes arrangements for continuing safe operations at the aerodrome. The plan documenting this program of work is the Certification Program Plan (CPP), which will help align and coordinate all stakeholders involved in the aerodromes certification activity.

Develop a Certification Program

11.2.1.6 Obtaining an Aerodrome Certificate requires the completion of the Certification Program (CP) conforming to DASR 139 requirements. A CPP is not mandated by the regulations, but a project should consider developing a CPP. A CPP will aid the process by gaining agreement with DASA, of the proposed approach to achieve certification. The plan then informs and aligns all stakeholders in an effort to increase efficiency in a complex process. Acquisition projects and complex changes should produce a detailed CP while a simplified CP may be acceptable for less complex changes.

11.2.1.7 DASA will review and endorse a CPP if found suitable to support the future application for a certificate. DASA will be available to support the applicant throughout the certification process and provide guidance and feedback where needed. This will reduce the likelihood of an application being incomplete at the time of submission.

11.2.1.8 The applicant should submit a mature draft of the document to the DASA aerodromes mailbox for comments and feedback. The Aerodrome and Heliport section in DASA and the applicant will discuss the content of the CPP until both parties are satisfied that the certification activities are appropriate and sufficiently detailed for the stage of the project. An applicant organisation may submit a signed CPP to DASA for endorsement.

Certification Basis

11.2.1.9 An Aerodrome's CB is an agreed set of requirements needed to support safe flight operations at the aerodrome. To receive an Aerodrome Certificate, the aerodrome must be compliant with the CB. The basis of a Defence Aerodrome CB is a set of standards, which are recognised, credible and defensible. The Authority identifies these recognised standards within Section 6 of the Defence Aviation Safety Design Requirements Manual (DASDRM) (For details on the DASDRM, refer to Annex A). The applicable requirements extracted from the DASDRM are tailored to take into account the operating intent of the aerodrome. The CB may also include any special detailed technical requirements that address unique issues beyond the scope of the design requirements contained in the DASDRM. A CB thus comprises of:

1. applicable design requirements prescribed in the relevant chapter of Section 6 of the DASDRM
2. any tailoring to the above design requirements to meet an aerodrome's operating intent
3. any additional technical requirements that are needed to address unique issues beyond the scope of design requirements in Section 6 of the DASDRM.

11.2.1.10 DASA has developed templates to support the creation of Certification Basis for land-based aerodromes intended primarily for use by fixed wing aircraft; land-based heliports, and shipborne heliports. These templates contain all the design requirements from Chapter 2, Chapter 3, and Chapter 4 of Section 6 of the DASDRM respectively that the applicant can use to develop a CB and track certification activities.

Superseded

11.2.1.11 For shipborne heliports the CB will normally be established as part of the Projects Material Seaworthiness Requirement Set (MSRS) as defined in the N-Library. Notwithstanding the Seaworthiness system requirements, the subset of a Projects MSRS related to aerodrome certification (those requirements based on the DASDRM design requirements) – the shipborne heliport CB requires DASA agreement.

Operating intent informing the Certification Basis

11.2.1.12 As the operations taking place at each Defence aerodrome are unique, not all the requirements contained in the DASDRM are applicable to every aerodrome. To help identify those requirements that are relevant and those requirements that are not, there is a clear need for an understanding of the operations taking place at an aerodrome. The achievement of the design, construction and certification of an aerodrome is unlikely without the understanding of the operations at the aerodrome. As such, a documented operating intent is critical to establishing a CB and gaining certification. A documented operating intent is also likely to help inform development of compliance demonstration programs and support on-going safe flight operations at the aerodrome.

11.2.1.13 A high-level description of the facilities and operations at an aerodrome are often captured in a Statement of Operating Intent (SOI) (or similar documents – similar documents may include the Statement of Operating Intent and Usage (SOIU) and the Operating and Support Intent (OSI)) for an aerodrome). While DASA does not mandate the development or update of a specific document for Defence aerodromes (such as a SOIU), it is important to have this information documented before commencing the development of the CB. The basis for tailoring DASDRM requirements is a documented operating intent, justifying the removal of different requirements that are not relevant to the aerodrome, or identifying and adding special technical requirements. The Certification Basis Templates provide the functionality to capture the justification of tailoring of the design requirement set.

Certification Basis tailoring

11.2.1.14 The provisional CB represents the 'target' aerodrome design and construction requirements (note – use of the term 'provisional CB' is simply because there may be additional tailoring identified as the design and production process develops). During design and construction of an aerodrome, it is unlikely that there will be compliance with all the design requirements of a provisional CB. These shortfalls require management to ensure elimination of any risks posed by the non-compliances or that they are otherwise minimised SFARP. Addressing these shortfalls will result in changes to the CB. These changes need to be done through the Military Aerodrome Certification Review Item (MACRI) where either alternate requirements are used which have been demonstrated to achieve an equivalent level of safety or limitations/treatments are applied to the CB requirement to eliminate or otherwise minimise risks SFARP to safe flight operations.

11.2.1.15 Tailoring of the CB must be based upon:

1. a safety argument that demonstrates an equivalent level of safety can be achieved through a tailored design requirement, or
2. detailed Safety Risk Management (SRM) (normally in the form of an Aerodrome Issue Paper (ADIP)) if compliance with the design requirement would adversely affect Defence capability, and risks to aviation safety can be eliminated or otherwise minimised SFARP through alternate means.

11.2.1.16 The Certification Basis Templates can be used to identify the tailoring that has occurred and reference all the supporting documentation.

Superseded

11.2.1.17 DASA approves aerodrome CBs and any changes to an extant CB. Approval of the provisional CB for an aerodrome can be through a formal standalone approval of the CB or combined with approval of the CPP.

11.2.1.18 Approval for updates to a CB can be through a formal standalone process similar to that undertaken for a provisional CB or combined with the CPP for the change. For a change, the applicant only needs to identify the affected CB requirements for approval.

11.2.1.19 DASA must approve all tailoring of the CB prior to the application of the aerodrome certificate.

Demonstrate compliance

11.2.1.20 Once the CB has been established, and the design and construction of an aerodrome commenced or completed, the applicant needs to demonstrate, through the production of evidence, that the design and construction of the aerodrome meets the agreed CB.

11.2.1.21 Compliance demonstration evidence must be available for inspection by the DASA (on a non-exhaustive basis) in order to provide independent assurance that the evidence is suitable, and that the evidence demonstrates compliance to the agreed CB requirements.

11.2.1.22 Compliance demonstration evidence is contained in compliance documents. It may consist of design data, test plans and reports, analyses, drawings, processes, material specifications, operating limitations, aerodrome manual and supplements, and maintenance program and supplements amongst others. The applicant is responsible for demonstrating compliance by the agreed means during the CP, and making the evidence available to DASA for inspection.

11.2.1.23 Generation of evidence is solely the responsibility of the applicant. All compliance documents must be independently checked by the applicant and signed as complete and accurate regardless of DASA's inspection requirements. The applicant shall compile a list of evidence produced to demonstrate compliance against each line item of the CB; and provide a formal declaration that the design and construction of the aerodrome entirely meets the requirements of the CB. The evidence can be captured in the DASA CB template tool or another applicant specified means. A 'User Guide – Certification Basis Template Guidance' provides information on how to use the CB template tool to capture the compliance demonstration evidence which can be obtained from DASA.

11.2.1.24 The process for the RANs Materiel Assurance, described in the N-Library, will normally be used to plan and complete compliance demonstration for shipborne heliports. However, the requirement to make all evidence that demonstrates compliance to the agreed CB available to DASA is still applicable.

11.2.1.25 Throughout the CP, DASA will inspect selected compliance evidence to the extent necessary to assure the safety of the design and construction of the aerodrome. DASA will review, on a non-exhaustive basis, any compliance evidence used to support the declaration of compliance to provide the independent assurance necessary to support the granting of an Aerodrome Certificate.

Management of non-compliances

11.2.1.26 During compliance demonstration activities and over the life of the aerodrome, shortfalls / non-compliances against the aerodrome CB design requirements may be identified. Non-compliances against the CB should be examined for impact to certification and safety of flight operations.

Superseded

11.2.1.27 Where it is not reasonably practicable to change the aerodrome design OR where evidence cannot be generated to demonstrate compliance with a design requirement in the CB, the applicant should pursue approval for tailoring of the CB. Central to this tailoring process are the MACRI and the ADIP.

11.2.1.28 A MACRI is a document, which captures an applicant's proposal to modify an aerodromes CB design requirement, and DASA approval of the modification. There are two types of MACRI, an Equivalent Safety Finding (ESF) MACRI and an Exception MACRI. Development of a MACRI should only proceed if it is not reasonably practicable to eliminate the risks through engineering / design changes. For details on the MACRI process, refer to Factsheet – Military Aerodrome Certification Review Items.

11.2.1.29 ADIP are used when an applicant identifies an enduring design deficiency, which requires a risk treatment decision by Command. An ADIP usually underpins an Exception MACRI but may also be used to support an ESF MACRI. A safety argument should normally be used to support an ESF MACRI. However, if the Safety argument is complex and the controls contentious, an ADIP can be used to capture the argument and controls and gain operator agreement. Factsheet *Aerodrome Issue Paper* describes what constitutes an ADIP, and illustrates the process for raising and processing an ADIP, including the roles of the applicant / person evaluating the Non-compliance, and the roles of the DASA and Command.

11.2.1.30 By Approving an ADIP, DASA is providing assurance that the risk management is following the 7-Step SRM process and is defensible. By approving a MACRI, DASA approves the tailoring of the CB. Once approved by DASA, any tailoring of the CB requirements should be captured in the CB Template, or an applicant specified template, with the corresponding MACRI information. For details on how to use the template to capture this information, refer to the User Guide – Certification Basis Template which can be obtained from DASA.

11.2.1.31 DASA reviews all MACRIs and supporting ADIP and will provide approval if the DASA is assured a credible and defensible safety argument or application of the SRM has been completed. The approval provides agreement to the change in the CB requirement.

Declare compliance

11.2.1.32 When applying for certification of an Aerodrome under DASR 139.80, the applicant must make a declaration of compliance. The purpose of the declaration is to ensure the applicant organisation has considered and confirmed that compliance has been demonstrated to all CB requirements and no aspect is unsafe for use as intended. The applicant must identify a suitable person to make the declaration – usually the person responsible for design/manufacture/inspection of the aerodrome.

11.2.1.33 The person chosen to declare compliance must be a competent, qualified and authorised individual. Whilst DASA does not mandate whom is such a person, the applicant is to propose and justify why the nominated person is suitable. DASA does however have the expectation that the person making the declaration would be a senior engineer of an accountable organisation. This person does not have to be a part of the applicant's organisation; though this should be clearly identified in the Certification Program Plan.

11.2.1.34 When all Military Aerodrome Certification Review Items (MACRIs) have been approved and all compliance demonstration evidence has been developed and approved, the applicant is in a position to make a declaration that the design and construction of the aerodrome entirely meets the requirements of the CB. The declaration can be made as part of the application for an Aerodrome

Superseded

Certificate, for which a DASA form has been developed (see Forms area below), or via another means (which could be formally agreed in the CPP).

11.2.1.35 The declaration of compliance is made by the applicant organisation, with the applicant declaring that:

1. the Design meets the Certification Basis
2. the Construction meets the Design
3. all non-compliance issues are addressed through DASA approved MACRIs.

11.2.1.36 Declaration of compliance can only be completed:

1. after DASA approval of all MACRIs
2. and after compliance has been shown against ALL requirements in the CB

11.2.1.37 An applicant can make their Declaration in the Aerodrome Certification application form (Application for Aerodrome Certificate). When submitting an application for an Aerodrome Certificate, the submission of the declaration of compliance must be accompanied with:

1. the Certification Check List (CCL) - to be made available and can be attached as an Annex to the application form
2. DASA must be given access to all compliance evidence referenced in the CCL
3. evidence of arrangements to support continued compliance with the CB
4. evidence of arrangements to manage design information for continuing safe operations.

11.2.1.38 Prior to completion of the declaration of compliance and all supporting documentation, the Applicant may choose to invite DASA to review completed compliance demonstration evidence and/or supporting documents.

11.2.1.39 The Applicant should be pro-active and engage with DASA as early as possible in the certification process to plan for early reviews of completed documents.

11.2.1.40 DASA will not review early draft versions, only mature drafts of documents.

11.2.1.41 The applicant can use the CB template, developed by the DASA, to keep track of compliance demonstration activities against each line item of the CB, including MACRI submissions and approvals. Evidence of arrangements to support continued compliance with the CB, and evidence of arrangements to manage design information for continuing safe operations can be referenced in this template. Once completed, the CCL sheet from the template can be attached as an annex to the Application form. While the use of this CB template is not mandatory, the information captured within a completed CCL needs to be made available to the DASA in an easily discernible manner. For details on how to use the CB template, refer to the User Guide – Certification Basis Template which can be obtained from DASA.

11.2.1.42 DASA will review the compliance declaration, including the personnel competency of the person making the declaration, as part of the aerodrome certification.

Superseded

11.2.1.43 DASA may choose to inspect some, most or all of the compliance demonstration evidence provided by the applicant. The applicant has the responsibility to ensure all compliance evidence is available to DASA.

Establishing arrangements for continued compliance

11.2.1.44 Continued (Design) aerodrome compliance encompasses all tasks, to be carried-out to verify that the conditions under which an aerodrome certificate has been granted, continue to be fulfilled throughout its period of validity. Arrangements that enable continued aerodrome compliance are an integral part of aerodrome certification. DASA must be assured that the aerodrome will continue to comply with the aerodrome certification basis and that the safe design of the aerodrome will be retained through the service life of the Aerodrome to issue and maintain certification.

11.2.1.45 Aerodromes can have a long service life, and changes are often made to the aerodrome design, construction and operation during that service life. Furthermore, the original design and/or construction of the aerodrome may include latent defects, not evident at the time of original certification. Arrangements to support continued aerodrome compliance with the aerodrome certification basis is essential. The following systems and procedures are a minimum to be implemented to support continued compliance:

1. A system to retain, and retention of all relevant design information, drawings and test reports; including inspection records for the aerodrome.

2. A system and procedures to capture and manage the configuration of the aerodrome design.

3. A system and processes to collect, investigate and analyse reports of and information related to failures, malfunctions, defects or other occurrences which might adversely affect safe operation of the aerodrome, and to implement corrective action if warranted.

11.2.1.46 For initial certification, the applicant is to establish and provide evidence of these systems and procedures. These arrangements will then be implemented and monitored by the AD OPR in service.

11.2.1.47 DASA will review, on a non-exhaustive basis, the information and procedures provided for continued aerodrome compliance arrangements amongst other things before issuing an aerodrome certificate. Furthermore, DASA may review any non-compliance, occurrences or design defects communicated by the applicant and/or the AD OPR for the potential to affect the certification status and whether the actions taken to maintain support to safe flight operations are credible and defensible.

11.2.1.48 A record of the documents and information that is provided for supporting continued safe operations can be captured in the Aerodrome Certification Basis Template. The template and guide for use of the template can be found on the DASA website.

Establishing arrangements for continuing safe operations

11.2.1.49 An Aerodrome Operator must ensure that, at any time in its operating life, an aerodrome condition supports safe flight operations. The design information that enables the AD OPR to execute the continuing function is an integral part of aerodrome certification. DASA must be assured that the AD OPR has sufficient information to ensure that the conditions for safe flight operation are met to issue and maintain certification. An applicant for aerodrome certification must provide (amongst other things) the design information and procedures in order to enable the AD OPR to ensure the

Superseded

continuing safe flight operations at the Aerodrome. The following information is the minimum required to be provided:

1. Documents that describe specific scheduled maintenance task and their frequency of completion

2. Descriptive data and instructions that enable inspections, processes and procedures necessary to keep the aerodrome in a condition for safe flight operation

11.2.1.50 The AD OPR will use this information to develop and conduct maintenance and inspection processes and procedures to ensure that the aerodrome is always in a condition to support safe flight operations.

11.2.1.51 DASA will review, on a non-exhaustive basis, the information and procedures associated with continuing safe operation of the aerodrome before issuing an aerodrome certificate. Upon becoming aware of any non-compliance, the applicant and/or the AD OPR should bring this to the attention of DASA as it has the potential to affect the certification status.

Application for an Aerodrome Certificate

11.2.1.52 On completion of all compliance demonstration, including approval of all MACRIs, the applicant should start completing the application form for an Aerodrome Certificate. An application to DASA for an aerodrome certificate should use DASA Form – Application for Aerodrome Certificate. Submit the form, along with the supporting documentation, via the DASA Aerodromes Group Mailbox for approval.

11.2.1.53 Aerodrome Continued Compliance and Continuing Safe Operation are also integral parts of Aerodrome Initial Certification. For issue of an Aerodrome Certificate by the DASA, the applicant must (amongst other things) implement arrangements to support continued aerodrome compliance with the CB and provide design information to support the continuing safe operation of the Aerodrome. Before an application is made these aspects should be completed.

11.2.2 Arrangements for maintaining aerodrome certification

Aerodrome design changes

11.2.2.1 Any change to the design, construction or operations of an aerodrome, that has appreciable effect on the safety of flight operations or changes the aerodrome configuration so that it deviates from the DASA agreed CB, invalidates the aerodrome certificate and therefore, must be presented to DASA for re-certification. The purpose of the re-certification process is to assure that the aerodrome continues to be subject to engineering rigour and that the aerodrome remains in a condition that supports safe-flight operations over its service life.

11.2.2.2 Approval of all design changes follows the same principles of certification of a new aerodrome. For all changes, including changes to the Operating intent that affect the design, the certification basis of the change must be established, the means of compliance determined and compliance with the certification basis demonstrated and declared. Alteration of any design data covered by the Aerodrome Certificate and used for Aerodrome Continued Compliance or authorised data for completing Aerodrome continuing compliance also requires a design change approval.

11.2.2.3 Changes that have no appreciable effect on the safety of flight operations do not require presentation to DASA. Any change which changes the agreed CB requires DASA approval. The

Superseded

expectation is that an AD OPR will use professional judgement in determining whether a design change has an 'appreciable' effect on safety, and when in doubt should consult DASA. Determinations for these changes must be available and may be subject to DASA review during oversight activities. The AD OPR is expected to apply the same rigour / standard in implementing those design changes without an appreciable effect on safety of flight, as they would for those changes when they apply to DASA. That is, they should comprehensively complete all steps of the certification process, as applicable, without needing to submit the application to DASA.

11.2.2.4 DASA will agree to CP and approve CB requirements for those changes submitted to DASA, inspect selected compliance evidence, approve all tailoring of requirements and approve all applications for changes. The applicant is encouraged to consult the DASA if there is any doubt regarding whether a change requires re-certification.

11.2.2.5 For any change, the applicant should discuss the content of the CP with DASA until both parties are satisfied, then submit a simplified CP to seek agreement from DASA.

11.2.2.6 An application for DASA's certification for an aerodrome is to be made by writing to DASA. The application should include reference to all information required to be developed by the CP. The Application for a change to the aerodrome certificate can be made using the Application for Aerodrome Certificate.

Annex:

(a) Aerodrome Design Requirements

Superseded

11.2. Aerodrome Certification

11.1 Aerodrome Regulation

11.1.1 DASR 139 Aerodromes Overview

11.1.1.1 To support safe aircraft operations at Defence aerodromes, the Defence Aviation Safety Authority (DASA) released the Defence Aviation Safety Regulations 139 – Aerodromes (DASR 139). These regulations require all Defence aerodromes to be classified as 'certified' or 'non-certified'. Where DASR 139 refers to the term 'aerodrome', it should be read to include:

1. airport
2. airfield
3. airbase
4. heliport (land based or shipborne).

11.1.1.2 DASR 139 deals with, *inter alia*, two key approvals:

1. Aerodrome Operator (AD OPR) Organisation approvals
2. Defence Certified Aerodrome approvals.

Classification of aerodromes (Certified/Non-Certified)

11.1.1.3 Defence aerodromes may be certified or non-certified. DASA's decision[1] to classify an aerodrome as a Certified Aerodrome is based on meeting one of the following four criteria[2]:

1. there is a terminal instrument flight procedure[3] (not including Airborne Radar Approach (ARA) per se) for the aerodrome[4]
2. there are regular civil commercial passenger operations at the aerodrome
3. there are frequent aircraft operations at the aerodrome[5]
4. Defence flight operations at the aerodrome are often inherently hazardous, beyond the scope of normal civilian operations—and the provision of a well-designed/ maintained aerodrome is a key safety risk control[6].

11.1.1.4 DASA developed these criteria through benchmarking certification criteria and information from the Civil Aviation Safety Authority, the European Union Aviation Safety Agency and the International Civil Aviation Organisation tailored to the context of Defence aviation operations at Defence aerodromes.

Guidance for Non-Certified Defence Aerodromes

11.1.1.5 Non-certified Defence aerodromes are not subject to DASR 139 requirements. However, a commander's obligations under the WHS Act 2011 still apply. The underlying principles in DASR 139 (and the Defence Aviation Safety Design Requirements Manual (DASDRM) Section 6 standards)

Superseded

provide guidance to the responsible commander[7] for operation of a non-certified aerodrome—in ensuring that the aerodrome equipment, systems and installations support safe aviation operations.

There could also be more than one responsible commander[8] at any one time[9], depending on the operation of the aerodrome.

11.1.1.6 If the design or operating intent change throughout the life of a non-certified aerodrome, certification and assurance may be warranted under DASR 139. Those responsible for operating/ managing the aerodrome should contact DASA for guidance if such changes (eg major design changes) occur.

Certified Aerodromes

11.1.1.7 The AD OPR organisation must submit an application to DASA for an Aerodrome Certificate for those aerodromes requiring certification. The Aerodrome Certification process is in Chapter 5.3 Annex V.

11.1.1.8 On determining that the aerodrome and the aerodrome operations meet all DASR 139 requirements, DASA will issue an amendment to the AD OPR Certificate (AD OPRC) Operations Specification (OpSpec) — authorising the approved AD OPR to operate the aerodrome as a DASR 139 Certified Aerodrome. Chapter 5.3 Annex B details the process for updating the OpSpec.

Aerodrome Operator management systems and documentation

Aerodrome Operator organisational structure

11.1.1.9 An AD OPR is an organisation consisting of operational, maintenance and engineering personnel that:

1. forms part of a Force Element Group or equivalent force structure
2. must achieve the roles and responsibilities of DASR 139. (See Chapter 5.3 Annex B for the AD OPR approval process).

11.1.1.10 Due to the complexities of the organisations, facilities and locations associated with individual aerodromes, clear understanding and documentation of an organisational structure will enhance command's ability to achieve safe flight operations. The Services outsource to other Defence Groups, such as Security and Estate Group, Chief Information Officer Group and Capability Acquisition and Sustainment Group, to deliver aerodrome capability. Contractors are utilised extensively to complete tasks. This occurs at the AD OPR and base level.

1.1.1.11 DASR AMC 139.30.2.g requires the AD OPR to include an 'outline of relevant aerodrome management arrangements' in the AD OPR Compliance Statement. This outline should include aerodrome management arrangements with subordinates, subordinate organisations (eg wings/ units), supporting Defence groups, contractors and other organisations that support DASR 139 compliance. The AD OPR should include details of formal agreements which such organisations or individuals in the Compliance Statement.

11.1.1.12 At the base level, DASR AMC 139.50.2 requires the Aerodrome Manual to include the aerodrome's organisation and management structure, including agreements with civil operators. The description of organisation and management arrangements should include relationships with organisations that support the AD OPR's local team to achieve and maintain DASR 139 compliance.

Superseded

This should include any subcontractors from supporting organisations and details of formal agreements.

Personnel competency

11.1.1.13 As the safe operation and maintenance of an aerodrome requires a large number of personnel working in a range of fields and disciplines, ensuring their competence is essential. To ensure AD OPR personnel meet the requirements of DASR AMC 139.100 (to obtain, complete and maintain effective competency), AD OPRs should define the training, qualifications and authorisations required for personnel undertaking a role in support of aerodrome operation. These may include training and assessment programs pertaining to airside awareness, aerodrome rescue and firefighting, operations, engineering and maintenance.

Aerodrome management systems and documentation

Aerodrome documentation

11.1.1.14 DASA requires evidence demonstrating suitable systems for the maintenance and operation of each aerodrome are in place. These artefacts are part of the Aerodrome Manual requirements. There are a number of systems, including the Quality Management System and Safety Management System, which the AD OPR may implement across the organisation or have aerodromes establish individually. Regardless, when applying to add a Certified Aerodrome to an AD OPRC OpSpec, the AD OPR must include details of the implemented organisational systems in the Aerodrome Manual.

11.1.1.15 DASA reviews these documents on receipt of an application for addition of a DASR 139 Certified Aerodrome to an AD OPRC OpSpec. These documents form part of the evidence supporting compliance with the regulation.

Aerodrome maintenance program

11.1.1.16 Failure to follow the aerodrome maintenance program may lead to DASA making a finding against the AD OPR approval, and can affect certification. Examples of arrangements (systems and procedures) used to enact the aerodrome maintenance program plan include:

1. repainting of markings – periodic repaint
2. electrical system works – continuity testing
3. periodic friction testing
4. obstacle surveys
5. aerodrome technical inspections
6. aerodrome serviceability inspections.

11.1.1.17 There is no requirement to submit an aerodrome maintenance program to DASA. However, the program should be available for DASA on request and may be reviewed as part of initial approval and oversight activities.

Superseded

11.2.1 Aerodrome Certificate

Certification process and programs

11.2.1.1 The Aerodrome Certificate is a certificate granted to an Aerodrome Operator (AD OPR) by DASA certifying that the aerodrome meets the technical specifications outlined in its certification basis. The Aerodrome Certificate addresses the requirements of DASR 139.80.

11.2.1.2 To achieve aerodrome certification, the following five primary activities must be undertaken:

1. define a DASA-agreed CB for the aerodrome
2. demonstrate that the aerodrome design and construction complies with the agreed CB
3. declare that the aerodrome design and construction complies with the agreed CB
4. implement arrangements to support continued aerodrome compliance with the CB
5. provide design information to support continuing safe operation of the aerodrome.

11.2.1.3 Each of these mandated activities (and other supporting aspects) form the basis of the certification process.

11.2.1.4 The following figure shows the aerodrome certification activities:

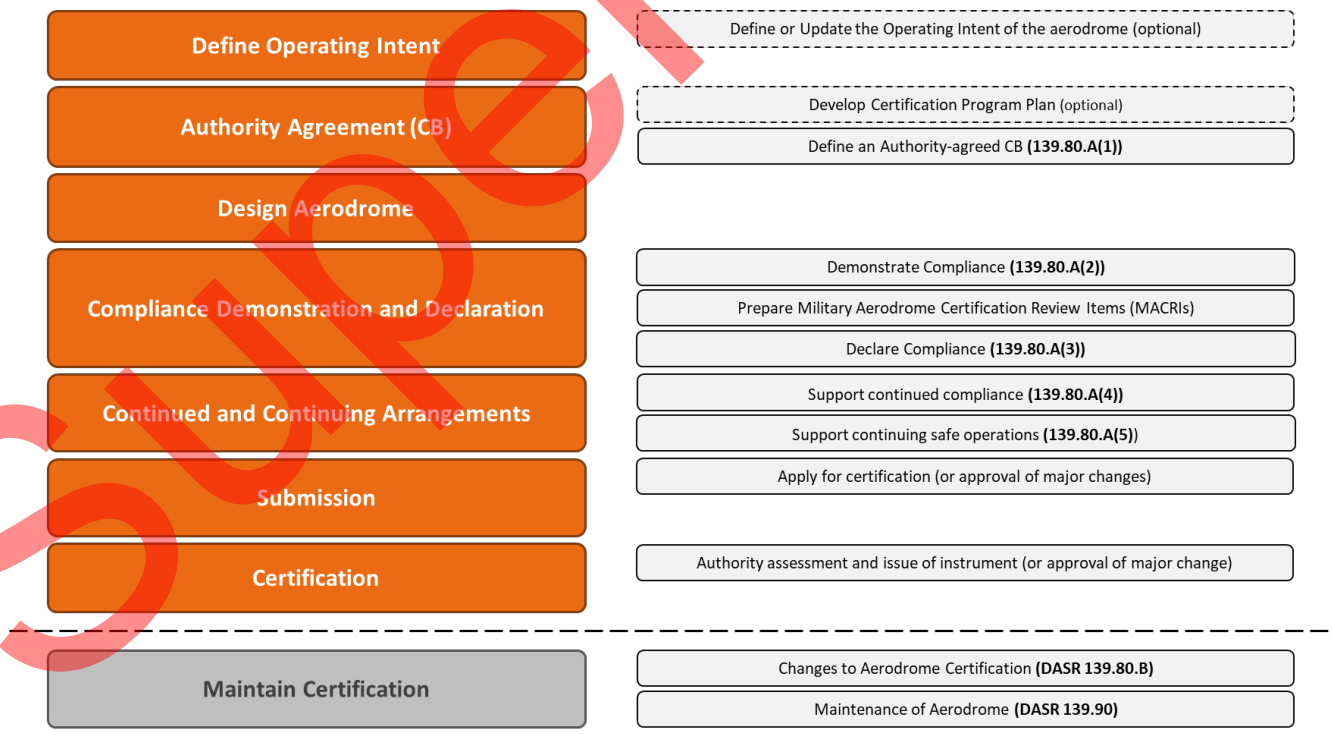

Figure 1: Aerodrome certification activities diagram

Superseded

11.2.1.5 The certification program of work captures the operating intent; establishes the design requirements; designs, constructs and demonstrates compliance to the design requirements; establishes arrangements for continued compliance to the certification basis; and establishes arrangements for continuing safe operations at the aerodrome. The plan documenting this program of work is the Certification Program Plan (CPP), which will help align and coordinate all stakeholders involved in the aerodromes certification activity.

Develop a Certification Program

11.2.1.6 Obtaining an Aerodrome Certificate requires the completion of the Certification Program (CP) conforming to DASR 139 requirements. A CPP is not mandated by the regulations, but a project should consider developing a CPP. A CPP will aid the process by gaining agreement with DASA, of the proposed approach to achieve certification. The plan then informs and aligns all stakeholders in an effort to increase efficiency in a complex process. Acquisition projects and complex changes should produce a detailed CP while a simplified CP may be acceptable for less complex changes.

11.2.1.7 DASA will review and endorse a CPP if found suitable to support the future application for a certificate. DASA will be available to support the applicant throughout the certification process and provide guidance and feedback where needed. This will reduce the likelihood of an application being incomplete at the time of submission.

11.2.1.8 The applicant should submit a mature draft of the document to the DASA aerodromes mailbox for comments and feedback. The Aerodrome and Heliport section in DASA and the applicant will discuss the content of the CPP until both parties are satisfied that the certification activities are appropriate and sufficiently detailed for the stage of the project. An applicant organisation may submit a signed CPP to DASA for endorsement.

Certification Basis

11.2.1.9 An Aerodrome's CB is an agreed set of requirements needed to support safe flight operations at the aerodrome. To receive an Aerodrome Certificate, the aerodrome must be compliant with the CB. The basis of a Defence Aerodrome CB is a set of standards, which are recognised, credible and defensible. The Authority identifies these recognised standards within Section 6 of the Defence Aviation Safety Design Requirements Manual (DASDRM) (For details on the DASDRM, refer to Annex A). The applicable requirements extracted from the DASDRM are tailored to take into account the operating intent of the aerodrome. The CB may also include any special detailed technical requirements that address unique issues beyond the scope of the design requirements contained in the DASDRM. A CB thus comprises of:

1. applicable design requirements prescribed in the relevant chapter of Section 6 of the DASDRM
2. any tailoring to the above design requirements to meet an aerodrome's operating intent
3. any additional technical requirements that are needed to address unique issues beyond the scope of design requirements in Section 6 of the DASDRM.

11.2.1.10 DASA has developed templates to support the creation of Certification Basis for land-based aerodromes intended primarily for use by fixed wing aircraft; land-based heliports, and shipborne heliports. These templates contain all the design requirements from Chapter 2, Chapter 3, and Chapter 4 of Section 6 of the DASDRM respectively that the applicant can use to develop a CB and track certification activities.

Superseded

11.2.1.11 For shipborne heliports the CB will normally be established as part of the Projects Material Seaworthiness Requirement Set (MSRS) as defined in the N-Library. Notwithstanding the Seaworthiness system requirements, the subset of a Projects MSRS related to aerodrome certification (those requirements based on the DASDRM design requirements) – the shipborne heliport CB requires DASA agreement.

Operating intent informing the Certification Basis

11.2.1.12 As the operations taking place at each Defence aerodrome are unique, not all the requirements contained in the DASDRM are applicable to every aerodrome. To help identify those requirements that are relevant and those requirements that are not, there is a clear need for an understanding of the operations taking place at an aerodrome. The achievement of the design, construction and certification of an aerodrome is unlikely without the understanding of the operations at the aerodrome. As such, a documented operating intent is critical to establishing a CB and gaining certification. A documented operating intent is also likely to help inform development of compliance demonstration programs and support on-going safe flight operations at the aerodrome.

11.2.1.13 A high-level description of the facilities and operations at an aerodrome are often captured in a Statement of Operating Intent (SOI) (or similar documents – similar documents may include the Statement of Operating Intent and Usage (SOIU) and the Operating and Support Intent (OSI)) for an aerodrome). While DASA does not mandate the development or update of a specific document for Defence aerodromes (such as a SOIU), it is important to have this information documented before commencing the development of the CB. The basis for tailoring DASDRM requirements is a documented operating intent, justifying the removal of different requirements that are not relevant to the aerodrome, or identifying and adding special technical requirements. The Certification Basis Templates provide the functionality to capture the justification of tailoring of the design requirement set.

Certification Basis tailoring

11.2.1.14 The provisional CB represents the 'target' aerodrome design and construction requirements (note – use of the term 'provisional CB' is simply because there may be additional tailoring identified as the design and production process develops). During design and construction of an aerodrome, it is unlikely that there will be compliance with all the design requirements of a provisional CB. These shortfalls require management to ensure elimination of any risks posed by the non-compliances or that they are otherwise minimised SFARP. Addressing these shortfalls will result in changes to the CB. These changes need to be done through the Military Aerodrome Certification Review Item (MACRI) where either alternate requirements are used which have been demonstrated to achieve an equivalent level of safety or limitations/treatments are applied to the CB requirement to eliminate or otherwise minimise risks SFARP to safe flight operations.

11.2.1.15 Tailoring of the CB must be based upon:

1. a safety argument that demonstrates an equivalent level of safety can be achieved through a tailored design requirement, or
2. detailed Safety Risk Management (SRM) (normally in the form of an Aerodrome Issue Paper (ADIP)) if compliance with the design requirement would adversely affect Defence capability, and risks to aviation safety can be eliminated or otherwise minimised SFARP through alternate means.

11.2.1.16 The Certification Basis Templates can be used to identify the tailoring that has occurred and reference all the supporting documentation.

Superseded

11.2.1.17 DASA approves aerodrome CBs and any changes to an extant CB. Approval of the provisional CB for an aerodrome can be through a formal standalone approval of the CB or combined with approval of the CPP.

11.2.1.18 Approval for updates to a CB can be through a formal standalone process similar to that undertaken for a provisional CB or combined with the CPP for the change. For a change, the applicant only needs to identify the affected CB requirements for approval.

11.2.1.19 DASA must approve all tailoring of the CB prior to the application of the aerodrome certificate.

Demonstrate compliance

11.2.1.20 Once the CB has been established, and the design and construction of an aerodrome commenced or completed, the applicant needs to demonstrate, through the production of evidence, that the design and construction of the aerodrome meets the agreed CB.

11.2.1.21 Compliance demonstration evidence must be available for inspection by the DASA (on a non-exhaustive basis) in order to provide independent assurance that the evidence is suitable, and that the evidence demonstrates compliance to the agreed CB requirements.

11.2.1.22 Compliance demonstration evidence is contained in compliance documents. It may consist of design data, test plans and reports, analyses, drawings, processes, material specifications, operating limitations, aerodrome manual and supplements, and maintenance program and supplements amongst others. The applicant is responsible for demonstrating compliance by the agreed means during the CP, and making the evidence available to DASA for inspection.

11.2.1.23 Generation of evidence is solely the responsibility of the applicant. All compliance documents must be independently checked by the applicant and signed as complete and accurate regardless of DASA's inspection requirements. The applicant shall compile a list of evidence produced to demonstrate compliance against each line item of the CB; and provide a formal declaration that the design and construction of the aerodrome entirely meets the requirements of the CB. The evidence can be captured in the DASA CB template tool or another applicant specified means. A 'User Guide – Certification Basis Template Guidance' provides information on how to use the CB template tool to capture the compliance demonstration evidence which can be obtained from DASA.

11.2.1.24 The process for the RANs Materiel Assurance, described in the N-Library, will normally be used to plan and complete compliance demonstration for shipborne heliports. However, the requirement to make all evidence that demonstrates compliance to the agreed CB available to DASA is still applicable.

11.2.1.25 Throughout the CP, DASA will inspect selected compliance evidence to the extent necessary to assure the safety of the design and construction of the aerodrome. DASA will review, on a non-exhaustive basis, any compliance evidence used to support the declaration of compliance to provide the independent assurance necessary to support the granting of an Aerodrome Certificate.

Management of non-compliances

11.2.1.26 During compliance demonstration activities and over the life of the aerodrome, shortfalls / non-compliances against the aerodrome CB design requirements may be identified. Non-compliances against the CB should be examined for impact to certification and safety of flight operations.

Superseded

11.2.1.27 Where it is not reasonably practicable to change the aerodrome design OR where evidence cannot be generated to demonstrate compliance with a design requirement in the CB, the applicant should pursue approval for tailoring of the CB. Central to this tailoring process are the MACRI and the ADIP.

11.2.1.28 A MACRI is a document, which captures an applicant's proposal to modify an aerodromes CB design requirement, and DASA approval of the modification. There are two types of MACRI, an Equivalent Safety Finding (ESF) MACRI and an Exception MACRI. Development of a MACRI should only proceed if it is not reasonably practicable to eliminate the risks through engineering / design changes. For details on the MACRI process, refer to Factsheet – Military Aerodrome Certification Review Items.

11.2.1.29 ADIP are used when an applicant identifies an enduring design deficiency, which requires a risk treatment decision by Command. An ADIP usually underpins an Exception MACRI but may also be used to support an ESF MACRI. A safety argument should normally be used to support an ESF MACRI. However, if the Safety argument is complex and the controls contentious, an ADIP can be used to capture the argument and controls and gain operator agreement. Factsheet *Aerodrome Issue Paper* describes what constitutes an ADIP, and illustrates the process for raising and processing an ADIP, including the roles of the applicant / person evaluating the Non-compliance, and the roles of the DASA and Command.

11.2.1.30 By Approving an ADIP, DASA is providing assurance that the risk management is following the 7-Step SRM process and is defensible. By approving a MACRI, DASA approves the tailoring of the CB. Once approved by DASA, any tailoring of the CB requirements should be captured in the CB Template, or an applicant specified template, with the corresponding MACRI information. For details on how to use the template to capture this information, refer to the User Guide – Certification Basis Template which can be obtained from DASA.

11.2.1.31 DASA reviews all MACRIs and supporting ADIP and will provide approval if the DASA is assured a credible and defensible safety argument or application of the SRM has been completed. The approval provides agreement to the change in the CB requirement.

Declare compliance

11.2.1.32 When applying for certification of an Aerodrome under DASR 139.80, the applicant must make a declaration of compliance. The purpose of the declaration is to ensure the applicant organisation has considered and confirmed that compliance has been demonstrated to all CB requirements and no aspect is unsafe for use as intended. The applicant must identify a suitable person to make the declaration – usually the person responsible for design/manufacture/inspection of the aerodrome.

11.2.1.33 The person chosen to declare compliance must be a competent, qualified and authorised individual. Whilst DASA does not mandate whom is such a person, the applicant is to propose and justify why the nominated person is suitable. DASA does however have the expectation that the person making the declaration would be a senior engineer of an accountable organisation. This person does not have to be a part of the applicant's organisation; though this should be clearly identified in the Certification Program Plan.

11.2.1.34 When all Military Aerodrome Certification Review Items (MACRIs) have been approved and all compliance demonstration evidence has been developed and approved, the applicant is in a position to make a declaration that the design and construction of the aerodrome entirely meets the requirements of the CB. The declaration can be made as part of the application for an Aerodrome

Superseded

Certificate, for which a DASA form has been developed (see Forms area below), or via another means (which could be formally agreed in the CPP).

11.2.1.35 The declaration of compliance is made by the applicant organisation, with the applicant declaring that:

1. the Design meets the Certification Basis
2. the Construction meets the Design
3. all non-compliance issues are addressed through DASA approved MACRIs.

11.2.1.36 Declaration of compliance can only be completed:

1. after DASA approval of all MACRIs
2. and after compliance has been shown against ALL requirements in the CB

11.2.1.37 An applicant can make their Declaration in the Aerodrome Certification application form (Application for Aerodrome Certificate). When submitting an application for an Aerodrome Certificate, the submission of the declaration of compliance must be accompanied with:

1. the Certification Check List (CCL) - to be made available and can be attached as an Annex to the application form
2. DASA must be given access to all compliance evidence referenced in the CCL
3. evidence of arrangements to support continued compliance with the CB
4. evidence of arrangements to manage design information for continuing safe operations.

11.2.1.38 Prior to completion of the declaration of compliance and all supporting documentation, the Applicant may choose to invite DASA to review completed compliance demonstration evidence and/or supporting documents.

11.2.1.39 The Applicant should be pro-active and engage with DASA as early as possible in the certification process to plan for early reviews of completed documents.

11.2.1.40 DASA will not review early draft versions, only mature drafts of documents.

11.2.1.41 The applicant can use the CB template, developed by the DASA, to keep track of compliance demonstration activities against each line item of the CB, including MACRI submissions and approvals. Evidence of arrangements to support continued compliance with the CB, and evidence of arrangements to manage design information for continuing safe operations can be referenced in this template. Once completed, the CCL sheet from the template can be attached as an annex to the Application form. While the use of this CB template is not mandatory, the information captured within a completed CCL needs to be made available to the DASA in an easily discernible manner. For details on how to use the CB template, refer to the User Guide – Certification Basis Template which can be obtained from DASA.

11.2.1.42 DASA will review the compliance declaration, including the personnel competency of the person making the declaration, as part of the aerodrome certification.

Superseded

11.2.1.43 DASA may choose to inspect some, most or all of the compliance demonstration evidence provided by the applicant. The applicant has the responsibility to ensure all compliance evidence is available to DASA.

Establishing arrangements for continued compliance

11.2.1.44 Continued (Design) aerodrome compliance encompasses all tasks, to be carried-out to verify that the conditions under which an aerodrome certificate has been granted, continue to be fulfilled throughout its period of validity. Arrangements that enable continued aerodrome compliance are an integral part of aerodrome certification. DASA must be assured that the aerodrome will continue to comply with the aerodrome certification basis and that the safe design of the aerodrome will be retained through the service life of the Aerodrome to issue and maintain certification.

11.2.1.45 Aerodromes can have a long service life, and changes are often made to the aerodrome design, construction and operation during that service life. Furthermore, the original design and/or construction of the aerodrome may include latent defects, not evident at the time of original certification. Arrangements to support continued aerodrome compliance with the aerodrome certification basis is essential. The following systems and procedures are a minimum to be implemented to support continued compliance:

1. A system to retain, and retention of all relevant design information, drawings and test reports; including inspection records for the aerodrome.

2. A system and procedures to capture and manage the configuration of the aerodrome design.

3. A system and processes to collect, investigate and analyse reports of and information related to failures, malfunctions, defects or other occurrences which might adversely affect safe operation of the aerodrome, and to implement corrective action if warranted.

11.2.1.46 For initial certification, the applicant is to establish and provide evidence of these systems and procedures. These arrangements will then be implemented and monitored by the AD OPR in service.

11.2.1.47 DASA will review, on a non-exhaustive basis, the information and procedures provided for continued aerodrome compliance arrangements amongst other things before issuing an aerodrome certificate. Furthermore, DASA may review any non-compliance, occurrences or design defects communicated by the applicant and/or the AD OPR for the potential to affect the certification status and whether the actions taken to maintain support to safe flight operations are credible and defensible.

11.2.1.48 A record of the documents and information that is provided for supporting continued safe operations can be captured in the Aerodrome Certification Basis Template. The template and guide for use of the template can be found on the DASA website.

Establishing arrangements for continuing safe operations

11.2.1.49 An Aerodrome Operator must ensure that, at any time in its operating life, an aerodrome condition supports safe flight operations. The design information that enables the AD OPR to execute the continuing function is an integral part of aerodrome certification. DASA must be assured that the AD OPR has sufficient information to ensure that the conditions for safe flight operation are met to issue and maintain certification. An applicant for aerodrome certification must provide (amongst other things) the design information and procedures in order to enable the AD OPR to ensure the

Superseded

continuing safe flight operations at the Aerodrome. The following information is the minimum required to be provided:

1. Documents that describe specific scheduled maintenance task and their frequency of completion

2. Descriptive data and instructions that enable inspections, processes and procedures necessary to keep the aerodrome in a condition for safe flight operation

11.2.1.50 The AD OPR will use this information to develop and conduct maintenance and inspection processes and procedures to ensure that the aerodrome is always in a condition to support safe flight operations.

11.2.1.51 DASA will review, on a non-exhaustive basis, the information and procedures associated with continuing safe operation of the aerodrome before issuing an aerodrome certificate. Upon becoming aware of any non-compliance, the applicant and/or the AD OPR should bring this to the attention of DASA as it has the potential to affect the certification status.

Application for an Aerodrome Certificate

11.2.1.52 On completion of all compliance demonstration, including approval of all MACRIs, the applicant should start completing the application form for an Aerodrome Certificate. An application to DASA for an aerodrome certificate should use DASA Form – Application for Aerodrome Certificate. Submit the form, along with the supporting documentation, via the DASA Aerodromes Group Mailbox for approval.

11.2.1.53 Aerodrome Continued Compliance and Continuing Safe Operation are also integral parts of Aerodrome Initial Certification. For issue of an Aerodrome Certificate by the DASA, the applicant must (amongst other things) implement arrangements to support continued aerodrome compliance with the CB and provide design information to support the continuing safe operation of the Aerodrome. Before an application is made these aspects should be completed.

11.2.2 Arrangements for maintaining aerodrome certification

Aerodrome design changes

11.2.2.1 Any change to the design, construction or operations of an aerodrome, that has appreciable effect on the safety of flight operations or changes the aerodrome configuration so that it deviates from the DASA agreed CB, invalidates the aerodrome certificate and therefore, must be presented to DASA for re-certification. The purpose of the re-certification process is to assure that the aerodrome continues to be subject to engineering rigour and that the aerodrome remains in a condition that supports safe-flight operations over its service life.

11.2.2.2 Approval of all design changes follows the same principles of certification of a new aerodrome. For all changes, including changes to the Operating intent that affect the design, the certification basis of the change must be established, the means of compliance determined and compliance with the certification basis demonstrated and declared. Alteration of any design data covered by the Aerodrome Certificate and used for Aerodrome Continued Compliance or authorised data for completing Aerodrome continuing compliance also requires a design change approval.

11.2.2.3 Changes that have no appreciable effect on the safety of flight operations do not require presentation to DASA. Any change which changes the agreed CB requires DASA approval. The

Superseded

expectation is that an AD OPR will use professional judgement in determining whether a design change has an 'appreciable' effect on safety, and when in doubt should consult DASA. Determinations for these changes must be available and may be subject to DASA review during oversight activities. The AD OPR is expected to apply the same rigour / standard in implementing those design changes without an appreciable effect on safety of flight, as they would for those changes when they apply to DASA. That is, they should comprehensively complete all steps of the certification process, as applicable, without needing to submit the application to DASA.

11.2.2.4 DASA will agree to CP and approve CB requirements for those changes submitted to DASA, inspect selected compliance evidence, approve all tailoring of requirements and approve all applications for changes. The applicant is encouraged to consult the DASA if there is any doubt regarding whether a change requires re-certification.

11.2.2.5 For any change, the applicant should discuss the content of the CP with DASA until both parties are satisfied, then submit a simplified CP to seek agreement from DASA.

11.2.2.6 An application for DASA's certification for an aerodrome is to be made by writing to DASA. The application should include reference to all information required to be developed by the CP. The Application for a change to the aerodrome certificate can be made using the Application for Aerodrome Certificate.

Annex:

(a) Aerodrome Design Requirements

Superseded

Aerodrome design requirements

(a) For Defence aerodromes, the DASA is responsible for establishing the initial safety requirements. These aviation safety requirements are prescribed within Section 6 of DASA's Defence Aviation Safety Design Requirements Manual (DASDRM) and are to be used when designing Defence certified aerodromes.

(b) DASA will identify a primary design standard, which represents international or domestic 'good practice' for aerodrome design and is an integrated requirement set, internally consistent and kept up-to-date by the sponsoring authority. The DASDRM aerodrome requirements leverage heavily, where possible, on a primary design standard that has been identified as domestic or international 'good practice' for aerodrome design, are an integrated requirement set, internally consistent and kept up-to-date by the sponsoring authority. These primary standards provide a sound foundation for aerodrome design, however due to Defences unique military role and environment, the DASDRM adapts the primary design standard through supplementation or tailoring. This may be needed where the primary design standard:

1. is silent on specific design elements needed for Defence aerodromes, such as military-specific capability requirements;
2. does include requirements for a particular design element, but Defence experience has shown it needs to be varied for the Defence operational context; and/or
3. is not entirely compatible with mandatory Australian legislative design requirements, for example electrical wiring.

(c) The DASA prescribe design requirements in support of safe flight operations. Non-aviation safety-related design requirements necessary for Defence capability, standardisation and interoperability with other defence forces are not included.

Superseded

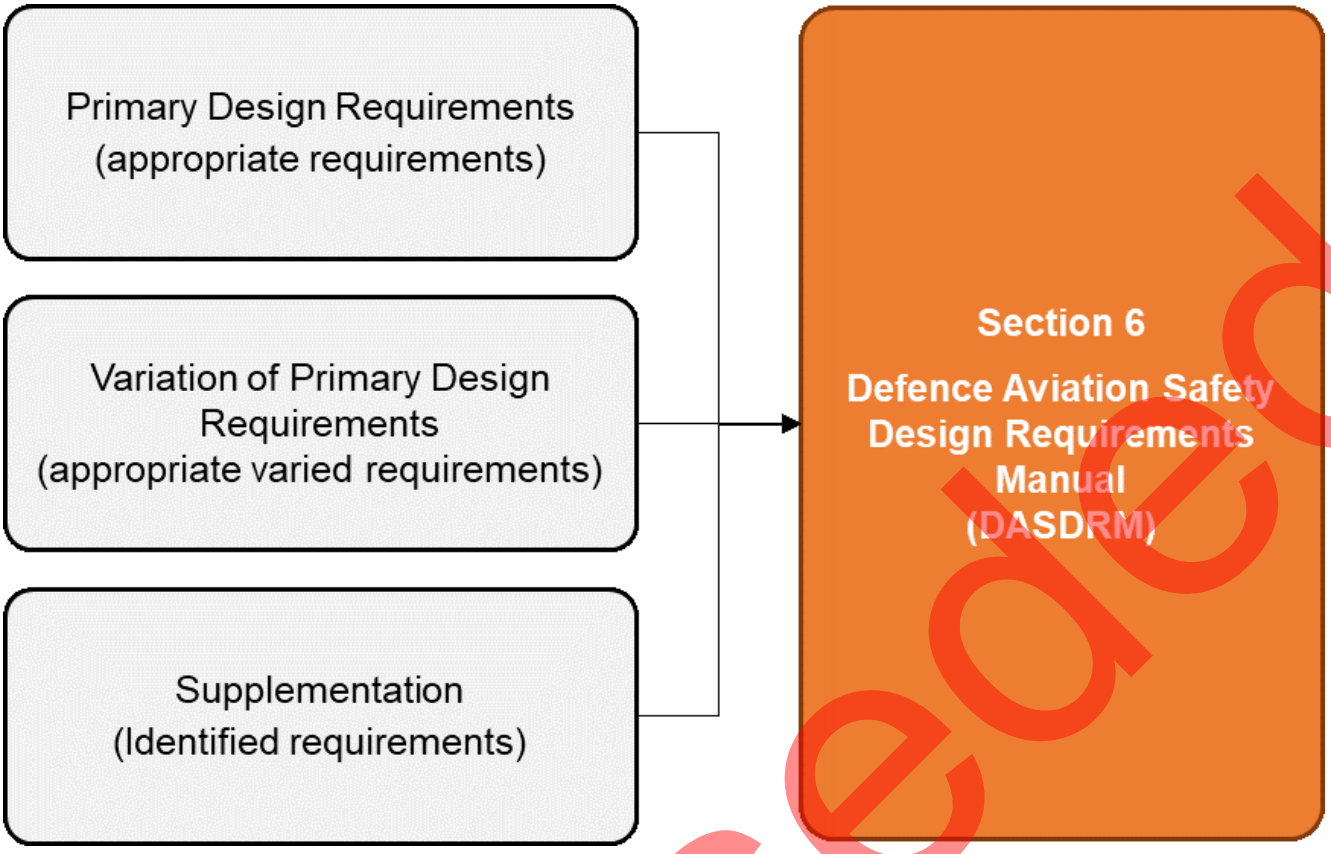

Figure 1: Defence Aviation Safety Design Requirements Manual (DASDRM)

(a) The DASDRM design requirements provide the starting point for developing the aerodrome certification basis – the requirements for which the aerodrome is to comply with to achieve certification. The DASDRM aims to cater for most Defence capability needs, although supplementation or tailoring may be needed for niche capabilities on an aerodrome.

(b) Aerodrome design requirements are identified in Defence Aviation Safety Design Requirements Manual DASDRM), Section 6 as follows:

Aerodrome Type	Applicable DASDRM Chapter	Primary (Aerodrome) Design Standard
Land based aerodromes	Section 6, Chapter 2	Civil Aviation Safety Authority (CASA) Part 139 (Aerodromes) Manual of Standards 2019 (Part 139 MOS) (September 2019), including the MOS Part 139H - Standards Applicable to the Provision of

Superseded

Aerodrome Type	Applicable DASDRM Chapter	Primary (Aerodrome) Design Standard
		Aerodrome Rescue and Fire Fighting Services (MOS Part 139H) (January 2005).
Land based heliports	Section 6, Chapter 3	International Civil Aviation Organisation (ICAO) Annex 14 Aerodromes Volume 2 Heliports (July 2020); and Unified Facility Criteria 3-260-01 Airfield And Heliport Planning And Design (to provide necessary militarisation)
Shipborne heliports	Section 6, Chapter 4	Australian Defence Force Maritime Materiel Requirements Set - DEF (AUST) 5000 - Volume 11 Ship Aviation Requirements (November 2017) for the Royal Australian Navy (RAN).

Table 1: Aerodrome Requirements as per DASDRM

(f) Systems and functions covered by the design requirements include:

1. physical characteristics of movement facilities
2. aircraft arresting systems, and recovery assist systems for shipborne heliports
3. obstacle restrictions and limitations

Superseded

4. visual aids provided by aerodrome markings, markers, signals, wind direction indicators, and so on

5. visual aids provided by aerodrome lighting

6. Communication, Navigation, Surveillance (CNS) and Meteorological (MET) facilities

7. earthing points

8. aircraft tie-down facilities

9. radio communication facilities

10. Aerodrome Rescue and Firefighting (ARFF) requirements.

(g) DASA prescribes design requirements for aerodrome systems and functions that are necessary to support safe flight at Defence aerodromes. The design requirements are within the DASDRM Section 6.

(h) Design requirements are separately prescribed for Defence aerodromes primarily used for fixed wing operations, land based heliports and shipborne heliports. DASA provides advice on interpreting the design requirements.

Superseded

13. Independent Reviews of Aviation Safety

13.1 Introduction

13.1.1 Joint Directive 21/2021 – *The Defence Aviation Safety Framework* prescribes the requirement, amongst other elements, for the establishment of a Defence Aviation Safety Program (DASP) within the Defence Aviation Safety Framework (DASF).

(a) The defined elements of the DASF are:

1. an individual accountable to the Defence diarchy for safety of Defence Aviation, namely the Defence Aviation Authority (Defence AA)
2. a Military Aviation Authority (MAA) within Defence aligned to ICAO constructs known as the Defence Aviation Safety Authority (DASA)
3. an ongoing program of work that assures Defence Aviation Safety, known as the Defence Aviation Safety Program
4. a published set of Defence Aviation Safety Regulations (DASR) that apply to the Defence Aviation system
5. an accident and incident investigative capability, independent of our Australian ICAO State (civil) aviation accident and incident investigative body.

13.1.2 In support of DASP oversight activities, the Defence AA convenes independent boards of review to examine, and make recommendations on, the safety of Defence Aviation activities. Otherwise known as Airworthiness Boards (AwB), these boards complement—but do not replicate—the regulatory and investigative functions of DASA. Importantly, they remain independent of Command and the broader Defence Aviation enterprise and report their findings and recommendations direct to the Defence AA.

13.1.3 In complementing DASA, the boards aim to improve aviation safety by reviewing the *system of systems* that supports and enables the reviewed aircraft platform or support system. Further, Airworthiness Boards assist in identifying strategic trends that may lead to one or more systems developing an unsafe condition over time. The majority of the AwB effort is apportioned to the review of extant capabilities in service.

13.1.4 Airworthiness Boards also support the process of introducing new aviation capabilities into Defence, namely Introduction-into-Service (IIS) AwBs. IIS AwBs analyse the proposed capability through the same *system of systems* lens and assess its readiness to operate and sustain through the initial period of service, after which the independent review transitions to an in-service AwB. The role of the MAA regulator in the IIS process is to assess applicant submissions for the issue of DASA Authorisations when the applicant is both meeting compliance against the regulations and meeting conformance to policy. Authorisations come in the form of certificates for products and approvals for organisations and span initial airworthiness, continuing airworthiness, flight operations and other operational approvals as necessary. The AwB will review the issuance of such Authorisations as evidence of system maturity and robustness that will form the basis of confidence in the system reported to the Defence AA. It is important to understand that the AwBs are separate to the DASA regulating function.

Superseded

13.1.5 The members chosen to conduct AwBs are senior ADF reserve officers with rich backgrounds in operational and technical disciplines, vast experience in operations, command, training, acquisition and sustainment who are able to draw on their experience to identify initial deviations or clear deficiencies that have the potential to lead to an unsafe system. Notably, they are not necessarily regulatory experts. Regulatory experts from DASA support the Board Members to interpret and understand the application of the DASR during AwBs. For the regulated community, it is important to understand this principle and the separation of roles and responsibilities within the DASP.

13.1.6 The Defence AA personally selects Board Members as trusted agents to report directly on elements of the system that are deficient or trending towards an unsafe condition. In that respect, they are able to make recommendations or identify issues with the MAA itself if they consider it necessary to do so. For administrative purposes, the Board Members are managed under a discrete part of HQ DASA, namely Aviation Safety Review within HQ DASA. A supporting staff team provided by HQ DASA directly support the Board Members in the execution of their duties. These support staff are not part of any regulatory directorate and remain at arm's length from regulatory processes.

13.2 Format

13.2.1 To adequately gain an insight into all aspects of aviation safety under consideration for a specific platform, the conduct of independent boards of review (commonly referred to as Airworthiness Boards) is divided into four distinct phases, namely:

1. Pre-board and Preparation
2. Site Visit
3. Board Conduct
4. Post-board and Reporting.

13.2.2 **Pre-board and Preparation.** The Pre-board and Preparation will vary dependent on whether the board is an in-service board or related to the introduction into service of a new Defence Aviation capability. The board consists of an operational member and a technical member at the O–7/O–8 level, with a single DASA O–4 Aviation Safety Review team Platform Coordinator supporting administration and an O–5/O–6 member as accountable coordinator/master of ceremonies.

13.2.3 For the case of an in-service board, the process is structured around the ongoing continuum of independent review that a Defence aviation capability has been subject to since its introduction. This process of review delivers a continuous narrative surrounding the Aviation Safety health of a capability, from a wide range of enabling functions including operations, initial and continued airworthiness, continuing airworthiness, logistic support, medical support and external supporting elements, which constitute the elements of fundamental inputs to capability.

13.2.4 The performance/compliance/conformance against the respective enabling functions are reported to the board using a series of checklists (reporting tools) that are authored by accountable parties[1] within those enabling functions. Included in this suite of inputs is a report of regulatory compliance and investigative reporting provided by DASA as the Military Aviation Authority. In isolation, the reports may identify weaknesses; as a sum of inputs, the reports will aggregate to provide a holistic picture. The reports also provide an indication of trends, positive or negative, during the review period. The collation of checklists/reports assists board members to identify areas of weakness and lines of inquiry to interrogate during the Site Visit and Board Conduct phases.

Superseded

13.2.5 To assist that process, DASA support staff will provide a subjective assessment/summary of the reporting, weighed up against previous reports for Board Member consideration. Until the collation of the reports, the board members will focus on historical reporting to build a picture of the capability. To assist, board members usually sit on the board of the same platform/system over consecutive review periods and changes to members are planned with a stagger of operational and technical members to ensure continuity.

13.2.6 For the case of an Introduction Into Service (IIS) board, the focus is slightly different as the capability is starting from scratch. In this case, the assigned Platform Coordinator and board members are far more involved in the process from the outset. The focus in this case is to understand how the capability has evolved from a project standpoint and to understand how it will fit into the force in being; moreover, how the introduction of a new capability will impact the broader aviation system. In this case, the board members conduct regular engagement with stakeholders up to 12 months in advance of planned In Service Date (ISD), pursuant to the relevant Stakeholder Engagement Plan. This enables the board members to provide periodic feedback, through to the formal Board Conduct phase, on the maturity of products that provides satisfaction of a supportable and sustainable system.

13.2.7 **Site Visit.** The Site Visit, conducted just prior to a board, is a critical part of the board process. It provides an opportunity for direct engagement with key stakeholders at the 'coal face' across all domains along with gaining a first-hand appreciation (through sentiment and visual cues) of the status of the capability. This is the prime opportunity to engage face-to-face with junior leadership, aircraft operators, maintenance and support staff and Industry to discuss topics in more detail than may be possible through the conduct of the formal board. From the pre-board research conducted, the board members will shape the visit to deliberately target areas of concern or observe areas of innovation that may be perceived to be at higher risk.

13.2.8 **Board Conduct.** The Board Conduct phase is the most formal part of the board process. This activity is formally recorded (both audio and written records) and runs in accordance with a set agenda in a methodical manner.

13.2.9 The board is normally conducted in a single day to minimise disruption to execution of business by the capability under review. For in-service boards, given the span and depth of information that is collated during the reporting period, it is possible that the conduct of the board could require an entire day. For less-complex capabilities, the Board Conduct process may only require a portion of the day. IIS Boards, given the continuous and regular engagement between board members and key stakeholders, are usually of reduced length and abbreviated in nature.

13.2.10 All Board Conduct activities commence with a short pre-board meeting (nominally 30 minutes) typically involving: the Board Members, MAO-AM, Senior CASG representative and the DASA senior representative, facilitated/coordinated by the O–5/O–6 accountable coordinator. This is an opportunity for the board members to announce their intent regarding the theme and key focus points of the board prior to its commencement.

13.2.11 The board itself is normally conducted at a large conference table with board members occupying the head of the table and representatives of the MAO in order of seniority down one side and the in-service agency (including Industry representation) down the other. Personnel with an interest, but not invited members, are normally seated behind the primary attendees where space allows.

13.2.12 The board members generally steer the discussion in accordance with their pre-determined lines of enquiry, but aligning to the agenda more generally. During the execution of the agenda the

Superseded

board members may point out issues of concern or notable findings that they record as Concerns, Notes and Observations.

13.2.13 At the conclusion of the board, another short meeting (nominally 30 minutes) with the same group detailed at para 10 is conducted. At this meeting, the principals discuss the Concerns, Notes and Observations that have arisen from the conduct of the board, along with any Airworthiness Board Corrective Action Requests (ACARs) that they intend to recommend to the Defence AA. The board members at that time may provide advice of their recommended review period before next board or reserve that advice for release in the Airworthiness Board Report (ABR). At the conclusion of this meeting, they return to the main forum to reiterate the same messages to the broader audience for their awareness.

13.2.14 **Post-board and Reporting.** From the minutes taken during the board, the ABR is drafted by the board members, assisted by the Platform Coordinator. Depending on the complexity of issues that arise, this process can take some time and MAOs should not be concerned nor align their schedules to any expected timeframe. Concurrent with this activity, any potential ACARs are drafted for recommendation/submission to the Defence AA.

13.2.15 Following release, the ABR is forwarded to the Office of the Chief of Air Force for attention of the Defence AA, along with any ACARs. The ABR will also include a recommended review period, which will inform scheduling of the next board. The Defence AA will read and make commentary against the report, seeking additional clarity or providing direction as required. Concurrent with this, the Environmental Commander of the capability under review is required to provide a response of no more than three pages to address any ACARs and Concerns raised by the board, with initial plans for remediation if possible. Environmental Commander responses are considered by the Defence AA separate to the ABR.

13.2.16 The post-board process does not stop following final sign-off and acceptance of responses. The Platform Coordinator within the DASA Aviation Safety Review team continues to monitor remediation actions against any ACARs to ensure progress is maintained pursuant to the remediation plan provided by the Environmental Commander. This monitoring continues until all associated staff work is completed and a logical closure of the ACAR is realised. Collective ACAR status is reported to the Defence AA quarterly and is formally reported biannually to the Defence Aviation Safety Board (DASB).

SECTION 1 - APPLICATION OF DEFENCE AVIATION SAFETY DESIGN REQUIREMENTS

CHAPTER 1 - PURPOSE, CONTENT AND STRUCTURE OF THE DEFENCE AVIATION SAFETY DESIGN REQUIREMENTS MANUAL

PURPOSE, CONTENT AND STRUCTURE OF THE DEFENCE AVIATION SAFETY DESIGN REQUIREMENTS MANUAL

INTRODUCTION

1.1 Joint Directive 21/2021 requires the Defence Aviation Safety Authority (hereinafter referred to as the Authority) to establish a Defence Aviation Safety Program which, inter alia, includes 'establishing and certifying the initial safety requirements and standards for Defence … aviation platforms/systems'. Inherent in this responsibility is the requirement for the Authority to prescribe minimum requirements for the design of Defence aircraft, engines, propellers and other aircraft-related equipment. The Defence Aviation Safety Program Manual Volume 1 requires the Authority to 'issue standards, inclusive of airworthiness codes, as required for the implementation of the DASR'. The Authority's repository for these 'standards and airworthiness codes' with respect to aircraft design for Defence aviation platforms and systems, also known as airworthiness design requirements, is the Defence Aviation Safety Design Requirements Manual (DASDRM).

1.2 This chapter of the DASDRM:

(a) describes the purpose and scope of the manual,

(b) explains the approach adopted by the Authority for prescribing airworthiness design requirements, and

(c) describes the structure of the manual.

PURPOSE AND SCOPE OF THE DASDRM

1.3 The DASDRM prescribes design requirements for aircraft systems and functions that are necessary to achieve safe flight in Defence's proposed configuration, role and operating environment. It also prescribes additional design requirements that may further improve the level of safety, and that should be implemented where reasonably practicable. In each case, the DASDRM identifies the hazard(s) that the design requirement is intended to treat, to provide a basis for informed risk management where an aircraft design fails to meet the design requirement. Airworthiness requirements for crewed aircraft are presented in Sections 2 and 3 of this manual, while Uncrewed Aircraft Systems (UAS) are covered in Section 4.

1.4 The Australian Work Health and Safety Act and the Work Health and Safety Regulations (collectively, WHS Legislation) apply to Defence aviation. Defence aircraft must therefore present a safe work environment for aircrew and passengers, and the airworthiness design requirements in this manual make a substantial contribution to this aim. By its nature, however, the concept of 'airworthiness' has a primary focus on safe flight. Consequently, airworthiness design requirements

Superseded

require supplementation if Defence is to fully meet its WHS Legislation obligations. Section 1, Chapter 2 of this manual expands on this important concept.

1.5 Similarly, capability and interoperability is not a specific consideration when establishing that an aircraft is capable of safe flight. However, robust design for capability and interoperability contributes to mission success, and therefore the safety of aircrew. Consequently, while capability and interoperability design requirements are not a primary focus of the DASDRM, design requirements that support capability and interoperability outcomes are included where appropriate. Section 1, Chapter 4 describes how capability and interoperability design requirements are incorporated into the DASDRM.

1.6 Finally, while the DASDRM focuses primarily on aircraft, it recognises that some off-aircraft systems (eg Mission Planning Systems, Health and Usage Monitoring Systems and aerodrome installations) can have a direct and substantial impact on safe flight. While these ground based systems clearly are not within the scope of airworthiness, they are relevant to the broader context of aviation safety and the Authority may therefore elect to prescribe relevant design requirements. These requirements are presented in Section 5 of the DASDRM for aviation support systems and Section 6 for aerodromes.

Design requirements and design standards

1.7 This chapter, and the remainder of the DASDRM, refers to both 'design requirements' and 'design standards', which may appear to the reader to be interchangeable. This is often, but not always, the case. The latter specifically refers to a standard published by a civilian or military standards body, for example a US MIL STD or an RTCA standard. Airworthiness design requirements, on the other hand, define the safety outcome being pursued. This can be achieved via a worded requirement (eg "PVC wiring must not be used in Defence aircraft") or via reference to a design standard.

PRESCRIBING AIRWORTHINESS DESIGN REQUIREMENTS

1.8 The Authority employs three foundational principles when prescribing airworthiness design requirements for Defence aircraft:

(a) the Authority recognises the airworthiness design requirements prescribed by several civil and military National/Military Airworthiness Authorities (NAAs/MAAs) as providing a sound foundation for the safe design of Defence aircraft;

(b) the Authority may prescribe supplementation to these airworthiness design requirements, where an aspect of a requirement is judged deficient or to support application to Defence's unique role and operating environment; and

(c) the Authority requires the conduct of a System Safety Program, to provide a robust means for identifying and analysing aircraft hazards during the design process, and for eliminating or minimising the resultant risks so far as is reasonably practicable.

1.9 These three foundational principles are examined in the following sections.

Superseded

1.10 Many NAAs/MAAs prescribe airworthiness design requirements for achieving safe flight through aircraft design (DASR 21 refers to these airworthiness design requirements as 'Airworthiness Codes'). An Airworthiness Code is a complete and consistent set of airworthiness design requirements that define those attributes of aircraft systems or equipment that underpin safe flight. Airworthiness design requirements are usually prescribed by civil NAAs based on aircraft types. For example, both the USA Federal Aviation Administration (FAA) and the European Aviation Safety Agency (EASA) prescribe separate suites of airworthiness design requirements for light and heavy fixed wing aircraft, and light and heavy rotorcraft.

1.11 The development and maintenance of an Airworthiness Code is a substantial undertaking. Rather than define a Defence-unique Airworthiness Code, the Authority has elected to recognise the suite(s) of airworthiness design requirements (ie Airworthiness Codes) prescribed by several other NAAs and MAAs that have been demonstrated through extensive operating history to achieve safe flight, and then prescribe supplementation as required. The Authority recognised 'Airworthiness Codes' are described in Section 1 Chapter 3 of this manual.

Supplementation of NAA Airworthiness Design Requirements

1.12 The Authority recognised Airworthiness Codes will inevitably require supplementation to account for:

(a) Defence's unique Configuration, Role and/or operating Environment (CRE);

(b) deficiencies in the level of safety provided by the airworthiness design requirements prescribed in the Code, detected by the Authority through local research or experience (eg investigations into aircraft incidents); or

(c) intentional ambiguities within the airworthiness design requirements, where it is assumed that tailoring will be required to meet the needs of the specific application.

1.13 Not all elements of aircraft design covered in Authority recognised Airworthiness Codes will require supplementation. Where supplementation or tailoring of an Airworthiness Code is required, the airworthiness design requirements prescribed by the Authority are contained in this manual. The expectation is that these airworthiness design requirements will be applied in a practical and pragmatic manner. To support their pragmatic implementation, the Authority has classified each airworthiness design requirement as either 'Essential' or 'Recommended'.

1.14 **Essential and Recommended airworthiness design requirements.** The Authority classifies each airworthiness design requirement as either Essential or Recommended, using the following criteria:

(a) **Essential -** an Essential airworthiness design requirement is one where non-compliance would result in a marked reduction in the level of safety afforded by the design. Essential design requirements may also be defined to satisfy legislation, and Defence policy and/or operational regulation requirements.

(b) **Recommended -** a Recommended airworthiness design requirement represents emerging aviation industry 'good practice' that is not yet widely accepted/implemented, or presents an opportunity to increase the level of safety afforded by the design (usually above that provided in Airworthiness Codes).

Superseded

1.15 While Essential airworthiness design requirements define the level of safety that must be achieved by a design, they are not immutable. The Authority, in consultation with the relevant capability manager where applicable, may approve an alternative airworthiness design requirement in the following circumstances:

(a) where analysis confirms the alternative design requirement achieves an equivalent level of safety;

(b) where analysis shows the alternative design requirement, supplemented by operational risk treatments, should achieve an equivalent level of safety; or

(c) where enforcing the Essential design requirement would have a marked negative effect on capability or cost, and an alternative (but less safe) design requirement is in Defence's best interests.

1.16 On occasion the Authority may, in consultation with the capability manager, agree to an alternative design standard that does not satisfy the Authority agreed safety criteria, where meeting the prescribed standard would have a pronounced impact on Defence capability and is not in Defence's best interest. In these circumstances, a tailored design standard could be agreed to contextualise the level of safety afforded by the design for the military role and operating environment of the aircraft. Any proposed tailoring of design standards by an applicant for type certification and/or design approval from the Authority, which results in changes to agreed safety criteria, must be supported by documented rationale that includes:

(a) the capability manager's confirmation that a clear (well-defined) and documented capability imperative for the proposed tailoring exists;

(b) the applicant's confirmation that compliance with the prescribed standard impedes that capability imperative;

(c) the applicant's characterisation of the delta between the prescribed standard and the tailored standard;

(d) the applicant's, with the assistance of the capability manager (or delegate), characterisation of the risk due to this delta; and

(e) the capability manager's (or delegate's) formal conclusion that the tailored safety criteria presents a credible and defensible level of safety for that Defence aircraft, contextualised for ADF operations.

1.17 Once the preceding outcomes have been confirmed, a Military Certification Review Item (MCRI) will be raised by the applicant to reflect the agreed tailoring including any essential risk controls to achieve the defined level of safety.

1.18 Given the nature of Recommended design requirements, their adoption is not mandated by the Authority. Nevertheless, the recommended requirements may assist duty holders to satisfy obligations under WHS legislation for eliminating or minimising risk SFARP. Consequently, the 'designer', in conjunction with the 'sponsor'[1] as a shared duty holder, should determine if adoption of a recommended requirement is reasonably practicable by assessing the improvement in the level of safety afforded by the recommended design requirement against the likely cost(s) of implementation.

Superseded

1.19 Compliance with design standards is the principal means by which safe design of an aircraft is achieved. However, in isolation, a standards-based approach may not provide a complete basis for Type Certification of an aircraft. After all, many standards are inherently stove-piped, and therefore further analytical effort is required to identify and control system-level hazards. Further, standards are often written with 'vanilla' applications in mind; novel aircraft design features are likely to pose novel hazards, which are not catered for within the standard.

1.20 System Safety is an engineering discipline that embraces safety as a core aspect of any given system design (or design change). System safety programs employ a suite of engineering tools and techniques to identify and analyse aircraft hazards during the design process, and provide a management framework to evaluate and control the resultant risks. When applied well, a system safety program is an essential adjunct to a standards-based design approach.

1.21 Formal system safety programs are required for all Defence aircraft acquisitions and Major changes to a type design. The Authority's requirements for System Safety programs are presented in Section 2 Chapter 2 of this manual.

MANUAL STRUCTURE

1.22 This manual comprises the following six sections:

(a) **Section 1 – Application of Airworthiness Design Requirements.** This section defines the purpose and scope of the DASDRM and defines the Airworthiness Codes that have been recognised by the Authority as providing a sound foundation for the design of Defence aircraft. It also describes the extent to which airworthiness design requirements contribute to Defence meeting its WHS Legislation obligations. Finally, Section 1 describes the application of capability and interoperability standards to aircraft designs.

(b) **Section 2 – Integrated Design Requirements.** This section prescribes airworthiness design requirements for those engineering disciplines that pervade most aspects of aircraft systems design or affect multiple systems such as system safety, electromagnetic environmental effects and crash protection.

(c) **Section 3 – Aircraft System Design Requirements.** This section prescribes airworthiness design requirements for aircraft systems such as communications, navigation, structures (fixed and rotary wing) and propulsion. The only systems included in this section are those where the Authority recognised Airworthiness Codes do not provide satisfactory coverage for Defence aircraft designs.

(d) **Section 4 – Uncrewed Aircraft Design Requirements.** This section prescribes airworthiness design requirements for UAS.

(e) **Section 5 – Aircraft Support Systems.** This section prescribes design requirements for aircraft support systems and ground based equipment, where the systems/equipment have a direct and substantial effect on safe flight, such as aeronautical life support equipment and mission planning systems.

(f) **Section 6 – Aerodrome Design Requirements.** This section prescribes airworthiness design requirements for Defence aerodromes and heliports.

WHS LEGISLATION AND AIRWORTHINESS DESIGN REQUIREMENTS

INTRODUCTION

2.1 When operating, Defence aircraft can present a hazard to aircrew, other aircraft occupants, and persons near or under the aircraft flight path. While stationary, Defence aircraft can present a hazard to maintenance and other ground personnel. The Australian Work Health and Safety Act and the Work Health and Safety Regulations (collectively, WHS Legislation) apply to Defence aviation, and therefore Defence has a legal obligation to ensure the health and safety of these persons. The design of the Defence aircraft can, in part, contribute to Defence satisfying this legal obligation, for example:

(a) The aircraft design can promote a safe airborne workplace for aircrew and other occupants through:

1. reducing the likelihood of a catastrophic in-flight mishap,
2. improving crash survivability for aircraft occupants,
3. implementing design controls for in-aircraft hazards that might injure aircraft occupants, and
4. implementing design controls for in-aircraft hazards that might affect the future (post-flight) health of aircraft occupants.

(b) The aircraft design can promote the safety of persons near or under the aircraft flight path through:

1. reducing the likelihood of a catastrophic in-flight mishap, and
2. reducing the ground impact energy (mainly relevant to uncrewed aircraft).

(c) The aircraft design can promote the safety of persons in close proximity to a stationary aircraft through:

1. implementing design controls for aircraft hazards that might injure ground personnel,
2. implementing design controls for aircraft hazards that might affect the future health of ground personnel, and
3. incorporating aircraft maintenance instructions that identify reasonably foreseeable hazards to maintenance personnel and present safe maintenance practices.

2.2 Airworthiness, by its nature, focuses primarily on an aircraft's suitability for flight, and consequently airworthiness design requirements have a similar focus. Airworthiness design requirements will therefore make a substantial contribution to those elements in paragraph 2.1 that are directly related to suitability for flight, but a lesser, or perhaps no, contribution to the remainder. For designers to execute their statutory responsibilities under the WHS Act (for example as required under Sections 22 and 24), they must comprehensively understand the contributions and limitations

Superseded

of airworthiness design requirements in ensuring the health and safety of persons affected by Defence aircraft.

2.3 This chapter examines the extent to which Airworthiness Codes, supplemented by the airworthiness design requirements in Sections 2 and 3 of this manual, can contribute to Defence's statutory obligation to ensure the health and safety of persons affected by Defence aircraft. It also suggests how airworthiness design requirements might be supplemented to further discharge this obligation.

THE LIMITATIONS OF AIRWORTHINESS CODES

2.4 Airworthiness Authorities, both civil and military, commonly define 'airworthiness' in terms of an aircraft's suitability for flight. Consequently, the civil and military Airworthiness Codes presented in Section 1 Chapter 3 of this manual focus firmly on achieving safe flight and landing (ie achieving an airworthy aircraft). At face value, this limited scope appears to address only a small subset of the hazards an aircraft could present to the health and safety of occupants. However, this is not necessarily the case. Airworthiness Codes can and do 'incidentally' promote the wider health and safety of aircraft occupants, while aircraft maintenance data can promote the safety of personnel on the ground. This section expands on these concepts, and identifies the health and safety delta that Duty Holders under the WHS Act must address.

Health and safety of aircraft occupants

2.5 The Airworthiness Codes in Section 1 Chapter 3 of this manual, when supplemented by the airworthiness design requirements in Sections 2 and 3, will substantially ensure the risk to occupants due to a catastrophic aircraft failure and subsequent ground impact, is minimised so far as is reasonably practicable. This is because the Codes and Authority prescribed supplementation are regularly reviewed and updated to reflect contemporary aviation industry benchmark requirements. As such, compliance with the associated design standards when coupled with a System Safety program contributes to satisfying a Duty Holder's responsibility to exercise knowledge of risks and ways of eliminating or otherwise minimising those risks.

2.6 Airworthiness Codes also recognise that properly functioning aircrew are an essential contributor to an airworthy aircraft. Consequently, they include design requirements that protect aircrew from a wide range of injuries, such as electric shock, burns, hypoxia, and so on. Fortuitously, design requirements for crash protection also contribute to protecting aircrew from injuries, since they require effective seatbelts (which can also protect from harm due to turbulence), an absence of sharp protrusions that might impede emergency egress (which protects aircrew during normal operations), restraint of items of mass (which also protects against harm due to movement of these items while airborne), and so on. Summarised, modern civil and military Airworthiness Codes make a substantial contribution to Defence's confidence that the risk to aircrew of injury is minimised so far as is reasonably practicable.

2.7 The protection of other aircraft occupants from injury, on the other hand, is less straightforward. In civil Airworthiness Codes, the protection of passengers from injury is still covered, albeit several design requirements are less rigorous for passengers (for example, harness seatbelts are not a requirement for passengers, there are different oxygen supply requirements for passengers, and so on). Despite these minor differences, however, modern civil Airworthiness Codes will normally cater well for the protection of passengers from injury. Military Airworthiness Codes, on the other hand,

Superseded

can be less prescriptive for passengers and more open to tailoring to meet capability requirements, so the protection of passengers from injury is not necessarily well covered.

2.8 Summarised, aircraft meeting the design requirements of this manual provide a substantial contribution to Defence's confidence that the risk of injury to aircrew will satisfy WHS Legislation requirements. Similar confidence is obtained for the risk of injury to passengers where civil Airworthiness Codes are employed, but supplementation may be needed for military Airworthiness Codes.

2.9 Readers will note some equivocation in paragraphs 2.5-8 as to whether aircraft meeting the design requirements in this manual will comprehensively satisfy Defence's statutory obligations to ensure the safety of aircraft occupants during flight. This equivocation is necessary because the Authority-prescribed reputable standards are not the only consideration when concluding the risks inherent in an aircraft design have been minimised so far as is reasonably practicable. Additional considerations are examined in annexes A and B. Furthermore, for a risk to be minimised so far as is reasonably practicable, there must be effective consultation, coordination and cooperation on risks between all concurrent Duty Holders.

2.10 The preceding paragraphs focused on the protection of aircrew and other occupants from injury (ie an immediate ill effect while the aircraft is in operation), because this is the purview of airworthiness. Airworthiness, and therefore Airworthiness Codes, normally will not cover the future ill effects to the health of aircrew and other occupants, for example due to:

(a) chemical hazards (eg carcinogenicity, gradual toxicity, etc);

(b) biological hazards;

(c) physical hazards (eg long-term effects of aircraft vibration);

(d) ergonomic hazards;

(e) personnel radiation hazards;

(f) acoustic hazards; and

(g) other hazards that may have a future ill effect on the health of aircrew and other occupants.

2.11 Consequently, Duty Holders will need to prescribe additional design requirements that specifically address future effects to the health of aircraft occupants. Guidance on this issue is presented later in this chapter.

Health and safety of persons near or under the aircraft flight path

2.12 The design of an aircraft can promote the safety of persons near or under the flight path through reducing the likelihood of a catastrophic in-flight mishap (and consequently ground impact), and reducing the ground impact energy. Neither will be specifically covered in this chapter, since the former is well covered through assuring the safety of aircraft occupants, while the latter is mostly unique to uncrewed aircraft (see Section 4 of this manual).

Superseded

2.13 Stationary aircraft can present a hazard to aircraft maintenance personnel and other personnel in close proximity to the aircraft. The design of an aircraft can promote the health and safety of these people through:

(a) an absence of hazards that might cause injury (eg sharp edges, protrusions, unprotected hot surfaces, etc);

(b) an absence of hazardous materials that might cause future ill effects to health; and

(c) the Authorised Maintenance Data accompanying the aircraft design can identify significant hazards to maintenance personnel and present sensible maintenance practices.

2.14 None of these outcomes is within the scope of 'airworthiness'. Consequently, Duty Holders will need to prescribe additional design requirements that specifically address these issues. Guidance is presented in the next section.

GUIDANCE ON PRESCRIBING ADDITIONAL DESIGN REQUIREMENTS (BEYOND AIRWORTHINESS DESIGN REQUIREMENTS)

2.15 There are many hazards to aircraft occupants and people on the ground that are not within the purview of 'airworthiness'. Consequently, additional design requirements must be prescribed, and analyses completed, if Defence is to meet its statutory obligations for new aircraft. The remainder of this chapter provides guidance to Duty Holders on prescribing additional design requirements, beyond those dedicated to airworthiness, to ensure the health and safety of affected persons.

Health and safety of aircraft occupants

2.16 Paragraph 2.10 of this chapter concluded that airworthiness design requirements do not satisfactorily address the future effects on the health of aircraft occupants. Where Defence is acquiring off-the-shelf aircraft, annex B provides guidance to Duty Holders on how to ensure future health risks are eliminated or otherwise minimised so far as is reasonably practicably. Where Defence is acquiring developmental aircraft, the 'Air Force Work Health and Safety Management System' including relevant best practice standards detailed in the Air Force Safety Manual may be used to derive additional design requirements for the aircraft. Further advice may be obtained from specialist Defence agencies with WHS domain expertise, including:

(a) the Defence Work Health and Safety Branch,

(b) HQAC A9 – Air Force Safety (AFS), and

(c) the Institute of Aviation Medicine (AVMED).

2.17 System Safety and WHS. A common, but potentially incorrect, proposition is that Defence's WHS responsibilities will be satisfied if an aircraft System Safety Program (SSP) has been established. While a SSP can make a positive contribution to achieving an aircraft design that satisfies statutory requirements, it is by no means automatically comprehensive. Positive contributions can include the following:

(a) SSPs should implement an enduring system for recording and managing hazards, which is a statutory requirement.

Superseded

(b) Some SSPs can include tools for identifying hazards to personnel, for example the Operating and Support Hazard Analysis (OSHA) and Health Hazard Analysis (HHA) tasks in MIL-STD-882.

(c) SSPs can impose an 'order of precedence' for treating hazards, and many of these will satisfy the WHS Legislation's 'hierarchy of controls'.

2.18 However, consider the following:

(a) System safety programs will normally assume that hazards are acceptable when their likelihood and/or consequence is sufficiently low, or in some cases where residual risk has been retained at an appropriate level. This approach is quite different to the requirements of the WHS legislation, which expects risks will be eliminated, or if this is not reasonably practicable, then the risk will be minimised so far as is reasonably practicable. Furthermore, this risk minimisation should iteratively continue until the cost of further risk minimisation is grossly disproportionate to the benefits, regardless of the residual 'risk level'.

(b) The usual SSP tools such as OSHA and HHA merely provide a framework and some general guidance for identifying WHS hazards; application of these tools does not inherently result in the identification or effective management of all hazards.

(c) The WHS benchmarks defined in overseas SSP documents (including the MIL-STD-882 OSHA and HHA) are relevant to their local statutory requirements and policies. These will certainly be different to Australian WHS Legislation and Defence WHS policies.

2.19 Summarised, an aircraft SSP can make a contribution to Defence meeting its statutory responsibilities, but only if it has been specifically designed to achieve this.

Health and safety of persons near stationary aircraft

2.20 Paragraphs 2.13-14 of this chapter concluded that stationary aircraft can present hazards to aircraft maintenance personnel and other personnel in close proximity to the aircraft, but these hazards are not addressed by airworthiness design requirements. Paragraph 2.16 presented guidance to Duty Holders for achieving an aircraft design that satisfies statutory obligations, and that guidance is equally relevant here.

2.21 Duty Holders should also produce Authorised Maintenance Data for the aircraft that contributes to the health and safety of maintenance personnel by identifying hazards and promoting safe maintenance practices. This can be particularly complex to achieve, since it requires a holistic assessment of the compatibility of the ICA processes with Defence maintainer training, local maintenance processes, maintenance policy, WHS Legislation, and so on. The information presented in the Air Force Safety Manual may assist Duty Holders in this endeavour.

FURTHER INFORMATION

2.22 As indicated previously in this chapter, airworthiness design requirements help Defence meet its statutory obligations. However, airworthiness design requirements focus primarily on the suitability for flight of an aircraft, whereas aircraft can present many hazards outside of this narrow scope. Consequently, additional design requirements will need to be prescribed. Further guidance on these additions should be sought from Defence's WHS specialist organisations, including the Defence Work Health and Safety Branch and HQAC A9 – Human Performance and Safety.

ANNEXES

ANNEX A - EXERCISING 'REASONABLE KNOWLEDGE' IN AIRCRAFT DESIGN

EXERCISING 'REASONABLE KNOWLEDGE' IN AIRCRAFT DESIGN

BACKGROUND

1. A key element of the WHS Legislation is the requirement for risks to be eliminated so far as is reasonably practicable (SFARP) or, where this is not reasonably practicable, for the risks to be minimised SFARP. In aircraft design, eliminating risks is often impractical. Consequently, minimisation of risk so far as is reasonably practicable is often necessary to satisfy Defence's statutory responsibilities.

2. In determining whether a risk control is reasonably practicable the WHS Legislation requires a duty holder to take into account 'what the person concerned knows, or ought reasonably to know, about: (i) the hazard or the risk; and (ii) ways of eliminating or minimising the risk.'[1]

3. Reasonable knowledge (ie what a person ought reasonably to know) of risks can be gained in multiple ways. The Safe Work Australia interpretive guideline, Model Work Health and Safety Act The Meaning of 'Reasonably Practicable', expands the concept of what a person ought reasonably to know (their 'state of knowledge') and includes the following sources of knowledge, among others, that are relevant to designers in the aviation context:

(a) reputable standards;

(b) consulting workers and others in the industry;

(c) industry publications, and scientific and technical literature;

(d) analysing previous incidents; and

(e) relevant WHS Regulations and 'codes of practice'.

4. This annex examines the contribution of each of these sources of knowledge to satisfying a designer's responsibility to exercise reasonable knowledge in aircraft design. This annex does not consider whether the identified sources of reasonable knowledge contribute to, or satisfy, a designer's broader statutory responsibilities with respect to WHS (eg ensuring the health and safety of maintenance personnel) unless directly relevant to aircraft design considerations.

REPUTABLE STANDARDS

5. A major source of knowledge of risks and associated controls in aircraft design is reputable standards. Standards applicable to aircraft design have been iteratively developed over many decades of civil and military aviation experience and represent the current state of knowledge for aircraft designers. Standards, including associated guidance material (eg Advisory Circulars, guidebooks, and so on), that are recognised by National/Military Airworthiness Authorities (NAAs/MAAs) and are employed within an appropriate context, have the potential to constitute 'reputable standards'.

6. The Authority promulgates reputable standards for Defence aircraft design in the DASDRM. The standards are drawn from the following sources, sometimes with supplementation to overcome known deficiencies:[2]

Superseded

(a) standards prescribed by Authority recognised NAAs/MAAs (ie Authority recognised Airworthiness Codes);

(b) standards issued by standards bodies that are widely accepted within civil/military aviation; and/or

(c) standards prescribed by legislation (either Commonwealth or State) that are applicable to Defence aviation.

7. However, it is not sufficient for designers to assume they have exercised reasonable knowledge simply because they have applied a standard extracted from this publication. The remainder of this section is dedicated to helping designers understand how the standards in this publication must be applied if they are to constitute reasonable knowledge.

Context is key

8. When an aircraft standard is created, the authors will inevitably have a particular context in mind. For example, the authors might assume the primary customer is civil aviation, and therefore the standard might be particularly relevant to the flight profiles and operating environments experienced by civil operators. Where Defence operates an aircraft in a more challenging way, it may invalidate some assumptions made by the authors.

9. Consequently, a standard in this publication can only contribute to reasonable knowledge to the extent that the application is relevant to the particular Defence aircraft. While Sections 2 and 3 of this publication provide some guidance on common areas where Defence's operating environment often differs from that assumed in a standard, this is by no means comprehensive. Even minor differences in configuration, role and operating environment (CRE) between the intended or assumed application of a reputable standard and those applicable to the Defence aircraft may reduce the standard's relevance and therefore limit its contribution to reasonable knowledge.

10. Professional judgement and experience is paramount in identifying such deltas. A robust CRE analysis and System Safety Program (SSP) will often assist designers in ensuring that the context adopted by/assumed in the reputable standard is consistent with the Defence context.

11. The following sections provide guidance in applying the standards prescribed in this publication and evaluating the correctness of their context.

PARTICULAR APPLICATIONS OF DASDRM REPUTABLE STANDARDS

12. **New Defence aircraft**. Section 1 describes the approach adopted by the Authority to recognising Airworthiness Codes issued by civil and military Airworthiness Authorities. The Authority has assessed these Codes[3] as providing a sound foundation for the safe design of Defence aircraft, and has supplemented the design requirements in the Codes with additional design requirements where necessary. The DASDRM consequently defines the Authority approved reputable standards for new Defence aircraft certifications.

13. Where a new Defence aircraft design is verified as complying with the reputable standards defined in this publication, a designer could sensibly conclude that potential risks, and ways of eliminating or minimising those risks, have been identified and the risk has therefore been minimised so far as is reasonably practicable. Such a determination should only be made where the designer has also confirmed that the context under which the standards were intended to be applied is consistent with the Defence aircraft context (refer to paragraphs 8 through 10).

Superseded

14. Some Authorities, however, allow the application of standards 'grandfathering' to reduce aircraft design and production costs. Grandfathering permits, in some circumstances, the use of older standards for new designs if the aircraft is based on a previously certified design. The adoption of older standards under this 'grandfathering' approach will not always provide the level of safety afforded by newer standards.

15. Designers cannot automatically assume that grandfathered standards represent 'reputable standards' for Defence aircraft design, since they are knowingly adopting outdated standards. On the other hand, grandfathering of standards is permitted (within limits) by major airworthiness authorities, and has been employed successfully for decades. Consequently, a Defence prohibition on grandfathering would be contrary to common well-established aviation industry practice (refer paragraphs 30 to 42). For a designer to confirm that risks have been minimised so far as is reasonably practicable, the concepts of adopting current reputable standards and confirming the adequacy of grandfathered standards must be merged. Consequently, where a Defence civil-derivative aircraft has the same configuration as their civil equivalent, and operates in a substantially similar role and environment, designers should:

(a) identify the delta between the grandfathered standard and the current version;

(b) establish whether any amended/additional requirements in the current standard would markedly improve the level of safety;[4] and

(c) if so, critically examine whether the cost of adopting the updated standard is grossly disproportionate to the benefit.

16. **Major design changes[5] to Defence aircraft.** Comprehensive application of the standards in this publication to Major changes to an aircraft type design inherently constitutes the application of reputable standards, provided the context of use is appropriate. However, common practice among Authority recognised civil Airworthiness Authorities is to not apply the latest airworthiness design requirements to a major design change where:

(a) the change is not significant (eg the general principles of construction and/or configuration is retained; the assumptions used to originally certify the design remain valid); or

(b) the change does not affect a system, component, equipment or appliance to which the previous iteration of the design requirements was applied; or

(c) implementation of the updated requirements is determined to not materially contribute to the level of safety or would be impractical (ie the application of the updated reputable standard is not reasonably practicable).[6] [7]

17. In these cases, provided the new design still meets the aircraft's type certification basis (TCB), it is accepted as sufficient by most civil airworthiness authorities. This approach is such common practice amongst civil airworthiness authorities, that it can be considered a benchmark for reasonable practice (and therefore reasonable knowledge).

18. Consequently, for Major changes to Defence aircraft type design, the modified aircraft must continue to satisfy the airworthiness design requirements prescribed in the approved aircraft TCB as a minimum. However, more recent versions of airworthiness design requirements should be evaluated to determine whether compliance with the later version would contribute materially to the level of safety afforded by the design and would be practicable to implement[8]. It is the determination of

Superseded

whether an updated standard 'materially contributes to the level of safety' and is practicable to implement that is often the most contentious issue faced by designers.

19. To establish whether an updated standard should be applied to a major change to type design, designers should:

(a) identify the differences between the standard defined in the aircraft's TCB and the updated standard, which define improved safety outcomes;

(b) assess the safety benefit that would be achieved by complying with the updated standard for the Defence aircraft CRE;

(c) identify the costs associated with complying with the updated standard (costs will include delays in incorporation of the change, impact on capability, additional funding, impact on training and so on); and

(d) based on this information, apply professional engineering judgement to determine whether compliance with the updated standard is reasonably practicable.

20. **Minor design changes to Defence aircraft.** Common aviation industry practice is to require that all Minor changes to aircraft designs comply only with the airworthiness standards defined in the aircraft's TCB. That is, there is no requirement to consider the most recent version of standards for Minor changes. The issue is whether these often superseded standards afford a level of safety that would not be materially improved through the application of an updated standard.

21. By definition, minor design changes should have, at most, a minor effect on aircraft safety. Consequently, Airworthiness Authorities accept that it is very unlikely that an updated standard would make a material contribution to aircraft safety. Such an approach is equally relevant to Defence aircraft. Nevertheless, designers should establish whether the standards applicable to a minor design change have been updated and apply normal professional engineering judgement to identify where updated standards should be applied. Note that, while the DASDRM occasionally identifies issues that warrant additional consideration for minor modifications to assist designers in applying professional judgement, the inclusions are by no means comprehensive[9].

22. **Tailoring of DASDRM standards.** Some reputable standards may inherently require tailoring to accommodate a specific aircraft context. Others may permit tailoring of some requirements to suit a particular aircraft role or operating environment. In these cases, a simple reference to the standard in the aircraft TCB is not sufficient to articulate the scope of the reputable standard applied and clarification of the scope and level of tailoring is required. Tailoring of standards may inadvertently remove requirements that are fundamental to the standard being considered a reputable standard. Therefore, designers should ensure that any tailoring of reputable standards does not remove key elements that underpin the level of safety afforded by application of the standard.

23. In some circumstances, the Authority has determined that certain requirements cannot be tailored out or that specified performance levels must be achieved for particular elements of a standard, and has included these requirements in this publication. However, the Authority's evaluation of potential tailoring of standards is not comprehensive and, therefore, additional tailoring may be appropriate depending on the design context. Prior to adopting tailoring of a standard, designers should ensure that the tailoring:

(a) only removes requirements that are not applicable to the Defence aircraft configuration, role and operating environment;

Superseded

(b) does not remove or reduce benchmark performance criteria or characteristics inherent in the standard (ie those upon which the standard relies to achieve the defined level of safety); and

(c) is compatible with the Defence aircraft role and operating environment.

24. Where doubt regarding the suitability of tailoring exists, the Authority should be petitioned for a determination on the proposed tailoring (Section 1 Chapter 1 of this publication provides further guidance).

REPUTABLE STANDARDS NOT INCLUDED IN THE DASDRM

25. Authority prescription of design requirements, which underpin the reputable standards defined in the DASDRM, is based on the following:

(a) a clear understanding of the relevance of the requirement to achieving safe flight for the Defence CRE;

(b) revising the requirement to reflect contemporary knowledge, based on monitoring advances by others (eg NAA/MAA, OEMs) and through local research (eg DSTG); and

(c) interpreting the requirement to assess the adequacy of alternative means of compliance, approve proposed tailoring and characterise risks due to any shortfalls in compliance.

26. In some cases, the Authority will hold the required expertise to prescribe and interpret design requirements in house or can quickly gain the expertise if needed. However, the expertise for some complex design disciplines/technologies is resident elsewhere in Defence; in those cases, the Authority may elect to delegate this responsibility to a particular Defence individual, who will normally be designated as a Standards Delegate of the Safety Authority (DoSA).

27. Occasionally, designers may identify potential 'reputable standards' that the Authority has not yet included in the DASDRM. These 'reputable standards' must be evaluated by a suitable subject matter expert to confirm that their adoption is appropriate for Defence aircraft designs. Where a designer considers that a standard not currently recognised by the Authority warrants inclusion in the Authority defined reputable standards in this manual, the designer should petition the Authority, or relevant Standards DoSA, for approval to use the standard.

RETROSPECTIVE APPLICATION OF UPDATED STANDARDS

28. Changes to reputable standards that occur after an aircraft is introduced into service may identify new ways of eliminating or reducing risks. Such changes could undermine the determination that risks to Defence aircraft safety have been minimised so far as is reasonably practicable.

29. Within the aviation industry, NAAs/MAAs hold broad responsibility for identifying and prescribing any changed reputable standards to which in-service aircraft must comply. Similarly, the Authority monitors changes to reputable standards defined in the DASDRM and evaluates the changes to determine whether their retrospective application to Defence in-service aircraft is warranted. Nevertheless, the actions of the Authority do not absolve designers from determining if retrospective application should be pursued. After all, designers have access to sources of information that are not necessarily available to the Authority, including OEMs, international operators, collaboration forums, and so on. Consequently, designers should monitor changes to reputable standards that are specific to the design they are responsible for, and confirm that retrospectivity of such changes is not reasonably practicable or take action to achieve compliance.

CONSULTING WORKERS AND OTHERS IN THE INDUSTRY

Superseded

30. Designers can gain knowledge of risks in aircraft design through consultation with aircrew and maintenance personnel, or through engagement with aviation industry organisations, aviation domain SMEs and aircraft manufacturers and designers. This section discusses the contribution of such consultation in developing a designer's 'state of knowledge' of risks, and ways of eliminating or reducing those risks, in aircraft design.

CONSULTING AIRCRAFT OPERATORS AND MAINTENANCE PERSONNEL

31. Aircraft operators and maintenance personnel provide designers with insight into risks that may be present in aircraft designs, particularly with regard to human-machine interface and procedural issues. Designers should consult with operators and maintenance personnel when developing Defence aircraft designs, to ensure that such risks are identified and appropriate controls are implemented.

32. Some common System Safety Program tools can assist in this consultation process. For example, the Operating and Support Hazard Analysis (O&SHA) and Health Hazard Analysis (HHA) in MIL STD-882 inherently require consultation with operators and maintainers on personnel injury hazards. Similarly, several system safety tools include a focus on human factors hazards (particularly in relation to the human-machine interface), and consequently drive operator consultation. Finally, forums such as the MIL-STD-882 System Safety Working Group encourage consultation on hazard identification and management between all key stakeholders. Each of these tools and forums can provide a contribution (but rarely a comprehensive solution) to robust operator and maintainer consultation.

IDENTIFYING GOOD PRACTICE

33. While the implementation of risk controls identified in reputable standards is integral to establishing good practice, other aviation industry organisations in both the civil and military aviation domains may have identified and implemented additional risk controls not prescribed within reputable standards for aircraft designs. These additional risk controls, known as 'industry good practice', should be evaluated by designers and implemented where appropriate.

34. To ensure that good practice is part of an engineer's consideration of potential risks and ways of controlling those risks in Defence aircraft design, designers should:

(a) engage with other aviation industry organisations that are responsible for developing similar aircraft designs to identify implemented controls; and

(b) evaluate the context under which the control was implemented to establish whether the control is applicable to the Defence aircraft (ie the control applies to the same risk and in the same context as that of the Defence aircraft design).

CONSULTING THE AIRCRAFT OEM AND OTHER RELEVANT DESIGN AGENCIES

35. OEMs have a comprehensive understanding of their aircraft design and access to relevant design data. OEMs may therefore have additional insight into risks associated with the design, and ways of eliminating or reducing those risks that is not immediately apparent through application of relevant reputable standards. For example, the OEM may have applied a bespoke design requirement to control a risk associated with a novel or unique feature. Defence also engages design agencies (other than aircraft OEMs) to provide engineering support. These design agencies may also have additional insight into risks associated with the design, particularly for the Defence CRE context. Consultation with OEMs and other relevant design agencies during design development is therefore a key component of developing a designer's state of knowledge.

CONSULTING AVIATION DOMAIN SUBJECT MATTER EXPERTS

Superseded

36. Designers may gain knowledge of hazards and associated risk controls through consultation with aviation domain experts such as Defence Science and Technology Group (DSTG), other Defence organisations (for example System Program Offices (SPOs) responsible for common aviation systems), industry experts such as standards bodies and committees, and academia. Where information is gathered from a reputable Defence source such as DSTG or a SPO, designers can consider this information to be a valid contribution to their reasonable knowledge. However, before relying on information gained from other domain SMEs, designers should evaluate the information to establish its validity and applicability before using the information in Defence aircraft design.

CONSULTING DOMAIN EXPERTS THROUGH COURSE PARTICIPATION

37. Many aircraft related courses include content on the identification of risks associated with aircraft design and potential risk controls. For those courses that are delivered by the Authority (including Standards DoSAs), such content can be considered to provide a valid contribution to a designer's body of knowledge.

38. For all other courses, the presenter may include additional content based on 'expert opinion' or experience. Consequently, while designers can consider the content to provide a general contribution to their reasonable knowledge, a designer should apply professional engineering judgement in its application to a particular aircraft hazard or risk.

CONSULTING PROFESSIONAL BODIES

39. Many professional bodies hold substantial domain knowledge either in specific technology related fields or in aviation more broadly and these may be an additional source of reasonable knowledge for designers. Examples include: Engineers Australia (and associated sub-Colleges and Technical Societies), the Royal Aeronautical Society, the Institute of Electrical and Electronics Engineers, and so on.

INDUSTRY PUBLICATIONS AND SCIENTIFIC AND TECHNICAL LITERATURE

40. Knowledge of aircraft design related risks and control measures can be sourced from industry publications and scientific and technical literature, to the extent that it directly relates to aviation and is developed and published by a reputable source. Such knowledge can be categorised as either acceptable at face value or requiring additional evaluation to establish its validity.

41. The following industry publications can be considered to provide a valid source of reasonable knowledge:

(a) generic aircraft OEM standard operating procedures or design guidelines/handbooks;

(b) material safety data sheets (and other approved industry safety data);

(c) technical reports/white papers published by reputable organisations (such as NASA); and

(d) technical reports produced by Government agencies (for example, DST Group or Australian National Audit Office).

42. Other publications may reflect the author's 'opinion' rather than established and verified knowledge and should be treated with caution. While they may inform a designer's body of knowledge, the content should be subjected to professional engineering judgement to confirm the validity of any identified risks and associated controls. Such publications include:

(a) generic reference books related to a particular engineering discipline or element of aircraft design; and

(b) conference proceedings and published scientific papers.

Superseded

ANALYSING PREVIOUS INCIDENTS

43. Accident/incident investigations and their outcomes are integral to informing designers of risks in aircraft design and potential ways of eliminating or controlling those risks. Information related to risks in aircraft design may be sourced from investigations into Defence aircraft accidents/incidents or investigations conducted by external organisations such as NAAs/MAAs or accident investigation bodies (for example the Australian Transport Safety Bureau).

44. **Internal accident/incident investigations.** While design organisations will have an established process for evaluating the outcomes of accident/incident investigations associated with the aircraft they are responsible for, there may be risks identified in other aircraft investigations that are also relevant to their aircraft type. These investigation outcomes provide a readily accessible source of information to add to a designer's body of knowledge of risks and means of controlling those risks in aircraft design.

45. **External accident/incident investigations.** Many NAAs/MAAs and national accident investigation bodies conduct investigations, make recommendations for safety improvements, and make their findings of causal factors and proposed remediation actions public. Some investigations may contain lessons learnt that may form part of the body of knowledge of risks, and ways of eliminating or minimising those risks, available to designers. Designers should maintain an awareness of the accidents/incidents that have occurred in aircraft that are similar (in terms of aircraft type and CRE) to that of the Defence aircraft design.

RELEVANT REGULATIONS AND 'CODES OF PRACTICE'

46. A Code of Practice is approved by the Minister responsible for work health and safety in the applicable jurisdiction and is 'a practical guide to achieve the standards of health and safety required under the model Work Health and Safety Act and model WHS Regulations'.[10] Codes of Practice provide duty holders with guidance on effective ways to manage work health and safety risks. While there are no Codes of Practice specifically applicable and approved for aviation, the 'generic' Codes of Practice issued under the authority of the WHS Legislation may apply to aircraft design[11]. These Codes of Practice should be considered by designers during aircraft design activities.

47. Finally, Australian legislation regarding specific WHS hazards (for example Radiation Protection Standards published by ARPANSA) and associated Defence policy may apply to aircraft design and should be considered by designers during aircraft design activities.

CONCLUSION

48. The application of the principles described in this annex will assist designers to apply an appropriate level of reasonable knowledge to the identification, elimination and minimisation of hazards and associated risks in aircraft design. However, designers must ensure that the knowledge is applicable to the Defence aircraft context and represents contemporary understanding of the hazards and controls for that design. Importantly, reasonable knowledge applied by designers is not static. Any decision that a risk has been minimised so far as is reasonably practicable will always be influenced by the particular circumstance. Changed circumstances include the evolution of standards and other knowledge that supported the original determination that reasonable knowledge had been applied. Consequently, designers should ensure that changes to applicable reputable standards (or other key knowledge sources) are monitored and assessed to ensure that identified hazards and controls remain valid.

Superseded

ANNEX B - GUIDANCE FOR DEFENCE DUTY HOLDERS WHEN ACQUIRING OFF-THE-SHELF AIRCRAFT

GUIDANCE FOR DEFENCE DUTY HOLDERS WHEN ACQUIRING OFF-THE-SHELF AIRCRAFT

1. Airworthiness design requirements are merely one source of constraint placed on aircraft designers. A military-sponsored aircraft design, for example, would mandate personnel safety requirements beyond airworthiness in the procurement specification. A new civilian aircraft, while not subject to such contractual constraints, would probably meet the WHS requirements of its expected main customers as a sensible business decision. Company liability concerns may also promote design practices that reduce risks to aircraft occupants and people on the ground. Consequently, in all likelihood, a new aircraft design will substantially meet Australia's WHS Legislation. The challenge is to identify any deficiencies, recognising that:

(a) WHS benchmarks will inevitably vary between countries

(b) military forces can moderate WHS requirements if they impede capability

(c) aircraft designers will be constrained in providing safe aircraft designs and maintenance instructions by cost and schedule pressures, and knowledge deficits.

2. This section proposes an approach to identifying the extent to which military or civilian off-the-shelf aircraft designs should satisfy Australia's WHS Legislation with respect to promoting the health and safety of aircraft occupants.

Military off-the-shelf aircraft

3. Where a military-specific aircraft is being procured off-the-shelf, information on the design of the aircraft is needed, so that deficiencies against Australia's WHS Legislation can be identified and the risk eliminated or otherwise minimised so far as is reasonably practicable. The following sources of aircraft design information may assist:

(a) the original aircraft procurement specification, if it defines requirements that contribute to personnel health and safety

(b) for aircraft designed under a MIL-STD-882 program, the artefacts produced by the aircraft designer to satisfy the Operating and Support Hazard Analysis (OSHA) and Health Hazard Analysis (HHA) tasks

(c) the aircraft hazard log (or equivalent), if it includes hazards to personnel health and safety as well as airworthiness hazards

(d) documents that define risk retention decisions by the certifying Airworthiness Authority

(e) the elements of the military Airworthiness Code (if employed) that contribute to personnel health and safety

(f) where possible, sourcing information specific to Australia's WHS Legislation from the aircraft designer

(g) a visual inspection of the aircraft, to identify design features that might present a hazard to personnel health and safety.

Civilian off-the-shelf aircraft

Superseded

4. The civil Airworthiness Codes in Section 1 Chapter 3 of this publication will normally cater well for the protection of aircraft occupants from injury. However, they normally will not cover future ill effects to the health of aircraft occupants, for example due to chemical hazards, radiation hazards, and so on. To confirm the aircraft does not risk the future health of aircraft occupants, information specific to Australia's WHS Legislation would need to be sourced direct from the aircraft designer. Further confidence might be gained through identifying countries where the aircraft type is widely operated, and comparing their WHS requirements against Australia's WHS Legislation.

Superseded

AIRWORTHINESS CODES

INTRODUCTION

3.1 To promote safe flight through aircraft design, some National Airworthiness Authorities and Military Airworthiness Authorities (NAAs/MAAs) prescribe airworthiness design requirements. Prescribed airworthiness design requirements are usually documented in an Airworthiness Code (DASR 21 refers) and represent a complete and consistent set of requirements that define those attributes of aircraft systems, or functions, that underpin safe flight.

3.2 As discussed in Section 1 Chapter 1 of this manual, it is not practical for Defence to create and maintain its own Airworthiness Code. Consequently, the Authority has recognised a number of civil and military Airworthiness Codes as providing a sound foundation for the safe design of Defence aircraft.

3.3 This chapter of the DASDRM:

(a) describes the application of Airworthiness Codes

(b) identifies and describes the Authority recognised Airworthiness Codes

(c) describes the approach adopted by the Authority to establishing the acceptability of aircraft designs not developed to an Authority recognised Airworthiness Code.

3.4 Uncrewed aircraft systems (UAS). The approach adopted by the Authority to prescribing UAS airworthiness design requirements is described separately in Section 4 of this manual.

APPLICATION OF AIRWORTHINESS CODES TO DEFENCE AIRCRAFT

3.5 An aircraft developed to an Authority recognised Airworthiness Code should substantially meet the level of safety expected by Defence. While the Authority might prescribe additional design requirements to address known deficiencies in the Airworthiness Code, or to encompass Defence's unique Configuration, Role and operating Environment (CRE), these are not normally substantial additions.

3.6 This section describes the Authority's approach to recognising Airworthiness Codes, and for identifying where supplementation to a Code is needed.

Recognising Airworthiness Codes

3.7 For the Authority to recognise an Airworthiness Code, as a minimum, the Code must:

(a) be prescribed by a recognised NAA/MAA

(b) have demonstrated a sound safety record

(c) prescribe a complete and consistent suite of airworthiness design requirements

Superseded

(d) be supported by associated guidance on how to achieve compliance with the airworthiness design requirements

(e) be accessible, ie published by the NAA/MAA in a consolidated and easily accessed format.

3.8 Where an Airworthiness Code is recognised by the Authority, unless otherwise stated in this manual the recognition automatically refers to the current version of the Code. Earlier versions of an Airworthiness Code may be acceptable to the Authority provided the changes between the earlier version and the current version have been analysed and the effect on safety characterised. Project Offices seeking to acquire Defence aircraft designed to an earlier version of a recognised Airworthiness Code are to petition the Authority for a decision on the acceptability of the earlier version.

Supplementing Recognised Airworthiness Codes

3.9 As mentioned previously, an aircraft developed to an Authority recognised Airworthiness Code should substantially meet the level of safety expected by Defence. However, for a particular aircraft acquisition, the Authority would normally prescribe supplementary airworthiness design requirements, as a result of:

(a) known inadequacies in the Airworthiness Code

(b) novel features included in the proposed design that are not accommodated by the Code

(c) proposed Defence-unique roles and/or operating environments that are outside the scope of the Code, and/or

(d) Defence policies or Australian legislated requirements not being covered by the Code.

3.10 Sections 2 and 3 of this manual present airworthiness design requirements that are commonly needed to supplement Airworthiness Codes. Where supplementation is not commonly required, a corresponding chapter has not been included in this manual. Regardless, the Authority may identify specific areas for deeper evaluation on a case-by-case basis for an aircraft acquisition or design change, and prescribe design requirements in addition to Sections 2 and 3 where warranted.

AUTHORITY RECOGNISED AIRWORTHINESS CODES

3.11 The previous section presented the criteria employed by the Authority for recognising Airworthiness Codes. This section identifies and defines those civil and military Airworthiness Codes that have been recognised by the Authority as providing a sound foundation for the safe design of Defence aircraft.

Federal Aviation Administration

3.12 The United States of America Federal Aviation Administration (FAA) is an Authority recognised civil NAA. The FAA prescribes airworthiness design requirements (commonly referred to as the Federal Aviation Regulations (FARs)) to assure safe aircraft design in the Code of Federal Regulations Title 14 (CFR 14) Aeronautics and Space, Chapter 1 Federal Aviation Administration, Department of Transportation, sub-Chapter C, Aircraft. Sub-Chapter C is further separated into Parts that prescribe specific airworthiness design requirements for an aircraft category or aircraft engines.

Superseded

3.13 Not all of the airworthiness design requirements prescribed in the FAR Parts under sub-Chapter C are applicable to Defence aircraft. Consequently, the Authority has recognised an Airworthiness Code based on the airworthiness design requirements prescribed by the FAA in the following FAR Parts:

(a) Part 23[1] – Airworthiness standards: Normal, utility, acrobatic and commuter category airplanes

(b) Part 25 – Airworthiness standards: Transport category airplanes

(c) Part 26 – Continued airworthiness and safety improvements for transport category airplanes

(d) Part 27 – Airworthiness standards: Normal category rotorcraft

(e) Part 29 – Airworthiness standards: Transport category rotorcraft

(f) Part 33 – Airworthiness standards: Aircraft engines

(g) Part 35 – Airworthiness standards: Propellers.

3.14 The FAA also prescribes minimum equipment and/or systems requirements in sub-Chapter D, Airmen, and sub-Chapter G, Air Carriers and Operators for Compensation or Hire: Certification and Operations, of CFR 14 Chapter 1 for specified operations, and these equipment/system requirements inherently levy airworthiness design requirements. The applicability and suitability, for Defence aircraft, of the airworthiness design requirements levied in the following FAR Parts will be established following determination of the type of operations to be undertaken by the Defence aircraft and the airspace in which these operations will occur:

(a) Part 91 – General Operating and Flight Rules

(b) Part 121 – Operating Requirements: Domestic, Flag and Supplemental Operations

(c) Part 135 – Operating Requirements: Commuter and On-demand Operations and Rules Governing Persons On Board Such Aircraft.

3.15 Accordingly, from Defence's perspective, the FAA's Airworthiness Code effectively consists of airworthiness design requirements from FAR Parts 23, 25, 26, 27, 29, 33 and 35, and those airworthiness design requirements inherently levied by FAR Parts 91, 121 and 135 that are relevant to Defence's proposed operations. This Airworthiness Code is accepted by the Authority as providing an acceptable foundation for the safe design of Defence aircraft. Further detail on the application of FAA prescribed airworthiness design requirements for particular aircraft types, technologies and systems, and operations is contained in the relevant chapters in Sections 2 and 3 of this manual.

European Aviation Safety Agency

3.16 The European Aviation Safety Agency (EASA) is the NAA responsible for conducting civil aircraft Type Certification on behalf of the countries of the European Union. EASA prescribes airworthiness design requirements within Certification Specifications (CSs) promulgated under the authority of Regulation (EC) No 216/2008 of 20/02/2008, Basic Regulation, and Commission Regulation (EU) No 748/2012 of 03/08/2012, Initial Airworthiness. EASA CSs are harmonised with the FAA FAR Parts with respect to aircraft Type Certification. Consequently, EASA CS-23, -25, -27, -29, -E and -P prescribe substantially the same requirements as those within the equivalent FAR Parts.

Superseded

3.17 Not all of the airworthiness design requirements prescribed in EASA CSs are applicable to Defence aircraft. Consequently, the Authority has recognised an Airworthiness Code based on the airworthiness design requirements prescribed by EASA in the following CSs:

(a) CS-23[2] – Normal, Utility, Aerobatic and Commuter Aeroplanes

(b) CS-25 – Large Aeroplanes

(c) CS-26 – Continued airworthiness and safety improvements for transport category airplanes

(d) CS-27 – Small Rotorcraft

(e) CS-29 – Large Rotorcraft

(f) CS-E – Engines

(g) CS-P – Propellers.

3.18 EASA also prescribes minimum systems and/or equipment requirements for specified operations in CSs, and these requirements inherently levy airworthiness design requirements. Further, EASA has issued operational regulations under European Commission Regulation (EU) No 965/2012, which prescribes technical requirements and administrative procedures related to air operations. These requirements inherently levy airworthiness design requirements through the specification of minimum systems and equipment necessary for specified operations in European airspace. The applicability and suitability, for Defence aircraft, of the airworthiness design requirements inherently levied in the following EASA CSs and EU regulations will be established following determination of the type of operations to be undertaken by the Defence aircraft and the airspace in which these operations will occur:

(a) CS-ACNS – Airborne Communications, Navigation and Surveillance

(b) CS-AWO – All Weather Operations

(c) Regulation (EU) 965/2012 Annex IV Commercial Air Transport, Subpart D Instruments, Data and Equipment CAT.IDE.A (Aeroplanes) and CAT.IDE.H (Helicopters)

(d) Regulation (EU) 965/2012 Annex V Specific Approvals.

3.19 Accordingly, from Defence's perspective, EASA's Airworthiness Code effectively consists of airworthiness design requirements from CS-23, -25, -26, -27, -29, -E and -P, and those requirements levied by operational CSs and EU regulations that are relevant to proposed Defence operations. This Airworthiness Code is recognised by the Authority as providing an acceptable foundation for the safe design of Defence aircraft. Further detail on the application of EASA prescribed airworthiness design requirements for particular aircraft types, technologies and systems, and operations is contained in the relevant chapters in Sections 2 and 3 of this manual.

Civil Aviation Safety Authority

3.20 The Civil Aviation Safety Authority (CASA) of Australia is an Authority recognised civil NAA. CASA prescribes airworthiness design requirements in the Civil Aviation Safety Regulations (CASRs). CASA's approach to prescribing airworthiness design requirements is to leverage extensively off those requirements prescribed in the associated FARs and CSs. For example, CASR Part 23 identifies 'the airworthiness standards for an aeroplane in the normal category, utility category, acrobatic category

Superseded

or commuter category' as those prescribed by the FAA and EASA in FAR Part 23, CS-VLA and CS-23 (with any changes identified by CASA in CASR Part 23).

3.21 The Authority has recognised an Airworthiness Code based on the airworthiness design requirements prescribed by CASA in the following CASRs:

(a) CASR Part 23[3] – Airworthiness standards for aeroplanes in the normal, utility, acrobatic or commuter category

(b) CASR Part 25 – Airworthiness standards for aeroplanes in the transport category

(c) CASR Part 27 – Airworthiness standards for rotorcraft in the normal category

(d) CASR Part 29 – Airworthiness standards for rotorcraft in the transport category

(e) CASR Part 33 – Airworthiness standards for aircraft engines

(f) CASR Part 35 – Airworthiness standards for aircraft propellers.

3.22 While CASA leverages extensively off the airworthiness design requirements prescribed by the FAA and EASA, CASA also prescribes minimum systems and/or equipment requirements for particular operations in CASR operational regulations and Civil Aviation Orders (CAOs), and these requirements inherently levy airworthiness design requirements. The applicability and suitability, for Defence aircraft, of the airworthiness design requirements levied in the following CASRs and CAOs will be established following determination of the type of operations to be undertaken by the Defence aircraft and the airspace in which these operations will occur:

(a) CASR Part 91 – General and Operating Flight Rules (and associated Manual of Standards)

(b) CASR Part 121 – Australian Air Transport Operations-Larger Aeroplanes (and associated Manual of Standards)

(c) CAO Part 20 – Air Service Operations

(d) CAO Part 82 – Air Operators Certificates.

3.23 Accordingly, from Defence's perspective, CASA's Airworthiness Code effectively consists of airworthiness design requirements from CASR 23, 25, 27, 29, 33 and 35, and those requirements levied by CASR Parts 91and 121, and CAOs, that are relevant to proposed Defence operations. This Airworthiness Code is recognised by the Authority as providing an acceptable foundation for the safe design of Defence aircraft. Further detail on the application of CASA prescribed airworthiness design requirements for particular aircraft types, technologies and systems, and operations is contained in the relevant chapters in Sections 2 and 3 of this manual.

US DoD

3.24 The United State Air Force (USAF), US Navy and US Army are MAAs recognised by the Authority. The US DoD airworthiness design requirements are published in military handbook MIL-HDBK-516C, Airworthiness Certification Criteria. This document follows a 'systems' based approach (rather than aircraft type), with references to applicable airworthiness criteria, design standards, means of compliance and tailoring for different aircraft types where required.

3.25 The airworthiness design requirements prescribed in MIL-HDBK-516C are recognised by the Authority as providing an acceptable foundation for the safe design of Defence aircraft. Importantly,

Superseded

previous versions of MIL-HDBK-516 (with the exception of MIL-HDBK-516B (Expanded Version)) are not MAA Airworthiness Codes recognised by the Authority. Only MIL-HDBK-516C (and MIL-HDBK-516B (Expanded Version)) prescribes airworthiness design requirements in a manner that satisfies the criteria for Airworthiness Code recognition described in paragraph 3.7. Note that MIL-HDBK-516C is intended to be tailored to prescribe airworthiness design requirements for specific aircraft types and roles.

UK MoD

3.26 The United Kingdom Ministry of Defence (UK MoD) is an Authority recognised MAA. The UK MoD prescribes airworthiness design requirements in Defence Standard DEF-STAN 00-970, Design and Airworthiness Requirements for Service Aircraft. DEF-STAN 00-970 is divided into a number of Parts that prescribe airworthiness design requirements for specific aircraft types and ancillary equipment categories as follows:

a. Part 1 – Combat Aeroplanes
b. Part 3 – Small Type Aeroplanes
c. Part 5 – Large Type Aeroplanes
d. Part 7 – Rotorcraft
e. Part 11 – Engines.

3.27 The airworthiness design requirements prescribed in the UK MoD Airworthiness Code defined in paragraph 3.26 are recognised by the Authority as providing an acceptable foundation for the safe design of Defence aircraft. However, like the US DoD Airworthiness Code, the UK MoD Code is intended to be tailored to prescribe airworthiness design requirements for specific aircraft types and roles.

AIRCRAFT NOT DESIGNED TO AN AUTHORITY APPROVED AIRWORTHINESS CODE

3.28 Occasionally, Defence will procure aircraft that were not developed to an Authority recognised Airworthiness Code. In these circumstances, the Authority will determine whether the airworthiness design requirements applied to the aircraft design provide an acceptable foundation for the safe design of Defence aircraft. There are two situations where such an assessment may be required:

(a) the aircraft design has been developed using an Airworthiness Code that has not yet been recognised by the Authority, or

(b) the aircraft design has been developed to satisfy a bespoke suite of airworthiness design requirements.

3.29 Each of these situations is discussed in the following paragraphs.

Aircraft designed to a non-Authority recognised Airworthiness Code

3.30 Where Defence proposes to procure an aircraft design that has been developed using an Airworthiness Code (either civil or military) that is not recognised by the Authority, the Authority will evaluate the Airworthiness Code to determine if it satisfies the criteria for Authority recognition at paragraph 3.7. Alternatively, the Authority will evaluate the airworthiness design requirements prescribed for the original aircraft design using the approach described in paragraphs 3.31 and 3.32 below. In either case, the design requirement supplementation described at paragraphs 3.9 and 3.10

Superseded

is likely to be applicable.
Aircraft designed to a bespoke suite of airworthiness design requirements

3.31 Defence may acquire aircraft that have been 'type certified' by Authority recognised MAAs (eg US Army, US Navy and French DGA), where the suite of airworthiness design requirements used to support this certification do not satisfy one or more of the criteria at paragraph 3.7 for Authority recognition as an Airworthiness Code. For example:

(a) The US Army has prescribed airworthiness design requirements in ADS-51-HDBK US Army Rotorcraft and Aircraft Qualification Handbook. However, ADS-51-HDBK does not satisfy the criteria at paragraph 3.7.c for an Airworthiness Code to prescribe a comprehensive suite of airworthiness design requirements.

(b) While the US Navy may adopt MIL-HDBK-516C when establishing the certification criteria for a particular aircraft design, the US Navy does not currently present these criteria in a consolidated Type Certification Basis (TCB) (which is a fundamental requirement of MIL-HDBK-516C)[4]. In essence, the US Navy defines a bespoke 'Airworthiness Code' for each aircraft certification program, but does not promulgate the Code in a manner that satisfies the criteria at paragraph 3.7.e regarding Airworthiness Code consolidation and ease of access.

3.32 While the Authority does not classify these sets of airworthiness design requirements as Airworthiness Codes, they may still be approved by the Authority on an individual basis (through approving the Defence aircraft TCB) as providing a suitable foundation for the safe design of a Defence aircraft. This might be achieved through comparison to a recognised Airworthiness Code, or by another method determined by the Authority. Regardless, the design requirements supplementation described at paragraphs 3.9 and 3.10 is likely to be equally applicable.

APPLICATION OF AUTHORITY RECOGNISED AIRWORTHINESS CODES TO MAJOR CHANGES

3.33 Regardless of whether an aircraft design conforms to an Authority recognised Airworthiness Code or not, any major design changes to Defence aircraft must satisfy the airworthiness design requirements prescribed in the approved aircraft TCB as a minimum. Where appropriate, more recent versions of airworthiness design requirements should be evaluated to determine whether compliance with the later version would contribute materially to the level of safety afforded by the design and would be practicable to implement. The determination of whether compliance with a later amendment to the applicable airworthiness design requirements is warranted, is conducted using the criteria defined in DASR 21.A.91, DASR 21.A.97 and DASR 21.A.101. Section 1 Chapter 2 Annex A provides further guidance on the application of earlier versions of Airworthiness Codes to major design changes.

RETROSPECTIVE APPLICATION OF AUTHORITY PRESCRIBED AIRWORTHINESS DESIGN REQUIREMENTS

3.34 The Authority prescribed airworthiness design requirements in this manual are not intended to be applied to in-service aircraft that are not undergoing modification (ie retrospective application). Where the Authority determines that retrospective application of an airworthiness design requirement is warranted, this will be promulgated via separate direction.

Superseded

DESIGN REQUIREMENTS FOR CAPABILITY AND INTEROPERABILITY

INTRODUCTION

4.1 It is not within the Authority's charter to prescribe design requirements for capability and interoperability. Rather, these design requirements are usually identified by the procurement organisation using the capability manager's specified performance requirements (ie Functional Performance Specifications (FPS)) as a basis, and with input from Defence domain specialists.

4.2 This chapter of the DASDRM describes how airworthiness design requirements may contribute to achieving capability and interoperability outcomes.

CAPABILITY DESIGN REQUIREMENTS

4.3 While many of the airworthiness design requirements in the DASDRM may have an effect on the capability provided by Defence aircraft, aviation safety not the achievement of capability outcomes is the principal purpose of Authority prescribed airworthiness design requirements.

4.4 Nevertheless, there are three circumstances where the Authority may identify capability design requirements and present these requirements in the DASDRM, as follows:

(a) where implementing an Authority prescribed airworthiness design requirement, to the letter, could have an adverse impact on capability, or

(b) where an Authority prescribed airworthiness design requirement inherently includes elements that focus on capability (eg missions system performance), in which case some guidance on the application of these requirements is reasonable, or

(c) where a specific capability standard or requirement needs to be captured in the suite of design requirements as it will have a substantial influence on the final design solution.

4.5 Note that it may be useful to consider capability requirements as a means of treating hazards associated with mission outcomes (eg failure of an IFF system may result in battlefield fratricide), and therefore apply tailored airworthiness design requirements to treat these hazards. However, such an application does not contribute to airworthiness, and should not be confused with the requirements comprising an aircraft's certification basis.

INTEROPERABILITY DESIGN REQUIREMENTS

4.6 It is not within the Authority's charter to prescribe design requirements for aircraft interoperability. However, as with capability design requirements, there may be occasions where Authority prescribed airworthiness design requirements impact Defence's interoperability needs. In these circumstances, the Authority may identify the interoperability requirement at the end of the associated chapter in the DASDRM.
Air Force Interoperability Council (AFIC) standards

Superseded

4.7 Defence aircraft interoperability requirements are largely satisfied through the application of the Air Force Interoperability Council (AFIC) series of standards. The AFIC aims to enhance interoperability between the United States, the United Kingdom, Canada, New Zealand and Australia. AFIC standards are developed and published by AFIC within the following domains:

(a) Agile Combat Support: capabilities and functions to establish, operate, sustain and close an airbase, including the deployment and recovery phases.

(b) Air Mobility: movement of personnel, materiel and forces by air to, from and within a theatre of operations.

(c) Counter Small Uncrewed Aerial Systems (C-sUAS): address Air specific C-sUAS requirements and contribute to Joint and Combined c-sUAS activities of benefit to AFIC nations.

(d) Joint All Domain Command and Control (JADC2): the art and science of decision making to rapidly translate decisions into action, leveraging capabilities across all domains and with mission partners to achieve operational and information advantage in both competition and conflict.

(e) Live, Virtual and Constructive – Operational Training (LVC-OT): includes such elements as training policy and systems, airspace and ranges, pods/instrumentation, aggressors/ contractor air, threat generators, networks, synthetics, operational training centres, workforce and so on.

(f) Aerospace Medicine: all matters concerning aviation medicine such as anthropometrics, aeromedical evacuation, effects of altitude, breathing oxygen and exposure limits for noise, vibration, heat and cold.

(g) Fuels: aviation fuels, oils, lubricants and gasses.

(h) Airworthiness: mutual recognition of AFIC Nation's Airworthiness Systems.

4.8 Defence aviation interoperability requirements are managed by the Air Capability Enablers within Air Force Headquarters. Organisations seeking to acquire or modify Defence aircraft that may be subject to interoperability considerations should seek advice from Air Capability Enablers in the first instance. Information related to AFIC standards and Defence aviation involvement in AFIC is available at the Air Force AFIC website.

4.9 Where a conflict exists between an Authority prescribed airworthiness design requirement and an AFIC standard, the Authority prescribed requirement takes precedence. Designers wishing to adopt the AFIC standard to satisfy interoperability requirements, in lieu of the Authority prescribed requirement, are to seek Authority agreement that the AFIC standard provides an equivalent level of safety or seek dispensation from the Authority for non-compliance with the prescribed requirement.

Superseded

SECTION 2 - INTEGRATED DESIGN REQUIREMENTS

CHAPTER 1 - APPLICATION OF INTEGRATED DESIGN REQUIREMENTS

APPLICATION OF INTEGRATED DESIGN REQUIREMENTS

1.1 A number of engineering disciplines associated with aircraft designs affect multiple aircraft systems or have an impact on most aspects of the design. For example, aviation software is present in virtually all aircraft systems and often performs functions that have a direct impact on the safe operation of Defence aircraft. The airworthiness design requirements associated with these disciplines are referred to in the DASDRM as 'integrated design requirements'.

1.2 Given the ubiquitous nature of these engineering disciplines, the airworthiness design requirements prescribed in the Authority recognised Airworthiness Codes are often generic and require considerable tailoring to satisfy the requirements of a particular aircraft for its intended configuration, role and operating environment. Consequently, for these engineering disciplines, the Authority has prescribed airworthiness design requirements to define the tailoring required for Defence's unique CRE.

Scope

1.3 Section 2 of the DASDRM presents the Authority prescribed airworthiness design requirements for the following integrated aircraft design engineering disciplines:

(a) system safety,

(b) aviation software,

(c) electromagnetic environmental effects,

(d) human factors engineering,

(e) crash protection,

(f) fire protection,

(g) smoke and fumes protection,

(h) equipment environmental qualification,

(i) defence long range operations, and

(j) aircraft/stores compatibility.

Superseded

SYSTEM SAFETY

INTRODUCTION

2.1 Hazards in aircraft design are largely managed by employing aerospace design standards, since these standards represent many years of experience in the identification, analysis and control of hazards. However, while a system may be comprised of individual components that meet relevant reliability, safety or performance benchmarks on their own, the integration of these sub-systems can give rise to hazards at the system level. System safety is an engineering discipline that encompasses safety as a core aspect of any given system design (or design change). System safety comprises a number of tools and techniques to identify aircraft hazards and implement controls for those hazards to satisfy prescribed safety objectives. The application of these tools and techniques is an essential adjunct to a standards based approach to design, noting that design standards may:

(a) not apply to a whole system, merely elements of the system

(b) not be relevant for novel applications, which can pose novel hazards

(c) not keep up with technology advances, since standards often have review and update cycles that span many years

(d) allow different options depending on the system's criticality.

2.2 The implementation of a robust and effective system safety approach to Defence aircraft design is prescribed by the Authority. As system safety involves a whole-of-system approach to design, achievement of safety objectives requires the application of the system safety tools and techniques during aircraft design activities, normally through the adoption of a formal System Safety Program. The framework and processes under which system safety is applied for Defence aircraft designs may be articulated in a dedicated artefact (for example via a System Safety Program Plan) or inherently included in a design organisation's design processes.

2.3 **Other National Airworthiness Authority (NAA)/Military Airworthiness Authority (MAA) approaches to system safety.** The Authority has evaluated recognised NAA and MAA approaches to implementing system safety, and the associated aviation system safety standards, and concluded that intelligent application and in some cases expansion is required to satisfy Defence's regulatory and statutory requirements. For example, system safety standards may not account for Defence's obligations under the WHS legislation, since they may permit 'risk acceptance' once a specified risk level has been achieved. To promote the 'intelligent application' of system safety standards, this chapter adopts a different structure to other DASDRM chapters. Here, the chapter first defines the outcomes that are needed for a robust system safety program. The chapter then identifies where recognised NAA/MAA approaches to system safety require particular attention if they are to meet the Authority's prescribed outcomes. This approach provides design organisations with guidance to embed robust system safety practices into their engineering procedures.

Superseded

Scope

2.4 This chapter presents Authority prescribed system safety design requirements that are applicable to design activities conducted for new aircraft and design changes. The Authority's prescribed design requirements for software safety are provided at Section 2 Chapter 3.

SYSTEM SAFETY REQUIREMENTS

2.5 The application of system safety to Defence aircraft designs achieves three key outcomes:

(a) Design safety objectives are:

1. defined, and
2. agreed by the Authority.

(b) Design hazards[1] are identified and controlled.

(c) Hazards identified during design, and associated controls, are documented.

2.6 Authority prescribed system safety design requirements that support the achievement of each of these outcomes are defined in the following paragraphs.

Defining safety objectives

2.7 The establishment of safety objectives for the particular aircraft type, cognisant of Defence's role and operating environment, is fundamental to the implementation of a robust system safety program and represents good aviation engineering design practice. Over many decades of aviation operations, these safety objectives have been demonstrated to achieve safe aircraft design. Consequently, the defined safety objectives represent the point at which further elimination or minimisation of identified hazards is unlikely to be reasonably practicable.

2.8 Safety objectives may be articulated as specific outcomes to be achieved (eg no single point failures having a catastrophic severity) or through objective safety criteria applicable to a particular hazard severity (eg Failure Probability Objectives (FPOs) and Design Assurance Levels (DALs)).

2.9 **SS Requirement (Essential) (Aircraft Acquisitions).** *Applicants for a Military Type Certificate must establish the quantitative safety criteria to be applied to the aircraft design (eg FPOs, catastrophic failure rate, and so on).*

2.10 A design organisation's design processes must describe how the organisation will ensure that quantitative safety criteria applicable to the Defence aircraft are identified and met for new aircraft designs. Prior to adopting the quantitative criteria as a basis for Defence aircraft certification, the design organisation must seek Authority agreement that the quantitative criteria represent an appropriate basis for safe aircraft operations and aircraft certification. The approved quantitative safety criteria will form an integral element of a Defence aircraft's Type Certification Basis.

2.11 **SS Requirement (Essential) (Aircraft Design Changes).** *Aircraft design changes must comply with the quantitative safety criteria from the initial aircraft design (ie the original aircraft design FPOs, catastrophic failure rate, and so).*

Superseded

2.12 Once the quantitative safety criteria have been agreed by the Authority, they must be applied to all design changes unless prior agreement to adopt amended safety criteria has been obtained from the Authority. Any proposal to adopt amended safety criteria will represent a change to the approved TCB and, therefore, a Military Certification Review Item (MCRI) must be raised and submitted to the Authority for approval, regardless of whether the design is a Major or Minor change.

2.13 **SS Requirement (Essential)**. Applicants for a Military Type Certificate or Major Change approval must seek Authority agreement where reduced 'at risk' time is proposed to be accounted for in satisfying prescribed safety objectives.

2.14 The use of limited exposure intervals (eg 'at risk' time) to justify a reduction in safety objectives for aircraft systems could lead designers into error. For example, it would be inappropriate to use a limited exposure interval for reducing safety objectives for a safety-critical system, where the adverse consequences of system failure cannot be clearly linked to a specific stage of flight or set of flight conditions (eg when establishing safety objectives for ejection seats). Where the use of 'at risk' time is proposed in support of meeting FPOs for a specific aircraft system, a determination on the adequacy of the proposed approach must be sought from the Authority.

2.15 **SS Requirement (Essential).** *The design or design change must not permit a single-point failure, or permit a combination of independent failures (including human errors associated with the human machine interface) involving safety-critical functions, which have a consequence of catastrophic, critical (MIL-STD-882 definition) or hazardous (FAR/CS 2x.1309 definition) severity.*

2.16 Safety-critical systems must be "fail-safe", such that any single failure will cause the system to revert to a state which will not result in an unsafe condition. Independent system failures and human machine interface errors that have a consequence of catastrophic, critical (MIL-STD-882 definition) or hazardous (FAR/CS 2x.1309 definition) severity must be eliminated through design.

2.17 When establishing compliance with this requirement, the failure of any single element, component or connection in a system or sub-system during any one flight must be assumed regardless of its probability, and such failures should not be catastrophic. Subsequent failures during the same flight, whether detected or latent, must also be assumed unless the joint probability of such failure conditions satisfies the relevant catastrophic, critical or hazardous FPO.

2.18 Compliance with this requirement must be demonstrated through a thorough safety assessment, including both qualitative and quantitative assessment of the design for each catastrophic, critical or hazardous failure condition identified by a Functional Hazard Assessment (FHA).

2.19 Redundant subsystems may also be implemented as a hazard mitigation strategy for safety-critical systems. These systems are used when the primary system fails and the function of that system is required to maintain continued safe flight and landing. The separation or shielding of redundant subsystems from damage, adverse operating effects of neighbouring systems/components, common cause faults and other environmental factors is essential for a safe design.

2.20 **SS Requirement (Essential).** *Information concerning unsafe system operating conditions must be provided to the crew to enable them to take appropriate corrective action.*

2.21 **SS Requirement (Essential).** *Systems and controls, including indications and annunciations, must be designed to minimise crew errors, which could create additional hazards.*

2.22 **SS Requirement (Essential).** *A 'safe' indication must not be presented to the crew when an 'unsafe' condition exists.*

Superseded

2.23 Where analysis identifies that some action by the crew is required to achieve safety objectives, the designer must verify that:

(a) any identified indications are actually provided by the system

(b) any identified indications will actually be recognised

(c) any actions required have a reasonable expectation of being accomplished successfully and in a timely manner.

2.24 When failure monitoring and indication are provided by a system, its reliability must be compatible with the safety objectives associated with the system function for which it provides the indication. In the case of aircraft conditions requiring immediate crew action, a suitable warning indication must be provided to the crew, if not provided by inherent aircraft characteristics.

2.25 Defence aircraft designs must also account for potential human error in interpretation of system operations and controls, or warnings, indications or annunciations, which could result in crew actions that introduce hazards. In particular, no probable system failure is to result in a 'safe' indication of an 'unsafe' condition so that the crew would incorrectly assume the system is available or functional. When an unsafe condition is annunciated or detected, the flying instructions must have clear and precise corrective procedures for handling the failure without an excessive increase in workload.

2.26 **SS Requirement (Essential).** *The design of a safety-critical system must prevent the inadvertent initiation by human error of a catastrophic failure condition.*

2.27 Defence aircraft designs must account for, and where reasonably practicable eliminate, potential impacts of human error in the design of safety-critical systems as a result of human machine interface issues. For example, the addition of a throttle lever detent prevents an inadvertent selection of reverse thrust without the conscious lifting of the throttle levers over the detent. Similarly, a guarded switch for activation of engine fire extinguishers prevents inadvertent switch selection.

2.28 **SS Requirement (Essential).** *The operation of non-required equipment (eg mission systems), must not interfere with the proper functioning of safety-critical systems or present a hazard themselves.*

2.29 Non-required systems do not need to perform their function throughout the entire aircraft operating and environmental conditions. However, in situations where the non-required equipment is to be operated, both normal operations and operation under failure conditions must not adversely affect safe aircraft operations, safety-critical systems or aircraft occupants. Hazardous conditions associated with normal operations, malfunction and erroneous behaviour of non-required equipment must be identified through FHAs.

Hazard identification and control

2.30 Robust hazard identification and control is a cornerstone of safe aircraft design. Design organisations must implement processes that support effective hazard identification and control that accounts for Defence's role and operating environment, and achieves the applicable safety objectives for each failure condition and associated hazard. Where safety objectives are not initially achieved, additional controls must be identified and implemented (using the hierarchy of controls) to meet the prescribed safety objectives.

Superseded

2.31 **SS Requirement (Essential).** *Systematic techniques must be implemented for identifying credible hazards attributable to hardware, software and human system integration.*

2.32 System safety tools and techniques provide a robust means of hazard identification. These tools and techniques expose failure conditions where required safety criteria are not met or where integrated system hazards exist that have not been identified via compliance with design standards. For aircraft design changes, the existing aircraft Hazard Log (or similar) may also assist in identifying relevant hazards.

2.33 A design organisation's design processes must describe the application of formal hazard identification techniques and any tailoring to suit the specific design activity being undertaken. In particular, the processes should describe how the design organisation intends to apply system safety tools and techniques defined in aerospace system safety standards, including for those hazards applicable to complex system interactions, such as formal Functional Hazard Assessment/Analysis and/or System/Sub-System Hazard Analyses.

2.34 **SS Requirement (Essential).** *Identified hazards must be analysed to verify the achievement of safety objectives, or additional controls must be identified and implemented to achieve safety objectives.*

2.35 Robust analysis of hazards identified during design activities is an essential contributor to aviation safety. A design organisation's design processes must therefore describe the application of formal hazard analysis techniques and any tailoring to suit the specific design activity being undertaken. Hazard analysis techniques, commensurate with the scope of the design and potential impact on aviation safety must be employed to identify potential controls. For example, Fault Tree Analyses, Common Cause Analyses, Zonal Safety Analyses, Particular Risk Analyses and so on should be adopted where the design is complex and/or the consequences of failure are severe.

2.36 **SS Requirement (Essential).** Hazard controls must be implemented in accordance with the hierarchy of risk controls.

2.37 As discussed at paragraph 2.8, good practice in the aviation industry requires the identification of hazards and the implementation of controls to achieve prescribed safety objectives. However, where prescribed safety objectives are not met, and therefore the design falls outside of this good practice, any residual hazards must be robustly addressed through the implementation of additional controls. Implementation of controls must be undertaken with an appropriate understanding and application of the hierarchy of risk controls. The hierarchy of controls, per Regulation 36 of the WHS legislation, requires:

(a) implementing one or more of: substitution of the hazardous design with something safer; isolation of the hazard from people; and reducing the risk through engineering controls (eg use of mechanical guards or circuit isolation devices)

(b) if a risk remains, implementing administrative controls (ie procedures and training)

(c) if a risk remains, implementing the use of PPE.

2.38 The System Safety Design Order of Precedence, described in MIL-STD-882, needs intelligent application to fully satisfy the hierarchy of controls. Importantly, the effectiveness of procedures and training as a sole treatment strategy for hazards is unreliable as the primary control over the system life cycle. Warnings, cautions or other written advisory notifications must not be used as the only risk reduction method for hazards having catastrophic, critical (MIL-STD-882) or hazardous (FAR/CS 2x.1309) severities.

Superseded

2.39 **SS Requirement (Essential).** *Consultation, co-operation and co-ordination between stakeholders must ensure all potential risk controls are identified and assessed for implementation.*

2.40 Consultation, co-operation and co-ordination frameworks enable robust hazard identification and analysis, and the identification and assessment of reasonably practicable controls, both design/ technical and operational in nature. A design organisation's design processes must include the means by which stakeholder consultation, co-operation and co-ordination will be achieved. Operational stakeholder engagement is essential to evaluate potential operational controls for hazards when the design cannot meet prescribed safety criteria due to an adverse impact on Defence capability. Importantly, the framework must ensure that proposed design changes do not invalidate or impact extant controls for hazards that may not be related to the design under consideration.

2.41 One framework under which consultation, co-operation and co-ordination can be enacted is through an established System Safety Group (SSG) or equivalent body, which is responsible for reviewing identified hazards and associated controls. If employed, the SSG should be structured to optimise timely and effective consultation, co-ordination and co-operation between technical, operational and maintenance subject matter experts, and other relevant specialists and stakeholders.

2.42 A key outcome of consultation, co-operation and co-ordination is the identification of and commitment to the means by which controls will be implemented, reviewed and maintained. Clear responsibilities for confirming that controls have been implemented and are being monitored for effectiveness must be established within the adopted framework.

2.43 **SS Requirement (Essential).** *Where meeting design safety objectives would have an unacceptable adverse effect on capability, the non-compliance must be approved by the Authority.*

2.44 Occasionally, compliance with design safety objectives may unacceptably impact Defence's required capability outcomes. Where prescribed safety objectives cannot be met, the applicant must submit for Authority consideration and agreement any proposal to amend safety objectives. The proposal to amend the safety objectives must be supported by clear risk characterisation associated with the amended safety objectives and confirmation by the relevant operational commander that the operational impact of compliance with the prescribed safety objectives is unacceptable. Only where the Authority concludes that the risk has been appropriately characterised, the operational commander has made an informed determination that the risk has been minimised so far as is reasonably practicable and residual risk retention is appropriate, will the Authority approve the amended safety objectives via a Military Certification Review Item (MCRI).

Documenting hazards

2.45 To ensure that all controls necessary to achieve prescribed safety objectives are effectively captured and monitored, and will be considered during future design activities, robust hazard documentation is required.

2.46 **SS Requirement (Essential).** *Hazards identified during design activities, and associated controls, must be documented.*

2.47 While the identification of hazards and associated controls through a robust system safety program will result in the achievement of safety objectives, the continued safety of the design will only be achieved if any controls associated with identified hazards are implemented and remain effective. Hazard documentation also assists designers to ensure that future design activities do not introduce changes that either remove an existing hazard control or impact the effectiveness of a

Superseded

control. Consequently, hazard documentation is required to provide a safety baseline for the design and to support future design activities.

2.48 One means of documenting hazards and controls is via a Hazard Log. If employed, a Hazard Log should be updated during the aircraft's service life whenever:

(a) previously unidentified hazards, or new hazards introduced as part of a design change, are identified

(b) new controls for an already identified hazard are implemented, or already implemented controls are removed/changed.

2.49 A Hazard Log (or equivalent) is a key artefact that supports the Military Type Certificate Holder to satisfy their obligations under DASR 21.A.44, regarding the in-service management of product hazards, and to support the outcomes required of organisational Safety Management Systems for the Defence aircraft. Where the relevant operational commander has agreed to retention of any safety risk that may be posed by hazards remaining after implementation of controls, a Hazard Log (or equivalent) may also be used to record risk retention details, including the criteria for review of control effectiveness and risk retention decision validity.

AUTHORITY RECOGNISED NAA/MAA APPROACHES TO SYSTEM SAFETY

2.50 As previously discussed the common civil and military system safety standards require intelligent application and in some cases expansion if they are to meet Authority prescribed system safety requirements. Where the application of these standards is subject to oversight by an Authority recognised NAA/MAA, and within the framework and scope of that authority's regulatory approach, application of the standards may entirely satisfy the Authority prescribed system safety requirements. However, where the standards are applied outside of the regulatory system of the relevant NAA/MAA, tailoring of the standards may result in the Authority prescribed requirements no longer being met.

2.51 This section describes how the adoption of common system safety standards, under Authority recognised NAA/MAA oversight, contributes to meeting the Authority prescribed system safety requirements in this chapter. This section also provides designers with guidance on the intelligent application of the common system safety standards, where a Defence aircraft design is not subject to oversight by an Authority recognised NAA/MAA.

Civil system safety approach

2.52 Common civil system safety standards applicable to aviation consist of the FAR/CS 2x.1309, the associated Acceptable Means of Compliance (AMC) (eg AC25.1309 and AMJ 25-1309), and the SAE standards ARP4754 Guidelines for Development of Civil Aircraft and Systems, and ARP4761 Guidelines and Methods for Conducting the Safety Assessment Process on Civil Airborne Systems and Equipment. The civil standards describe methodologies and processes to establish safety objectives (both quantitative and qualitative) for the aircraft design, and to identify and control hazards. Indeed, the civil approach to system safety in aircraft design is closely aligned with Defence's approach to system safety.

2.53 **Designs certified by an Authority recognised NAA.** For new aircraft or modifications to existing aircraft, the extant civil certification applies where the Defence aircraft design meets the configuration, role and operating environment (CRE) approved by the certifying authority. Application

Superseded

of the civil system safety standards in this case will achieve compliance with all Authority prescribed system safety requirements, since:

(a) the role and operating environment of the aircraft is known and accounted for, by both the designer and certifying NAA, in the civil certification program

(b) risk retention due to shortfalls against the prescribed safety objectives is not permitted by Authority recognised NAAs

(c) there is a well-established history of designers enacting system safety programs that meet recognised NAA requirements for the development of safe aircraft designs using appropriate hazard controls

(d) hazards will have been documented, and controls established and published in relevant OIP to ensure safety objectives continue to be met.

2.54 However, designs certified under a civil certification framework may not provide clear disclosure of all hazards and associated controls (per paragraphs 2.47 through 2.51), which is an important contributor to the MTCH meeting their DASR obligations. Consequently, additional insight into these hazards and implemented controls, or the ability to access this information where required, should be arranged.

2.55 **Designs developed using civil system safety standards, but not certified by an Authority recognised NAA.** As discussed above, application of the civil system safety standards within a civil regulatory context will satisfy the Authority's system safety requirements. Similarly, where the civil system safety standards are faithfully applied to designs that are not certified by an Authority recognised NAA, the design should also satisfy the Authority's prescribed safety objectives. However, where the prescribed safety objectives are not met, or the Defence aircraft CRE is outside of the scope of the CRE approved by the original certifying NAA, additional analysis of hazards that may be impacted will be required.

2.56 For all Defence aircraft designs where the civil system safety standards are adopted, the designer must ensure that the civil standards are rigorously applied. In particular, all prescribed safety objectives must be met, and the hierarchy of controls, per paragraphs 2.38 and 2.39, must be applied to those design elements where safety objectives cannot be met. Where the Defence CRE is outside of the scope of the CRE approved for the extant civil certification, designers must ensure that the CRE deltas are assessed to confirm that prescribed safety objectives are still met for the Defence CRE, or that additional controls are implemented where required. Finally, any identified hazards must be documented per paragraphs 2.47 through 2.51 to support in-service hazard management.

US Military system safety approach

2.57 MIL-HBK-516 Airworthiness Certification Criteria and MIL-STD-882 Department of Defense Standard Practice – System Safety define the US DoD system safety requirements for military systems. MIL-STD-882 describes methodologies and processes to establish safety objectives (both quantitative and qualitative) for the aircraft design, and to identify and control hazards.

2.58 **Designs certified by an Authority recognised US MAA.** US militaries have a well-established history of producing safe aircraft designs under their regulatory systems, which includes application of MIL-STD-882 and the adoption of system safety requirements prescribed in MIL-HDBK-516. Therefore, for new aircraft or modifications to existing aircraft, where the Defence configuration, role and operating environment (CRE) is consistent with that assumed for the US certification, application

Superseded

of MIL-STD-882 will achieve compliance with the majority of Authority prescribed system safety requirements.

2.59 However, a key aspect of the MIL-STD-882 approach to system safety is the ability for the 'program executive' to accept residual risk associated with hazards where the quantitative safety criteria (established per paragraphs 2.9 and 2.11 of this chapter) have not been met. This acceptance of residual risk may be inconsistent with both theDASRs and WHS legislation obligations. Therefore, any hazards 'accepted' under the MIL-STD-882 system safety approach will need to subsequently be evaluated by Defence, and additional controls implemented if reasonably practicable, to satisfy Defence regulatory and statutory requirements.

2.60 Finally, designs certified under a recognised US MAA certification framework may not provide clear disclosure of all hazards and associated controls (per paragraphs 2.47 through 2.51), which is an important contributor to the MTCH meeting their DASR obligations. Consequently, additional insight into these hazards and implemented controls, or the ability to access this information where required, should be arranged.

2.61 **Designs developed and certified outside of an Authority recognised US MAA's regulatory system.** When employed outside of the context of a recognised US MAA's regulatory approach, MIL-HBK-516 and MIL STD-882 require considerable intelligent application if the Authority requirements for identification and control of hazards are to be met. The following issues may result in non-compliance with Authority prescribed system safety requirements:

(a) The specific system safety activities (ie 'tasks') described in MIL-STD-882 are intended to be tailored, such that only those relevant to the particular design under consideration are conducted. Therefore, intelligent selection of relevant 'tasks' is required if Authority prescribed safety outcomes are to be met.

(b) The MIL-STD-882 approach to documenting and characterising risk associated with hazards may lead to the definition of 'acceptable' risk levels, which is inconsistent with the DASR approach to hazard management and Australian WHS legislation.

(c) The adoption of a purely MIL-STD-882 system safety program may lead a designer into error since it does not require that all safety objectives are met and therefore implies that the designer has some discretion in terms of compliance.

(d) The MIL-STD-882 approach to identifying hazards may not be undertaken using formal system safety tools and techniques that are commensurate with the degree of criticality and/or complexity of the design under consideration.

(e) MIL-STD-882 does not explicitly include considerations for fail safe design (noting that fail safe design is included in MIL-HBK-516C Airworthiness Certification Criteria, although not all US military aircraft designs adopt this Airworthiness Code) or for establishing safety criteria for systems with limited at risk exposure times.

2.62 Where a designer proposes to adopt MIL-HBK-516 and MIL-STD-882 for Defence-unique designs that will be certified outside of a recognised US MAA regulatory approach, all of the potential shortfalls at paragraph 2.63 will need to be resolved through intelligent application of the standard. In all cases, the Authority prescribed system safety requirements detailed in the preceding sections of this chapter must be met.

Superseded

2.63 DEF STAN 00-056 Safety Requirements for Defence Systems describes the generic UK MoD approach to implementing system safety for Defence systems, including aircraft designs. DEF STAN 00-056 is primarily a risk management standard that describes the process by which military equipment can be verified to have satisfied the UK safety legislation requirements. Without considerable intelligent application, the standard's 'risk management' approach is incompatible with the DASR approach to type certification/design approval and is inconsistent with Australian WHS legislation. As a result, DEF STAN 00-056 can only be used as the system safety standard for Defence aircraft design activities where agreement with the Authority has been reached on how the perceived deficiencies in the standard can be resolved.

SYSTEM SAFETY GUIDANCE

2.64 Further guidance on implementing the system safety requirements prescribed in this chapter can be provided by the chapter sponsor.

AVIATION SOFTWARE

INTRODUCTION

3.1 Software is utilised extensively in modern aircraft to implement a range of functionality, some of which may be safety critical. Software that controls safety critical functions may introduce risks that must be evaluated and treated during the development program through a robust software management system that incorporates the disciplines of software safety and software assurance. The application of these software engineering principles and practices, as defined within contemporary standards, is required to establish and maintain the functional integrity and safe behaviour of software installed on aviation platforms.

3.2 The term aviation software defines software that is designed for installation within a part or appliance of an aeronautical product. The implementation of a robust and effective software management approach to Defence aviation software design is prescribed by the Authority. This chapter defines the airworthiness design requirements for robust applications of aviation software. It then identifies common approaches to the management of aviation software that meet the Authority's prescribed design requirements. This chapter also includes some brief guidance on considerations for development assurance of Airborne Electronic Hardware (AEH). Due to its close relationship to software development assurance, the AEH guidance is temporarily included in the Additional Aviation Software Guidance below pending specific AEH content publication in this Manual.

Scope

3.3 This chapter presents the Authority prescribed airworthiness design requirements for aviation software.

AVIATION SOFTWARE DESIGN REQUIREMENTS

3.4 The design of aviation software that performs safety critical functions requires the application of two key software engineering principles that support the production of safe software:

(a) Software safety, which is integrated with system safety, where software hazards are identified, analysed and treated within the context of systems engineering principles.

(b) Software assurance, which defines the engineering rigour applied commensurate to the criticality of the functions performed by the Software.

3.5 Authority prescribed software design requirements that support the achievement of this outcome are defined in the following paragraphs.

Software Safety – Identifying Software Related Hazards

3.6 A software specification error, design flaw, or the lack of initial safety requirements can contribute to or cause a system failure or erroneous operator behaviour. Software safety is used to

Superseded

address software's contribution to aircraft hazards. It is an element of the aircraft's system safety and software development program and cannot be undertaken independently of the total effort.

3.7 **Design Requirement (Essential).** *Software safety must be applied as part of the system safety program to identify any derived requirements and determine the worst credible failure condition for aviation software.*

3.8 The Defence aviation approach to system safety and associated Authority prescribed requirements are detailed in Section 2, Chapter 2 and involves the identification of system level hazards. Software safety identifies the software contribution to those hazards, the development of derived requirements to mitigate the hazards and identifies the commensurate software assurance level to adequately mitigate the hazards.

3.9 Software safety brings together elements of traditional system safety approaches in conjunction with approaches used to address the unique properties of software. A major distinction of software safety assessments against the aircraft level system safety aspects is the absence of likelihood (probabilities) for each consequence; i.e. while the consequences of software failures can be clearly identified, software risks cannot be characterised in terms of likelihood. Software failures will consistently occur given the same inputs or conditions. Instead, the worst credible failure conditions are assessed utilising methods such as Functional Hazard Assessment (FHA) and Hazard and Operability Study (HAZOP) to identify software related hazards, the consequences related to realisation of these hazards and potential mitigation actions. The worst credible failure condition of aviation software is dependent on how it influences functional hazards at the system level; i.e. software safety links the software architecture to hazards and their failure pathways through to the system level.

3.10 Software safety, when properly implemented, enables the proper identification and tracing of requirements, not only those applied from the system level, but also those requirements that are derived from design decisions. These derived requirements are used to incorporate design criteria and may be generic; e.g. performance and timing criteria or mandating the use of partitioning.

3.11 Since software safety is a subset of system safety, it must be an integral component of the formal system safety program discussed at Section 2, Chapter 2. The following documents present robust frameworks for identifying the relevant tasks, processes, activities, and guidance for inclusion in the system safety program:

(a) IEEE-STD-1228-1994 Standard for Software Safety Plans

(b) U.S. Department of Defense Joint Software Systems Safety Engineering Handbook, Version 1.0.

3.12 A Development Assurance Level (DAL), commensurate with the worst credible failure condition identified, is utilised to establish the required software assurance safety objectives. The assignment of DALs is equally applicable to complex electronic hardware (CEH) hazards. DALs are obtained through proper application of ARP 4754A Guidelines for Development of Civil Aircraft and Systems. The Authority is to be consulted on the use of other system or software safety standards as they may require tailoring to satisfy software safety objectives.

Software Assurance – Mitigating Software Related Hazards

3.13 Software assurance is closely coupled to software safety. As previously discussed, the DAL for a given system is obtained through application of system safety and software safety. The assigned DAL

Superseded

determines the processes applied to establish confidence that system development has sufficient rigour to limit the likelihood of development errors that could impact aircraft safety.

3.14 **Design Requirement (Essential).** *Aviation software must satisfy the prescribed objectives required for the Development Assurance Level commensurate with its worst credible failure condition.*

3.15 Software assurance is an activity that includes a range of certification objectives (or certification activities) to be satisfied in all phases of the development. The applicability of these certification objectives is dependent on the DAL of the software, with higher assurance levels requiring an increased scope of certification objectives, thus providing a greater level of confidence in the software. The scope of certification objectives can cover the planning, requirements, development and verification phases of the program, as well as configuration management, quality assurance and certification liaison activities.

3.16 Software assurance is achieved through proper application of RTCA DO-178C Software Considerations in Airborne Systems and Equipment Certification. Specific CEH design/assurance considerations are described in EASA CM SWCEH-001 Development Assurance of Airborne Electronic Hardware and RTCA DO-254 Design Assurance Guidance for Airborne Electronic Hardware. While other Software Assurance standards exist, as discussed later, tailoring of those standards to the satisfaction of the Authority may be required to satisfy an appropriate level of software assurance.

Software Lifecycle – Integration of the Software Principles

3.17 Aviation software has a life cycle that must be managed during development and in-service. Effective software life cycle management is an inherent part of the software safety and software assurance approaches. Software assurance objectives exist for assessment of the lifecycle processes and products, the rigour of which is based on the system DALs.

3.18 Effective management of the software life cycle ensures that compliance with the aviation software design requirements is considered at the planning stage, throughout development, and in-service operation. Software life cycle considerations can include supportability, documentation, tools, intellectual property, personnel expertise, interface control, problem reporting and tracking systems, language selection, and hardware requirements. In managing the aviation software life cycle, the authority preferred approach is presented in ISO/IEC/IEEE 12207:2017(E) Systems and software engineering – Software life cycle processes.

AUTHORITY RECOGNISED APPROACHES TO AVIATION SOFTWARE

3.19 Section 1 Chapter 3 describes the Authority approach to recognition of Airworthiness Codes, which represent prescribed airworthiness requirements from a recognised civil or military Airworthiness Authority. The Airworthiness Codes do not specify a single standard or method to manage the integrity of aviation software, but each describes and implies an ecosystem of activities that must be undertaken. This section describes common NAA and MAA applications of aviation software safety and assurance and how they meet the Authority's design requirements.

Civil Aviation Approach

3.20 NAAs such as the Federal Aviation Administration (FAA), the European Aviation Safety Agency (EASA) and the Civil Aviation Safety Authority (CASA) adopt the SAE ARP 4761 and 4754 standards for the application of system safety and software safety.

Superseded

3.21 RTCA DO-178C Software Considerations in Airborne Systems and Equipment Certification, alternatively known as EUROCAE ED-12C, is recognised by these NAAs as acceptable means of compliance for aviation software assurance. This standard satisfies the associated NAA's Airworthiness Requirements (generally Federal Aviation Regulation (FAR) or Certification Specification (CS) 2x.1301 and 2x.1309).

3.22 RTCA DO-178C is not intended to be implemented in isolation, and acceptability is based on integration with other requirements of the relevant Airworthiness Code. Consequently, civil authorities undertake software safety and software assurance within an ecosystem of design requirements, standards and associated guidance material. A visual example of the ecosystem defined by civil authorities, in this case for FAR 25, is provided in Annex A. Intelligent application of the ecosystem as utilised by the NAA/MAA will meet the airworthiness design requirements detailed in this chapter.

3.23 For legacy aircraft undergoing design changes related to software, the guidance material listed below provides the conditions for the continued use of older versions of the standard:

(a) EASA AMC 20-115D – "Airborne Software Development Assurance Using EUROCAE ED-12 and RTCA DO-178"

(b) FAA AC 20-115D – "Airborne Software Development Assurance Using EUROCAE ED-12 and RTCA DO-178" and FAA AC 00-69 – "Best Practices for Airborne Software Development Assurance Using EUROCAE ED-12( ) and RTCA DO-178()".

Military Aviation Approach

3.24 MIL-HDBK-516 Airworthiness Certification Criteria defines the US DoD aviation software requirements for military systems within Sections 14 and 15 and references various specifications, standards and handbooks as means of compliance. This provides the freedom to utilise military standards such as NATO AOP-52 and the Joint Software Systems Safety Engineering Handbook (JSSSEH) as well as the above civilian standards. This approach facilitates civilian-military interfaces such as the application of MIL-STD-882E for system safety and DO-178C for software assurance.

3.25 The UK MoD term for aviation software is 'Safety Related Programmable Elements' as detailed within DEF STAN 00-970 PART 13 Issue 13. The software safety and software assurance approach to 'Safety Related Programmable Elements' is further detailed within DEF STAN 00-55 Requirements for the Safety of Programmable Elements in Defence Systems, which is the source for software related airworthiness requirements. While DEF STAN 00-970 adopts the civilian standards as a means of compliance for both system safety and software assurance, it allows legacy platforms to retain compliance against DEF STAN 00-55 Issue 2. Note also that the underlying UK MoD system safety requirements do not fully align with Defence requirements, and can require considerable tailoring prior to application, as detailed in Section 2, Chapter 2.

3.26 The application of the preceding military approaches requires tailoring and prior agreement with the Authority. Software standards such as JSSSEH and DEF STAN 00-55 are largely guidance material and, without intelligent application, may result in incomplete objective evidence that can be used to demonstrate that appropriate software safety and software assurance has been achieved.

Superseded

ADDITIONAL AVIATION SOFTWARE GUIDANCE

3.27 Development assurance of AEH requires similar considerations to aviation software. The assignment of a DAL is equally applicable to specific AEH hazards, hence a DAL, commensurate with the worst credible failure condition identified, is utilised to establish the required AEH development assurance safety objectives. Until further guidance can be provided within this Manual, designers are to refer to EUROCAE ED-80/RTCA DO-254 Design Assurance Guidance for Airborne Electronic Hardware as an acceptable means of compliance for development assurance of AEH. Additional guidance is available within EASA CM–SWCEH-001 Issue 01 Revision 02 Development Assurance of Airborne Electronic Hardware issued 08 January 2018 and FAA Order 8110.105A Simple and Complex Electronic Hardware Approval Guidance issued 05 April 2017.

3.28 Further guidance on implementing the aviation software requirements prescribed in this chapter and addressing AEH design assurance can be provided by the chapter sponsor.

ELECTROMAGNETIC ENVIRONMETNAL EFFECTS

INTRODUCTION

4.1 The interaction of electrical and magnetic fields emanating from systems within an aircraft, or the interaction between the aircraft and the external environment, can create unwanted effects, which may adversely impact the safe flight of Defence aircraft. Protection of Defence aircraft designs against Electromagnetic Environmental Effects (E3) therefore must be established as part of initial design, subsequent modification, ongoing maintenance, and any time an aircraft or system experiences a change in its Configuration, Role or operating Environment (CRE).

4.2 Authority recognised Airworthiness Codes prescribed by National and Military Airworthiness Authorities (NAAs and MAAs) include airworthiness design requirements for E3, together with extensive guidance in most instances. However, the NAA/MAA prescribed design requirements require tailoring to:

(a) account for the unique CRE of Defence aircraft;

(b) ensure that the requirements are applied in a pragmatic manner, particularly for non-safety related systems and equipment; and

(c) ensure that radiation hazards posed by aircraft emitters comply with relevant Australian legislation and Defence policy requirements.

Scope

4.3 This Chapter presents the Authority prescribed airworthiness design requirements for Defence aircraft E3. The Chapter also presents design requirements to establish E3 protection of mission systems.

Structure of this chapter

4.4 The application of E3 design requirements prescribed by NAAs and MAAs is not straightforward. While many of the E3 requirements prescribed by NAAs and MAAs ensure that E3 will not impact safe flight, the approaches adopted often differ and may not adequately account for Defence's CRE. To account for these differences in E3 protection approaches, this Chapter presents design requirements utilising the following elements of E3 described in MIL-STD-464C Electromagnetic Environmental Effects Requirements for Systems as the basis, with tailoring to satisfy Defence's CRE where required:

(a) Margins

(b) Intra-system Electromagnetic Compatibility (EMC)

(c) Subsystems and equipment Electromagnetic Interference (EMI)

(d) Electrostatic charge control

Superseded

(e) External Radio Frequency (RF) Electromagnetic Environment (EME)

(f) High-power microwave (HPM) sources and Electromagnetic Pulse (EMP)

(g) Lightning

(h) Electromagnetic radiation hazards

(i) Electrical bonding

(j) External grounds

(k) Life cycle E3 hardness

(l) Emanations Security (EMSEC)

(m) System radiated emissions (Emissions Control (EMCON))

(n) Electromagnetic spectrum supportability.

4.5 This chapter presents the Authority prescribed E3 airworthiness design requirements for Defence aircraft acquisitions and modifications, and E3 design requirements for supporting Defence aircraft capability. Finally, the Chapter provides guidance associated with E3 management and planning.

DEFENCE AIRCRAFT ACQUISITION E3 DESIGN REQUIREMENTS

4.6 To ensure that adequate E3 protection is afforded for the Defence aircraft's CRE, this section presents Authority prescribed E3 airworthiness design requirements applicable to Defence aircraft acquisitions.

Margins

4.7 **Design Requirement (Essential).** *The application of margins during Defence aircraft E3 certification programs must satisfy the E3 airworthiness design requirements prescribed in an Authority recognised Airworthiness Code.*

4.8 **Design Requirement (Essential).** *A 16.5 dB margin (of the maximum no-fire stimulus (MNFS) threshold) must be applied to all electro-explosive devices that could impact safe operation of Defence aircraft.*

4.9 Margins are applied during E3 certification of aircraft systems and equipment to ensure that the equipment will continue to function when exposed to the proposed external and intra-system EME. Margins allow for inherent differences in equipment build quality and installations, and variability in test methods and outcomes. Authority recognised Airworthiness Codes presented in Section 1 Chapter 3 ensure that adequate margins are applied during E3 certification programs. However, these Codes (particularly civil Codes) may not cover the application of margins to Electrically Initiated Devices (EIDs), which is fundamental to ensuring that EIDs do not pose a hazard to safe flight (or personnel safety) when exposed to the associated EME, or do not suffer functional loss due to such exposure.

Superseded

4.10 **Design Requirement (Essential).** *Intra-system EMC, subsystems and equipment EMI, and electrostatic charge control certification for Defence aircraft must satisfy the E3 airworthiness design requirements prescribed in an Authority recognised Airworthiness Code.*

4.11 All Authority recognised Airworthiness Codes prescribe requirements for intra-system EMC, subsystems and equipment EMI, and electrostatic charge control. These requirements ensure that there should be no adverse impact to safe flight due to intra-system interference or electrostatic discharge.

External RF EME

4.12 **Design Requirement (Essential).** *The EME in which a Defence aircraft will operate must be established, and the associated High Intensity Radiated Field (HIRF) environment certification levels must be applied to the design.*

4.13 The ability of Defence aircraft to operate safely in the external EME must be ensured through appropriate design, testing and analysis. Authority recognised Airworthiness Codes define HIRF environments for 'normal' aircraft operations (fixed and rotary wing). However, the 'normal' HIRF environments in these Codes and associated E3 standards may not provide adequate levels of protection for Defence's CRE. The adequacy of the certified EME must be confirmed through comprehensive evaluation of the actual EME the Defence aircraft is expected to operate within. Further, the civil Codes generally do not define a HIRF environment for shipboard operations, but may define requirements based on special conditions where the aircraft is intended to operate to/from ships. Consequently, where Defence civil-derivative aircraft are required to operate to/from or in the vicinity of RAN vessels, an understanding of the HIRF environment certification (and influence over any design considerations if possible) must be established to support compliance demonstration for the Defence CRE.

High Power Microwave (HPM) Sources and Electromagnetic Pulse (EMP)

4.14 **Design Requirement (Essential).** *Where a requirement exists for High Power Microwave (HPM) and Electromagnetic Pulse (EMP) protection for Defence aircraft, the design requirements for HPM and EMP prescribed in MIL-STD-464C must be met.*

4.15 HPM emitters (such as microwave weapons and counter measures) or EMP (eg nuclear blast effects) may adversely affect safety of flight systems. Given the nature of these threats, civil Airworthiness Codes do not include protection against these hazards. Where a capability need exists for Defence aircraft to be protected against HPM and/or EMP effects, compliance with relevant MIL-STD-464C requirements must be demonstrated.

Lightning

4.16 **Design Requirement (Essential).** *Lightning strike certification for Defence aircraft must satisfy the E3 airworthiness design requirements prescribed in an Authority recognised Airworthiness Code.*

Superseded

4.17 **Design Requirement (Essential).** *Ordnance fitted to Defence aircraft must satisfy the requirements prescribed in MIL-STD-464C to remain safe during and after experiencing a lightning strike.*

4.18 Authority recognised Airworthiness Codes prescribe requirements for lightning effects that ensure safe flight for Defence aircraft following lighting strikes. However, the civil Codes and associated standards do not prescribe requirements for lightning protection of ordnance, which must be demonstrated through the application of the requirements prescribed in MIL-STD-464C.

Electromagnetic Radiation Hazards

4.19 Radio Frequency (RF) emissions from Defence aircraft may pose hazards to fuel, ordnance and personnel. Military Airworthiness Codes and supporting standards prescribe requirements for protection against Hazards of Electromagnetic Radiation to Fuel (HERF) and to Ordnance (HERO). Civil Airworthiness Codes do not consider HERO, and only consider HERF in an oblique manner. Finally, both civil and military Codes either do not explicitly cover Hazards of Electromagnetic Radiation to Personnel (HERP) or rely on radiation protection standards that do not satisfy Australian legislation.

4.20 **Design Requirement (Essential).** *Explosive ordnance intended for use on Defence aircraft must be certified as safe for operation and integration onto the aircraft, in the applicable EME, in accordance with the requirements prescribed in DEOP 115.*

4.21 HERO design requirements are prescribed by MAAs to ensure that ordnance is capable of withstanding specified EME and remain both safe and functional. Defence policy on HERO, published by EODIV in DEOP 115 Defence Electro-explosive Hazards Manual, details the approved Defence approach to classification and certification for safe storage, transportation, handling, maintenance and operation of ordnance. DEOP 115 refers to MIL-STD-464 to define the EME that Defence EO must be certified within. Normally, EODIV assesses each proposed item of EO for HERO and issues appropriate data to platform engineering organisations to support integration onto Defence aircraft. Note that ordnance safety also depends on compliance with all other elements of E3 protection described in this chapter. Consequently, in addition to DEOP 115 requirements, all other applicable Authority prescribed E3 design requirements must be met.

4.22 **Design Requirement (Essential).** *Safe distances from fuel sources during fuelling operations, including during air-air refuelling, defined in accordance with the requirements of USAF TO 31Z 10-4 or NAVSEA OP 3565 Vol 1, must be established for RF emitters fitted to Defence aircraft.*

4.23 Authority approved military Airworthiness Codes prescribe requirements to ensure that fuel will not be ignited by aircraft radiated EME. The Authority approved civil Codes are not as comprehensive. MIL-STD-464C prescribes these requirements via references to USAF TO 31Z-10-4 Electromagnetic Radiation Hazards and NAVSEA OP 3565 (Vol 1) Electromagnetic Radiation Hazards to Personnel, Fuel and Other Flammable Material. In particular, identification and treatment of hazards associated with RF emitters during refuelling operations (including air-air refuelling where relevant) is essential. Note that fuel safety also depends on compliance with all other elements of E3 protection described in this chapter. Consequently, in addition to defining appropriate safe distances, all other applicable Authority prescribed E3 design requirements must be met.

4.24 **Design Requirement (Essential).** *Aircraft occupants must not be exposed to RF levels that exceed the thresholds defined in the Defence Radiation Safety Manual.*

Superseded

4.25 Radio frequency emissions from Defence aircraft may pose hazards to personnel. Designers must ensure that Defence aircraft systems and equipment do not expose occupants to RF levels that exceed the specifications on Radiation Hazards contained in the Defence Radiation Safety Manual. Designers must also analyse emissions from Defence aircraft systems and establish appropriate safe distances to ensure that persons outside the aircraft are not exposed to RF levels that exceed the specifications on Radiation Hazards contained in the Defence Radiation Safety Manual.

Electrical bonding

4.26 **Design Requirement (Essential).** *Defence aircraft systems, subsystems and equipment must be electrically bonded to satisfy the requirements of an Authority recognised Airworthiness Code.*

4.27 **Design Requirement (Recommended).** *Metal interfaces in Defence aircraft systems, subsystems and equipment should be electrically bonded to provide a 2.5 mΩ bond in accordance with MIL-STD-464C.*

4.28 Appropriate electrical bonding minimises E3 susceptibility of aircraft systems and equipment. Electrical bonding is common practice in aircraft wiring and electrical/electronic systems and equipment, and is comprehensively covered in Authority recognised Airworthiness Codes. While the actual bond resistance between systems and equipment that will ensure safe flight is not impacted is system dependent, a 2.5 mΩ bond between metal surfaces has been demonstrated to ensure that RF potentials between systems and equipment will not adversely affect system operation.

External grounds

4.29 **Design Requirement (Essential).** *Defence aircraft must be able to be connected to an external ground.*

4.30 External grounding of the airframe is used to control current flow and static charge/discharge paths when the aircraft is on the ground. External grounding minimises hazards associated with personnel electric shock, and inadvertent ignition of ordnance, fuel and flammable vapours.

Life cycle E3 hardness

4.31 **Design Requirement (Recommended).** *Requirements for maintaining the E3 hardness of Defence aircraft during in-service operations and support should be established using the guidance in MIL-STD-464C.*

4.32 Authority recognised Airworthiness Codes may not prescribe requirements to maintain the E3 hardness levels established by the initial design, so they are not compromised by inadequate life-cycle support including maintenance, repair, surveillance and corrosion control. These requirements are comprehensively covered in MIL-STD-464C, and provide specific consideration of E3 issues when formulating ICA and when determining the most appropriate support program to manage in-service support E3 issues.

E3 DESIGN REQUIREMENTS FOR CHANGES TO TYPE DESIGN

4.33 In addition to the applicable airworthiness design requirements prescribed in the preceding section of this Chapter, this section presents Authority prescribed E3 airworthiness design

Superseded

requirements for changes to Defence aircraft type design, noting that any change must be considered within the context of the Defence aircraft's CRE.

4.34 **Design Requirement (Essential).** *Modifications to Defence aircraft systems, subsystems and equipment must comply with the E3 airworthiness design requirements prescribed in the aircraft's certification basis.*

4.35 **Design Requirement (Recommended).** *Modifications to Defence aircraft systems, subsystems and equipment should comply with the E3 design requirements prescribed in MIL-STD-464C.*

4.36 To avoid the introduction of EMI/EMC hazards, particularly for safety of flight systems and equipment, design changes to Defence aircraft must not compromise the extant the level of E3 hardness established by the certified aircraft design. Potential impact on E3 hardness should be identified during development of changes to Defence aircraft designs, and design treatments must be implemented for any reduction. Where reasonably practicable, changes to Defence aircraft designs should incorporate E3 protection improvements by following the design principles in MIL-STD-464C.

4.37 **Design Requirement (Essential).** *Requirements for maintaining the E3 hardness of Defence aircraft modifications during in-service operations and support must be established using the guidance in MIL-STD-464C.*

4.38 E3 hardness levels established during design of Defence aircraft modifications must not be compromised by inadequate life-cycle support including maintenance, repair, surveillance and corrosion control. Requirements for maintaining E3 hardness throughout the life-cycle of Defence aircraft are comprehensively covered in MIL-STD-464C, and provide specific consideration of E3 issues when formulating ICA and when determining the most appropriate support program to manage in-service support E3 issues.

CAPABILITY DESIGN REQUIREMENTS

4.39 Compliance with all of the Authority prescribed E3 airworthiness design requirements in this Chapter would ensure that mission systems will not be impacted by E3. However, this level of compliance would come with substantial costs in both design and certification effort that may not be commensurate to the risk associated with mission system failure. For example, depending on the Defence aircraft mission profiles, mission systems may not be exposed to the potential worst-case EME, and verifying that mission systems can operate within this EME would not be warranted. Consequently, considerable tailoring of the requirements is likely to be warranted to ensure that mission systems will function correctly when required, without imposing the additional verification evidence requirements associated with safety of flight systems and equipment compliance.

4.40 This section presents guidance on tailoring that may be appropriate for ensuring that mission systems in Defence aircraft are not adversely impacted by E3.

Margins

4.41 As previously discussed, margins allow for inherent differences in equipment build quality and installations, and variability in test methods and outcomes. The application of margins, however, imposes additional testing and/or design development costs to ensure that the margin is achieved. For mission systems, these additional requirements are only likely to be warranted where the loss of capability would be unacceptable if the certified EME is exceeded.

Superseded

4.42 **Capability Design Requirement.** *Margins for mission systems should be established on the basis of the criticality of the system to the achievement of the required capability.*

External EME

4.43 Since missions systems, by definition, are not critical to safe flight, requiring these systems to be capable of withstanding the EME defined in MIL-STD-464C (or the EME associated with Defence's role and operating environment) may not be warranted. To ensure that an appropriate EME is defined for mission systems, the Defence aircraft mission profiles should be evaluated to establish whether mission systems that support a critical capability will be exposed to the worst-case EME established for the aircraft's CRE. Where this is the case, the mission systems should be verified as being capable of continued operation when exposed to this EME. Otherwise, the mission systems' ability to withstand the potential EME that they are likely to be exposed to should be verified.

4.44 **Capability Design Requirement.** *The EME that mission systems should be certified to withstand should be established during design development and compliance verified during design certification.*

4.45 Current civil requirements for 'mission systems', ie those systems not required for safe flight, do not mandate certification to the EME defined in the associated Airworthiness Codes or AMC. For example, the FARs do not prescribe compliance with the requirements for continued functionality in the defined HIRF environments for non-essential systems and equipment. Consequently, this equipment may only be certified to withstand an EME as low as 1 V/m, which is clearly below a level that would be acceptable for Defence mission systems. Where verification of mission systems EME certification was, or is proposed to be, based on civil design requirements, verification activities must be critically evaluated to confirm the EME levels applied to mission systems are appropriate.

Emanations Security (EMSEC)

4.46 EMSEC requirements for Defence are published by the Australian Signals Directorate in Australian Communications – Electronic Security Instructions (ACSI) 71(C). EMSEC does not impact safety of flight, and the need for EMSEC is a capability requirement driven by the Defence aircraft's CRE.

4.47 **Capability Design Requirement.** *Where required, Defence aircraft EMSEC should comply with the requirements of ACSI 71 (D), Annex D.*

System radiated emissions (Emissions Control (EMCON))

4.48 Control of system emissions may be required to support operations in close proximity to other platforms and to limit threat capability detection and tracking. Similar to the requirement for EMSEC, EMCON is a capability requirement driven by the Defence aircraft's CRE.

4.49 Capability Design Requirement. Where required, Defence aircraft EMCON should comply with the requirements of MIL-STD-464C.

Superseded

4.50 EM spectrum approvals for Defence aircraft systems are managed by the Defence Spectrum Office in accordance with the requirements of the Defence Spectrum Manual. Approval of RF spectrum use should be achieved prior to Defence aircraft operations.

4.51 **Capability Design Requirement.** *Defence aircraft EM spectrum approval should be provided in accordance with the requirements of the Defence Spectrum Manual.*

E3 MANAGEMENT AND PLANNING

4.52 While not essential for the achievement of a safe aircraft design from an E3 perspective, Defence experience has demonstrated that a successful E3 certification and control program depends on appropriate and sufficiently detailed planning. Consequently, the Authority recommends the use of an E3 planning document (the E3 Control Program Plan (E3CPP)) to assist designers to achieve an E3 compliant design, while limiting test and analysis overheads to only those required for the specific certification activity under consideration.

4.53 An E3CPP should be developed for all new Defence aircraft acquisitions, and for all Major modifications that could have a substantial impact on E3 certification. The E3CPP should include a description of the following:

(a) the proposed management framework for the E3 control program

(b) the Defence aircraft EME

(c) E3 design and mitigation strategies considered for incorporation or incorporated into the aircraft design

(d) the tests and analyses required to support E3 certification, together with references to any test results

(e) any E3 shortfalls identified, which could not be treated by design, and any associated alternative risk treatment strategies employed.

E3 WHS REQUIREMENTS

4.54 Exposure to radiation emitted by Defence aircraft systems and equipment can result in serious health issues. Defence must comply with Commonwealth WHS legislation for the purposes of ensuring the safety of persons in the workplace. Defence's radiation safety requirements for personnel are prescribed in the Defence Radiation Safety Manual, which requires compliance with the Australian Radiation Protection and Nuclear Safety Act 1998. Additional compliance requirements for Defence are prescribed in the Defence Work Health and Safety Manual, Volume 2, Part 3C, Chapters 1-4. The safety of both aircraft occupants and personnel outside of the aircraft must be ensured and personnel safe distances, defined in accordance with the requirements of the Defence Radiation Safety Manual, must be established for RF emitters fitted to Defence aircraft.

Superseded

4.55 Further guidance on E3 design considerations and the application or tailoring of E3 design requirements for Defence aircraft mission systems and equipment can be provided by the chapter sponsor.

HUMAN FACTORS ENGINERING

INTRODUCTION

5.1 The safe design of a system, in part, comes from recognising that the roles and performance of the human components within those systems form part of the design process. This chapter provides guidance on the application of Human Factors Engineering (HFE) design requirements.

5.2 When considering new designs or modifications, the designer should ensure the identification of average human capabilities, and the minimisation of performance requirements which exceed those capabilities, through application of appropriate human factors design requirements. All safe system designs should therefore not only take into account the limitations of people but also build in safeguards to mitigate 'worst credible scenarios' should the limitations be exceeded. The application of HFE considerations in new design or modifications can be broadly separated into two areas:

(a) HFE Considerations in individual System Design, which covers the application of HFE in each aircraft system's design, to optimise normal and worst credible scenario operations; and

(b) HFE Considerations in Systems Integration, which ensures HFE consideration of the workloads placed on personnel when the integrated aircraft system is not operating as intended, in worst credible scenarios.

Scope

5.3 The ADF Human Factors Engineering design requirements are applicable to aircraft acquisition and major modification projects and minor changes to type design. This chapter presents the Authority prescribed design requirements for HFE.

HUMAN FACTORS ENGINEERING STANDARDS APPLICATION

5.4 Design Requirement (Essential). HFE for Defence aircraft designs must satisfy the requirements of one of the following standards:

(a) US DoD MIL-STD-1472 G Human Engineering

(b) UK military standard DEF STAN 00.25 Human Factors for Design of Equipment

(c) the applicable FAA/EASA regulations for the aircraft type.

5.5 While HFE design considerations for civil certified platforms can be found embedded within the various systems' design requirements within FAR/EASA regulations, most commercial manufacturers still apply the requirements defined in MIL-STD-1472 for HFE certifications of airborne systems under the FAA. Consequently, for civil certified platforms, the commercial HFE standards are either the FARs/JARs, and/or MIL-STD-1472, depending on the scope of the new design.

Superseded

5.6 Design Requirement (Essential). Methods and techniques for assessing hazards arising from HFE considerations must be integrated within the System Safety Program.

5.7 HFE considerations are an essential element of a successful System Safety Program, and must therefore be assessed together with hardware and software safety considerations. Further guidance on the considerations for System Safety Programs is detailed in Section 2, Chapter 2 – System Safety.

5.8 Design Requirement (Recommended). HFE considerations should be formally captured and documented.

5.9 A consolidated document that captures all HFE considerations, HFE tools and methods utilised provides a beneficial management and coordination tool. The complexity of the document is commensurate to the relative platform risks, the weapon system's configuration, role and environment, design complexity and HFE coordination required. Commonly within Defence, a Human Engineering Program Plan (HEPP) is generated as the consolidated document.

ADDITIONAL HUMAN FACTORS ENGINEERING GUIDANCE

5.10 Further guidance on Human Factors Engineering design considerations can be provided by the chapter sponsor.

CRASH PROTECTION

INTRODUCTION

6.1 Aircraft that comply with Contemporary Crash Protection Design Requirements (CCPDR) reduce the likelihood of crew and passengers suffering fatalities and serious injuries in the event of a survivable crash. MAO's are required to to maintain a system to 'eliminate or otherwise minimise risk SFARP to personnel on aircraft that do not meet CCPDR' and to 'evaluate Defence aircraft against the CCPDR'. To support the ongoing risk management of ADF aircraft, the Authority prescribes the CCPDR applicable to Defence aircraft. Where previously specific DASR were used to enforce compliance to the CCPDR, the contemporary understanding of risk management in aircraft crash protection has evolved such that it may be managed like other risks to personnel safety. This chapter is intended to represent the technical requirements, with DASP Volume 3 Chapter 6.10 Aircraft Crash Protection representing the additional information and guidance on the quantification and communication of crash protection risk.

Scope

6.2 This chapter presents the Authority prescribed CCPDR.

CONSIDERATIONS FOR DEFINING CCPDR

6.3 This section discusses the basis for the Authority prescribed CCPDR in terms of the design principles associated with crash protection, the definition of 'benign' and 'challenging' environments and the broad application of civil and military Authority approved Airworthiness Codes, to provide context for the application of the CCPDR.

Aircraft Crash Protection Design Principles

6.4 A successful crash protection strategy is one that protects occupants from fatalities and serious injury in potentially survivable crashes while limiting capability reductions, implementation costs and additional maintenance overheads. To optimise occupant protection, a systems approach to crash protection is necessary, encompassing the following five key crash protection principles:

(a) **Aircraft crash resistance.** The ability of the aircraft structure to provide a protective shell for occupants in the event of a survivable crash is a key factor for occupant survival. The structure and equipment should be designed to allow deformation in a controlled, predictable manner so that forces imposed upon the occupants will be tolerable while still maintaining a protective shell. Restraint of concentrated (or high) mass items should prevent parts of the aircraft becoming projectiles within the cabin during a crash creating crushing or blunt trauma hazards (eg engines/transmission/blades coming through the roof, internally mounted items dislodging, and so on).

Superseded

(b) **Occupant retention.** Protection should be afforded to occupants by the aircraft's retention system, which comprises the seat, seat retention and occupant restraint system assembly. The retention system plays a major role in preventing occupant contact injuries associated with body parts flailing into aircraft structures and plays a predominant role in energy absorption (seating design).

(c) **Cargo and equipment retention.** Restraint systems should be designed to control cargo and ancillary equipment displacements that are hazardous to occupants during a survivable crash.

(d) **Post-crash emergency escape provisions.** Occupants should retain the ability to rapidly evacuate the aircraft during non-crash ground emergencies, and after survivable crash conditions. The ability to escape is impacted by aircraft deformation, lighting, escape hatches, and so on.

(e) **Post-crash injury prevention.** The crash protection system should be designed to prevent post-crash environmental hazards that could seriously injure occupants. For hazards which cannot be prevented, the crash protection system should protect occupants from exposure to the hazards. Potential post-crash environmental hazards include fire, toxic fumes and submersion. This principle can be extended to include equipment that can improve post-crash survivability after the crash sequence. Such equipment includes first aid kits, survival kits and emergency locator transmitters.

6.5 These five design principles are addressed by a number of civil and military crash protection design requirements and associated standards. While not considered within the context of the discussion in this Chapter, Aeronautical Life Support Equipment (ALSE) is also a key contributor to crash protection, in particular post-crash injury prevention. Section 5 Chapter 2 of this manual presents the Authority prescribed design requirements for ALSE and should be read in conjunction with this Chapter.

'Benign' and 'Challenging' environments

6.6 Civil and military design requirements for aircraft crash protection are structured to accommodate the differences between civil and military operations. In the case of civil operations, the prescribed requirements define a level of crash protection that is appropriate for normal operations in civil aircraft, including consideration of the likelihood of a survivable crash occurring. Military requirements, on the other hand, recognise that due to military operations the likelihood of crashes occurring in broad terms, and therefore the likelihood of a survivable crash occurring, for some military aircraft will be higher than for most civil aircraft. Therefore, the military requirements prescribe more demanding crash protection attributes. The determination of the appropriate suite of crash protection design requirements to apply to a particular Defence aircraft type requires consideration of the circumstances in which a survivable crash is most likely to occur. The application of an appropriate suite of CCPDR to a Defence aircraft type is informed by establishing whether the aircraft will operate in a 'benign' or 'challenging' environment.

6.7 The following paragraphs discuss the characteristics that would normally be considered as constituting operations in a challenging environment for fixed and rotary wing aircraft. For the purposes of determining which CCPDR apply to a particular Defence aircraft type, if the aircraft operations do not include the characteristics associated with challenging environments, then the operations may be considered 'benign'.

Superseded

6.8 **Fixed wing.** For fixed wing aircraft, the take-off and landing phases of flight carry an inherently higher risk of crashing[1]. Where military aircraft are routinely conducting tactical take-off / landing, and therefore the likelihood of survivable and non-survivable crashes is increased above the civil norm, this is considered a 'challenging' CP environment. While low level tactical flight also increases the likelihood of crashes, the prevalent crashes under these circumstances are expected to be non-survivable and, therefore, are not considered 'challenging' from a CP perspective.

6.9 **Rotary wing.** The rotary wing 'challenging' environment includes all helicopter operations where the likelihood of a crash is higher than that which would be expected in normal civil operations. This includes regular low level tactical flight[2], extended hover near to the ground, regular ship landings under conditions not experienced during similar civil operations (eg ship landing sites with limited clearance, high sea states), and so on.

6.10 Determining whether an aircraft will operate in a 'benign' or 'challenging' environment will operate in a 'benign' or 'challenging' environment establishes the appropriate suite of CCPDR to apply to Defence aircraft, Consequently, an assessment of the proposed Defence aircraft operations to ascertain the expected environment from a crash protection perspective should be completed, prior to conducting a CP evaluation. The characterisation of operations as 'routine' or 'regular' in the above environment definitions would be expected where such operations form part of the Defence aircraft's defined roles and would therefore normally be included in the SOIU. Where operations usually considered as constituting a 'challenging' environment are only rarely conducted (for example a few times during the aircraft's life and only under contingency approval), these operations would not normally warrant consideration as a 'challenging' environment for CP purposes.

Authority approach to establishing CCPDR for benign and challenging operating environment contexts

6.11 This section discusses the Authority's approach to establishing CCPDR for benign and challenging environment contexts through the application of crash protection design requirements prescribed in Authority recognised Airworthiness Codes.

6.12 **Benign Environment Contemporary Crash Protection Standard.** Civil operations are, unsurprisingly, conducted in an operating environment that is consistent with the definition of a benign crash protection environment context as described in paragraphs 6 through 10. Consequently, the design requirements prescribed in Authority recognised civil Airworthiness Codes present an appropriate benchmark against which to assess Defence aircraft crash protection attributes for operations in benign environments. The FAA's Federal Aviation Regulations (FARs) and EASA's Certification Specifications (CSs) present airworthiness design requirements for fixed wing aircraft (Parts 23 and 25) and rotary wing aircraft (Parts 27 and 29). These design requirements cover the elements of crash protection such as seat crashworthiness, fire protection, emergency provisions and cargo retention without explicitly identifying the requirements as 'crash protection'. Although similar in most respects, the FAR and CS crash protection requirements do have some differences. The Authority has determined that the contemporary civil crash protection design requirements for benign operating environments are defined by the most demanding of requirements between the FARs and CSs. Operational regulations can also impose airworthiness design requirements beyond those in the design FARs/CSs (ie Parts 23, 25, 27 and 29). Some of these additional requirements may be relevant to crash protection, for example the requirement for additional safety equipment, improved flammability performance of cabin interiors and so on. Consequently, the Authority has included in the benign contemporary crash protection standard the relevant requirements from FAR Parts 91, 121, 125 and 135 and the applicable Commercial Air Transport (CAT) operational regulations

Superseded

in European Commission Regulation (EU) No 965/2012 Laying down technical requirements and administrative procedures related to air operations pursuant to Regulation (EC) No 216/2008 of the European Parliament and of the Council.

6.13 Summarising, the Authority prescribes the sum of the following as the benign environment contemporary crash protection standard applicable to Defence aircraft:

(a) Airworthiness design requirements provided by the latest amendment of the:

1. relevant FAR or CS, plus

2. the alternate relevant FAR or CS requirements that provide an increase to the level of crash protection, plus

(b) Additional design requirements specified in the operational regulations of the:

1. relevant FAR, CS, EU CAT, plus

2. the alternate relevant FAR, CS, EU CAT requirements that provide an increase to the level of crash protection.

6.14 Annex A presents the elements of the above standards that constitute the Authority prescribed benign environment contemporary crash protection standard.

6.15 **Challenging Environment Contemporary Crash Protection Standard.** The US DoD handbooks and standards follow a systems approach to crash protection, and in this respect are superior to the civil standards. Furthermore, they recognise the likely differences in crash scenarios between military and civil aircraft, and specifically cater for the military environment. Therefore, the military standards account for operations that constitute the challenging environment as defined at paragraphs 6 through 10, and present an appropriate benchmark against which to assess Defence aircraft crash protection attributes for operations in challenging environments. MIL-STD-1290A Light Fixed and Rotary-Wing Aircraft Crash Resistance is the prevalent crash protection standard for US military platforms and the Authority has determined that it provides adequate coverage to form the basis of the Authority prescribed challenging environment contemporary crash protection standard for Defence aircraft. Nevertheless, there are a number of crash protection elements, such as head injury criteria (HIC) and femur loads and equipment requirements prescribed in operational FARs, and EU Regulation 965/2012, where the civil design requirements are more onerous than those prescribed in MIL-STD-1290A. Consequently, the Authority has prescribed the challenging environment crash protection standard for Defence aircraft as the requirements prescribed in MIL-STD-1290A supplemented by the relevant requirements from FARs/CSs and civil operational regulations.

6.16 Summarising, the Authority prescribes the sum of the following as a contemporary challenging environment contemporary crash protection standard applicable to Defence aircraft:

(a) design requirements prescribed in the latest amendment of MIL-STD-1290A, plus

(b) HIC and femur load requirements of FAR or CS 2X.562 (whichever is most demanding) using the FAR/CS appropriate for the type and size of aircraft, plus

(c) equipment requirements specified in the most demanding operational regulations of the FARs and EU CAT.

6.17 Annex B presents the elements of the above standards that constitute the Authority prescribed challenging environment contemporary crash protection standard.

Superseded

6.18 Importantly, the challenging environment contemporary crash protection standard (ie MIL-STD-1290A) has been specifically developed for rotary wing and light fixed wing aircraft operating contexts and associated crash scenarios. Therefore, a straightforward application of the challenging environment standard to large fixed wing aircraft is not appropriate. Consequently, the Authority has determined that the challenging environment contemporary crash protection standard for large fixed wing aircraft is the Annex A benign environment crash protection standard (FAR/CS 25 plus relevant operational regulations) supplemented by applicable Annex B challenging environment crash protection standard (ie MIL-STD-1290A) requirements, where the Annex B requirements are more onerous. Applicable requirements from MIL-STD-1290A will be defined based on the characteristics of the aircraft that are represented in the MIL-STD and for which an improvement in the level of crash protection could be expected through application of the more onerous requirement. For example, restraining items of mass to the load cases in MIL-STD-1290A may not afford an improvement in crash protection if the structure of large fixed wing aircraft will disintegrate well before these loads are reached in a challenging environment survivable crash scenario.

DEFENCE AIRCRAFT CRASH PROTECTION DESIGN REQUIREMENTS

6.19 This section presents the Authority prescribed CCPDR for Defence aircraft. Unlike most other Authority prescribed design requirements in the DASDRM, the CCPDR prescribed in this section are applicable to Defence aircraft throughout the aircraft's life-of-type, not just for acquisition.

6.20 **Design Requirement (Essential).** *The following Authority prescribed CCPDR must be applied to Defence aircraft:*

(a) *Aircraft operating in a benign environment*

1. *Small fixed wing and rotary wing Defence aircraft having a civil or civil-derived certification pedigree – the CCPDR defined in Annex A to this Chapter.*

2. *Small fixed wing and rotary wing Defence aircraft having a military certification pedigree – the CCPDR defined in Annex A to this Chapter or the CCPDR in Annex B to this Chapter (noting that compliance with Annex B exceeds the benchmark requirements).*

3. *Large fixed wing aircraft Defence aircraft having a civil, civil-derived or military certification pedigree – the CCPDR defined in Annex A to this Chapter.*

(b) *Aircraft operating in a challenging environment*

1. *Small fixed wing and rotary wing aircraft having a civil or civil-derived certification pedigree - the CCPDR defined in Annex A to this Chapter **supplemented by** applicable requirements defined in Annex B, where the Annex B requirements are more onerous; or the CCPDR in Annex B to this Chapter.*

2. *Small fixed or rotary wing aircraft having a military certification pedigree – the CCPDR defined in Annex B to this Chapter.*

3. *Large fixed wing Defence aircraft having a civil, civil-derived or military certification pedigree – the CCPDR defined in Annex A to this Chapter **supplemented by** applicable requirements defined in Annex B, where the Annex B requirements are more onerous.*

6.21 Crash protection afforded to occupants of Defence aircraft is maximised by aircraft designs that comply with the suite of CCPDR as defined in Annex A or B, as applicable. Where the CCPDR

Superseded

have not been, or cannot be reasonably practicably met by Defence aircraft designs, the identification of shortfalls and communication and treatment of associated risks to personnel safety should be undertaken in accordance with the requirements of DASP Volume 3 Chapter 6.10 Aircraft Crash Protection.

6.22 The determination of CCPDR for large fixed wing aircraft that operate in a challenging environment will be dependent on the type of operations being undertaken. The CCPDR for these aircraft types and operations is likely to be a combination of Annex A plus requirements from Annex B (ie MIL-STD-1290A) that are determined to be applicable to the likely survivable crash scenarios for that aircraft type. However, in the absence of an analysis of the operating environment to establish which crash protection features warrant additional consideration or the adoption of more onerous requirements, the Authority is unable to prescribe generic CCPDR for these aircraft.

CHANGES TO TYPE DESIGN AFFECTING CRASH PROTECTION

6.23 **Design Requirement (Essential).** *Changes to the type design must not degrade the level of crash protection afforded by the extant Defence aircraft design.*

6.24 **Design Requirement (Essential).** *Changes to the type design must meet the relevant requirements of the Authority prescribed CCPDR.*

6.25 Proposed changes to the aircraft configuration must retain the extant level of crash protection of the aircraft and satisfy the relevant Authority prescribed CCPDR. The Authority will not ordinarily approve a design change that results in a reduced level of crash protection from that inherent in the extant aircraft baseline. However, where such a reduction is unavoidable (eg due to a capability imperative), the shortfall must be assessed in terms of the impact on safety versus capability gains of the proposed change to establish whether reasonably practicable controls to either eliminate or further minimise the risk can be implemented. Informed risk treatment decisions can only be made if the evaluation presents a robust assessment of the magnitude of the reduction, together with options for reasonably practicable risk treatment to improve the level of crash protection. Design changes must also be evaluated against the relevant CCPDR and reasonably practicable design features that improve the level of crash protection afforded to occupants must be incorporated. Any shortfalls against the CCPDR must be managed in accordance with the requirements of DASR AMC1 to 21.A.17A.

NOTE

Where a design change (either Minor or Major) impacts the crash protection attributes of a Defence aircraft, the change must be evaluated against the CCPDR and a determination made regarding whether compliance with the CCPDR has been achieved.

CRASH PROTECTION REQUIREMENTS FOR CARGO CARRIAGE

6.26 While the civil and military crash protection design requirements and standards referred to above include considerations for cargo carriage, these considerations are often not contextualised for the Defence operational environment. The cargo load restraint standards prescribed in Section 5 Chapter 5 of this manual have been developed specifically for the Defence military context of strategic and tactical airlift, both with and without passengers. The military standards also consider required capability outcomes and the necessary flexibility to achieve operational goals. None of these aspects feature in considerations for civil load restraint (particularly for cargo) and therefore direct

Superseded

application of the civil requirements may not be appropriate for Defence aircraft, depending on the aircraft's role and type of operations.

2.27 Prior to adopting the cargo restraint requirements in Section 5 Chapter 5 as the CCPDR for a particular aircraft type, the designer must confirm with the capability manager that the context of application of the cargo load restraint requirements is consistent with the proposed Defence aircraft operational context. Further, any additional risk treatments (such as operational treatments to limit exposure of passengers to injury/death as a result of loss of cargo restraint in a survivable accident) must be considered and implemented where reasonably practicable, including the adoption of the civil-like cargo carrying requirements where practicable.

6.28 For some Defence aircraft the context of operations is not consistent with the context for which the Section 5 Chapter 5 requirements were derived. For example, the KC-30A will occasionally be required to carry Defence cargo, but the loading/unloading of this cargo is not usually required to be conducted in adverse operational conditions requiring rapid access and ease of transfer. Under these circumstances, the extant civil requirements remain appropriate as the basis for the CCPDR related to cargo carriage.

6.29 For the purposes of cargo carriage, the military cargo load restraint standards prescribed in Section 5 Chapter 5 represent the minimum standard for load restraint in military aircraft, and may be adopted in lieu of the cargo carriage restraint requirements prescribed in CCPDR subject to the following design requirements, and the considerations for carriage of cargo under DASR.ACD.

6.30 ***Design Requirement (Essential).*** *For Defence aircraft undertaking military cargo carrying operations[3], restraint of cargo must satisfy the load restraint limits for the cargo type and transportation mode prescribed in DASDRM Section 5 Chapter 5 Aerial Delivery of Materiel.*

6.31 ***Design Requirement (Essential).*** *For Defence aircraft undertaking civil-like cargo carrying operations, restraint of cargo must satisfy the load restraint limits for the cargo type and transportation mode prescribed in Authority recognised civil Airworthiness Codes.*

ADDITIONAL CRASH PROTECTION GUIDANCE

6.32 Further guidance on implementing the crash protection requirements prescribed in this chapter can be provided by the chapter sponsor.

ANNEXES

ANNEX A - BENIGN ENVIRONMENT CONTEMPORARY CRASH PROTECTION STANDARD

BENIGN ENVIRONMENT CONTEMPORARY CRASH PROTECTION STANDARD

As discussed in Section 2 Chapter 6, the Authority prescribed benign environment contemporary crash protection standard is the sum of the following:

(a) Airworthiness design requirements provided by the latest amendment of the:

1. relevant FAR or CS, plus
2. the alternate relevant FAR or CS requirements that provide an increase to the level of crash protection, plus

(b) Additional design requirements specified in the operational regulations of the:

1. relevant FAR, CS or EU CAT, plus
2. the alternate relevant FAR, CS or EU CAT requirements that provide an increase to the level of crash protection.

Table 6–A–1 lists the airworthiness design requirement clauses from the FARs/CSs that provide crash protection requirements. Tables 6–A–2 through 6–A–5 list the operational regulation clauses from the FARs and EU CAT. Note that some of the clauses in each table also include design requirements that are not related to crash protection. Section 5 chapter 2 of this manual should also be consulted to include relevant Authority prescribed requirements for Aeronautical Life Support Equipment (ALSE).

Table 6–A–1 FAR/CS 23, 25, 27 and 29 Crash Protection Clauses

Subject	FAR/CS 23 (1)	FAR/CS 25 (1)	FAR/CS 27 (1)	FAR/CS 29 (1)

Additional Guidance Material

Superseded

The FAA issues additional guidance material in the form of Advisory Circulars (ACs). EASA Acceptable Means of Compliance (AMC) perform a similar function. These provide a means to demonstrate compliance with certain clauses of the FARs/CSs. AMC is issued with the CSs and frequently refers to related FAA ACs. The FAA ACs are separate documents. The following ACs are relevant to crash protection.

Fixed Wing Aircraft

(a) AC 25-9A–Smoke Detection, Penetration and Evacuation Tests and Related Flight Manual Emergency Procedures covers smoke and smoke dispersal requirements.

(b) AC 25-16–Electrical Fault and Fire Prevention and Protection provides acceptable means to minimise the potential and effects of electrical faults, overheat, smoke and fire.

(c) AC 25-17A–Transport Airplane Cabin Interiors Crashworthiness Handbook is a general AC covering the applicable cabin interior crashworthiness requirements of FAR 25. This AC does not include crashworthiness aspects such as fuel tank/system design, fuselage deformation and prevention of post-crash fires, but does incorporate guidance in seat/restraint system design, fire extinguishing, safety equipment and oxygen equipment. Appendix 3 of this AC provides a list of applicable FAA cabin interior crashworthiness ACs.

(d) AC 23.562-1–Dynamic Testing of Part 23 Airplane Seat/Restraint Systems and Occupant Protection provides guidance for demonstrating compliance with the FARs applicable to the dynamic testing of aircraft seats and occupant protection (e.g. 23.562, 23.785, and 23.787).

(e) AC 25.562-1B–Dynamic Evaluation of Seat Restraint Systems and Occupant Protection on Transport Airplanes provides guidance for demonstrating compliance with the FARs applicable to the dynamic testing of aircraft seats and occupant protection (e.g. 25.562, 25.785, 25.787, and 25.789).

(f) AC 25.783-1A–Fuselage Doors, Hatches and Exits provides guidance for demonstrating compliance with the structural and functional safety standards of fuselage doors and their operating systems.

(g) AC 25.785-1B–Flight Attendant Seat and Torso Restraint System Installations provides design requirements particular to flight attendant seating.

(h) AC 25.803-1–Emergency Evacuation Demonstrations discusses both full scale testing and analysis / test combinations as a means of compliance with FAR 25.803.

(i) AC 25.807-1–Uniform Distribution of Exits provides guidance for demonstrating compliance with the FAR 25.807(c) requirement of uniform distribution of required emergency exits.

(j) AC 25.812-1A/-2–Floor Proximity Emergency Escape Path Marking Systems provides guidance for demonstrating compliance with the FAR 25.812. AC 25.812-2 specifically discusses photo luminescent elements.

(k) AC 25.853-1–Flammability Requirements for Aircraft Seat Cushions provides guidance for demonstrating compliance with the requirements of the FARs pertaining to flammability of aircraft seat cushions.

(l) AC 25.856-1–Thermal / Acoustic Insulation Flame Propagation Test Method Details provides guidance for demonstrating compliance with 25.856a and part VI of Appendix F to FAR 25.

Superseded

(m) AC 25.856-2A–Installation of Thermal/Acoustic Insulation for Burnthrough Protection provides guidance for demonstrating compliance with FAR 25.856b and part VII of Appendix F to FAR 25.

(n) AC 25.994-1–Design Considerations to Protect Fuel Systems during a Wheels-Up Landing provides guidance for demonstrating compliance with the requirements of FAR 25.994 and protecting fuel system components located in the engine nacelles and the fuselage.

(o) AC 20-135–Powerplant Installation and Propulsion System Component Fire Protection Test Methods, Standards and Criteria provides guidance for demonstrating compliance with the powerplant fire protection requirements of FARs 23 through 29 and testing to define if a material is 'fireproof' or 'fire resistant'.

(p) AC 120-47–Survival Equipment for use in Overwater Operations provides information regarding the survival equipment that should be carried during aircraft extended overwater operations.

Rotary Wing Aircraft

(a) The FAA has produced ACs 27-1B – Certification of Normal Category Rotorcraft and 29-2C–Certification of Transport Category Rotorcraft. These ACs provide guidance for demonstrating compliance with certification requirements in FARs 27 and 29 respectively. This inherently includes consideration for all the crash protection principles covered in this Chapter. For instance, AC 27-1B contains subsections providing guidance for demonstrating compliance with seat/restraint system dynamic impact testing, fire protection, structural strength requirements, etc.

Superseded

ANNEX B - CHALLENGING ENVIRONMENT CONTEMPORARY CRASH PROTECTION STANDARD

CHALLENGING ENVIRONMENT CONTEMPORARY CRASH PROTECTION STANDARD

(a) As discussed in Section 2 Chapter 6, the Authority prescribed challenging environment contemporary crash protection standard is the sum of the following:

1. design requirements provided by the latest amendment of MIL-STD-1290A, plus
2. HIC and femur load requirements of FAR or CS 2X.562 (whichever is most demanding) using the FAR/CS appropriate for the type and size of aircraft, plus
3. equipment requirements specified in the most demanding operational regulations of the FARs, CSs and EU CAT.

(b) This annex presents additional detail on the application of the components of the challenging environment CCPDR.

Design requirements specified in MIL-STD-1290A

(c) MIL-STD-1290A presents a contemporary military crash protection standard requiring minimal supplementation, other than from design standards referred to within MIL-STD-1290A including:

1. MIL-DTL-27422D–Detail Specification for the Tank, Fuel, Crash-Resistant, Ballistic-Tolerant, Aircraft
2. MIL-S-58095A–Seat System: Crash-Resistant, Non-Ejection, Aircrew, General Specification for
3. MIL-S-85510–Seats, Helicopter Cabin, Crashworthy, General Specification for
4. MIL-H-83796B–Hose Assembly, Rubber, Lightweight, Medium Pressure, General Specification for
5. MIL-PRF-83282D–Hydraulic Fluid, Fire Resistant
6. MIL-DTL-25579F–Hose Assembly, High Temperature, Medium Pressure General Specification for
7. MIL-H-38360B–Hose Assemblies, High Temperature, High Pressure, 3000 psi, Hydraulic and Pneumatic.

(d) JSSG 2010-7 and the Aircraft Crash Survival Design Guide provide additional detailed guidance on the application of crash protection design requirements in the military context.

Head Injury Criteria and Femur Load Requirements

(e) MIL-STD-1290A must be supplemented with FAR or CS 2X.562 (whichever is more demanding) for measuring head injury and femur loads in the design of seats. The associated FAA advisory circulars (ACs 27-1B, 29-2C, 23.562-1 or 25.562-1B as applicable) provide additional guidance on means of compliance for these crash protection design features.

Operational Regulations

(f) MIL-STD-1290A must be supplemented with the operational regulation clauses of the FARs and EU CAT that provide crash protection requirements detailed in Annex A to Section 2

Superseded

Chapter 6. These operational requirements are equally applicable to, and form part of, the Authority prescribed challenging environment contemporary crash protection design standard.

Superseded

FIRE PROTECTION

INTRODUCTION

7.1 Fires represent one of the most severe hazards that can occur in an aircraft. Fire protection measures are therefore essential design characteristics in aircraft that minimise the likelihood of a fire occurring and, where a fire does occur, ensure that the crew are alerted to the presence of and can effectively combat the fire, and if necessary take action to land and evacuate the aircraft.

7.2 For the majority of Defence aircraft the fire protection design requirements prescribed in Authority recognised civil and military Airworthiness Codes defined in Section 1 of this manual satisfy prescribed safety objectives for Defence aircraft fire protection. However, modifications to civil aircraft to provide military capability may be inconsistent with the 'normal' approach to fire protection adopted within civil Codes, and therefore the level of fire protection afforded by the design may be compromised. Consequently, the Authority prescribes fire protection airworthiness design requirements to supplement the civil Codes and provide a basis for verifying the acceptability of Defence aircraft fire protection measures.

Scope

7.3 This Chapter presents Authority prescribed airworthiness design requirements for Defence aircraft fire protection.

DEFENCE AIRCRAFT FIRE PROTECTION DESIGN REQUIREMENTS

7.4 Where a Defence civil-derivative aircraft is substantially unmodified from that originally certified by an Authority recognised National Airworthiness Authority (NAA), compliance with an Authority recognised civil Airworthiness Code defined in Section 1 will satisfy the prescribed fire safety objectives for Defence aircraft. Military aircraft certified by an Authority recognised Military Airworthiness Authority (MAA) are designed from first principles to provide the required capability and all associated systems and equipment needed to support military functions will have been subjected to the associated military Code fire protection design requirements for that aircraft type. Any modifications to military aircraft that are subject to MAA certification, will similarly be certified under this 'first principles' approach. Consequently, for Defence military aircraft compliance with the fire protection design requirements in an Authority recognised military Airworthiness Code satisfies prescribed fire safety objectives for Defence aircraft.

7.5 **Design Requirement (Essential).** *Defence aircraft must satisfy the fire protection design requirements prescribed in an Authority recognised Airworthiness Code as defined in Section 1 of this manual.*

7.6 Notwithstanding compliance with a civil Airworthiness Code, civil-derivative aircraft that are modified to provide military capabilities may have additional equipment and systems fitted in areas of the aircraft where such equipment is not usually accommodated. Civil-derivative aircraft modifications may also include equipment that does not comply with the materials properties usually

Superseded

applied to aircraft equipment to provide adequate fire protection. In this case, compliance with the fire protection design requirements of an Authority recognised civil Airworthiness Code may not afford a level of fire safety that satisfies prescribed safety objectives. Where a Defence civil-derivative aircraft configuration includes modifications from the original certified baseline design to include systems/equipment that is not 'normal' (ie similar in function and hazards) to the original certified aircraft design, the Authority prescribed fire protection airworthiness design requirements defined in this chapter must also be met.

CIVIL-DERIVATIVE AIRCRAFT MODIFIED FOR DEFENCE PURPOSES

The Authority's approach to prescribing fire protection design requirements for Defence civil-derivative aircraft

7.7 The Authority prescribed fire protection design requirements ensure that military-unique modifications to civil-derivative aircraft do not unacceptably degrade the inherent level of fire protection afforded by the original civil certified design. Fire protection design requirements prescribed in civil Airworthiness Codes may not account for the modified design; for example, high powered electrical and electronic equipment installed in compartments which do not usually accommodate such equipment may pose ignition hazards that are not adequately treated within civil airworthiness design requirements for electrical and electronic bays. To verify the acceptability of the fire protection measures in a Defence civil-derivative aircraft, any unique features must be analysed to evaluate their impact on the level of fire protection afforded by the design.

7.8 To ensure that airworthiness design requirements for fire protection account for the potential hazards that may be present as a result of military modifications to Defence civil-derivative aircraft, the Authority prescribes design requirements based on the fundamental fire protection concepts of fire prevention, fire detection and fire suppression. Modified Defence civil-derivative aircraft designs may pose the following hazards that could compromise the adequacy of fire protection design requirements in civil Codes:

(a) unusual military configurations not normally present in civil aircraft designs that introduce new or additional fuel sources, eg the use of commercial equipment to provide a military capability that is manufactured from materials that do not comply with contemporary fire prevention standards for civil aviation (compromised fire prevention);

(b) the presence of ignition sources, eg high power electrical/electronic equipment, that are unlikely to be found in civil aircraft systems, or are located in areas of the aircraft where ignition sources are not normally found (compromised fire prevention);

(c) the absence of a means by which the presence of fire is notified to the crew in a modified area of the aircraft, eg lack of fire detection due to no requirement for detection in civil aircraft electrical and electronic bays (compromised fire detection); and

(d) a lack of access to the compartment in which the modified equipment is located, which may impede evaluation and suppression of a fire (compromised fire suppression).

7.9 Any one or combination of the hazards associated with modifications in Defence civil-derivative aircraft identified in paragraph 7.8 may result in a marked degradation of fire protection requiring treatment. Consequently, each aspect of proposed modifications must be evaluated to clearly establish if fire protection attributes have been compromised and if additional risk treatment is warranted. This section presents the Authority prescribed fire protection airworthiness design requirements for fire prevention, detection and suppression in Defence civil-derivative aircraft.

Superseded

7.10 Fire prevention is usually achieved in civil Airworthiness Codes by treating hazards associated with ignition and fuel. Fire prevention may be achieved through combustible materials hazards reduction (flammability), installation hazards reduction (reducing ignition sources), isolation and separation (of fuel and ignition sources), ventilation, cooling, drainage, electrical bonding and lightning protection. The effectiveness of two of these fire prevention elements, namely materials flammability and reducing or isolating/separating ignition and fuel sources, may be reduced as a result of modifications in civil-derivative aircraft.

7.11 Fire protection requirements in civil Airworthiness Codes rely on the behaviour of materials in the presence of an ignition source (limiting the potential for the material to ignite) and the ability of the material to sustain a fire once it is ignited (self-extinguishing properties). However, military-unique modifications in civil-derivative aircraft may include equipment containing materials that do not comply with contemporary flammability requirements and may compromise the extant fire protection afforded by the aircraft design. Such shortfalls may not be unacceptable to Defence, provided the overall fire protection of the aircraft is not compromised. Consequently, the Authority has prescribed the following design requirement to ensure such equipment is identified, and its impact on fire protection is assessed.

7.12 **Design Requirement (Essential).** *Material properties of equipment used in modifications to Defence civil-derivative aircraft must comply with the applicable flammability requirements prescribed in an Authority recognised Airworthiness Code.*

NOTE

A 'systems' approach is required to establish if the level of fire protection afforded by modified Defence civil-derivative aircraft satisfies fire safety objectives. This consists of identifying additional hazards posed by the design (ie fuel and ignition sources), then determining whether the extant fire detection and suppression is adequate or if additional detection and/or suppression is warranted. Consequently, non-compliance with the materials flammability requirements may not require resolution through design change to incorporate compliant materials, but may be adequately treated through enhanced (or existing) fire detection and suppression.

7.13 Military-unique modifications in civil derivative aircraft may also include ignition sources in locations on an aircraft where such sources are not normally present, or where the ability to isolate/ separate the ignition source from fuel is limited, which may increase the likelihood of ignition. Such configurations may undermine the basis of, or impose additional fire hazards not accounted for in, the civil Codes (for example, the configuration may now be considered an electrical and electronic bay (EE bay) and fire protection considerations may therefore be limited). The impact on fire safety associated with changes to potential ignition sources, particularly where the source cannot be isolated or separated from fuel sources, must be evaluated. Consequently, the Authority has prescribed the following airworthiness design requirement to ensure that ignition sources introduced by military-unique modifications to Defence civil-derivative aircraft do not unacceptably compromise fire safety.

7.14 **Design Requirement (Essential).** *Where modifications in Defence civil-derivative aircraft include ignition sources that are not normally found in that location on civil certified aircraft (and therefore potentially are not accounted for within a civil Airworthiness Code), the level of fire safety in the presence of the ignition source must be demonstrated, through a systems safety analysis, to meet prescribed fire safety objectives.*

Superseded

7.15 Fire detection provides the crew with notification of a potential fire. The detection method may use a purpose-designed smoke and/or fire detector system or an indirect means such as visual monitoring or smell. In either case, the means used must provide notification to the crew of a fire with adequate time to respond to and extinguish the fire before it becomes established. Civil aircraft fire detection requirements are predicated on the ability of materials, which comply with contemporary flammability requirements, to be self-extinguishing once the ignition source is removed or, where this is not possible, to provide the crew with sufficient time to conduct effective fire suppression actions. However, fire detection systems may not be required for certain types of hidden compartments in civil aircraft (for example, civil Airworthiness Codes do not normally require fire detection in EE bays).

7.16 The effectiveness of fire detection in modified Defence civil-derivative aircraft may be compromised where the properties of materials reduce the time between ignition and a fire becoming established, or the modification impacts the effectiveness of the detection means implemented in the original civil design for that compartment or area of the aircraft (for example, additional ignition sources that increase the likelihood of a fire). Consideration of fire detection in addition to that normally required through compliance with the civil Codes would only be required where the military-unique modification resulted in an 'unusual' configuration within a compartment of the aircraft where a fire is unlikely to be detected via other means (eg vision or smell). For example, fitment of electrical equipment in hidden or inaccessible compartments not normally fitted with this equipment may pose additional ignition hazards that require treatment through fitment of purpose-designed fire detection.

7.17 Fire detection in Defence civil-derivative aircraft designs must ensure that notification of ignition is provided with adequate time for the crew to undertake the required fire suppression actions (for example, removal of power from equipment). Consequently, the following fire detection design requirement is prescribed by the Authority.

7.18 **Design Requirement (Essential).** *Modified compartments of Defence civil-derivative aircraft may result in the presence of materials or additional ignition sources not normally located in that compartment on civil certified aircraft. In these cases, the means of detecting a fire must be verified as providing adequate notification to the crew, or purpose-designed fire detection that complies with the following must be fitted:*

(a) *MIL-HDBK-516C, Section 8.4.7 Fire Detection, and Section 8.4.20 Detection and Control of Overheating, or*

(b) *DEF STAN 00-970 Section 4.26.24 Fire Detection and Warning.*

Fire suppression

7.19 Fire suppression may be provided through indirect or purpose-designed means. Indirect fire suppression is afforded through timely notification of a fire and crew action to remove the ignition source, which in turn extinguishes the fire. Purpose-designed fire suppression, on the other hand, provides the crew with the ability to directly combat a fire, usually through the application of an extinguishing agent. Purpose-designed fire suppression may be required where the time taken to alert the crew to an ignition, and for the ignition source to be removed, exceeds the time that the fire prevention measures remain effective, or where the fuel and/or ignition sources cannot be removed (eg engine bays).

Superseded

7.20 Fire suppression requirements in the civil Airworthiness Codes may not take into account unusual features of a military modification in inaccessible compartments of Defence civil-derivative aircraft (for example, materials that are not self-extinguishing following removal of the ignition source). Consequently, the Authority has prescribed the following fire suppression design requirement.

7.21 **Design Requirement (Essential).** *The ability of crew to remove sources of ignition following notification of a fire must be verified as providing effective fire suppression in modified inaccessible compartments of Defence civil-derivative aircraft, or purpose-designed fire suppression that complies with the following NAA airworthiness design requirements must be fitted:*

(a) ***USAF.*** *MIL-HDBK-516C, Section 8.4 Fire and Hazard Protection, or*

(b) ***UK MoD.*** *DEF STAN 00-970, Section 4.26 Fire Precautions.*

Fuel tank ignition prevention and flammability

7.22 Fire protection design requirements for civil aircraft, particularly large fixed wing aircraft (ie FAR 25 and CS 25) include requirements for fuel tank ignition prevention and fuel tank flammability assessment and, for those aircraft where fuel tank flammability exceeds the defined threshold, flammability reduction means. There are a number of circumstances under which compliance with the fuel tank flammability requirements may not be achieved for Defence civil-derivative aircraft (for example, acquisition of used aircraft where retrospective compliance is not required, or an 'administrative' dispensation granted by a civil NAA for military aircraft). Non-compliance with these requirements could lead to an unacceptable degradation in fuel tank fire safety. Consequently, the following design requirement is prescribed by the Authority.

7.23 Design Requirement (Essential). Defence civil-derivative aircraft must comply with requirements for fuel tank ignition prevention and flammability in FAR/CS 25.981, and FAR/CS Part 25 Appendix M Fuel Tank Flammability Reduction Means and Appendix N Fuel Tank Flammability Exposure.

ADDITIONAL FIRE PROTECTION GUIDANCE

7.24 Further guidance on Defence aircraft fire protection requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

SMOKE AND FUMES PROTECTION

INTRODUCTION

8.1 Smoke and fumes in Defence aircraft, particularly from electrical fires which can generate substantial smoke and toxic gases, can rapidly incapacitate crew and passengers. The type and the severity of the event, crew actions and the degree of their success, can all influence the severity of the outcome of smoke and fumes events.

8.2 While the Authority recognised Airworthiness Codes defined in Section 1 of this manual inherently prescribe some smoke and fumes protection requirements, these are not sufficiently detailed to establish the adequacy of smoke and fumes protection for Defence aircraft crew and passengers. For example, the civil Codes largely prescribe smoke and fumes protection requirements on the basis of the aircraft type, while some military Codes prescribe requirements (if any) on the basis of an aircraft's operational role. Consequently, the Authority prescribes airworthiness design requirements for smoke and fumes protection to supplement the Airworthiness Codes and provide a basis for verifying the acceptability of Defence aircraft smoke and fumes protection measures.

Scope

8.3 This Chapter prescribes Authority supplementation to the smoke and fumes protection elements of recognised civil and military Airworthiness Codes. Importantly, the airworthiness design requirements in this Chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of this manual.

DEFENCE AIRCRAFT SMOKE AND FUMES PROTECTION DESIGN REQUIREMENTS

8.4 Smoke and fumes protection is required to prevent the incapacitation of flight crew and other aircrew, and to protect the breathing of passengers, during smoke and fumes events in Defence aircraft. Smoke and fumes protection is afforded to aircraft occupants through a combination of the use of materials that minimise the generation of smoke and fumes when exposed to fire or heat sources, and the implementation of personal protective measures for occupants, that enable continued safe operation of the aircraft in the presence of smoke and fumes. This chapter only covers the latter of these two aspects. The use of materials that minimise the generation of smoke and fumes is covered in Section 2 Chapter 7 Fire Protection and Section 3 Chapter 8 Electrical Power Systems.

8.5 Defence aircraft smoke and fumes protection requirements are influenced by two primary considerations: the worst case duration of a smoke and fumes event; and the elements of the design that protect the crew and passengers from adverse physiological effects of smoke and fumes. The Authority prescribed smoke and fumes protection design requirements in this Chapter define the basis for establishing the 'worst case smoke and fumes event duration' for Defence aircraft, and whether the design affords an adequate level smoke and fumes protection for:

Superseded

(a) the flight crew responsible for flying the aircraft

(b) 'emergency response crew' (eg crew involved in locating the source, extinguishing fire, aiding passengers with breathing equipment, and so on)

(c) passengers and other crew.

Worst-case smoke and fumes event duration

8.6 The worst-case smoke and fumes event duration is the time taken to identify the source, combat the source and reduce the smoke and fumes to a level where safe flight and landing and passenger safety is not compromised. Civil and military design standards do not prescribe minimum durations for smoke and fumes protection of aircraft occupants. Consequently, the Authority requires that the worst-case smoke and fumes event duration is established, to ensure that smoke and fumes protection measures remain effective throughout a smoke and fumes event.

8.7 **Design Requirement (Essential).** *The worst-case smoke and fumes event duration for a Defence aircraft must be established.*

8.8 An evaluation of the likely sources of smoke and fumes in occupied spaces of Defence aircraft must be conducted, in conjunction with operational representatives, to establish the worst-case smoke and fumes event duration for all aircraft operations. While a minimum smoke and fumes protection 'time' is not prescribed in Authority recognised civil or military Airworthiness Codes, some civil design requirements prescribe requirements to ensure 'breathing protection' for between ten and fifteen minutes. These times are largely based on the requirement to provide supplemental breathing during an emergency descent following loss of aircraft pressurisation, until the aircraft reaches an altitude at which breathing can be sustained. While these timeframes may also represent the worst-case duration of a smoke and fumes event for some aircraft, for others they may be excessive or inadequate.

8.9 The worst-case event duration for a particular Defence aircraft will depend on the configuration, role and operating environment of the aircraft (for example, a helicopter is likely to have a much lower worst-case event duration, given its lower operating altitude and ability to land in many locations, than a large fixed wing aircraft). Nevertheless, recorded smoke and fumes events in civil and military aircraft suggest that a suitable benchmark worst-case event duration is twenty minutes, and this should be adopted where a bespoke duration for a particular Defence aircraft type cannot be established. Where a smoke and fumes event continues beyond twenty minutes duration, the cause of the event is likely to result in a non-survivable accident and smoke and fumes protection for occupants beyond this duration is therefore of little benefit.

Flight crew and emergency response crew smoke and fumes protection

8.10 Flight crew must be able to continue to communicate (with each other, passengers and other external parties, eg ATC) and to safely operate the aircraft, and emergency response crew must be able to conduct emergency response procedures or undertake fire fighting activities, during a smoke and fumes event. The airworthiness design requirements prescribed by other NAAs in Authority recognised Airworthiness Codes do not include smoke and fumes design requirements with sufficient detail to ensure that the adequacy of protective measures can be verified for the Defence aircraft configuration, role and operating environment. Therefore, the Authority has prescribed the following

Superseded

supplementation for flight and emergency response crew smoke and fumes protection in Defence aircraft.

8.11 **Design Requirement (Essential)**. *For the worst-case smoke and fumes event duration, flight crew smoke and fumes protection must provide:*

(a) *clear vision*

(b) *the ability to breathe*

(c) *the ability to safely operate the aircraft*

(d) *the ability to communicate with other crew members and passengers, and to use aircraft radio equipment while protection measures are in use.*

8.12 **Design Requirement (Essential).** *Emergency response crew smoke and fumes protection must provide:*

(a) *clear vision for the worst-case smoke and fumes event duration*

(b) *the ability to breathe for the worst-case smoke and fumes event duration*

(c) *portability, to enable movement about the aircraft and to conduct emergency procedures for fire fighting, for the predicted period of time required to complete the emergency procedure or fight a fire*

(d) *the ability to communicate with other crew members and passengers while protection measures are in use.*

8.13 Inadequate flight crew smoke and fumes protection may result in an otherwise survivable smoke and fumes event becoming catastrophic, if the crew are unable to continue to safely operate the aircraft. Inadequate emergency response crew smoke and fumes protection may result in an initially minor smoke and fumes event becoming an uncontrollable emergency if the crew is unable to respond appropriately to the initial onset of smoke/fumes. The flight and emergency response crew smoke and fumes protection measures in Defence aircraft must be evaluated and the adequacy of crew breathing, vision, aircraft operation and communication must be verified for the worst-case smoke and fumes event duration.

8.14 Flight and emergency response crew smoke and fumes protection may be provided by evacuation of smoke and fumes from occupied spaces, isolation of the flight deck and/or the provision of protective breathing equipment. Where protective breathing equipment is fitted to Defence aircraft, it is likely to be the primary means by which smoke and fumes protection is afforded for vision and breathing while ensuring the crew can continue to safely operate the aircraft (or combat the source) and communicate where required. When protective breathing equipment is required to satisfy the Authority prescribed design requirements for flight and emergency response crew smoke and fumes protection, the requirements defined in FAR/CS 25.1439 and FAR 121.337 may be used as a guide for verifying the adequacy of the equipment.

Passengers and other crew smoke and fumes protection

8.15 Breathing protection, necessary to sustain life, must be provided to passengers during a smoke and fumes event. While the Authority recognised civil Airworthiness Codes include emergency oxygen supply requirements for passengers, these systems are generally only required to support breathing in the event of depressurisation, and may not be intended to support breathing during a smoke and

Superseded

fumes event. Consequently, such systems are usually designed to afford breathing protection for the minimum time required to descend to an altitude at which breathing can be sustained. The Authority recognised military Airworthiness Codes do not include any design requirements for protection of passenger breathing during smoke and fumes events. Therefore, the Authority has prescribed the following supplementation for passenger smoke and fumes protection in Defence aircraft.

8.16 **Design Requirement (Essential).** *Passenger smoke and fumes protection must provide the ability to breathe for the worst-case smoke and fumes event duration.*

8.17 Passengers and other crew are not normally required to participate in emergency procedures until the aircraft has landed. Nevertheless, passengers must be physically capable of evacuating the aircraft once it is safe to do so and, therefore, cannot become prematurely incapacitated during smoke and fumes events. Passenger breathing protection may be accomplished via supplemental breathing systems, filtration of cabin air or evacuation of smoke and fumes. The passenger smoke and fumes protection measures in Defence aircraft must be evaluated and the adequacy of passenger breathing must be verified for the worst case smoke and fumes event duration. Where evacuation of smoke and fumes from occupied spaces is proposed as the sole means of affording passenger breathing protection, the adequacy of the evacuation means must be evaluated and confirmed to provide the required protection.

Ejection seat aircraft smoke and fumes protection

8.18 Military aircraft fitted with ejection seats often operate at cabin altitudes for which supplemental breathing systems are required to support safe aircraft operation. These systems are likely to satisfy the smoke and fumes protection requirements for breathing protection for the worst-case smoke and fumes event duration, and the ability to communicate. However, the equipment worn by flight crew in these aircraft may not satisfy the requirement to ensure adequate vision is maintained (eg helmet visors may not ensure that clear vision is maintained during a smoke or fumes event). The Authority recognised military Airworthiness Codes do not include requirements for protection against the effects of smoke and fumes in ejection seat aircraft (other than breathing protection).

8.19 Ultimately, the crew has the option of ejecting if smoke and fumes prevent continued safe aircraft operation and, therefore, establishing the worst case smoke and fumes event duration and conducting a detailed evaluation of the smoke and fumes protection afforded by ejection seat aircraft designs is not normally warranted. However, limiting the circumstances under which ejection is necessary provides safety benefits in terms of reducing the likelihood of injury during ejection, and may improve capability through reducing the number of ejection events. Therefore, the Authority has prescribed the following supplementation for crew smoke and fumes protection in Defence ejection seat aircraft.

8.20 **Design Requirement (Recommended).** *Additional smoke and fumes protection measures that potentially limit the circumstances under which an ejection may be required should be identified and implemented where reasonably practicable.*

ADDITIONAL SMOKE AND FUMES PROTECTION GUIDANCE

8.21 Further guidance on implementing the smoke and fumes protection requirements prescribed in this chapter can be provided by the chapter sponsor.

EQUIPMENT ENVIRONMENTAL QUALIFICATION

INTRODUCTION

9.1 During military aircraft operations, avionics and other aircraft equipment is often exposed to extreme environmental conditions. This equipment must continue to function adequately when exposed to these environmental extremes and, therefore, must satisfy the requirements of an appropriate environmental standard.

9.2 While aircraft equipment will normally be designed to comply with either a civil or military environmental standard, the environmental conditions defined within the standard may not reflect those in which the Defence aircraft will operate. Further, civil Airworthiness Codes may not require equipment qualification for operations in the often much harsher environments experienced during military operations. Consequently, the Authority prescribes airworthiness design requirements for environmental qualification of aircraft equipment to supplement the Airworthiness Codes and provide a basis for verifying the acceptability of aircraft equipment for safe operation or to satisfy capability requirements for Defence aircraft.

Scope

9.3 This Chapter prescribes Authority supplementation to the aircraft equipment environmental qualification requirements in recognised civil and military Airworthiness Codes. Importantly, the airworthiness design requirements in this chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of this manual.

EQUIPMENT ENVIRONMENTAL QUALIFICATION DESIGN REQUIREMENTS

9.4 This section presents the Authority prescribed environmental qualification design requirements, applicable to Defence aircraft, that support safe operation of aircraft equipment when exposed to the expected environmental conditions.

9.5 **Design Requirement (Essential).** *An applicant for an airworthiness instrument must identify, and propose to the Authority for approval, any supplementation to the aircraft's Primary Certification Code necessary to account for the identified environmental conditions.*

9.6 While the majority of Defence aircraft will operate in environmental conditions that are appropriately covered by the requirements prescribed in Authority recognised Airworthiness Codes, some Defence aircraft are required to operate in environments that were not considered by the original designers. Further, qualification testing may identify shortfalls against the requirements of the standard that, while acceptable to the original certifying authority, may not be appropriate for Defence operations. In these cases, the delta between the 'certified' environmental conditions and those in which the aircraft is required to operate, must be established and any associated hazards analysed to determine whether the shortfall(s) poses a risk to safe flight and whether supplementation of the Code is therefore required.

Superseded

9.7 Since Defence airworthiness design requirements establish the basis for safe aircraft operations, they are not usually applied to mission systems whose functions are not required for safe flight. However, environmental qualification is equally applicable to mission systems. After all, verifying that aircraft equipment can safely operate in the identified environmental conditions would be meaningless, without confirmation that the aircraft mission systems can adequately perform their intended functions in those in-flight and on ground environmental conditions where mission systems functionality is required. The following design requirements are not prescribed by the Authority, but should be considered when establishing requirements for Defence aircraft equipment environmental qualification.

9.8 **Capability design requirement.** *The in-flight and on ground environmental conditions in which Defence aircraft mission systems equipment is required to operate should be established.*

9.9 **Capability design requirement.** *Defence aircraft mission systems equipment should be capable of operating in the identified environmental conditions where mission systems functionality is required.*

9.10 The aircraft Type Certification Basis will define the environmental conditions under which aircraft equipment that provides safety related functions is required to operate in flight. These conditions can be used as the basis for establishing the environmental conditions that missions systems may be subjected to and therefore identify, on the basis of the potential impact on capability, whether mission equipment should be able to withstand the same in-flight conditions.

9.11 In addition to establishing the in-flight environmental conditions, Defence aircraft systems may be required to operate for extended periods in ground environmental conditions that may not be suitably catered for in the extant civil and military environmental standards. For example, aircraft systems may need to be operated on the ground to support:

(a) flight crew, mission crew and technician training;

(b) preparation and preservation of aircraft in a state of readiness to support contingency operations; and

(c) fault finding or other maintenance activities.

9.12 The worst-case environmental conditions and time that mission systems and equipment may be required to operate on the ground should be established, and the ability of Defence aircraft equipment to function adequately under these conditions should be evaluated. The results of this evaluation may be used to support decisions on further testing/qualification of aircraft equipment and/or supplemental environmental conditioning on the ground or aircraft environmental control systems enhancements.

9.13 Note that the ground environmental categories defined in DEF (AUST) 5168 Issue 2, The Climatic and Environmental Conditions Affecting the Design of Military Materiel may define Australian unique environments that are not encapsulated in the common civil and military environmental standards. Where relevant, these ground environmental conditions should also be considered when establishing the worst-case environments for Defence aircraft operations.

Superseded

9.14 Further guidance on implementing the equipment environmental qualification requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

DEFENCE LONG RANGE OPERATIONS

INTRODUCTION

10.1 DASR SPA.40 Defence Long Range Operations (DLRO) requires Military Air Operators (MAO) to establish a DLRO management system for Defence aircraft. The AMC and GM to DASR SPA.40 provides the context under which technical assessment of Defence aircraft for suitability to conduct DLRO will be undertaken, and in-service DLRO management requirements will be established, as part of the MAO's risk assessment considerations. DASR SPA.40 applies to fixed wing multi-engine turbine aircraft operated by Defence that may carry Defence personnel on long range flights. The approved aircraft Statement of Operating Intent and Usage (SOIU) forms the basis for applicability and the MAO is responsible for determining which aircraft should be managed under DLRO.

10.2 The determination of whether a Defence aircraft is subject to DLRO management is a capability and safety decision for the MAO. To support informed risk-based decision making on the technical suitability of a Defence aircraft to conduct DLRO, technical assessment of affected Defence aircraft must be conducted.

10.3 DLRO is, conceptually, similar to civil Extended Diversion Time Operations (EDTO) and consequently the Authority employs the EDTO airworthiness design requirements as a benchmark against which to assess Defence aircraft for DLRO. However, some important context for Defence aircraft must first be established to ensure that the civil standards are applied in a pragmatic manner. EDTO requirements apply only on specific routes where the aircraft operator is at the 'higher consequence' end of the civil aviation operations spectrum (ie EDTO normally only applies to 'regular public transport' and charter operators operating at significant distances from diversion airfields). For example, while EDTO may be prescribed for a Qantas A330 operating on a designated EDTO route in civil airspace, the same aircraft type operated by a private organisation without fare paying passengers on the same route will not be required to comply with EDTO requirements. Consequently, aviation industry 'good practice' for EDTO does not include strict compliance with EDTO requirements for all aircraft undertaking these operations.

10.4 Similarly, the Authority does not prescribe compliance with the civil EDTO requirements. Rather, the EDTO standards are used as the basis against which Defence aircraft technical aspects can be evaluated to identify hazards and associated risk treatments, and provide the MAO with a comprehensive basis upon which to make informed risk-based decisions in support of DLRO approval. While technical risk treatment would usually be pursued as the initial step in resolving shortfalls against prescribed design requirements, in this instance, operational controls may be equally valid and provide the same benefit in terms of safety outcomes. Therefore, it may be possible for the risk associated with DLRO to be minimised so far as is reasonably practicable without enforcing strict compliance with the civil EDTO standards for aircraft design or implementing potential design treatments for identified shortfalls. Consequently, the Authority has adopted the following approach to prescribing design requirements for DLRO:

(a) an analysis of the aircraft design features that support safe DLRO must be conducted against the civil EDTO standards;

Superseded

(b) shortfalls against the civil EDTO standards, and potential design risk treatments, must be identified;

(c) the shortfalls must be communicated to the MAO for a determination on whether operational controls would be effective in treating the risk, or whether design treatment will be required; and

(d) a continuing airworthiness program (ie a system of maintenance and a performance monitoring program) must be established to ensure that the design features that support safe DLRO are not compromised in service.

10.5 Finally, contemporary civil approaches to EDTO approvals accommodate the differences in hazards posed by one-engine inoperative operations at extended diversion times in aircraft with two engines and aircraft having more than two engines, through the application of more onerous requirements for two engine aircraft. Given the similarity in context between EDTO and DLRO, a similar approach for Defence aircraft is appropriate. Consequently, this chapter presents distinct Authority prescribed requirements for undertaking DLRO assessments on Defence aircraft having two and more than two engines respectively.

Scope

10.6 This chapter presents Authority prescribed design and continuing airworthiness requirements for Defence aircraft that are subject to DLRO management.

DEFENCE AIRCRAFT DLRO DESIGN REQUIREMENTS

10.7 This section presents the Authority prescribed DLRO design requirements for Defence aircraft.

Two engine Defence aircraft

10.8 **Design Requirement (Essential).** *Where the MAO has determined that a Defence aircraft having two engines is subject to DLRO management, the aircraft design must be evaluated against the design requirements prescribed in one of the following:*

(a) *CASA CAAP 82-1 – Extended Diversion Time Operations, or*

(b) *FAR Part 25 Appendix K – Extended Operations, in conjunction with FAA AC 120-42B – Extended Operations, or*

(c) *EASA AMC 20-6 – Extended Range Operation with Two-Engine Aeroplanes ETOPS Certification and Operation.*

10.9 The airworthiness design requirements for EDTO defined by the CASA, FAA or EASA provide an appropriate benchmark against which to establish the level of safety afforded by two engine Defence aircraft for DLRO. Defence aircraft designs must be evaluated against the requirements defined in the civil standards at paragraph 10.8 to identify shortfalls, characterise associated risks, and identify potential technical risk treatments to eliminate or minimise the risk. The outcomes of this evaluation, including risk treatment options and any residual risk, must be communicated to the MAO to support informed risk-based decisions on the aircraft's suitability for conducting DLRO.

Superseded

10.10 Where even a 'basic' evaluation of a two engine Defence aircraft design against the civil EDTO requirements cannot be accomplished, the Authority must be petitioned for agreement on a suitable benchmark and means of establishing compliance for the DLRO technical evaluation on a case-by-case basis. Examples might include:

(a) a military aircraft design for which long range operations was not originally considered and for which no design data to substantiate claims exists (eg for engine reliability); or

(b) the design complies with a bespoke suite of requirements that do not correlate to the civil EDTO, but meet the intent (eg P-8 designed to conduct long range over water operations).

Defence aircraft having more than two engines

10.11 **Design Requirement (Essential).** *Where the MAO has determined that a Defence aircraft having more than two engines is subject to DLRO management, the aircraft design must be evaluated against the requirements defined in ICAO Doc 10085 Extended Diversion Time Operations (EDTO) Manual for aircraft having more than two engines.*

10.12 The airworthiness design requirements for EDTO defined by the ICAO in ICAO Doc 10085 provide an appropriate benchmark against which to establish the level of safety for DLRO afforded by Defence aircraft having more than two engines. Per the ICAO requirements, the following is applicable to DLRO for Defence aircraft having more than two engines:

(a) The type certification standards and system of maintenance defined for the aircraft type in the applicable Authority recognised airworthiness code (refer Section 1 Chapter 3) are suitable for DLRO. There is no requirement for additional DLRO specific compliance demonstration, establishment of a maintenance program or performance/reliability monitoring program (eg engine performance monitoring) other than those programs already identified and implemented for 'normal' aircraft initial/continuing airworthiness and operations.

(b) A review of time limited systems (TLS) is required to confirm that the aircraft has the capability to safely divert to a suitable airfield at all times during DLRO, with any TLS limitations being published in aircraft documentation (eg MMEL/MEL and AFM) where required. This review should include DLRO significant systems, to identify the system having the most time-limiting impact and inform the decision on maximum diversion times permitted under the DLRO approval. The outcomes of this assessment, must be communicated to the MAO to support informed risk based decisions on the aircraft's suitability for conducting DLRO.

Extension/amendment of existing DLRO approvals for Defence aircraft (two and more than two engines)

10.13 Where a change is proposed to an existing DLRO approval, such as an extension to the approved diversion time, the technical basis upon which the DLRO approval was granted may be invalidated. Therefore, to support ongoing validity of the DLRO approval, proposed changes to the extant approval must be evaluated and verified to not impact the technical basis for DLRO, or the MAO must be advised of any change to the risks communicated via the original DLRO assessment.

10.14 **Design Requirement (Essential).** *Where an existing DLRO approval is to be extended/ amended, the impact of the proposed changes on the DLRO technical assessment must be evaluated and the MAO must be advised of any impact on associated risks.*

Superseded

DLRO DESIGN REQUIREMENTS FOR CHANGES TO TYPE DESIGN

10.15 Design changes to Defence aircraft may undermine the basis upon which the original DLRO approval was granted, resulting in additional hazards and associated risks. Where a design change impacts the suitability of the design for conducting DLRO, the basis upon which the technical recommendation for DLRO was made must be reassessed. The assessment must consider the impact of proposed changes, particularly for DLRO significant systems or continuing airworthiness arrangements. Where the assessment identifies a change in the risk profile associated with DLRO, the outcomes of the assessment must be communicated to the MAO, together with recommended risk treatment, to inform the decision on continued DLRO approval.

10.16 **Design Requirement (Essential).** *Changes to the type design that may impact the suitability of the Defence aircraft to conduct DLRO must be evaluated and confirmed to have no impact on the basis for DLRO approval, or any identified impacts must be communicated to the MAO.*

DLRO CONTINUING AIRWORTHINESS REQUIREMENTS

System of maintenance/monitoring and reporting requirements

Defence aircraft having more than two engines

10.17 As previously highlighted, DLRO maintenance and reliability requirements for Defence aircraft having more than two engines are satisfied through compliance with the applicable Authority recognised airworthiness code (eg FAA FAR Part 25 and Part 33, EASA CS-25 and CS- 33, MIL-HDBK-516C, DEF STAN 00-970). Consequently, for Defence aircraft having more than two engines, no DLRO specific maintenance or reliability programs are required in addition to those implemented for 'normal' aircraft continuing airworthiness and operations.

Two engine Defence aircraft

10.18 Continuing airworthiness programs provide a substantial contribution to reducing risks in civil EDTO. Similarly, maintenance and performance monitoring programs adapted to account for additional hazards posed by DLRO enhance the level of safety for Defence two engine aircraft. Further, since they are principally extensions to existing maintenance and performance monitoring programs, DLRO specific programs are likely to be reasonably practicable to implement. The system of maintenance and the performance monitoring and reporting systems in EDTO standards provide a reasonable benchmark for similar requirements in the DLRO context for two engine Defence aircraft. Therefore, the following DLRO continuing airworthiness requirement, based on the civil EDTO requirements, is prescribed by the Authority.

10.19 **Design Requirement (Essential).** *Where a two engine Defence aircraft is subject to DLRO management, a DLRO system of maintenance, and performance monitoring and reporting systems, must be defined to satisfy the requirements of:*

(a) *CASA CAAP 82-1 – Extended Diversion Time Operations, or*

(b) *FAR Part 25 Appendix K – Extended Operations, in conjunction with FAA AC 120-42B – Extended Operations, or*

(c) *EASA AMC 20-6 – Extended Range Operation with Two-Engine Aeroplanes ETOPS Certification and Operation.*

Superseded

10.20 Where the proposed DLRO system of maintenance and/or the performance monitoring program for a Defence aircraft does not satisfy the requirements of the civil EDTO standards, the Authority is to be petitioned for a determination on the adequacy of the proposed programs.

ADDITIONAL DEFENCE LONG RANGE OPERATIONS GUIDANCE

AIRCRAFT/STORES COMPATIBILITY

INTRODUCTION

11.1 Defence aircraft are often fitted with aircraft stores. A store is defined as 'any device intended for internal or external carriage and mounted on aircraft suspension and release equipment, whether or not the item is intended to be separated in flight from the aircraft' and includes items such as sonobuoys, external fuel tanks and countermeasures.

11.2 Design standards are used for establishing the extent of compatibility between an aircraft, specific stores and suspension equipment and hence for justifying the airworthiness of stores for use on aircraft. Air Warfare Engineering Squadron (AWE SQN) maintains subject matter expertise for ASC and provides sponsorship of this chapter of the DASDRM. AWE SQN has identified shortfalls in extant Airworthiness Codes promulgated by civil and military Airworthiness Authorities as described in Section 1 of this manual. Consequently, the Authority has prescribed airworthiness design requirements for ASC to supplement these Airworthiness Codes to afford an adequate level of safety to personnel and property as well as enabling interoperability with allied nations.

Scope

11.3 This chapter identifies the Authority prescribed design standards for ASC which are applicable to aircraft acquisitions, changes to type design and capability and should be read in conjunction with relevant airworthiness regulations and DEOP 102. The standards identified are of specific relevance to ASC and do not include those that are purely applicable to munitions, explosives or ordnance (refer to Directorate Ordnance Safety's eDEOP 101 / DEOP 102 for these). This chapter also provides guidance on how a requesting agency can work with AWE SQN to tailor the standards to meet the requirements of a particular design.

ASC DESIGN REQUIREMENTS

11.4 This section presents the ASC airworthiness design requirements for stores fitted to Defence aircraft. A full list of the ASC standards referred to in this chapter is provided in Annex A. The standards are subdivided into the following groups for ease of reference:

11.5 **A/SC Terminology, Definitions and Glossary.** This includes the standards that define the terminology used in ASC, aircraft armament plus Safety and Suitability for Service (S3) of munitions and explosives.

11.6 **Airworthiness Standards.** These standards are applied to ensure that the integration of stores on to the aircraft does not adversely affect safe flight. These include standards which address general design, store/stores suspension equipment design and aircraft store environmental aspects.

11.7 **WHS Standards.** The application of WHS standards helps to ensure the health and safety of personnel and the public both in the air and on the ground. These standards address areas such as flight termination systems, range safety, safe escape, safety and S3 for aircraft stores.

Superseded

11.8 **Compatibility Standards.** These standards address the aircraft store interface and are applied to ensure that the store is compatible with the aviation system. This includes arming systems, electrical and mechanical connections, ground fit and compatibility criteria, and compatibility aspects for aircraft stores.

11.9 **Capability Standards.** The application of these standards helps to ensure that when the weapon is integrated onto the platform it can provide the required capability.

11.10 **Miscellaneous.** This includes interoperability and self-damage analysis of aircraft stores.

11.11 **Design Requirement (Essential).** Defence ASC designs must meet the requirements of the approved ASC 'standard', MIL-HDBK-1763 or MIL-HDBK-516C Sections 5 and 17, 'Aircraft/Stores Compatibility: Systems Engineering Data Requirements and Test Procedures'.

11.12 When a requirement for a new capability is approved, the acquisition process requires the development of a certification strategy that will include a Statement of Work (SOW) and/or Data Item Descriptor (DID). For ASC related designs, MIL-HDBK-1763 (specifically appendix C) provides a list of the ASC data requirements in the form of an Aircraft Stores Compatibility Engineering Data Package (ASCEDP). Whilst MIL-HDBK-1763 and MIL-HDBK-516C Sections 5 and 17 provide the complete requirements for an ASC design, there is typically a requirement to conduct some tailoring of the data requirements. Whenever there is a proposal to tailor the Authority prescribed standard, AWE SQN should be consulted to ensure that the airworthiness of the design is maintained. This may be accomplished by the Commonwealth before tendering a capability or by suppliers as part of the acquisition process.

11.13 **Design Requirement (Essential).** Defence ASC designs must meet the requirements of the relevant AIR STDs and STANAGs listed in Annex A.

11.14 Australia is actively involved in a number of international working groups relating to standards and agreements. The two most significant are the Air Force Interoperability Council (AFIC), formerly known as the Air and Space Interoperability Council (ASIC) and Air Standardisation Co-ordination Committee (ASCC), via Air Standards (AIR STD) and the North Atlantic Treaty Organisation (NATO) via Standardisation Agreements (STANAGs). Many of these standards and agreements have airworthiness implications and are called out by MIL-HDBK-1763 or MIL-HDBK-516C Sections 5 and 17, however, others are in place to promote and maintain a level of interoperability and commonality with allies. The standards relevant to ASC are detailed in Annex A to assist assessment / compliance during the development of any new ASC design. If compliance cannot be shown to a relevant AIR STD or STANAG, AWE SQN is to be consulted for further guidance.

11.15 **Design Requirement (Essential)**. To prevent damage to an aircraft from its own ordnance Safe Escape information (data and procedures) must be developed or acquired.

11.16 Safe Escape data and procedures provide protection for the releasing aircraft, and any other platforms that might be operating in conjunction with the releasing aircraft, to an acceptable level of risk. AWE SQN maintains subject matter expertise for the technical analysis and development of aircraft safe escape information. There are no current standards for the development of Safe Escape information to meet the acceptable risk levels defined by operational commanders. There are differences in acceptable risk levels for safe escape between nations (and services) from which the ADF receives safe escape information. Therefore, before any foreign information is utilised, AWE SQN must be approached to analyse the implications of these differences.

Superseded

CAPABILITY DESIGN REQUIREMENTS

11.17 The following requirements are not prescribed by the Authority, but should be considered for aircraft acquisitions or modifications to ASC where capability is a determining factor.

11.18 **Design Requirement.** Defence ASC Designs must meet the Australian Unique Capability Requirements defined in Annex B.

11.19 Australia has a unique legislative and operating environment to the rest of the world. This requires unique Aircraft/Stores considerations to ensure the ADF can operate safely. The requirements detailed in Annex B ensure that the risk to personnel and property is understood and the system meets an appropriate level of safety when the aircraft/stores system is exercised.

11.20 Commensurate with the requirements of Annex B, as well as maintaining subject matter expertise for ASC, AWE SQN can generate and approve Weapon Danger Areas (WDA). Before the acquisiton of a new system requiring a WDA it will be necessary to liaise with AWE SQN to determine what format the WDA will take and what data is necessary.

ADDITIONAL AIRCRAFT / STORES COMPATIBILITY GUIDANCE

11.21 **Tailoring**. Due to the number and variety of ASC configurations in Defence, tailoring or deviation from the ASC prescribed standards will often be necessary and may only occur following consultation with AWE SQN. Aircraft or Store Project Offices are advised to engage with AWE SQN on ASC aspects of projects as early as possible in the capability life cycle to ensure data and airworthiness requirements for ASC configurations can be satisfied and supported. Guidance on the tailoring process can be found in MIL-HDBK-516C Section 1.2.1.

11.22 **Products.** When AWE SQN provides airworthiness advice it is generally in the form of an ASC Flight Clearance Recommendation (FCR) or Interim Flight Clearance (IFC). This will normally address all aspects of an ASC standard, as well as the additional considerations identified above. Occasionally, technical information may be provided in another format to assist and inform risk retention authorities. Examples are compliance demonstration, procedures and other Technical Advice (TA) reports. In all cases, compliance with MIL-HDBK-1763, MIL-HDBK-516C Sections 5 and 17 or the standards listed in annex A will form the basis of all ASC products and advice.

11.23 **Novel / alternative standards.** Suppliers may use, or seek to use, novel or new processes to show that an acceptable airworthiness basis exists for an ASC design, even if this does not strictly comply with prescribed standards listed in Annex A. Whenever a new, novel or alternative standard or method of compliance is proposed, AWE SQN is to be petitioned for a formal determination of the acceptability of the solution.

11.24 Further guidance on Aircraft / Stores Compatibility is available from the chapter sponsor (airwarfarecentre.enquiries@defence.gov.au).

ANNEX B AUSTRALIAN SERVICE SUPPLEMENT FOR ASC

AUSTRALIAN SERVICE SUPPLEMENT FOR ASC

Weapon Danger Areas

(a) Criterion: For all ASC designs that pose a hazard to personnel or infrastructure on the ground, a Weapon Danger Area (WDA) must be developed. Confirm a WDA has been developed, or can be developed in accordance with Australian WDA requirements.

(b) Standard: Ensure the weapon's supplied WDA meets the safety and risk requirements outlined in the applicable references. The development of a WDA ensures that the risk to personnel, property and the General Public is understood and acceptable when the aircraft stores system is exercised

(c) Method of Compliance: AWE SQN engineering report, output from an approved WDA tool e.g. Range Safety Template Tool (RSTT), Weapon Danger Zone Tool (WDZT), AMRAAM Footprint Utility Tool (AFUT) or equivalent. The appropriate standard will depend on the store design and the associated area in which it is to be used.

(d) References:

1. Defence Training Area Management Manual (DTAMM)
2. Air Force Air Weapons Practice Manual - AFAWPMAN
3. ANP3319 – RAN Firing Manual
4. AWC OPS 04-34 - Approval of Air Weapon Danger Areas
5. Chief of Air Force Policy – Use of Probabilistic Weapons Danger Areas for Air Force Air Launched Weapons on Australian Ranges

Toxicology and Environmental Hazards

(e) Criterion: Verify the hazardous materials associated with the aircraft-store combination is correctly documented and appropriate authorities or regulators are notified.

(f) Standard: All hazardous materials are documented with SDS's, appropriate PPE for handling the materials is stated in operation or maintenance manuals, residues from store usage are characterised and appropriately managed. Provide assurance to a reasonable level the materials left in the environment from functioning or jettisoning the store meet extant Australian EPA requirements.

(g) Method of Compliance: Verification methods include analysis, test, demonstration, simulation, inspection and review of documentation. Verification is accomplished by initial installation testing, qualification testing, physical fit checks, static ground fire testing, safety analysis, safe separation test certification, and live fire testing during Developmental Test and Evaluation (DT&E) and Operational Test and Evaluation (OT&E).

CYBER SECURITY

INTRODUCTION

12.1 Within the aviation safety domain, cyber security is commonly understood as the protection of information systems against intentional unauthorised electronic interactions (IUEI). Aircraft systems and parts are increasingly interconnected, and those interconnections are vulnerable to cyber security threats. These threats have the potential to affect the airworthiness of an aircraft due to unauthorised access, use, disclosure, denial, disruption, modification or destruction of electronic information or electronic aircraft system interfaces.

12.2 The implementation of a robust and effective cyber security approach to Defence aircraft design supports aviation safety. The objective of this approach is to take into account the interdependencies between aviation safety and security in order to mitigate the potential effects of cyber security threats on aircraft airworthiness. This approach will reduce the vulnerability of aircraft systems, and ultimately improve safety, by reducing the risk of cyber security incidents or accidents.

12.3 The Authority has evaluated recognised NAA and MAA approaches to cyber security, and their associated aviation cyber security standards, and concluded that intelligent application and in some cases expansion is required to effectively implement cyber security into Defence aircraft designs. A number of Authority recognised NAAs and MAAs have not yet defined or promulgated prescribed cyber security design requirements. Further, cyber security standards may not account for Defence's obligations under the WHS legislation, since they may permit 'risk acceptance' once a specified risk level has been achieved. To promote the intelligent application of cyber security standards, this chapter first defines the requirements that should be satisfied for robust cyber security. The chapter then identifies where recognised NAA/MAA approaches to cyber security require particular attention if they are to meet the Authority's prescribed requirements. This approach, which should be applied using the system safety principles in Section 2 Chapter 2, provides design organisations with guidance to embed robust cyber security practices into their engineering procedures.

12.4 Note that the prescribed requirements are currently only recommended to allow for the broader Defence Cyber Strategy to mature, whilst offering designers the opportunity to proactively apply current international good practice design requirements. The Authority will monitor recognised NAA and MAA prescription of design requirements as well as the maturity of the broader Defence Cyber Strategy and at an appropriate time update the prescribed requirements in this chapter.

Scope

12.5 This chapter presents Authority-prescribed cyber security design requirements that are applicable to design activities conducted for new manned aircraft and changes to the aircraft type design.

CYBER SECURITY REQUIREMENTS

12.6 The desired cyber security outcomes are that:

(a) Information systems within Defence aircraft subject to Australian military type certifications are protected from IUEIs

Superseded

(b) Changes to the type design of in-service Defence aircraft do not compromise protections from IUEIs

(c) In-service management of Defence aircraft contributes to protections from IUEIs through effective instructions for continuing airworthiness and an effective continued airworthiness management framework.

Initial Aircraft Certification

12.7 **Cyber Security Requirement (Recommended).** *Aircraft equipment, systems and networks, considered separately and in relation to other systems, should be protected from IUEIs that may result in adverse effects on the safety of the aircraft. Protection should be ensured by showing that the security risks have been identified, assessed and treated as necessary.*

12.8 Compliance with this requirement can be demonstrated through adopting the cyber security processes defined in EUROCAE ED-202A Airworthiness Security Process Specification dated June 2014/RTCA DO-326A Airworthiness Security Process Specification dated 6 Aug 14. These documents provide a process centred on a focused security risk assessment which:

(a) determines the security environment for the information security of the aircraft

(b) identifies the attack paths

(c) assesses the safety consequences of the threats

(d) evaluates, by considering the existing security protection means, the level of threat that would impact safety

(e) determines whether the risks, which are the result of the combination of the severities and the potentiality to attack (or, inversely, the difficulty of attacking), are acceptable.

12.9 Guidance material for conducting the risk assessments can be found in EUROCAE ED-203A Airworthiness Security Methods and Considerations dated June 2018/RTCA DO-356A Airworthiness Security Methods and Considerations dated 21 Jun 18. Designers should engage with the appropriate Defence Cyber experts for assistance in determining the security environment, attack paths and associated level of threat.

12.10 **Cyber Security Requirement (Recommended).** *Instructions for continuing airworthiness and a continued airworthiness management framework should be defined and promulgated to ensure that the security protections of the aircraft's equipment, systems and networks are maintained.*

12.11 International good practice recognises that the management of cyber security risks extends into the operational life of type-certificated aircraft. Effective continued and continuing airworthiness programs need to be informed by the results of the security risk assessments created to support type certification. Guidance on this requirement can be found in EUROCAE ED-203A/RTCA DO-356A Airworthiness Security Methods and Considerations and EUROCAE ED-204/RTCA DO-355 Information Security Guidance for Continuing Airworthiness dated June 2014.

Changes to aircraft type design

12.12 **Cyber Security Requirement (Recommended).** *Changes to the type design of Defence aircraft should ensure the ongoing protection from IUEIs, where known, that may result in adverse effects on*

Superseded

the safety of the aircraft. Protection should be ensured by showing that the security risks have been identified, assessed and treated as necessary.

12.13 Changes to the aircraft type design may undermine the cyber security protections provided by the original military type certification, resulting in changes to cyber security hazards and their associated risks. Accordingly, the process described in the RTCA/EUROCAE process specifications detailed in paragraph 12.7 should be followed, limited in scope to the proposed change to type design. Designers should engage with the appropriate Defence Cyber experts for assistance in determining the security environment, attack paths and associated level of threat.

12.14 **Cyber Security Requirement (Recommended).** *Amendments to instructions for continuing airworthiness, and the continued airworthiness management framework should be promulgated as part of a change to type design, where necessary, to ensure that the security protections of the aircraft's equipment, systems and networks are maintained.*

12.15 Changes to the aircraft type design may require updates to the ongoing management of cyber security risks. Accordingly, the process described in the RTCA/EUROCAE specifications detailed in paragraph 12.10 should be followed, limited in scope to the proposed change to type design.

AUTHORITY-RECOGNISED NAA/MAA APPROACHES

12.16 This section describes the extent to which the cyber security elements of type certifications by Authority-recognised NAA/MAAs may be relied upon if offered as evidence of prior certifications.

12.17 Where the application is based on a prior certification from a recognised NAA/MAA, the applicant may be able to rely on a security risk assessment provided for the prior certification. Whether the applicant can rely on such risk assessments, wholly or in part, depends on the:

(a) scope, conditions and caveats of the relevant NAA/MAA recognition certificate

(b) extent that decisions in the risk assessment on whether identified risks were acceptable are valid given Australian WHS statutory obligations

(c) extent that Australian changes to the aircraft's configuration, role and environment (CRE) vary the cyber security risks identified in the risk assessment, or introduce new cyber security risks.

12.18 **Australian WHS legislation.** EUROCAE ED-202A/RTCA DO-326A Airworthiness Security Process Specification requires that decisions on risk acceptability be assessed using criteria defined by the relevant airworthiness authority. Accordingly, risk assessments performed for other NAAs/MAAs would not consider Australian WHS legislation. To comply with Australian statutory obligations, for any identified risks that were not eliminated during the prior certification, the applicant and relevant Military Air Operator (MAO), would decide whether the risks can be eliminated SFARP. If elimination is possible through reasonably practicable design controls, such design controls should be implemented before the aircraft enters service. If such design controls are not reasonably practicable, the applicant and MAO should consider the design controls necessary to minimise risks SFARP. If risk-minimising design controls are reasonably practicable, such design controls should be implemented before the aircraft enters service. If the implemented design controls would not eliminate the identified risks, then the MAO should undertake in-service risk management of the residual risks, including the implementation of reasonably practicable operational controls.

12.19 **CRE changes.** The applicant will need to consider the effect of any Australian CRE changes on the cyber security risks identified in security risk assessments provided as part of prior certifications. Such changes may require the security risk assessment to be supplemented by further analysis so that

Superseded

it considers all cyber security risks relevant to the Australian CRE. Where such analysis identifies new, or varies previously identified risks, the applicant and MAO should consider how to eliminate or otherwise minimise the risks as previously discussed.

12.20 If the applicant cannot rely on a security risk assessment provided as part of a prior certification, then the applicant would need to perform the process in the RTCA/EUROCAE process specifications detailed in paragraph 12.7, or engage a suitable organisation to perform one. Such a requirement is consistent with any other application where prior certification does not satisfy the entirety of the requirement, the applicant needs to undertake additional compliance demonstration activity to resolve the shortfall. The identified cyber security risks should be eliminated or otherwise minimised as previously discussed. Residual risks would be communicated to the MAO.

Civil cyber security approaches

12.21 **EASA.** To ensure designers consider cyber security hazards to aircraft airworthiness, EASA has introduced cyber design requirements into the following certification standards: CS-25 (Large Aeroplanes), CS-27 (Small Rotorcraft), CS-29 (Large Rotorcraft) CS-APU (Auxiliary Power Units), CS-E (Engines), CS-ETSO (European Technical Standard Orders) and CS-P (Propellers). The provisions take a common form, requiring the applicant to show during certification that the possible security risks posed by IUEI have been identified, assessed and mitigated as necessary. To demonstrate compliance with EASA's cyber security design requirements, EASA AMC 20-42 provides acceptable means, guidance and methods to perform security risk assessments and mitigation for aircraft information systems. The AMC refers to the three RTCA/EUROCAE cyber-related specifications detailed in paragraphs 12.7, 12.8 and 12.10.

12.22 The requirements in this chapter were based on EASA's approach to considering cyber security during aircraft type certification. Accordingly, security risk assessments performed during prior EASA certifications may be used provided a CRE assessment is performed and previously accepted risks are reconsidered by applying Australian WHS legislation.

12.23 **FAA.** The FAA has not yet introduced cyber security design requirements into its published airworthiness codes. Instead, it has implemented separate cyber security design requirements for what are termed 'connected aircraft', that is aircraft in which the main aircraft backbone, connecting flight-critical avionics as well as passenger information and entertainment systems, is performed in a manner that makes the aircraft an airborne interconnected network. Connected aircraft are certified with a special condition reflected on the aircraft Type Certificate Data Sheet, requiring operator actions to mitigate electronic security risks. At this time the Authority cannot determine the FAA considerations relevant to each aircraft's special condition.

12.24 Given that the FAA has not yet amended its airworthiness codes, applicants cannot rely on prior FAA certifications as a means of compliance with the cyber security design requirements detailed in this chapter. Nevertheless, available information relevant to the cyber security aspects of the FAA certification can inform Australian Defence security risk assessments.

Military cyber security approaches

12.25 **United States Navy (USN).** The USN approach is a policy called CYBERSAFE, based on recognised cyber security principles. Cyber security has been integrated into type certification processes as described within NAVAIR M-13034.1 Airworthiness and CYBERSAFE Process Manual, dated 13 Apr 16. Both the manual and instruction confirm that the key document is a flight clearance, either interim or permanent, issued by COMNAVAIRSYSCOM. As part of the flight clearance process,

Superseded

airworthiness and CYBERSAFE technical assessments are performed, with the resultant Flight Clearance confirming that an aircraft is both airworthy and meets the specified cyber security requirements. Circa 2021, insufficient information is available to confirm that the USN applies a security risk assessment equivalent to the process described in the RTCA/EUROCAE process specifications detailed in paragraphs 12.7, 12.8 and 12.10. Accordingly, applicants cannot rely on prior USN certifications as a means of compliance with the cyber security design requirements detailed in this chapter. Nevertheless, available information relevant to the cyber security aspects of USN certifications can inform Australian Defence security risk assessments.

12.26 **United States Air Force (USAF).** Despite attempts to glean information from published material and through DASA recognition channels, circa 2021, DASA cannot determine the United States Air Force regulatory approach to protecting aircraft from cyber hazards to aviation safety. Accordingly, applicants cannot rely on prior USAF certifications as a means of compliance with the cyber security design requirements detailed in this chapter. Nevertheless, available information relevant to the cyber security aspects of USAF certifications can inform Australian Defence security risk assessments.

12.27 **US Army.** Despite attempts to glean information from published material and through DASA recognition channels, circa 2021, DASA cannot determine the US Army regulatory approach to protecting aircraft from cyber hazards to aviation safety. Accordingly, applicants cannot rely on prior US Army certifications as a means of compliance with the cyber security design requirements detailed in this chapter. Nevertheless, available information relevant to the cyber security aspects of US Army certifications can inform

Australian Defence security risk assessments.

12.28 **UK MAA.** The UK MAA has amended its Defence Standard 00-970 Design and Airworthiness Requirements for Service Aircraft to introduce cyber security design requirements. These changes reference DEF STAN 00-55 Requirements for Safety of Programmable Elements in Defence Systems. Designers should ensure that platform cyber security vulnerabilities for safety-related software and complex electronic hardware do not purposefully or accidentally threaten airworthiness. An acceptable means of compliance with the cyber security requirements of DEFSTAN 00-055 are the RTCA/EUROCAE process specifications detailed in paragraph 12.7. Accordingly, security risk assessments performed during prior UK MAA certifications may be used provided a CRE delta assessment is performed and risks accepted within the UK MAA certification are reconsidered by applying Australian WHS legislation.

SECTION 3 - AIRCRAFT SYSTEM DESIGN REQUIREMENTS

CHAPTER 1 - APPLICATION OF SYSTEM DESIGN REQUIREMENTS

APPLICATION OF SYSTEM DESIGN REQUIREMENTS

1.1 For the majority of Defence aircraft systems, the airworthiness design requirements prescribed in the Authority recognised Airworthiness Codes define the requirements that underpin safe aircraft design. However, there are a number of systems for which these Airworthiness Codes are inadequate for Defence's intended configuration, role and operating environment (CRE).

1.2 Where airworthiness design requirements prescribed in the Authority recognised Airworthiness Codes may be inadequate for Defence's CRE, the Authority has identified supplementation. This section of the DASDRM presents that supplementation.

1.3 Where strict application of an Airworthiness code may affect capability or interoperability, design requirements to reduce these effects are also provided.

Scope

1.4 Section 3 of the DASDRM presents the Authority prescribed airworthiness design requirements for the following aircraft systems and technologies:

(a) communications systems,

(b) flight recorder and locating equipment,

(c) navigation systems,

(d) surveillance and avoidance systems,

(e) oxygen systems,

(f) lighting systems,

(g) electrical systems,

(h) environmental control systems,

(i) air vehicle subsystems (mechanical),

(j) aircraft performance and handling,

(k) aircraft structural integrity,

(l) propulsion systems,

(m) airborne lasers, and

(n) indicating systems.

Superseded

COMMUNICATION SYSTEMS

INTRODUCTION

2.1 While traditional voice communications continue to provide a principal element of aviation communications, other forms of communication, such as digital data transfer, are becoming increasingly prevalent in supporting navigation, surveillance and tactical operations. The ICAO Manual on Required Communication Performance highlights the need for communications to be assured in high density airspace using a mixture of traditional voice and data link communications. A number of communication systems are also mandatory for flight in specified civil airspace, particularly to satisfy performance based navigation.

2.2 For the majority of communication systems, compliance with the airworthiness design requirements prescribed in an Authority recognised Airworthiness Code provides assurance of the safe design and operation of these systems in Defence aircraft. However, many civil and military Airworthiness Codes do not prescribe design requirements for communication systems that support specific aircraft operations (eg Required Navigation Performance) or missions. Such requirements are generally defined in supporting guidance material that is only invoked when the aircraft operator seeks approval to conduct the applicable operations. Consequently, the Authority prescribes airworthiness design requirements for communication systems to supplement the Airworthiness Codes and provide a basis for verifying the acceptability of the associated communication systems for safe operations or to satisfy capability requirements for Defence aircraft.

Scope

2.3 This Chapter prescribes Authority supplementation to the aircraft communications systems elements of recognised civil and military Airworthiness Codes. Importantly, the airworthiness design requirements in this chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of this manual.

DEFENCE AIRCRAFT COMMUNICATION SYSTEMS DESIGN REQUIREMENTS

2.4 Communications systems must meet the requirements prescribed for operations in specific classes of airspace, and to navigate in civil airspace and along specified civil routes. Prior to establishing the airworthiness design requirements that must be met for a Defence aircraft's communication systems, the designer must confirm the global airspace and navigation environment in which the Defence aircraft will operate, and consequently establish the communications systems requirements necessary to achieve safe aircraft operations.

Superseded

2.5 **Design Requirement (Essential).** *The communication systems fitted to Defence aircraft must satisfy the minimum systems/equipment and functional requirements for proposed operations in civil airspace as prescribed by the administering NAA.*

2.6 **Design Requirement (Essential).** *The communication systems fitted to Defence aircraft must satisfy the minimum systems/equipment and functional requirements for proposed navigation in civil airspace as prescribed by the administering NAA.*

2.7 When establishing the communication systems and equipment to be fitted to Defence aircraft, designers must ensure that the minimum systems required to support proposed operations in world-wide civil airspace (both for communication between aircraft and/or ATC and for navigation in civil airspace) are installed and satisfy the applicable design standards. In particular, civil airspace routes are increasingly adopting Performance Based Communications and Surveillance protocols, which require communications systems to meet prescribed performance criteria (ie data link capabilities and communication expiry times) to operate on those routes. Failure to ensure required communication systems are installed may result in loss of crew situational awareness or limitations on access to civil airspace.

2.8 Noting that inadequate communications capability may result in denial of access to civil airspace, and that Defence aircraft acquisition can be an extended activity, designers should ensure that communication systems functional requirements are identified both for current civil airspace operations and for future operations (3-5 years post introduction into service). This will ensure that Defence aircraft are capable of safely operating in civil airspace without restriction in the short to medium term.

Very High Frequency (VHF) channel separation

2.9 **Design Requirement (Essential).** Defence aircraft that will operate in airspace that requires an 8.33 kHz channel separation must be fitted with VHF communications equipment that satisfies the requirements of:

(a) *ED-23C, Minimum Operational Performance Standards for Airborne VHF receiver-transmitter operating in the frequency range 117.975 – 137.00 MHz, or*

(b) *TSO-C169a, VHF Radio Communications Transceiver Equipment Operating within Radio Frequency Range 117.975 to 137.000 Megahertz.*

2.10 The Authority recognised civil Airworthiness Codes require aircraft VHF transmitters, receivers and transceivers to operate with a minimum channel separation of 25 kHz. To provide additional capacity for VHF communications in congested airspace, EASA has adopted reduced VHF channel separation to 8.33 kHz. Lack of equipment with an 8.33 kHz channel separation capability could lead to the crew being unable to communicate with ATC or other airspace users. Operations in European civil airspace therefore may be restricted unless VHF equipment having 8.33 kHz separation is installed.

Superseded

2.11 **Design Requirement (Essential).** *Data link communications used for traffic detection, separation and collision avoidance fitted to Defence aircraft must satisfy the civil standard applicable to operations in the associated civil airspace.*

2.12 Certain types of operations in civil airspace rely on data link communications systems to provide situational awareness or air traffic direction/advice to the crew. The lack of this communications equipment may lead to limited access to associated civil airspace or loss of crew situational awareness.

CAPABILITY AND INTEROPERABILITY DESIGN REQUIREMENTS

2.13 This section presents design requirements that are not prescribed by the Authority, but identify particular design issues that designers should consider when establishing requirements for Defence aircraft communication systems.

2.14 **Capability design requirement.** *Defence aircraft communication systems should satisfy the functional requirements prescribed by coalition partners for intercommunications and mission/ capability.*

2.15 A number of communications systems, such as secure voice communications and data link systems, provide essential capability functions that support interoperability. Failure to identify requirements for these systems and ensure that adequate functionality is provided could result in coalition partner refusal to conduct joint operations with Defence aircraft, or incorrect identification of Defence aircraft as 'hostile' during operations. Consequently, designers should ensure that all communication systems and associated functionality necessary to support joint operations are identified and captured in Defence aircraft design requirements. The AFIC standards may provide designers with a baseline from which to derive communication requirements for Defence aircraft.

2.16 **Capability design requirement.** *Where required, Defence aircraft communication systems should comply with the Emanations Security requirements detailed in Section 2 Chapter 4 Electromagnetic Environmental Effects.*

2.17 Inadequate protection of voice or data communications from unauthorised interception may compromise Defence capability.

ADDITIONAL COMMUNICATION SYSTEMS GUIDANCE

2.18 Further guidance on implementing the communications systems requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

FLIGHT RECORDER AND LOCATING EQUIPMENT

Superseded

INTRODUCTION

3.1 Aircraft flight recorder equipment provides data that may be used for the purposes of accident/ incident investigation, and therefore contribute to the safety of future aircraft operations. Locating equipment provides the means by which an aircraft and personnel can be located following an accident. DASR ORO.85 Flight Recorder and Locating Equipment requires a Military Air Operator (MAO) to ensure that Defence aircraft are fitted with flight recorder and locating equipment appropriate to its military configuration, role and operating environment (CRE) to:

(a) locate aircraft and personnel in the event of an aircraft crash

(b) provide data that can be downloaded, interpreted and analysed by approved personnel to assist in the prevention of further aviation safety occurrences.

3.2 While the Authority recognised civil Airworthiness Codes defined in Section 1 of this manual prescribe suitable requirements for flight recorder and locating equipment, clear and comprehensive design requirements are not prescribed in all Authority recognised military Airworthiness Codes. Consequently, the Authority prescribes airworthiness design requirements for flight recorder and locating equipment to supplement the Airworthiness Codes.

Scope

3.3 This Chapter presents Authority prescribed airworthiness design requirements for Defence aircraft flight recorder and locating equipment.

FLIGHT RECORDER AND LOCATING EQUIPMENT DESIGN REQUIREMENTS

Flight recorder equipment design requirements

3.4 Flight recorder equipment is any type of receiver installed in the aircraft for the primary purpose of complementing accident/incident investigation. Flight recorder equipment in Defence aircraft normally consists of a Flight Data Recorder (FDR), a Cockpit Voice Recorder (CVR) and an Underwater Locating Device (ULD). For the purpose of defining design requirements for flight recorder equipment, Defence aircraft have been grouped into the following three broad categories:

(a) large fixed wing, multi-engine aircraft

(b) small fixed wing, fighter/attack/trainer aircraft

(c) rotary wing aircraft.

3.5 The following paragraphs define the Authority prescribed flight recorder equipment airworthiness design requirements. Where reference to a specific standard is made within these requirements, the latest version of the standard applies.

3.6 **Design Requirement (Essential).** *Flight recorder equipment fitted to Defence aircraft must satisfy the requirements defined in Section 2 of EUROCAE ED-112 Minimum Operational Performance Specification for Crash Protected Airborne Recorder Systems, as follows:*

(a) **Large fixed wing aircraft.** *ED-112 Part I for Class 1 CVRs, and ED-112 Part II for Class A FDRs, including data recording requirements.*

(b) **Small fixed wing aircraft.** *ED-112 Part I for Class 1 CVRs, and ED-112 Part II for Class B FDRs, including data recording requirements.*

(c) **Rotary wing aircraft.** *ED-112 Part I for Class 1 CVRs, and ED-112 Part II for Class B or D FDRs, including data recording requirements.*

3.7 Defence aircraft flight recorder equipment should provide sufficient data both in terms of number and type of parameters and recording timeframe to support comprehensive accident and incident investigations. EUROCAE ED-112 defines the contemporary requirements against which civil flight recorder installations are certified, and provides an acceptable basis for Defence aircraft flight recorder equipment certification. For certain aircraft types (eg Navy helicopters) deployable FDRs that comply with ED-112 Part II Class D requirements may be more appropriate, and this should be established in consultation with the capability manager prior to specifying the required design standard.

3.8 While ED-112 has been adopted by the Authority as the benchmark airworthiness design requirement for flight recorder equipment, military aircraft are often not designed to satisfy the ED-112 standard. However, some parameters used for accident investigation purposes may be available from other aircraft sources or their absence may not preclude a successful accident/incident investigation. Therefore, before embarking on often expensive modifications to comply with the full scope of ED-112 requirements, the Authority should be approached for advice on the acceptability of the current flight recorder installation.

3.9 **Design Requirement (Essential).** *In addition to data recording requirements defined in ED-112, unique design or operational characteristics of Defence aircraft that may impact safe flight must be evaluated to establish if recording of additional parameters for these features is warranted.*

3.10 Defence aircraft configurations may include military unique safety related design features that are not included within the 'standard' suite of recorded parameters required by ED-112. In particular, mission system modifications may introduce failure modes or operational characteristics that adversely impact safe flight. A flight recorder system that complies only with the requirements of ED-112 may not capture data parameters associated with these systems and, therefore, may not furnish accident investigators with sufficient data to identify the cause of an accident. Consequently, Defence aircraft modifications, particularly those fitted to civil-derivative Defence aircraft, must be evaluated to determine whether recording of additional data parameters is warranted.

3.11 **Design Requirement (Essential).** *Flight recorder equipment must remain powered throughout all phases of aircraft operation, and following total loss of aircraft primary power sources.*

3.12 Electrical power to flight recorder equipment must be maintained throughout all aircraft operating modes to ensure the continued recording of aircraft parameters post power failure. To establish the adequacy of power supply arrangements for ensuring data integrity for future incident/accident investigation purposes, the potential for complete aircraft power supply failure to the flight recorder equipment should be evaluated. Where flight recorder equipment is not powered from an aircraft supply that ensures continued recorder operation following primary aircraft power supply failure (eg connection via the essential/battery bus), a supplementary flight recorder power supply

Superseded

will be required. In these circumstances a Recorder Independent Power Supply (RIPS), which ensures that the equipment will continue to record aircraft data parameters, may be appropriate. RIPS fitted to Defence aircraft flight recorder equipment should comply with the requirements of ED-112 Section 5.

3.13 **Design Requirement (Essential).** Underwater location devices (ULD) must comply with the following:

(a) *37.5 kHz ULD fitted to non-deployable flight recorder equipment:*

1. *SAE AS8045A,*
2. *EUROCAE ED112, and*
3. *TSO C-121b.*

(b) *8.8 kHz airframe ULD fitted to Defence aircraft:*

1. *ARINC Specification 677, or*
2. *SAE AS6254A, and*
3. *ETSO C-200a.*

3.14 ULDs assist in the location of flight recorder equipment (in particular the data storage module(s)) and the aircraft itself following an aircraft accident over water. Consequently, all Defence aircraft flight recording equipment must be fitted with a ULD that transmits a signal compatible with extant search and rescue monitoring requirements and has appropriate battery life. Where ULD are fitted to Defence aircraft airframes, to aid in location of aircraft wreckage that may have become separated from the flight recorder equipment, these ULDs also must transmit signals compatible with extant search and rescue monitoring requirements.

Locating equipment design requirements

3.15 This section presents design requirements for Defence aircraft locating equipment (Emergency Locator Transmitter (ELT) systems). An ELT provides the means by which an aircraft and personnel can be located following an aircraft accident. ELTs broadcast distinctive signals on designated frequencies and, depending on application, may be automatically or manually activated.

3.16 **Design Requirement (Essential).** *Emergency Locator Transmitter (ELT) fitted to Defence aircraft must provide dual 121.5/406 MHz capability and comply with FAA TSO-C126 or EASA ETSO-2C126, 406 MHz Emergency Locator Transmitter.*

3.17 The fitment of 406 MHz ELTs enables the emergency satellite monitoring system to detect a crashed aircraft, while the 121.5 MHz capability will assist with radio location of the crash site by search and rescue aircraft when in close proximity. Note that portable signalling equipment, such as personal locator beacons, may also be fitted to Defence aircraft (or carried on board with crew/ passengers) and should also be confirmed as being compatible with current emergency response search and rescue frequencies. Any proposal to utilise such portable signalling equipment as a substitute for the fixed aircraft ELT must be communicated to the capability manager who will determine if such use is appropriate in consultation with the Authority.

Superseded

CONTINUING AIRWORTHINESS REQUIREMENTS

3.18 **Continuing airworthiness requirement.** *A flight recorder equipment maintenance program should be established so that Defence aircraft flight recording equipment and associated sensors remain operable during the aircraft's service life.*

3.19 Flight recorder equipment, and associated sensors, maintenance requirements should be established and promulgated, and include as a minimum:

(a) an annual check of the serviceability of data sensors

(b) annual download and analysis of flight recorder data to confirm fidelity of the recording.

3.20 Detailed considerations for the conduct of annual checks of flight recorder equipment are contained in the Defence Aviation Safety Manual.

3.21 **Continuing airworthiness requirement.** *An ELT maintenance program should be established so that Defence aircraft ELTs remain operable during their service life.*

3.22 ELT maintenance requirements should be established and promulgated, and include as a minimum:

(a) an ELT functional test at least every 12 months

(b) corrosion inspection performed during each required battery change

(c) battery change in accordance with the manufacturers guidelines followed by a functional check.

CAPABILITY REQUIREMENTS

3.23 **Capability requirement.** *Recorded data security risk assessments should be conducted on Defence aircraft flight recorder equipment, with associated controls identified, implemented and documented.*

3.24 Flight recorder designs may not afford adequate protection against unauthorised access to sensitive information that may be processed by and recorded on flight recorder equipment. Consequently, a security assessment of the system and data recorded should be undertaken to identify potential implications of unauthorised access. Where potential security risks are identified, these should be evaluated and appropriate controls (eg design - installation of 'zeroise' features or data encryption; or procedural - requirements for disabling data recording functions during certain operational scenarios) should be implemented where warranted. Any protective measures implemented or required to be conducted during aircraft operations should be documented in the aircraft's security program documentation (eg the aircraft specific Security Classification and Categorisation Guide).

ADDITIONAL FLIGHT RECORDER AND LOCATING EQUIPMENT GUIDANCE

3.25 Further guidance on implementing the flight recorder and locating equipment requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

NAVIGATION SYSTEMS

INTRODUCTION

4.1 Defence aircraft operate in a global airspace environment that includes civil airspace that is subject to prescribed access criteria. This airspace is a shared resource and, to maintain airspace limitations such as separation minima, civil airworthiness authorities prescribe minimum performance requirements for aircraft navigation systems. While International Civil Aviation Organisation (ICAO) rules for civil aviation are not applicable to State registered aircraft, it is becoming increasingly difficult for civil air traffic authorities to cater for Defence aircraft if they are not capable of similar navigation performance to civil aircraft. This may result in Defence aircraft being subjected to civil airspace restrictions, for example sub-optimal altitudes and routing and, in some instances, exclusion from certain airspace (despite the ICAO exemption).

4.2 Some civil operations, such as operations under Instrument Flight Rules (IFR), require compliance with specific airworthiness requirements for aircraft equipment and/or operations. Where Defence aircraft require unimpeded access to civil airspace subject to IFR, the Defence aircraft must satisfy an equivalent level of safety to civil aircraft operating in the airspace to avoid posing a risk to other airspace users. Further, Defence operations under the same conditions as civil IFR operations, whether in designated airspace or not, should endeavour to satisfy the same (or substantially similar) requirements to afford a level of safety for Defence aircraft crew and passengers commensurate with these type of operations.

4.3 DASR RoA.05, Rules of the Air, requires capability managers to 'ensure that Rules of the Air as they apply to Defence Aviation as stipulated within Defence AIP are harmonised with ICAO and national civil practice wherever practical in order to assure Defence Aviation interoperability with non-Defence aviation activities'. To verify that Defence aircraft designs satisfy the requirements for operating in civil airspace (eg to operate on Performance Based Navigation (PBN) routes or conduct operations under IFR), the Authority prescribes airworthiness design requirements for navigation systems. Where shortfalls are identified against the 'essential' Authority prescribed design requirements in this chapter (eg to accommodate military unique functions), but the Defence aircraft navigation system is expected to substantially meet the relevant standard, the Authority must be petitioned for a determination regarding the shortfalls.

Scope

4.4 This Chapter presents Authority prescribed airworthiness design requirements for Defence aircraft navigation systems. Importantly, the airworthiness design requirements in this chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of this manual. Further, there may be additional airspace access requirements (such as requirements for communications and display systems) related to operations in civil airspace that must be considered when establishing the suitability of an aircraft to operate in that airspace. Where applicable, compliance with these additional requirements must also be verified.

Superseded

4.5 The determination of whether a Defence aircraft requires particular navigation systems capabilities is, ultimately, a capability and safety decision for the capability manager. Where the capability manager determines that unimpeded operations in civil airspace or along specified civil routes are required, navigation systems must meet the requirements prescribed for navigation in that airspace. Prior to establishing the airworthiness design requirements that must be met for a Defence aircraft's navigation system, the global airspace and navigation environment in which the Defence aircraft will operate must be identified to support the establishment of navigation systems requirements necessary to achieve safe aircraft operations. This section presents the Authority prescribed navigation systems design requirements for Defence aircraft.

Performance Based Navigation (PBN) design requirements

4.6 Civil airspace separation minima (from other aircraft in the area and from obstacles along the route) are predicated on the aircraft's ability to navigate to a predetermined accuracy threshold, or to advise the crew when this accuracy is not available so that air traffic controllers can make alternative separation arrangements. Defence aircraft operations in PBN designated airspace may present a risk to other airspace users, and to the Defence aircraft itself, if the aircraft is unable to maintain the required navigation performance and neither air traffic controllers nor other airspace users are aware of this performance limitation. Consequently, to permit Defence aircraft operations that are compatible with, and safely support interoperability in, civil PBN airspace, the Authority prescribes Area Navigation (RNAV) / Required Navigation Performance (RNP) airworthiness design requirements based on the associated civil standards. Where a Defence aircraft requires unimpeded access to civil airspace for which a PBN specification applies, the airworthiness design requirements associated with the relevant PBN specification, and prescribed by an Authority recognised NAA, apply.

4.7 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to RNP 10 designated airspace, the navigation system must satisfy the performance and functional requirements prescribed by any one of the following:*

(a) *CASA AC 91U-2(0), Required Navigation Performance 10 (RNP 10) Operational Authorisation, or*

(b) *FAA AC 20-138D, Airworthiness Approval of Positioning and Navigation Systems, or*

(c) *EASA AMC 20-12, Recognition of FAA Order 8400.12A for RNP-10 Operations.*

4.8 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to RNAV 5 designated airspace, the navigation system must satisfy the performance and functional requirements prescribed by any one of the following:*

(a) *CASA AC 91.U-01, Navigation Authorisations, or*

(b) *FAA AC 90-96A, Approval of U.S. Operators and Aircraft to Operate Under Instrument Flight Rules (IFR) in European Airspace Designated for Basic Area Navigation (B-RNAV) and Precision Area Navigation (P-RNAV), or*

(c) *EASA AMC 20-4A, Airworthiness Approval and Operational Criteria for the Use of Navigation Systems in European Airspace Designated For Basic RNAV Operations.*

Superseded

4.9 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to RNAV 1 and/or RNAV 2 designated airspace, the navigation system must satisfy the performance and functional requirements prescribed by any one of the following:*

(a) *CASA AC 91.U-01, Navigation Authorisations, or*

(b) *FAA AC 90-100A, U.S Terminal and En Route Area Navigation (RNAV) Operations, or*

(c) *JAA TGL 10, Airworthiness and Operational Approval for Precision RNAV Operations in Designated European Airspace.*

4.10 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to RNP 4 designated airspace, the navigation system must satisfy the performance and functional requirements prescribed by either of the following:*

(a) *CASA AC 91U-3(0), Required Navigation Performance 4 (RNP 4) Operational Authorisation, or*

(b) *FAA AC 20-138D, Airworthiness Approval of Positioning and Navigation Systems.*

4.11 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to RNP 1 and/or RNP 2 designated airspace, the navigation system must satisfy the performance and functional requirements prescribed by either of the following:*

(a) *CASA AC 91.U-01, Navigation Authorisations, or*

(b) *FAA AC 20-138D, Airworthiness Approval of Positioning and Navigation Systems.*

4.12 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to Advanced RNP (A-RNP) airspace, the navigation system must satisfy the performance and functional requirements prescribed by the following:*

(a) *CASA AC 91.U-01 Navigation Authorisations, or*

(b) *FAA AC 20-138D Airworthiness Approval of Positioning and Navigation Systems.*

4.13 **Design Requirement (Essential).** *Where Defence aircraft operation on a defined RNP Approach (RNP APCH) route is required, the navigation system must satisfy the performance and functional requirements prescribed by any one of the following:*

(a) *CASA AC 91.U-01, Navigation Authorisations, or*

(b) *FAA AC 20-138D, Airworthiness Approval of Positioning and Navigation Systems, or*

(c) *EASA AMC 20-27A, Airworthiness Approval and Operational Criteria for RNP APPROACH (RNP APCH) Operations Including APV BARO-VNAV Operations.*

4.14 **Design Requirement (Essential).** *Where Defence aircraft operation on a defined RNP Authorisation Required Approach (RNP AR APCH) route is required, the navigation system must satisfy the performance and functional requirements prescribed by any one of the following:*

(a) *CASA AC 91.U-01, Navigation Authorisations, or*

(b) *FAA AC 20-138D, Airworthiness Approval of Positioning and Navigation Systems, or*

(c) *EASA AMC 20-26, Airworthiness Approval and Operational Criteria for RNP Authorisation Required (RNP AR) Operations.*

Superseded

4.15 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to RNP 0.3 designated airspace, the navigation system must satisfy the performance and functional requirements prescribed by either of the following:*

(a) *CASA AC 91.U-01, Navigation Authorisations, or*

(b) *FAA AC 20-138D, Airworthiness Approval of Positioning and Navigation Systems.*

NOTES

Compliance with the requirements of one navigation specification does not automatically verify compliance with the requirements of all other navigation specifications with less stringent accuracy requirements (eg compliance with RNP 1 does not verify compliance with RNP 4). Notwithstanding the above 'note', where a Defence aircraft satisfies the requirements for A-RNP operations, then the aircraft is also capable of conducting RNAV 5, RNAV 2, RNAV 1, RNP 2, RNP 1 and RNP APCH operations. However, demonstration of RNAV 5, RNAV 2, RNAV 1, RNP 2, RNP 1 and RNP-APCH, in combination, does not automatically equate to A-RNP. Additional functions, such as Radius to Fix (RF) Path Terminator that are optional for other RNP specifications, are required for A-RNP.

Vertical Navigation design requirements

4.16 Required Vertical Separation Minimum (RVSM). RVSM describes the reduction of standard vertical separation to 1000 feet for aircraft flying above Flight Level (FL) 290 in designated RVSM airspace. Defence aircraft operating in designated RVSM airspace with a navigation system that does not provide the required performance or functionality to support such operations may pose a hazard to other airspace users as a result of loss of separation assurance. Therefore, Defence aircraft that are not RVSM compliant and have a requirement to operate in RVSM designated airspace may be subjected to limitations on their use of that airspace (eg limited to operations only during low volume civil traffic periods, or restrictions on Flight Level). To permit Defence aircraft operations that are compatible with, and safely support interoperability in, civil RVSM airspace, the Authority prescribes RVSM airworthiness design requirements based on the associated civil NAA standards.

4.17 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to Reduced Vertical Separation Minimum (RVSM) designated airspace, the navigation system must meet the requirements prescribed by any one of the following:*

(a) *CASA CAAP 181A-1 (2), Reduced Vertical Separation Minimum (RVSM) Approvals, or*

(b) *FAA AC 91-85B, Authorization of Aircraft and Operators for Flight in Reduced Vertical Separation Minimum Airspace, or*

(c) *EASA CS-ACNS, Certification Specifications and Acceptable Means of Compliance for Airborne Communications, Navigation and Surveillance.*

4.18 Vertical Navigation (VNAV). VNAV is used in conjunction with RNAV/RNP lateral approach procedures to define requirements for the vertical flight paths and vertical tracking to the path of instrument approaches. VNAV is conducted using either barometric vertical navigation (baro-VNAV) equipment, or via GPS equipment with Satellite Based Augmentation System (SBAS) capability. Circa 2021, SBAS is not available in Australian controlled airspace (Geoscience Australia has initiated an SBAS project due for completion in 2023/24). Defence aircraft cannot conduct a VNAV approach unless the aircraft is fitted with a navigation system that supports VNAV capability. VNAV systems that do not provide the required performance or functionality may result in aircrew loss of situational awareness, descent below minima and, ultimately, CFIT.

Superseded

4.19 **Design Requirement (Essential).** Where Defence aircraft operation on a defined Vertical Navigation (VNAV) approach is required, the navigation system must meet the requirements prescribed by the following:

(a) **Baro-VNAV.**

1. *CASA AC 91.U-01, Navigation Authorisations, or*
2. *FAA AC 20-138D, Airworthiness Approval of Positioning and Navigation Systems, or*
3. *EASA AMC 20-27A, Airworthiness Approval and Operational Criteria for RNP APPROACH (RNP APCH) Operations, including BARO-VNAV Operations.*

(b) **GPS supported VNAV.**

1. *FAA AC 20-138D, Airworthiness Approval of Positioning and Navigation Systems, or*
2. *EASA AMC 20-28, Airworthiness Approval and Operational Criteria related to Area Navigation for Global Navigation Satellite System approach operation to Localiser Performance with Vertical guidance minima using Satellite Based Augmentation System.*

Database design requirements

4.20 **Design Requirement (Essential).** *Database data for navigation of Defence aircraft must be provided by accredited suppliers, approved in accordance with applicable Authority recognised NAA regulations or DASR ANSP.*

4.21 All RNAV/RNP applications use aeronautical data to define ground-based navigation aids, runways, gates, waypoints and route/procedure to be flown. The safety of RNAV/RNP operations is dependent upon the precision, resolution, and integrity of this data. Further information on the use and approval of Aeronautical Information Databases is contained in Section 5 Chapter 3, Mission Planning Systems.

Instrument Flight Rules design requirements

4.22 Civil NAAs publish airworthiness requirements for the conduct of flights under Instrument Flight Rules (IFR). These requirements describe both aircraft systems and aircrew competency and authorisation. Defence aircraft systems and equipment requirements for IFR operations should satisfy airworthiness design requirements that support safe operations when reliance on visual flight cues is not possible. The IFR requirements of Authority recognised civil NAAs provide a widely accepted benchmark for aircraft systems used to support safe IFR operations. Consequently, the Authority prescribes IFR design requirements for Defence aircraft based on the civil IFR requirements. Where a Defence aircraft requires unimpeded access to civil airspace in which IFR applies, the relevant airworthiness design requirements prescribed by an Authority recognised civil NAA must be satisfied.

4.23 Authority recognised NAAs have promulgated IFR certification and approval requirements based on aircraft categories and types of operations, which may not be representative of the aircraft types operated by the ADF or the roles in which these aircraft are employed. Therefore, the application of the NAA requirements to Defence aircraft may not be straightforward. The IFR airworthiness design requirements prescribed in this chapter are presented using the generic aircraft type categories used within civil type certification programs (ie Parts 23, 25, 27 and 29 aircraft types

Superseded

and military equivalents). Consequently, the correct aircraft 'category' must be established for a particular Defence aircraft to identify which Authority prescribed design requirements are applicable.

4.24 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to IFR designated airspace, the aircraft must satisfy the airworthiness design requirements prescribed by an Authority recognised civil NAA for the applicable aircraft category as follows:*

(a) **Part 23 (and military equivalent) certified Defence aircraft – single/dual pilot and less than 9 passengers.**

1. **FAA.** *IFR certification/approval requirements detailed in FAR Part 23 and FAR 91.205, supplemented with:*

   i. *fitment of a landing light(s), and*

   ii. *equipment and systems requirements prescribed in the ADF General Planning Australia (GPA) and Flight information Handbook Australia (FIHA) publications, or*

2. **EASA.** *IFR certification/approval requirements detailed in EASA CS-23 and EU CAT IDE.A.115, IDE.A.130, IDE.A.135, IDE.A.325, IDE.A.335, IDE.A.345 and IDE.A.350, supplemented with:*

   i. *equipment and systems requirements prescribed in the ADF General Planning Australia (GPA) and Flight information Handbook Australia (FIHA) publications.*

(b) **Part 25 (including Part 23 commuter/charter and military equivalent) certified Defence aircraft – dual pilot and/or 9 or more passengers/crew.**

1. **FAA.** *IFR certification/approval requirements detailed in FAR Part 25 (and relevant sections of FAR Part 23 applicable to commuter category aircraft) and applicable requirements from FAR 91.205, 121.323, 121.325, 121.349, 125.203, 125.205, 135.163 and 135.165, supplemented with:*

   i. *equipment and systems requirements prescribed in the ADF General Planning Australia (GPA) and Flight information Handbook Australia (FIHA) publications, or*

2. **EASA.** *IFR certification/approval requirements detailed in EASA CS-25 and EU CAT IDE.A.130, IDE.A.135, IDE.A.325, IDE.A.335, IDE.A.345 and IDE.A.350, supplemented with:*

   i. *equipment and systems requirements prescribed in the ADF General Planning Australia (GPA) and Flight information Handbook Australia (FIHA) publications.*

(c) **Part 27 (and military equivalent) certified Defence aircraft – single/dual pilot and less than 9 passengers.**

1. **FAA.** *IFR certification/approval requirements detailed in FAR Part 27 (including FAR 27 Appendix B) and FAR 91.205, supplemented with:*

   i. *fitment of a landing light(s); and*

   ii. *equipment and systems requirements prescribed in the ADF General Planning Australia (GPA) and Flight information Handbook Australia (FIHA) publications, or*

Superseded

2. **EASA.** *IFR certification/approval requirements detailed in EASA CS-27 (including CS-27 Appendix B) and EU CAT IDE.H.115, IDE.H.130, IDE.H.135, IDE.H.335, IDE.H.345 and IDE.H.350, supplemented with:*

i. *equipment and systems requirements prescribed in the ADF General Planning Australia (GPA) and Flight information Handbook Australia (FIHA) publications.*

NOTE

The requirements for static pressure sources defined in CASR Part 91 Manual of Standards may be used in lieu of those defined in FAR Part 27 Appendix B or EU CAT.IDE.H.130.

(d) **Part 29 (including Part 27 commuter/charter and military equivalent) certified Defence aircraft – dual pilot and/or 9 or more passengers/crew.**

1. **FAA.** *IFR certification/approval requirements detailed in FAR Part 29 (including FAR 29 Appendix B) and FAR 91.205, 135.163 and 135.165, supplemented with:*

i. *equipment and systems requirements prescribed in the ADF General Planning Australia (GPA) and Flight information Handbook Australia (FIHA) publications, or*

2. **EASA.** *IFR certification/approval requirements detailed in EASA CS-29 (including CS-29 Appendix B) and EU CAT IDE.H.115, IDE.H.130, IDE.H.135, IDE.H.160, IDE.H.335, IDE.H.345 and IDE.H.350, supplemented with:*

i. *equipment and systems requirements prescribed in the ADF General Planning Australia (GPA) and Flight information Handbook Australia (FIHA) publications.*

NOTE

The requirements for static pressure sources defined in CASR Part 91 Manual of Standards may be used in lieu of those defined in FAR Part 29 Appendix B or EU CAT.IDE.H.130

NOTE

While the airworthiness design requirements in the civil Airworthiness Codes described above provide the benchmark IFR design requirements for Defence aircraft, Defence operational requirements such as those defined in the ADF GPA and FIHA may override the minimum equipment and systems prescribed by civil NAAs.

VHF Omni-directional Range (VOR) Navigation and Instrument Landing Systems (ILS)

4.25 VOR navigation systems provide a ground-based radio navigation aid infrastructure that may be used for navigation when GPS or other independent navigation sources are unavailable. ILS provides a ground-based radio navigation approach aid to guide an aircraft down a predetermined safe approach path to the runway threshold. Both of these systems support safe operations in certain PBN designated airspace and safe landing in adverse weather conditions at airfields around the globe. Consequently, the Authority prescribes VOR and ILS design requirements to define the required level of performance when used for these operations in Defence aircraft.

4.26 **Design Requirement (Essential).** *VOR receivers fitted to Defence aircraft must satisfy the requirements of:*

(a) *TSO-C40c VOR Receiving Equipment Operating Within the Radio Frequency Range of 108-117.95 Megahertz (MHz), or*

Superseded

(b) *ETSO-2C40c VOR Receiving Equipment Operating Within the Radio Frequency Range of 108-117.95 Megahertz (MHz).*

4.27 **Design Requirement (Essential).** *ILS receivers fitted to Defence aircraft must satisfy the requirements of:*

(a) *TSO-C34e, ILS Glide Slope Receiving Equipment Operating within the Radio Frequency Range of 328.6-335.4 Megahertz (Mhz) and TSO-C36e Airborne ILS Localizer Receiving Equipment Operating Within the Radio Frequency Range of 108-112 Megahertz (MHz), or*

(b) *ETSO-2C34f ILS Glide Slope Receiving Equipment Operating within the Radio Frequency Range of 328.6-335.4 Megahertz (Mhz), and ETSO-2C36f Airborne ILS Localizer Receiving Equipment Operating Within the Radio Frequency Range of 108-112 Megahertz (MHz).*

4.28 The performance of VOR and ILS systems used to support PBN and ILS operations may be adversely affected by external radio frequency transmissions. Operations in certain airspace regions around the globe (in particular Europe, Africa, Russia and the Middle East) may expose Defence aircraft VOR and ILS navigation systems to an increased risk of FM interference from civil radio stations. Compliance with the standards prescribed in paragraphs 4.27 and 4.28, inherently covers FM immunity for Defence aircraft VOR and ILS.

ADDITIONAL NAVIGATION SYSTEMS GUIDANCE

4.29 Further guidance on implementing the navigation systems design requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

SURVEILLANCE AND AVOIDANCE SYSTEMS

INTRODUCTION

5.1 Surveillance systems contribute to aircraft safe separation and support the provision of safe and effective air traffic control services. Aircraft avoidance systems provide warnings and alerts to aircrew of impending hazards associated with proximity to other air traffic or terrain.

5.2 While Defence aircraft without surveillance and avoidance systems would not normally be precluded from operations in civil airspace, sub-optimal routes and timings may be imposed. Therefore, fitment of surveillance and avoidance systems in Defence aircraft is, ultimately, a capability and safety decision for the capability manager.

5.3 When operating in civil airspace, Defence aircraft may present a hazard to civil aircraft if the Defence aircraft does not provide the same surveillance and avoidance systems capabilities as those required by civil NAAs for civil aircraft operations. The civil NAA standards for surveillance and avoidance systems usually provide an appropriate benchmark for surveillance and avoidance systems performance and ensure appropriate interoperability with civil aircraft in civil airspace. Military Airworthiness Codes may not prescribe standards for surveillance and avoidance systems, and civil Codes may prescribe different standards for similar operations in civil airspace. Finally, where Defence operations only present a hazard to the Defence aircraft (rather than a third party risk to other airspace users), and/or where the concept of operations for the Defence aircraft differs from that in civil aircraft (for example Terrain Awareness and Warning Systems (TAWS)), applying the civil standards to Defence aircraft may not be useful or warranted. Consequently, the Authority prescribes airworthiness design requirements for Defence aircraft surveillance and avoidance systems.

Scope

5.4 This Chapter prescribes Authority supplementation to the aircraft surveillance and avoidance systems elements of recognised civil and military Airworthiness Codes. Importantly, the airworthiness design requirements in this chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of the DASDRM.

SURVEILLANCE SYSTEMS DESIGN REQUIREMENTS

5.5 This section presents the Authority prescribed airworthiness design requirements for Defence aircraft surveillance systems.

Aircraft transponders

5.6 ATC transponders provide responses to interrogations from ground based secondary surveillance radar, to support aircraft safe separation and may be used by other aircraft to support traffic collision avoidance. ATC transponder equipment is mandated for all civil aircraft operating in

Superseded

certain classes of civil airspace. Some civil NAAs are mandating retrospective fitment of ATC transponder equipment with functionality that exceeds the 'basic' aircraft identification and altitude data traditionally provided by ATC transponders (eg CASA requires all aircraft operating in Australian airspace to be fitted with a Mode S transponder in specified locations and classes of airspace).

5.7 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to civil airspace in which the fitment and operation of an ATC transponder is mandated for civil aircraft, the Defence aircraft transponder must satisfy the requirements prescribed by the relevant civil NAA, as follows:*

(a) *for operations in Australian airspace, CASR Part 91 Manual of Standards*

(b) *for operations in US airspace, FAA FAR 91.215, ATC transponder and altitude reporting equipment and use*

(c) *for operations in European airspace, EASA Certification Specifications and Acceptable Means of Compliance for Airborne Communications, Navigation and Surveillance (CS-ACNS) Book 1 Subpart D Section 1, 2 or 3 as applicable*.

5.8 While lack of an ATC transponder may not preclude access to civil airspace, such access may be severely limited since the transponder affords air traffic controllers the situational awareness necessary to provide separation advice and control to airspace users, and provides other airspace users with traffic collision avoidance advice and commands in congested airspace. An ATC transponder that does not comply with the associated civil airworthiness design requirements may not provide the required performance or functionality to support air traffic control services and traffic collision avoidance, and may therefore pose a hazard to other airspace users.

Automatic Dependent Surveillance – Broadcast (ADS-B)

5.9 Automatic Dependent Surveillance – Broadcast (ADS-B) provides 'radar-like' air traffic information to support civil aviation operations in Australia, the United States and Europe. ADS-B provides transmission and reception of broadcast messages, which detail an aircraft's position (latitude and longitude), altitude, velocity, aircraft identification and other parameters. Civil NAAs have implemented a program of prescribing ADS-B fitment to civil aircraft operating in specified classes of airspace. For example, CASA has mandated ADS-B compliance for all civil aircraft operating under Instrument Flight Rules or above FL 290 in Australian airspace.

5.10 **Design Requirement (Essential).** *Where a Defence aircraft requires unimpeded access to ADS-B designated airspace, the equipment must satisfy the requirements prescribed by the relevant civil NAA, as follows:*

(a) *for operations in Australian airspace, CASA AC 21-45v2.2 Airworthiness Approval of Airborne Automatic Dependent Surveillance Broadcast Equipment*

(b) *for operations in US airspace, FAA AC 20-165B Airworthiness Approval of ADS-B Out Systems, for a 1090 MHz Extended Squitter system*

(c) *for operations in European airspace, EASA Certification Specifications and Acceptable Means of Compliance for Airborne Communications, Navigation and Surveillance (CS-ACNS) Book 1 Subpart D Section 4 – 1090 MHz Extended Squitter ADS-B.*

5.11 ADS-B equipment fitted to Defence aircraft must satisfy the ADS-B design requirements prescribed by the relevant NAA for operations in designated ADS-B airspace. Non-compliance with

Superseded

these requirements could pose a hazard to other airspace users if the equipment fails to accurately report the Defence aircraft's flight data, or incorrectly receives and / or interprets other aircraft data.

NOTE

The minimum data messages required for US and European ADS-B operations may not be achieved by ADS-B equipment that complies with the CASA requirements. While ADS B equipment compliant with CASA's airworthiness requirements may be technically capable of broadcasting all FAA and EASA mandatory data messages, the equipment may not be configured to do so, since some of the mandatory system status messages are not required by CASA. Therefore, where Defence aircraft ADS-B operations in US or European airspace are required, the minimum broadcast capabilities of Defence equipment must be verified to comply with the relevant FAA and / or EASA requirements.

Continuing airworthiness requirements for ATC transponders

5.12 **Continuing airworthiness requirement.** *ATC transponder serviceability testing should be conducted at least every two years, per the requirements detailed in FAA Part 43 Appendix F.*

5.13 ATC transponder systems require periodic testing to confirm that the system continues to generate data that meets the civil benchmark standards and can be safely used by air traffic controllers to manage associated airspace.

AVOIDANCE SYSTEMS DESIGN REQUIREMENTS

5.14 This section presents the Authority prescribed airworthiness design requirements for Defence aircraft avoidance systems.

Traffic Alert and Collision Avoidance Systems (TCAS)

5.15 The Traffic Alert and Collision Avoidance System (TCAS) monitors the traffic situation around an aircraft and provides information on the approximate bearing and altitude of other aircraft, generates collision warnings to the pilot that another aircraft is in near vicinity (Traffic Advisories (TA)) and provides suggested avoidance actions (Resolution Advisories (RA)). While civil NAAs prescribe fitment of TCAS in large passenger carrying aircraft operating in certain classes of airspace and operations, there is no consistent application of a TCAS mandate. The lack of TCAS on Defence aircraft does not preclude or limit access to civil airspace. Nevertheless, TCAS provides a safety benefit that may be warranted for Defence aircraft operations in civil airspace (or for unique military operations where aircraft are in close proximity) and a determination should be sought from the capability manager regarding the requirement for TCAS.

5.16 Only TCAS II Version 7.0/7.1 systems comply with ICAO TCAS II requirements. Where civil NAAs do prescribe TCAS fitment, the TCAS II Version 7.0/7.1 requirements are levied. Therefore, the Authority has adopted the associated civil airworthiness design requirements as the benchmark for Defence aircraft TCAS.

5.17 Design Requirement (Essential). Where TCAS is fitted in a Defence aircraft, the equipment must comply with the requirements prescribed in FAA AC 20-151C Airworthiness Approval of Traffic Alert and Collision Avoidance Systems (TCAS II) Versions 7.0 & 7.1 and Associated Mode S Transponders.

5.18 TCAS equipped aircraft conduct coordinated responses to potential conflicts to avoid mid-air collisions. A Defence aircraft fitted with a non-compliant TCAS may respond to a RA generated by

Superseded

another TCAS equipped aircraft in an uncoordinated manner, which may lead to mid-air collision. Consequently, where TCAS capability is confirmed to be required for Defence aircraft operations, the TCAS system must comply with the civil requirements to ensure compatibility with other airspace users.

Terrain Awareness and Warning Systems (TAWS)

5.19 Terrain Awareness and Warning Systems (TAWS), also known as Ground Proximity Warning Systems, provide aircrew with both aural and visual alerts to reduce controlled flight into terrain (CFIT). Civil NAAs have prescribed TAWS fitment for certain types of aircraft and operations. While some NAAs require aircraft to have TAWS, unlike other systems described in this Chapter, the lack of TAWS capability does not pose any third party risk. The decision to fit TAWS is therefore a capability decision based on the additional safety benefit provided during Defence aircraft operations.

5.20 **Design Requirement (Essential).** *Authority advice must be sought to define airworthiness design requirements for TAWS fitted to Defence aircraft.*

5.21 Circa 2021, military NAAs have not prescribed airworthiness design requirements for TAWS. Further, military aircraft often require TAWS functions and performance to provide terrain avoidance advice and commands in a 'tactical' environment that is not normally associated with civil operations.

5.22 Given the lack of military TAWS standards, the Authority has not established design requirements based on a specific civil or military standard and, instead, has adopted an approach of establishing design requirements on a case by case basis. Nevertheless, noting that the civil standards for TAWS support safe civil aircraft operations in close proximity to terrain, the civil TAWS requirements provide an appropriate safety benchmark. Consequently, TAWS compliance with the following civil requirements is likely to ensure safe TAWS operation in Defence aircraft provided that the CRE remains substantially similar to that for which the TAWS was originally certified:

(a) FAA AC 25-23 Airworthiness Criteria for the Installation Approval of a Terrain Awareness and Warning System (TAWS) for Part 25 Airplanes,

(b) FAA AC 23-18 Installation of Terrain Awareness and Warning System (TAWS) Approved for Part 23 Airplanes,

(c) EASA CS-ACNS Book 1 Subpart E Section 1 – Terrain Awareness and Warning System (TAWS), or

(d) FAA TSO-C194/EASA ETSO-C194 Helicopter Terrain Awareness and Warning System (HTAWS).

5.23 When prescribing design requirements for TAWS, the Authority will adopt a systems approach. TAWS rely on the integrity of: the terrain data, the aircraft navigation systems that establish where the aircraft is in relation to terrain obstacles, and the TAWS processing hardware and algorithms. The civil standards identified above utilise this 'systems' approach to prescribing TAWS requirements; however, they may not cater for the intended TAWS operational use in a Defence aircraft. Failure to install TAWS equipment and associated data that satisfies appropriate performance and design assurance requirements could contribute to CFIT. Consequently, the Authority will confirm airworthiness design requirements for TAWS in Defence aircraft on a case-by-case basis to ensure that appropriate TAWS requirements are defined for the proposed aircraft operations.

Superseded

CAPABILITY AND INTEROPERABILITY DESIGN REQUIREMENTS

5.24 This section presents design requirements that are not prescribed by the Authority, but identify particular capability and interoperability design considerations for establishing requirements for Defence aircraft surveillance systems.

Identification Friend or Foe (IFF)

5.25 IFF systems ensure that Defence aircraft in national and international operations are not identified by other coalition assets as 'hostile'. IFF systems that are not compliant with a design standard prescribed by coalition partners may prevent Defence aircraft from being correctly identified during operations. Where an IFF system is necessary to satisfy capability requirements, Defence requires Mark XIIA IFF systems to be fitted to Defence aircraft.

5.26 **Capability Requirement.** *IFF systems fitted to Defence aircraft should be certified to the US DoD AIMS (Air Traffic Control Radio Beacon System, Identification Friend or Foe, Mark XII/XIIA System) 03-1000B Amendment 2.*

5.27 Mark XIIA IFF systems provide the performance, security and encryption capacity required for interoperability with ADF European and US coalition partners. Per the Mode 5 IFF Capability Realisation Plan, only IFF MK XIIA systems that meet the requirements in the current version of the US DoD AIMS standards are acceptable for Defence aircraft IFF operations, including Mode 5 Level 1 and Level 2 operations.

ADDITIONAL SURVEILLANCE AND AVOIDANCE SYSTEMS GUIDANCE

5.28 Further guidance on implementing the surveillance and avoidance systems requirements prescribed in this chapter can be provided by the chapter sponsor.

OXYGEN SYSTEMS

INTRODUCTION

6.1 Defence aircraft are fitted with breathing equipment to supply oxygen, or a mixture of air and oxygen, to crew and passengers to protect against the effects of hypoxia at cabin altitudes above 10,000 feet. Hypoxia occurs whenever a physiologically inadequate amount of oxygen is available to, or is utilised by, body tissues and the brain.

6.2 Defence experience with aircraft oxygen system failures (and subsequent impact on either crew or aircraft safety) has identified shortfalls in extant Codes and associated standards promulgated by civil and military Airworthiness Authorities as described in Section 1 of this manual. Consequently, the Authority has defined airworthiness design requirements for Defence aircraft oxygen systems to supplement these Codes.

Scope

6.3 This Chapter prescribes Authority supplementation to the aircraft oxygen system elements of recognised civil and military Airworthiness Codes. Importantly, the airworthiness design requirements in this chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of this manual.

DEFENCE AIRCRAFT OXYGEN SYSTEM DESIGN REQUIREMENTS

6.4 This section presents design requirements for oxygen systems fitted to new Defence aircraft. Additional design requirements specific to gaseous, liquid, on-board oxygen generating and chemical oxygen generating systems are presented at paragraphs 6.15 through 6.34.

6.5 **Design Requirement (Essential)**. *Defence aircraft oxygen systems must comply with the requirements of DASR ORO.60, Provision and Use of Oxygen in Aircraft.*

6.6 To provide protection against the effects of hypoxia, DASR ORO.60 requires supplemental oxygen systems to support crew and passenger breathing when the aircraft is operating at defined altitudes.

6.7 **Design Requirement (Essential)**. *Cadmium plated components must not be used in oxygen systems where they are exposed to enriched oxygen flow.*

6.8 Cadmium plated components exposed to enriched oxygen may release cadmium (which has known adverse health effects) into the oxygen flow.

6.9 **Design requirement (Essential)**. *Oxygen system venting must be shown by analysis to not pose a hazard to safe aircraft operation.*

Superseded

6.10 Routing of oxygen system vent lines into internal aircraft compartments may lead to high oxygen concentrations in the vicinity of fuel sources, which increases the risk of fire. Overboard venting usually provides an effective means of ensuring that vented oxygen does not pose a hazard to the aircraft operators or maintainers. Where venting internally is proposed, a cavity analysis must be conducted to identify any potential hazards associated with oxygen venting and the analysis must confirm that relevant oxygen system safety objectives have been met (in particular fire risk, which should be verified via a relevant Oxygen Hazards and Fire Risk Analysis (OHFRA)). Venting near fuel or ignition sources must not occur.

6.11 **Design Requirement (Essential)**. *For aircraft in which the cabin altitude is not maintained below 10,000 feet at all aircraft operating altitudes during normal operation, an indication must be provided that warns the flight crew when the cabin altitude is greater than 10,000 feet and nil or continuous oxygen flow occurs for at least 15 seconds on any oxygen regulator.*

6.12 An indication of nil or continuous flow warns the crew that a sufficient supply of oxygen (to prevent the onset of hypoxia) may not be available if the cabin altitude remains above 10,000 feet. Supplemental oxygen is required at cabin altitudes above 10,000 feet, hence a nil flow warning is required, while a continuous flow warning may be an indication of failure either before or after the regulator or of mask removal. Appropriate warning to the crew may be provided by a master caution light in conjunction with a warning panel light and an audible warning signal.

6.13 **Design Requirement (Recommended)**. *Materials used in aircraft oxygen systems should meet the requirements defined in ASTM G63 and ASTM G94, supplemented with the following:*

(a) *annealed copper tubing qualified to AS 1572-1998 should be used where tubing is exposed to oxygen pressures greater than 500 psi*

(b) *corrosion resistant steel tubing qualified to ASTM A269 should only be used where tubing is exposed to oxygen pressures less than 500 psi*

(c) *aluminium alloy tubing qualified to MIL-T-7081D should only be used where tubing is exposed to oxygen pressures less than 150 psi.*

6.14 The selection of appropriate materials for use in aircraft oxygen systems depending on oxygen pressure, and design of the storage, distribution and delivery system, reduces the likelihood of oxygen system fires. Oxygen system designs that are certified as compliant with Authority recognised Codes will have been designed to comply with materials properties that satisfy relevant safety objectives. However, for changes to designs, adoption of the requirements detailed ASTM G63 Standard Guide for Evaluating Nonmetallic Materials for Oxygen Service and ASTM G94 Standard Guide for Evaluating Metals for Oxygen Service will inform the selection of materials having the appropriate characteristics to ensure safe oxygen system design. Nevertheless, the inherent flexibility in these standards may lead to system tubing being used that does not result in associated fire hazards (and risks) being minimised so far as is reasonably practicable. Therefore, the Authority has prescribed an adaptation of these standards that represents current good practice material selection and should be reasonably practicable to implement for Defence aircraft oxygen system design changes.

Gaseous oxygen systems

6.15 In addition to the oxygen system design requirements prescribed at paragraphs 5 through 14, the following airworthiness design requirements are applicable to Defence aircraft gaseous oxygen systems.

Superseded

6.16 **Design Requirement (Essential).** *A filter with particle retention of 10 micron or less must be used in gaseous oxygen system filler valves or the level of filtration incorporated into the design must be demonstrated by analysis to afford an equivalent level of safety.*

6.17 Particulate contamination in gaseous oxygen systems, particularly high pressure systems, can result in a significantly increased likelihood of oxygen system fire, through the action of particle impact in high velocity flow environments generating sufficient heat to ignite materials. While extant civil and military oxygen system design standards require fitment of an inlet filter, this is often of a considerably higher micron rating that does not adequately capture particles known to have caused fires in Defence aircraft. However, the combination of inlet filter, maintenance practices during refilling, cleanliness of supply and additional supply filtration all assist in preventing particulate contamination of oxygen systems that could cause a fire hazard. Therefore, where inlet filtration greater than 10 micron is proposed, the designer must demonstrate through analysis that the combination of these factors affords an equivalent level of safety.

6.18 **Design Requirement (Essential).** *Pressure reduction in high pressure oxygen systems must occur at, or as close as possible to, the supply source.*

6.19 The direct supply of high pressure oxygen to oxygen system regulators or other system components results in high velocity gas flows through regulator valves and components where oxygen flow is restricted. This increases the risk of oxygen system fires through both particle impact and adiabatic heating processes. Designing high pressure piping to be as short as possible, significantly reduces the potential for these ignition mechanisms to be present.

6.20 **Design Requirement (Essential).** *Where aluminium oxygen cylinders, or composite oxygen cylinders with an aluminium liner, are proposed to be used in Defence aircraft, an analysis of the operating environment must demonstrate that the cylinder will not pose a hazard to the aircraft during operation.*

6.21 The use of aluminium or composite oxygen cylinders in aircraft increases the likelihood of the cylinder experiencing an explosive failure if it suffers a ballistic impact. Aluminium and composite cylinders are often used in civil aircraft oxygen system designs due to their improved weight versus pressure holding capability. Where an aluminium or composite oxygen cylinder is proposed for use in a Defence aircraft, the capability manager must be engaged to confirm that the Defence aircraft operating environment does not pose an increased likelihood of ballistic impact compared to the baseline aircraft.

Liquid oxygen systems

6.22 In addition to the oxygen system design requirements prescribed at paragraphs 5 through 14, the following airworthiness design requirements are applicable to Defence aircraft liquid oxygen systems.

6.23 **Design Requirement (Essential).** *Liquid oxygen systems fitted to Defence civil derivative aircraft must be certified as compliant with an approved military airworthiness code or must be certified by an Authority recognised civil NAA as having met the relevant safety objectives for aircraft oxygen systems.*

6.24 Current civil NAA airworthiness codes do not define sufficient design requirements for liquid oxygen systems. Consequently, where a civil derivative aircraft design includes liquid oxygen systems, such systems must be certified using either a recognised military airworthiness code (which will include appropriate requirements for liquid oxygen systems) or certified by an Authority recognised

Superseded

civil NAA as having met a suite of airworthiness design requirements that the Authority has determined provide an equivalent level of safety (usually defined within a Special Condition to the original NAA type certification).

6.25 **Design Requirement (Essential).** *Stabilisation times must be established and promulgated for non-stabilised liquid oxygen converters used in Defence aircraft.*

6.26 Non-stabilised liquid oxygen converters can suffer from thermal stratification, which can lead to loss of oxygen supply if the converter is moved/shaken before thermal equilibrium has been reached. Stabilisation of liquid oxygen converters can take many hours and, during this period, there will be an increased likelihood of oxygen system failure. Where a non-stabilised converter is fitted to a Defence aircraft and is designed to be replenished in-situ, the stabilisation time must be documented in the relevant aircraft maintenance publications. Where a non-stabilised converter can be removed for replenishment and allowed to stabilise prior to reinstallation, required stabilisation times must be promulgated in relevant oxygen replenishment instructions.

On-board oxygen generating systems

6.27 In addition to the oxygen system design requirements defined at paragraphs 5 through 14, the following airworthiness design requirements are applicable to Defence aircraft OBOG systems.

6.28 **Design Requirement (Essential).** *Defence aircraft OBOGS must comply with the airworthiness design requirements prescribed in:*

(a) *DEF STAN 00-970 Part 13, or*

(b) *an alternative standard agreed by the Authority.*

6.29 The oxygen system airworthiness design requirements prescribed in the Authority recognised civil Airworthiness Codes are generic in nature and do not include a complete and consistent suite of requirements for evolving oxygen system technologies such as OBOGS. Further, the civil requirements may not adequately cover aspects of military operations, such as the need for crew to be supplied with a continuous source of oxygen for the duration of flight. Consequently, the Authority has prescribed a benchmark standard, DEF STAN 00-970, which presents a complete and consistent suite of OBOGS design requirements for the military context.

6.30 **Design Requirement (Essential).** *Where the back-up oxygen supply is also used to support crew breathing during the ejection sequence, analysis must demonstrate that the back-up supply has sufficient capacity to support breathing for all crew during:*

(a) *any foreseeable OBOGS failures*

(b) *ejection following OBOGS failure.*

6.31 Using the same oxygen source for both OBOGS back-up and ejection increases the likelihood that the source will be depleted during an OBOGS failure, which may pose a hypoxia hazard to the crew if ejection above 10,000 feet is required. ADF experience has revealed that OBOGS designs suffer from failure modes that result in the crew using the back-up supply more frequently than assumed. In these circumstances, the crew may be unaware of, or unable to ascertain, the remaining capacity of the back-up oxygen supply. This may result in insufficient oxygen being available should an ejection subsequently be required at an altitude where breathing cannot be sustained. Further, given that the OBOGS relies on engine operation to supply oxygen, an engine failure at altitude (for a single engine aircraft) may lead to depletion of the back-up supply before a height is reached at which safe

Superseded

ejection can occur. The designer must confirm that the capacity of the ejection sequence oxygen supply, when also used as the OBOGS back-up, provides an adequate level of protection against hypoxia, and satisfies the associated oxygen system design safety objectives.

Chemical oxygen generators

6.32 The following airworthiness requirement is applicable to Defence aircraft chemical oxygen generators.

6.33 **Design Requirement (Essential).** *Where an oxygen system design change includes the installation of chemical oxygen generators, airworthiness design requirements for the chemical oxygen generator must be defined and proposed for Authority agreement.*

6.34 Chemical oxygen generators may pose unique hazards associated with the exothermic chemical reaction if not designed and certified for use in an aircraft environment. Authority recognised NAAs have included some requirements for chemical oxygen generators in their associated Airworthiness Codes (eg FAR 25.1450), and compliance with these requirements as part of an NAA certification will satisfy relevant oxygen system safety objectives. However, where chemical oxygen generators are not part of the original certified design, and are proposed to be fitted to a Defence aircraft, the NAA requirements may not be suitable for adoption in the military context of use. Therefore, the airworthiness requirements to be applied to the chemical oxygen generators must be defined, and proposed for Authority agreement. SAE AS 1304 Rev B Continuous Flow Chemical Oxygen Generators and SAE AS 1303 Portable Chemical Oxygen may assist designers in establishing suitable equipment and performance requirements for chemical oxygen generators, noting that these standards may require tailoring to accommodate unique military role and operating environment considerations.

INTEROPERABILITY AND CAPABILITY DESIGN REQUIREMENTS

6.35 Design attributes in Defence aircraft oxygen systems may result in interoperability constraints or fire hazards that could result in loss of an aircraft during maintenance activities (and potentially have WHS implications for personnel). Consequently, the following requirements, while not prescribed by the Authority, should be considered for aircraft acquisitions and modifications where interoperability or capability issues are determining factors.

6.36 **Interoperability design requirement.** *Gaseous and liquid oxygen replenishment couplings should comply with the requirements defined in AFIC AIR STD FG 4030, Characteristics of Gaseous Breathing Oxygen, Liquid Breathing Oxygen and Supply pressures, Hoses and Replenishment Couplings.*

6.37 Defence aircraft oxygen systems designs may adversely impact interoperability with other nations and/or continued operational availability, if they are not designed to permit replenishment using support equipment at deployed locations. In particular, civil-derivative aircraft may not be designed for interoperability.

6.38 **Capability design requirement.** *Oxygen cylinders should have an ON/OFF valve that provides a means of gradually increasing system oxygen pressure in a controlled fashion.*

6.39 Fast acting ON/OFF valves on aircraft oxygen cylinders release a high velocity ‘slug’ of oxygen that may impact on components in the distribution system, generating substantial heat and increasing the likelihood of a fire. Given that supply on/off valves in aircraft can only be operated by

Superseded

ground crew during maintenance, such fires are likely to result in capability impacts as a result of loss of the aircraft and pose a WHS hazard to personnel.

ADDITIONAL OXYGEN SYSTEM DESIGN GUIDANCE

6.40 Further guidance on implementing the oxygen systems requirements prescribed in this chapter can be provided by the chapter sponsor.

LIGHTING SYSTEMS

INTRODUCTION

7.1 Aircraft lighting systems enable the crew to: see essential flight data and aircraft information in all ambient light conditions, discern external physical conditions/features during operations (particularly during take-off and landing), implement 'see and avoid' barriers to airspace conflicts, and so on. For the majority of lighting systems, compliance with the airworthiness design requirements prescribed in an Authority recognised Airworthiness Code satisfies an appropriate benchmark for the safe design and operation of these systems in Defence aircraft. However, some lighting systems requirements associated principally with military operations (such as Night Vision Imaging Systems (NVIS) compatibility, external lighting to support formation flight, air-air refuelling lights and so on) are not, or may be only minimally, covered in civil Airworthiness Codes. Consequently, the Authority prescribes airworthiness design requirements for Defence aircraft lighting systems.

Scope

7.2 This Chapter presents Authority prescribed airworthiness design requirements for Defence aircraft lighting systems. Importantly, the design requirements in this chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of this manual.

7.3 This Chapter does not include requirements for emergency lighting. These requirements and any associated Authority prescribed supplementation are detailed in Section 2 Chapter 6 Crash Protection. Further, there may be additional systems/equipment required to support NVIS operations (eg radio altimeter for helicopter NVIS operations) that are not included within the scope of this Chapter, but for which compliance must be verified before the aircraft can be certified as being NVIS compatible.

LIGHTING SYSTEMS DESIGN REQUIREMENTS

7.4 Lighting systems requirements may be prescribed by civil NAAs on the basis of aircraft type or to support safe operations (for example, operation under Instrument Flight Rules requires fitment of specific external lighting). Lighting systems must also be compatible with aircrew equipment (including NVIS) and support safe flight during military-unique operations such as air to air refuelling.

7.5 **Design Requirement (Essential).** *The lighting systems fitted to Defence aircraft must satisfy the minimum systems/equipment and functional requirements prescribed by any one of the Authority recognised NAAs/MAAs, as follows:*

(a) ***FAA.*** *The relevant FAR Part 23, 25, 27 or 29 lighting requirements, and the requirements prescribed in FAR 91.205 for operations in US civil airspace.*

(b) ***EASA.*** *The relevant CS 23, 25, 27 or 29 lighting requirements, and the requirements prescribed in EU CAT.IDE.A.115 or EU CAT.IDE.H.115 for operations in European civil airspace.*

Superseded

(c) ***CASA.*** *The relevant FAR/CS Part 23, 25, 27 or 29 requirements, and the requirements prescribed in CASR Part 91 Manual of Standards for operations in Australian airspace*

(d) ***USAF.*** *The relevant lighting requirements of MIL-HDBK-516C, including the requirements for 'operations in commercial airways'.*

(e) ***UK MoD.*** *The relevant lighting requirements of DEF STAN 00-970.*

7.6 Note that the preceding Authority prescribed design requirement includes both the Authority recognised civil Airworthiness Codes defined in Section 1 of this manual, plus additional operational regulations that do not form part of the basic suite of civil NAA prescribed 'design' requirements. Military Airworthiness Authorities do not prescribe 'operational regulations' for aircraft lighting in the same way as civil NAAs; however, the Authority recognised military Airworthiness Codes inherently prescribe lighting design requirements that satisfy the civil Codes requirements for operations in specified civil airspace.

7.7 **Design Requirement (Essential).** *Lighting systems required for military-unique operations must satisfy the requirements prescribed in an Authority recognised military Airworthiness Code.*

7.8 Lighting systems on Defence aircraft support safe operations in shared airspace through enabling the crew to conduct 'see and avoid' separation in low visibility and during the conduct of military operations such as formation flight. Failure to install appropriate lighting could pose a hazard to other airspace users. When establishing the lighting systems to be fitted to a Defence aircraft, the minimum systems required to support proposed operations (eg air-air refuelling, formation flight and so on) must be installed and satisfy the applicable design standards.

7.9 **Design Requirement (Essential).** *Where NVIS is intended for use in a Defence aircraft, the aircraft lighting systems must satisfy the compatibility requirements for the relevant NVIS Type and Class specified in:*

(a) *MIL-STD-3009, Lighting, Aircraft, Night Vision Imaging System (NVIS) Compatible, or*

(b) *STANAG 3224 Aircraft Interior and Exterior Lighting Night Vision Goggle (NVG) and Non-NVG Compatible.*

7.10 Aircraft NVIS generally use helmet mounted, binocular, image intensifier tubes to produce an enhanced image of the environment outside the aircraft in light conditions too low for normal flying operations or navigation by visual means. Aircraft cockpit lighting that is incompatible with NVIS can interfere with the proper operation of NVIS in two ways. Firstly, incompatible light may be reflected into the field of view of the NVIS, leading to obscuration of the outside environment by a false image. Secondly, incompatible light (either direct or reflected) can trigger the automatic gain control function of the NVIS, reducing image contrast.

7.11 Authority recognised civil Airworthiness Codes do not prescribe comprehensive NVIS airworthiness design requirements. While two published RTCA documents define functional and performance requirements for NVIS use and operations in civil aircraft, neither standard provides a comprehensive basis for establishing the compatibility of aircraft lighting with NVIS. Consequently, where NVIS is intended for use in Defence aircraft, the aircraft lighting must satisfy the NVIS compatibility requirements prescribed in the associated military standards. While the military standards only require ground test (or do not specify testing) to be conducted to demonstrate NVIS compatibility, FAA guidance includes a requirement for flight test to be conducted, particularly for helicopter NVIS operations. Designers should consider whether flight test is warranted to support verification of compliance with NVIS compatibility standards.

Superseded

7.12 Authority prescribed design requirements for NVIS equipment are presented in Section 5 Chapter 2, Aeronautical Life Support Equipment, of this manual.

ADDITIONAL LIGHTING SYSTEMS GUIDANCE

7.13 Further guidance on implementing the lighting systems design requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

ELECTRICAL SYSTEMS

INTRODUCTION

8.1 Aircraft electrical systems comprise those electrical components which generate, distribute, control and protect the supply of AC and/or DC electrical power for other systems, and provide signal and electrical interfaces between aircraft systems. Electrical systems that do not satisfy appropriate design requirements may pose hazards to safe aircraft operations by: providing inadequate or unsuitable power for essential aircraft system loads, increasing the likelihood of fire or explosion, increasing the potential for critical aircraft system failures and so on. To ensure that these hazards are not realised the Authority prescribes design requirements for aircraft electrical systems.

Scope

8.2 This Chapter presents the Authority prescribed airworthiness design requirements for Defence aircraft electrical systems and electrical wiring interconnection systems. Importantly, the airworthiness design requirements in this chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of this manual.

ELECTRICAL SYSTEMS DESIGN REQUIREMENTS

8.3 This section presents the Authority prescribed electrical systems airworthiness design requirements applicable to Defence aircraft.

8.4 **Design Requirement (Essential).** *The aircraft's battery capacity must be evaluated to confirm that there is sufficient capacity to supply all essential loads, and to support continued safe flight and landing for the intended Defence operations.*

8.5 While the Authority recognised Airworthiness Codes define battery capacity requirements (in terms of the time that the battery must supply essential loads) for emergency operations, the actual battery capacity required to support continued safe flight and landing will be dependent on the intended operations of the Defence aircraft. Given that Defence operations are likely to vary from those assumed within the original aircraft type certification, the battery capacity must be evaluated and confirmed to be adequate for all proposed Defence operations.

8.6 **Design Requirement (Essential).** *Rechargeable Lithium-ion batteries used as a primary power source in Defence aircraft must meet the requirements prescribed in FAA AC 20-184 Guidance on Testing and Installation of Rechargeable Lithium Battery and Battery Systems on Aircraft.*

8.7 **Design Requirement (Essential).** *Non-rechargeable Lithium-ion batteries used as a power source in Defence aircraft systems and equipment must meet the requirements prescribed in Annex A - Airworthiness Requirements for Equipment with Non-rechargeable Lithium Batteries.*

Superseded

8.8 Li-ion batteries may pose additional fire hazards not normally present when lead-acid or Ni-Cd batteries are used as main aircraft power sources. Most Authority recognised Airworthiness Codes do not prescribe design requirements tailored to ensure the safety of Li-ion batteries installed in Defence aircraft, and compliance with the requirements prescribed in FAA AC 20-184 for rechargeable Lithium-ion batteries, or Annex A for non-rechargeable Lithium-ion batteries as appropriate, is therefore required.

8.9 **Design Requirement (Essential).** *Electrical loads associated with aircraft design changes must be evaluated and confirmed to be safely accommodated within the aircraft's electrical power generation capacity.*

8.10 Aircraft electrical loads are subject to constant changes as electrical components are replaced with alternatives due to design changes, obsolescence and so on. Failure to appropriately manage the electrical load can lead to overloading the power generation and distribution system, which may pose an airworthiness risk particularly during operations in an emergency.

Electrical wiring interconnection systems

8.11 Some types of wire insulation may produce toxic fumes in the event of fire, or are known to exhibit properties that notably increase the likelihood of electrical arcing as they degrade over time. The Authority approved Airworthiness Codes may not comprehensively cover the use of these wiring types, or consider the sometimes harsher environments in which this wiring must function in military aircraft. Consequently, the Authority has prescribed additional wiring interconnection system design requirements to ensure that electrical wiring systems are adequately safe for Defence aircraft applications.

8.12 **Design Requirement (Essential).** *Wiring insulation containing PVC must not be used in Defence aircraft electrical wiring interconnection systems.*

8.13 Polyvinyl chloride (PVC) releases hydrogen chloride gas when burnt or subject to high temperatures, which transforms into hydrochloric acid on contact with moisture (causing sight and breathing impairment). Consequently, PVC wiring, particularly where it is hidden or inaccessible during flight, presents a hazard to safe aircraft operations and must not be used in any fixed aircraft wiring installations. PVC insulated wiring can often be introduced into Defence aircraft through carriage of Portable Electrical Devices (PED), or use of Commercial off the Shelf (COTS) role equipment. In these circumstances, the Authority prescribed design requirements for PEDs and COTS role equipment in Section 5 Chapter 6 apply.

8.14 **Design Requirement (Recommended).** *Polyimide wiring insulation should not be used in Defence aircraft electrical wiring interconnection systems.*

8.15 Polyimide (Kapton) wiring is susceptible to hydrolysis, characterised by breakdown and cracking of the insulation material, wet arc tracking and dry arc tracking. Typically the use of polyimide wiring insulation should be avoided, or restricted from areas that expose the wire to caustic fluids or gases, where repeated flexing of the wire is required or where repeated exposure to water is expected, especially in the presence of ultraviolet light. Where the use of polyimide wiring insulation is unavoidable, appropriate management procedures should be implemented.

Superseded

8.16 **Design Requirement (Essential).** *To ensure interconnection system integrity is maintained in-service, electrical wiring interconnection system ICA must be defined and promulgated as prescribed in FAR/CS 25 Appendix H.*

8.17 In the past, Defence has experienced severe degradation of interconnection systems due to inadequate maintenance and/or poor husbandry. To ensure that interconnection systems integrity is maintained throughout the aircraft's service life, electrical wiring interconnection system ICA must developed (as required) and include: mandatory replacement times for interconnection system components, enhanced zonal inspection requirements, tasks and intervals to reduce the likelihood of ignition sources, cleaning of interconnection system components, protection and caution information to prevent contamination of interconnection systems and so on.

8.18 **Design Requirement (Essential).** *Where polyimide wiring insulation is used in Defence aircraft interconnection systems, requirements to ensure that polyimide wiring integrity is maintained in-service must be defined and promulgated.*

8.19 Polyimide wiring insulation has historically been a challenge for Defence to manage, often due to the harsher environments in which Defence aircraft operate. This has resulted in degradation of the wiring insulation and loss of interconnection system integrity. The unique features of polyimide wiring insulation may demand different maintenance regimes to those promulgated in ICA for other wiring insulation. Therefore, the need for specific ICA for polyimide insulated wiring installed in Defence aircraft must be considered, and developed and promulgated where required.

8.20 **Design Requirement (Essential).** *In-service management requirements must be defined and promulgated, for any lead-free solder used in Defence aircraft electrical systems or electrical/ electronic equipment.*

8.21 The use of lead-free solder in aircraft applications has highlighted a number of potential hazards related to the solder's ability to maintain an effective electrical joint over time. Nevertheless, EU legislation has resulted in the adoption of lead free solder in many aircraft components, including wiring interconnection systems. Recent FAA research has highlighted the risks and challenges associated with management of lead-free solder, including reliability of solder joints, tin whisker susceptibility, maintenance/repair requirements, configuration control and obsolescence. Provided that lead free solder is appropriately managed, its use on Defence aircraft does not pose an airworthiness risk. Therefore, appropriate in-service management requirements must be defined and promulgated for any lead-free solder use on Defence aircraft.

ELECTRICAL SYSTEM CAPABILITY DESIGN REQUIREMENTS

8.22 Aircraft electrical power demands do not remain constant over the aircraft's service life. All aircraft are subject to design changes and these changes often result in increased power requirements. To avoid costly retrofit of increased power generation capacity, potential future power requirements should be considered during initial aircraft design or major changes to the electrical supply and interconnection system, and a determination made whether the power generation and distribution systems provide an acceptable level of growth capacity. DEF STAN 00-970 requires an additional power generation capacity of at least 50% greater than the maximum continuous demand, and 10% growth capacity for interconnection systems. While not an Authority prescribed design requirement, these additional generating capacity and interconnection system requirements represent a reasonable benchmark for Defence aircraft.

Superseded

8.23 **Capability Design Requirement.** *Additional power generation and distribution capacity should be considered during initial aircraft electrical power system design, or major changes to the electrical supply system, to accommodate future potential growth in power demand.*

8.24 **Capability Design Requirement.** *Additional interconnection system capacity should be considered during initial electrical wiring interconnection system design, or major changes to the interconnection system, to accommodate future potential growth.*

ADDITIONAL ELECTRICAL SYSTEM DESIGN GUIDANCE

8.25 Further guidance on implementing the aircraft electrical systems design requirements prescribed in this chapter can be provided by the chapter sponsor.

CHAPTER 1 - INTRODUCTION

1. Purpose

1.1. This Annex provides an acceptable means to show compliance to the airworthiness requirements for installed non-rechargeable Lithium cells, batteries and batteries within end items on aircraft as defined in RTCA, Inc., document RTCA DO-227A, Minimum Operational Performance Standards for Non-Rechargeable Lithium Batteries. This Annex provides guidance on how to obtain installation approval for installed non-rechargeable Lithium cells, batteries and batteries within end items on aircraft.

1.2. The guidance in this Annex is intended for battery manufacturers, installers, maintenance personnel, and users of installed non-rechargeable lithium cells, batteries and batteries within end items on aircraft. The term "must" within this Annex, refers to mandatory requirements necessary to show compliance.

1.3. For the purpose of this Annex, all installed non-rechargeable lithium cells, batteries and batteries within end items will be referred to as lithium batteries.

2. Scope

2.1. Chapter 2 of this Annex applies to the certification of installed lithium batteries on aircraft approved pursuant to Title 14 of the Code of Federal Regulations (14 CFR) parts 23, 25, 27, and 29 for:

1. 2.1.1. Type certificates (TC)

Superseded

1. 2.1.2. Amended type certificates (ATC)

1. 2.1.3. Supplemental type certificates (STC)

1. 2.1.4. Amended supplemental type certificates (ASTC)

1. 2.1.5. Parts manufacturer approvals (PMA).

2.2. Chapter 3 of this Annex provides guidance on maintenance and operational considerations for lithium batteries on aircraft.

3. Non-rechargeable Lithium cells, Batteries and Batteries within End Items Covered in this Annex

3.1. Lithium batteries are installed in various aircraft types and serve various purposes. Lithium batteries are of different sizes, chemistries, and produced under different manufacturing processes. They are also of different levels of complexity. Some of the benefits of lithium batteries include weight savings, high energy density per unit weight and per unit volume, relatively constant voltage during discharge, good low-temperature performance, and long shelf life. Because of their high energy content and potential thermal instability, lithium batteries can present hazards if improperly designed, tested, used, and/or stored. Some of the uses for lithium batteries on today's aircraft include, but are not limited to:

1. 3.1.1. Emergency Locater Transmitters

1. 3.1.2. Defibrillators

1. 3.1.3. Back up batteries for avionics equipment

1. 3.1.4. Special function batteries (such as flashlights, electronic equipment, life vests, safety equipment, avionics equipment, communications equipment, and emergency medical equipment).

1. 3.2. Lithium batteries have certain failure and operational characteristics, as well as maintenance requirements that differ significantly from those of aircraft nickel-cadmium and lead-acid non-rechargeable batteries. The introduction of lithium batteries into aircraft raises some concern about associated battery monitoring systems (such as temperature or state of charge) and should be evaluated and tested regarding the expected extremes in the aircraft operating environment. Lithium batteries typically have different electrical impedance characteristics than lead-acid or nickel-cadmium batteries. Other components of the aircraft electrical system should be evaluated regarding these characteristics as a system.
3.3. Lithium batteries have certain failure conditions due to impurities, manufacturing defects, foreign object deposit or abuse/misuse of the battery. These conditions have known to create conditions that may result in thermal runaway (per RTCA DO-227A, Minimum Operational Performance Standards for Non-Rechargeable Lithium Batteries). A thermal runaway results from the initiation of an irreversible exothermic chemical reaction within the cell causing an uncontrollable release of internal electrical and chemical energy resulting in a rapid and accelerating temperature rise to a peak, with an accompanying collapse of cell voltage, and the chemical decomposition of metallic Lithium.

4. Background

4.1. The proposed use of lithium batteries for equipment and systems on the aircraft has prompted the Federal Aviation Administration (FAA) to review the adequacy of its guidance.

Superseded

4.2. At present, there is limited in-service experience with the use of lithium battery technology in applications on aircraft. However, users of this technology from aircraft operators to personal computer users, wireless manufacturers, and the electric vehicle industry have noted safety problems with lithium batteries. These conditions may result from imbalance, reverse charge over-discharging, flammability of cell components and internal cell defects. In general, lithium batteries are significantly more susceptible to internal failures that can result in self-sustaining increases in temperature and pressure (thermal runaway) than nickel-cadmium or lead-acid batteries. Results of the above mentioned failures could lead to a potentially dangerous smoke, fire and/or fume event.

4.2.1. Fast or Imbalanced discharging. Fast discharging or an imbalanced discharge of one cell of a multi-cell battery may create an overheating condition that could result in an uncontrollable venting condition, leading to a potential thermal event or an explosion.

4.2.2. Flammability. Unlike nickel-cadmium and lead-acid batteries, lithium batteries use higher energy and current in an electrochemical system to maximize energy storage of lithium. Some lithium battery manufacturers use liquid electrolytes and/or cathodes which is extremely flammable and/or explosive. The electrolyte and cathode, as well as the electrodes, can serve as a source of fuel for an external fire if the battery casing is breached.

4.2.3. Internal Failures. In general, these batteries are significantly more susceptible to internal failures that can result in self-sustaining increases in temperature and pressure (i.e., thermal runaway) than their nickel-cadmium or lead-acid counterparts. The metallic lithium can ignite, resulting in a self-sustaining fire or explosion.

CHAPTER 2 - INSTALLATION OF LITHIUM BATTERIES ON AIRCRAFT

1. **Certification Process.** This chapter provides certification guidance for the installation of lithium batteries on aircraft.

2. Acceptable Means of Compliance (MOC) for Installation Approval

2.1. **Certification Plan.** Prepare a certification plan that provides a method of compliance to the airworthiness regulations, including special conditions (if any) for the installation of the lithium batteries on the aircraft. We recommend submitting the certification plan early in the process. Include the following items at a minimum:

1. 2.1.1. Project description and schedule

1. 2.1.2. System description, including a description of the aircraft system interfaces and any aircraft system modifications made to accommodate the aircraft battery system installation

1. 2.1.3. System safety assessment

1. 2.1.4. Certification basis and MOC, including itemized MOC to all applicable requirements or special conditions

1. 2.1.5. Communication and coordination of the test plan(s)

1. 2.1.6. Conformity plan

1. 2.1.7. Instructions for continued airworthiness

1. 2.1.8. Compliance and substantiation documentation.

Superseded

2.2. **Compliance Checklist.** Lithium battery installations must meet all applicable airworthiness regulations applicable to the product and all applicable special condition imposed. The installations should also meet the guidance in this chapter and the applicable airworthiness regulations. Table 2 provides a guide to airworthiness regulations that may be applicable.

Note: For 14 CFR part 23, Table 2 lists applicable regulations with Amendment 23-64. Circa 2021, the Authority does not recognise FAR 23 Amendment 23-64. Consequently, for Defence aircraft having a FAR 23 primary certification code, amendment levels should use equivalent subpart regulations at the applicable amendment level respectively.

Table 2. Airworthiness Regulations Concerning Lithium Battery Installations

21.50(b)	Instructions for Continued Airworthiness and Maintenance Manuals
25/27/29.301	Loads
23.2210	Structural design loads
25/27/29.303	Factor of safety

27.1367	Switches
23.2600	Flightcrew interface
23.2610	Instrument markings, control markings, and placards
27/29.1559	Limitations placard

1.

1. 2.2.1. Additional requirements (beyond those listed in Table 2) and method of compliance pertaining to lithium batteries are the following:

i. 2.2.1.1. ***For Part 23 Certificated Aircraft:*** See installation guidance in Appendix F of this Annex that addresses installing non-rechargeable lithium battery in part 23 airplanes.

ii. 2.2.1.2. ***For Part 25 Certificated Aircraft:*** Non-rechargeable lithium batteries are considered to be novel and unique for the purposes of aircraft design and certification. As such, special conditions (SCs) for non-rechargeable lithium battery installations are required on transport category airplanes. Appendix C of this Annex provides typical non-rechargeable lithium battery SCs.

Superseded

Applicants, who elect to follow the SCs in Appendix C of this Annex for non-rechargeable lithium battery installations, should raise a suitable MCRI detailing these SCs. An acceptable method of compliance (MOC) with the non-rechargeable lithium battery SCs in Appendix C of this Annex and related Part 25 requirements is provided in Appendix D of this Annex. Appendix D of this Annex also provides guidance related to the applicability statements in previously issued non-rechargeable lithium battery SCs.

iii. 2.2.1.3. ***For Parts 27 and 29 Certificated Rotorcraft:*** For rotorcraft, see Appendix E of this Annex for safety objective requirements and means of compliance.

iv. 2.2.1.4. For Button and/or Coin cell batteries (less than 2Wh): The use of Underwriters Laboratories (UL) 1642 Standard is an acceptable MOC for showing that Safety Objectives 1 through 6 are met for 2 watt-hours of energy button/coin sized non-rechargeable lithium batteries . Meeting the minimum performance standard for TSO C142b-7 is an acceptable means of showing compliance for cells or batteries less than 5 Wh.

v. 2.2.1.5. ***For all aircraft in general:*** Interconnection of lithium battery cells in battery packs introduces failure modes that require unique design considerations, such as provisions for thermal management. Based on laboratory testing and events, both independent of aviation and within actual aviation applications, including the events of 2013, the FAA now more fully recognizes potential hazards and failure modes associated with non-rechargeable lithium batteries including:

– 2.2.1.5.1. *Internal failures:* In general, lithium batteries are significantly more susceptible to internal failures that can result in self-sustaining increases in temperature and pressure (i.e., thermal runaway) than their nickel-cadmium or lead-acid counterparts. These failures can result in toxic, flammable, or corrosive fluid leakage, gas venting, fire and explosion.

– 2.2.1.5.2. *Fast or imbalanced discharging:* Fast discharging or an imbalanced discharge of one cell of a multi-cell battery may create a thermal runaway that could result in an uncontrollable venting of corrosive flammable gases, fluid leakage, fire and explosion.

– 2.2.1.5.3. *Flammability:* Lithium batteries contain more energy and deliver higher currents than nickel cadmium and lead acid batteries of similar size, and may use liquid electrolytes that can be extremely flammable. The electrolyte, as well as the electrodes, can be fuel for an external fire if the battery casing is breached.

1. 2.2.2. Some known potential hazards and failure modes associated with non-rechargeable lithium batteries are:

i. 2.2.2.1. *Internal failures:* In general, these batteries are significantly more susceptible to internal failures that can result in self-sustaining increases in temperature and pressure (i.e. thermal runaway) than their nickel-cadmium or lead-acid counterparts. The metallic lithium can ignite, resulting in a self-sustaining fire or explosion.

Superseded

ii. 2.2.2.2. *Fast or imbalanced discharging:* Fast discharging or an imbalanced discharge of one cell of a multi-cell battery may create an overheating condition that results in an uncontrollable venting condition, which in turn leads to a thermal event or an explosion.

iii. 2.2.2.3. *Flammability:* Unlike nickel-cadmium and lead-acid batteries, lithium batteries use higher energy and current in an electrochemical system that can be configured to maximize energy storage of lithium. They also use liquid electrolytes that can be extremely flammable. The electrolyte, as well as the electrodes, can serve as a source of fuel for an external fire if the battery casing is breached.

3. Test Requirements

3.1. **Environmental Test Requirements.** Lithium battery systems on aircraft must meet environmental qualification standards in:

1. 3.1.1. RTCA/DO-160G, Environmental Conditions and Test Procedures for Airborne Equipment, dated December 8, 2010, or the most recent revision

1. 3.1.2. RTCA DO-227A, Minimum Operational Performance Standards for Non-Rechargeable Lithium Batteries, dated September 21, 2017

1. 3.1.3. These environmental tests are representative of the conditions that the battery system may encounter during its life cycle. Consider the following areas when determining the scope and type of environmental tests:

i. 3.1.3.1. Equipment configuration

ii. 3.1.3.2. Installation specific environment encountered on in-service platforms

iii. 3.1.3.3. Duration of exposure periods

iv. 3.1.3.4. Geographical locations

v. 3.1.3.5. Frequency of environmental occurrences alone or in combination with other approved systems.

4. Means of Compliance Testing and Validation

4.1. **Ground and Flight Test Requirements for Installed Lithium Batteries**

1. 4.1.1. When ground and/or flight tests are required per the compliance checklist for the project, the tests should be performed to demonstrate the lithium battery systems and the systems in which they are installed will perform their intended functions.

1. 4.1.2. When ground and/or flight tests are required per the compliance checklist for the project, they should be performed to demonstrate the lithium battery systems and the systems in which they are installed will not have any adverse effect on the aircraft.

1. 4.1.3. When an EMI/RFI test is required per the compliance checklist of the project. The electromagnetic compatibility test should be performed to determine the installation of the lithium battery does not have any adverse effect on aircraft systems and that the aircraft systems do not have any adverse effect on the lithium battery. Demonstrate the battery system functions during all intended aircraft operation.

5. System Safety Assessment

Superseded

5.1. Perform a system safety assessment to show compliance with 25/27/29.1309, 23.2510 and all applicable special conditions/requirements. This assessment should address concerns associated with the installation of the lithium batteries, the possibility of direct (or indirect) injury to a person, any adverse effect on crew function, or any adverse effect on other aircraft equipment and systems. These adverse effects could be a result of normal operation or a failure in the lithium batteries. Your system safety assessment should consider, but not be limited to, the following:

1. 5.1.1. The level of hazards associated with installation and use of lithium batteries

1. 5.1.2. Whether the lithium batteries installation design assurance level is appropriate for performance and safety requirements based on location and intended function

1. 5.1.3. No interference due to any failures of the lithium batteries

1. 5.1.4. System separation and zonal analysis

1. 5.1.5. Impact on flight crew and egress procedures

1. 5.1.6. Protection against fire, smoke, and electrical shock hazards

1. 5.1.7. Other safety analysis appropriate to the system being installed

1. 5.1.8. Statement of compliance for each requirement.

5.2. The safety assessment of the lithium battery installation should address the battery system, the aircraft interface, and the aircraft functional loads to which the battery system provides power.

6. **Software.** All lithium batteries that use software should comply with RTCA/DO-178C, Software Considerations in Airborne Systems and Equipment Certification, or equivalent, for the appropriate design assurance level. You can find additional guidance in the following FAA ACs:

6.1. AC 25.1309-1A, System Design and Analysis

6.2. AC 29-2C, Certification of Transport Category Rotorcraft

6.3. AC 27-1B, Certification of Normal Category Rotorcraft

6.4. AC 23.1309-1E, System Safety Analysis and Assessment for Part 23 Airplanes

6.5. AC 20-115D, Airborne Software Development Assurance Using EUROCAE ED-12( ) and RTCA DO-178( ).

7. **Complex Electronic Hardware.** All lithium batteries hardware that contains complex electronic hardware should comply with the most recent revision, of AC 20-152, RTCA, Inc., Document RTCA/ DO-254, Design Assurance Guidance for Airborne Electronic Hardware, dated June 30, 2005.

8. **State of Charge.** Lithium batteries that are not maintained at a high enough state of charge degrade at a significantly higher rate.

9. Flammability

Superseded

9.1. Unlike nickel-cadmium and lead-acid cells, some types of lithium cells use electrolytes in a liquid state known to be flammable. This material can serve as a source of fuel for an external fire if a cell failure occurs. Lithium batteries have the potential to ignite spontaneously or experience an uncontrolled temperature and pressure increase, resulting in propagation to adjacent cells.

9.2. Pursuant to 23.2325, 23.2330, 25/27/29.853, 25/27/29.863, and 25.869, aircraft battery equipment must meet the flammability requirements of that ensure the protection of structure and critical systems. Test the materials to ensure they meet applicable certification requirements.

9.3. Pursuant to Part 25, Appendix F, the FAA Aircraft Materials Fire Test Handbook, DOT/FAA/AR-00/12 Chapters 1 through 10 and Chapter 15, describes an acceptable method of compliance for material Test Criteria and Procedures. Pursuant to 25.856(a), Appendix F, Part VI, Amendment 25-111, provides the criteria for using exposed thermal and acoustic insulation material as part of the battery equipment. Refer to the test methods described by AC 25.856-1, Thermal/Acoustic Insulation Flame Propagation Test Method Details.

10. Instructions for Continued Airworthiness (ICA)

10.1. During the certification process of the lithium batteries, complete the ICA in accordance with the following:

1. 10.1.1. Section 21.50(b)

1. 10.1.2. Sections 23/25/27/29.1529

1. 10.1.3. Sections 25.1709 and 25.1729

1. 10.1.4. Part 23, appendix A, Part 27/29 appendix A, part 25 appendix H

1. 10.1.5. FAA Order 8110.54, Instructions for Continued Airworthiness, Responsibilities, Requirements, and Contents.

10.2. Develop the ICA so it is compatible with other maintenance instructions for the aircraft.

10.3. Refer to Chapter 3 of this Annex for additional details specific to the maintenance of lithium batteries on aircraft.

10.4. The ICA should also include, but not limited to, the following information:

1. 10.4.1. Specifics of the lithium battery installation, including individual component part numbers and any other unique installation requirements

1. 10.4.2. Electrical wiring diagrams/schematics, electrical equipment drawings

1. 10.4.3. Configuration control, storage instructions.

10.5. The ICA must contain the recommended battery manufacturer’s maintenance and inspection requirements to ensure the batteries whose function is required for safe operation of the aircraft will function when installed in the aircraft. The ICA must contain:

1. 10.5.1. Operating instructions and equipment limitations in an installation maintenance manual.

1. 10.5.2. Installation procedures and limitations sufficient to ensure cells or batteries, when installed according to the installation procedures, still meet the airworthiness

Superseded

requirements of the aircraft. The limitations must identify any unique aspects of the installation.

1. 10.5.3. Maintenance requirements for measurements of battery capacity at appropriate intervals to ensure the batteries whose function is required for safe operation of the aircraft will perform their intended function when installed in the aircraft.

1. 10.5.4. Scheduled servicing information to replace batteries at the battery manufacturer's recommended replacement time.

1. 10.5.5. Maintenance and inspection requirements to visually check for battery and/or charger degradation.

1. 10.5.6. Maintenance instructions, basic control and operation, testing, servicing, maintenance schedule, inspection, troubleshooting, removing and replacing parts, repairs, special tools, fixtures and equipment, component manual.

10.6. The ICA should also contain maintenance procedures for lithium batteries in spares storage to prevent the replacement of batteries with batteries that have experienced degraded charge retention ability or other damage due to prolonged storage.

10.7. The ICA must contain instructions to replace batteries based on the battery manufacturer maintenance manual. Replacement of individual cells within a lithium battery must be approved by the battery manufacturer and the DASA. Do not mix cells from different manufactures within a lithium battery, unless an alternate means proposed by the OEM and approved by the DASA exists.

CHAPTER 3 - MAINTENANCE AND OPERATIONAL CONSIDERATIONS FOR LITHIUM BATTERIES

1. **Introduction.** Lithium batteries can be hazardous if not maintained and handled properly. This chapter provides guidance for maintenance considerations for aircraft lithium batteries.

2. **Aircraft Battery Maintenance.** Follow each battery manufacturer's maintenance and inspection requirements for their specific aircraft lithium battery. In-service performance of lithium batteries for a given installation will depend on several factors that include but are not limited to the following:

2.1. ***Lithium Battery Chemistry.*** The electrolyte used in lithium batteries can be a highly reactive substance, and care must be observed in maintaining the lithium batteries in accordance with the OEM maintenance manual.

2.2. ***Age.*** To determine the life and age of the lithium battery, record the installation date of the battery. During normal battery maintenance, document battery age in either the aircraft maintenance log or the shop maintenance log. Do not keep batteries in service longer than recommended by the battery manufacturer.

2.3. ***State of Charge.*** State of charge of the lithium battery is determined by the cumulative effect of discharging the battery. Therefore, safeguards must be implemented to ensure the aircraft does not begin flight with a battery not sufficiently charged to accomplish its intended function.

2.4. State of Health. Determine the state of health of the lithium battery by recording the following:

1. 2.4.1. Length of time the battery has been in service.

Superseded

1. 2.4.2. The State of Charge of the battery. The output of this function may be used for dispatch or maintenance purposes.

1. 2.4.3. Any activation of temporary safety devices such as resettable fuses or positive temperature coefficient (PTC), if present in the design.

2.5. **Mechanical Integrity.** To ensure proper mechanical integrity, the battery must be installed and connected correctly and be free of any physical damage. The build-up of explosive gases can be avoided by incorporating positive battery and battery compartment venting systems. Check periodically to ensure the venting system is securely connected and oriented in accordance with the maintenance manual's installation procedures. Follow the procedures approved for the specific aircraft and battery system to ensure the battery system is capable of delivering specified performance. The venting system should take into account specific installation requirements of the aircraft.

2.6. **Shop-Level Maintenance Procedures.** Shop procedures must follow the battery manufacturer's recommendations.

2.7. **Aircraft Battery Inspection.** Evidence of battery failure can sometimes be detected by a general visual inspection. Battery manufacturer-recommended inspections should include, but not be limited to, the following actions:

1. 2.7.1. Inspect battery terminals and all other connections for evidence of corrosion, pitting, arcing, and burns. Clean as required.

1. 2.7.2. Inspect the battery for improper installation (loose terminal screws, battery terminal links, or connector).

1. 2.7.3. Inspect the battery mounting.

1. 2.7.4. Inspect for evidence of physical damage.

2.8. Prior to installation on aircraft batteries in a rotable stock (which are parts and components that are easily exchanged between product) must be functionally checked at the battery manufacturer's recommended inspection intervals. Some failure modes may include degraded charge retention capability, settling of particulates, or other damage due to prolonged storage.

3. Aircraft Battery Replacement

3.1. Make sure replacement batteries are in airworthy condition. Refer to the battery manufacturer maintenance manuals for proper maintenance of lithium batteries. Refer to the aircraft maintenance procedures for replacement of lithium batteries.

3.2. The ICA should include the battery manufacturer's requirements for the battery mandatory replacement schedule and periodic maintenance.

3.3. Installation of lithium batteries differs from aircraft system to aircraft system. Refer to the applicable aircraft manuals to remove and install batteries.

3.4. When replacing batteries, check for corrosion and moisture on the battery interfaces.

3.5. The maintenance record should reflect all battery replacements. Record the expiration date of the battery.

Superseded

3.6. The lithium batteries should be replaced with an approved battery for the specific aircraft application.

3.7. Deep discharge may result in potential unsafe condition. Replace the battery based on the battery manufacturer's recommendation.

4. Aircraft Battery Storage and Handling

4.1. Follow the battery manufacturer's recommended storage procedures that will permit users to achieve the best results from their batteries.

4.2. Storage requirements vary with the battery type. Record the date of 100% state of charge and, if the battery is not used within the battery manufacturer's recommended interval, service the battery per the battery manufacturer's recommendation.

4.3. Handling procedures and precautions vary with battery size and configuration. Follow the battery manufacturer's recommendation to prevent mishandling of the battery.

4.4. Follow the battery manufacturer's recommendation procedure to prevent electrostatic discharge during storage and handling.

4.5. For packaging and shipping, follow the battery manufacturer's recommended procedures.

4.6. Check batteries before use for any leakage or deformity. Do not use the batteries if there is any evidence of leakage or deformity.

4.7. Aircraft vibration and/or contact oxidation can result in poor electrical connections. Ensure proper connector maintenance procedures are followed.

4.8. Observe the following precautions when handling lithium batteries:

1. 4.8.1. Do not store lithium batteries with other hazardous or combustible materials.

1. 4.8.2. Do not heat or incinerate lithium batteries.

1. 4.8.3. Do not dispose of lithium batteries with other waste unless allowed by applicable regulations.

1. 4.8.4. Use special care in handling lithium batteries. Do not open, puncture, crush, disassemble, or subject batteries to physical abuse.

4.9. Lithium batteries can be a personal safety hazard due to the possibility of lethal shock and must be labelled to clearly indicate the hazard.

4.10. Follow all battery manufacturer's recommended safety precautions and procedures.

4.11. Material Safety Data Sheets must be enclosed with lithium batteries for shipping.

4.12. Wear protective clothing before handling and disposing of lithium batteries.

TERMS AND DEFINITIONS

For purposes of this Annex, the following definitions apply:

Battery Cell. In a battery, a cell is a single energy or charge-storing unit within a pack of cells that form the battery. Each cell has a voltage rating that is combined with the other cells' voltages to form the overall battery voltage rating.

Battery. One or more electrically connected cells, assembled in a single container having positive and negative terminals. A battery may include inter-cell connectors and protective and other devices.

Battery System. One or more electrically connected batteries that provide power to equipment. A battery system may include a charger, controlling circuitry and means for monitoring of battery temperature, battery state, and current as well as system testing and related functions.

Charged Battery. A battery that has been fully charged in accordance with the battery battery manufacturer's instructions or as defined in the design documentation.

Serviced Battery. A battery fully prepared and maintained in accordance with the battery manufacturer's instructions or as defined in the design documentation.

Service Life. The maximum combined storage and installed life of an undischarged cell or battery. Service life cannot be greater than shelf life and will be stated by the equipment manufacturer. The end of service life is indicated by a "replace-by" or expiration date. Service life is equivalent to useful life.

Shelf Life. The maximum period at which an undischarged cell or battery stored under standard conditions retains 80 percent of rated ampere-hour capacity. The cell/battery manufacturer specifies shelf life.

System. A combination of components, parts, and elements, which are interconnected to perform one or more functions.

Superseded

PREVIOUSLY ISSUED NON-RECHARGEABLE LITHIUM BATTERY SPECIAL CONDITIONS FOR TRANSPORT AIRPLANES

For the purpose of this appendix, both a battery and battery system is referred to as a battery. A battery system consists of the battery and any protective, monitoring, and alerting circuitry or hardware inside or outside of the battery. It also includes vents (where necessary) and packaging. The Federal Aviation Administration (FAA) has issued several special conditions (SCs) for non-rechargeable lithium battery installations on transport category airplanes (and these SCs have been adopted by the DASA). These SCs are located in this appendix. Applicants, who propose using these SCs for their project, must submit a MCRI indicating their intentions to the DASA.

Definition of Key Terms

In this policy, the terms “must,” “should,” and “recommend” have specific meanings:

(a) The term “must” refers to a regulatory requirement that is mandatory for design approval. The functional impact of the term “must” is that the requirement has to be met to achieve design approval.

(b) The term “should” refers to instructions for a particular acceptable method of compliance (MOC). The functional impact of the term “should” is that all proposed alternative MOC are evaluated through the issue paper process.

(c) The term “recommendation” refers to a recommended practice that is optional. There is no functional impact of the term “recommend” because it is optional.

(d) “End Item” is used in this appendix and is defined in RTCA/DO-227A, Minimum Operational Performance Standards (MOPS) for Non-Rechargeable Lithium Batteries, appendix D.

Background

Recent events involving rechargeable and non-rechargeable lithium batteries prompted a broad evaluation of these energy storage technologies. In January 2013, two independent events involving rechargeable lithium-ion batteries revealed unanticipated failure effects. On July 12, 2013, an event involving a non-rechargeable lithium battery in an emergency locator transmitter installation demonstrated additional unanticipated failure effects. The FAA has been issuing SCs for certification projects involving the installations of non-rechargeable lithium batteries. At this time, all of the published SCs have been the same. These SCs are listed below.

In lieu of title 14, Code of Federal Regulations (14 CFR) 25.1353(b) (1) through (4) at amendment 25-123 or 25.1353(c) (1) through (4) at earlier amendments, each non-rechargeable lithium battery installation must:

(a) Be designed to maintain safe cell temperatures and pressures under all foreseeable operating conditions to prevent fire and explosion.

(b) Be designed to prevent the occurrence of self-sustaining, uncontrollable increases in temperature or pressure.

(c) Not emit explosive or toxic gases, either in normal operation or as a result of its failure, that may accumulate in hazardous quantities within the airplane.

(d) Meet the requirements of 25.863.

Superseded

(e) Not damage surrounding structure or adjacent systems, equipment, or electrical wiring from corrosive fluids or gases that may escape in such a way as to cause a major or more severe failure condition.

(f) Have provisions to prevent any hazardous effect on airplane structure or systems caused by the maximum amount of heat it can generate due to any failure of it or its individual cells.

(g) Have a failure sensing and warning system to alert the flightcrew if its failure affects safe operation of the airplane.

(h) Have a means for the flightcrew or maintenance personnel to determine the battery charge state if the battery's function is required for safe operation of the airplane.

Note: A battery system consists of the battery and any protective, monitoring, and alerting circuitry or hardware inside or outside of the battery. It also includes vents (where necessary) and packaging. For the purpose of these special conditions, a "battery" and "battery system" are referred to as a battery.

Superseded

GUIDANCE FOR INSTALLING NON-RECHARGEABLE LITHIUM BATTERIES ON TRANSPORT AIRPLANES

For the purpose of this appendix, both a battery and battery system is referred to as a battery. A battery system consists of the battery and any protective, monitoring, and alerting circuitry or hardware inside or outside of the battery. It also includes vents (where necessary) and packaging. The Federal Aviation Administration (FAA) has issued several special conditions (SCs) for non-rechargeable lithium battery installations on transport category airplanes (and these SCs have been adopted by the DASA). These SCs are provided in Appendix C of this Annex.

This appendix provides an acceptable method of compliance with the non-rechargeable lithium battery SCs in Appendix C of this Annex and related 14 CFR part 25 requirements. It also provides guidance related to the applicability statements in previously issued non-rechargeable lithium battery SCs.

D.1 Methods of Compliance with SCs

RTCA/DO-227A, Minimum Operational Performance Standards (MOPS) for Non-Rechargeable Lithium Batteries, sections 1 Purpose and Scope and 2 Equipment Performance Requirements and Test Procedures, provide design requirements and guidelines that are pertinent to designing safe batteries and to meeting part 25 installation requirements and these SCs. Consider each of these requirements and guidelines when designing cells and batteries.
Special Conditions 1 and 2 below are intended to ensure that the cells and battery are designed to eliminate the potential for uncontrollable failures. However, a certain number of failures will still occur due to various factors many of which are beyond the control of the designer. Therefore, these SCs as a whole are intended to protect the airplane and its occupants even when a failure occurs. These SCs are independent of each other. Demonstrating compliance with one of these SCs does not constitute compliance with the other SCs. The methods of compliance are as follows:

D.1.1 Method of Compliance (MOC) for SC 1. Show that the individual cells meet the requirements in RTCA/DO-227A, section 2.2.1 Cell Functional and Safety Requirements. Use the test procedures in RTCA/DO-227A, section 2.4.1 Cell Test Procedures and Criteria and show that the associated evaluation criteria are met.

D.1.2 Method of Compliance for SC 2. Whereas, SC 1 requires that each individual cell within a non-rechargeable lithium battery be designed to maintain safe temperatures and pressures, SC 2 addresses these same issues but for the entire battery. Special Condition 2 requires that the battery be designed to prevent propagation of a thermal event, such as self-sustained, uncontrollable increases in temperature or pressure from one cell to adjacent cells. Show that the battery installation meets the requirements in RTCA/DO-227A, sections 2.2.2 Battery Functional and Safety Requirements and 2.2.3 End Item Functional and Safety Requirements. Use the test procedures in RTCA/DO-227A, sections 2.4.2 Battery Test Procedures and Criteria and 2.4.3 End Item Test Procedures and Criteria and show that the associated evaluation criteria are met. RTCA/DO-227A, section 2.2.2 states, “If a single-cell battery is identical to the cell being tested for qualification, then the battery tests in this section shall be conducted unless they are identical to the cell tests.” In these cases, where the battery tests are identical to the cell tests, show that the cell tests are met in lieu of the battery tests to support demonstrating compliance with SC 2.

D.1.3 Method of Compliance for SC 3 – 6. Use the worst case test data from the MOCs for SCs 1 and 2 to support demonstrating compliance with SCs 3 - 6. The DASA considers that the RTCA/DO-227A,

Superseded

section 2.4.3.2.2 End Item Thermal Runaway Containment Test usually provides these worst case data.

D.1.4 Method of Compliance for SC 3. RTCA/DO-227A, appendix A, section A.5 Battery Emission Hazard discusses potential gas emissions from batteries and their effects. An acceptable MOC with SC 3 includes using the tests required under SCs 1 and 2 to demonstrate that all emitted gases are contained or vented overboard (i.e., vented outside the airplane) through designed ports. Section D.2.1 System Safety Assessment of this policy statement provides guidance for conducting a system safety assessment for a design that vents these gases overboard. Special Condition 3 does allow explosive and toxic gases to be uncontained and not vented overboard, provided they do not accumulate in hazardous quantities within the airplane. Consider the gases emitted from not only the cells but also the battery materials (e.g., insulation separators) when demonstrating compliance by this means.

D.1.5 Method of Compliance for SC 4. The amendment level of 25.863 is determined by 14 CFR 21.17 or 21.101, as appropriate. The amendment level is not determined by the issuance or effective date of the special conditions. The Aviation Rulemaking Advisory Committee (ARAC) draft Advisory Circular (AC) 25.863-1, Flammable Fluid Fire Protection (Aviation Rulemaking Advisory Committee (ARAC) draft Advisory Circular (AC) 25.863-1 http://www.faa.gov/regulations_policies/rulemaking/committees/documents/media/TAEpihT5-9231998.pdf4) gives acceptable guidance on 25.863. Section 25.863 is a "fail-safe" regulation that requires means to minimize the likelihood of a fire and the resultant hazards if fire does occur. When applying 25.863 to a battery installation, as explicitly required by SC 4, conduct a hazard assessment assuming that a battery failure ignites any resultant flammable fluids or gases, and provide provisions to address the associated hazards. This may result in the need to provide a battery enclosure that vents overboard. 25.1309(c) in accordance with FAA Policy Statement PS-ANM-100-00-113-1034, dated January 4, 2001.

D.1.6 Method of Compliance for SC 5. Show that when fluid escapes the battery, it is not corrosive or it is managed in a way (e.g., contained, isolated, or vented overboard) to protect the surrounding structure and adjacent systems, equipment and electrical wiring.

D.1.7 Method of Compliance for SC 6. Show that the effects of the heat, and any related effects, from the tests performed under SCs 1 and 2 do not constitute a hazard to the structure or systems of the airplane. If the effects of the heat or any related effects constitute a hazard to the structure or systems of the airplane, design mitigation at the airplane level may be applied to bring the design into compliance with this SC.

D.1.8 Method of Compliance for SC 7. Pursuant to 25.1309(c), SC 7 requires flightcrew alerting when the failure of a battery installation, in itself or in relation to a system that performs an airplane-level function, could result in "unsafe system operating conditions" as stated in 25.1309(c). The alert must meet the applicable paragraphs of 25.1322. The applicant should refer to the current AC 25.1309-1A System Design and Analysis for guidance. The ARAC recommended draft AC 25.1309-Arsenal, System Design and Analysis, dated June 10, 2002, also provides guidance that may be applied to a project if the applicant receives an equivalent level of safety finding to 25.1301 and 25.1309(c) in accordance with FAA Policy Statement PS-ANM-100-00-113-1034, dated January 4, 2001.

D.1.9 Method of Compliance for SC 8. The following are examples of "means" by which the flightcrew or maintenance personnel to determine the battery charge state:

(a) A manually activated system (e.g., push button) that displays the available charge of each battery unit.

(b) An automatic system that records the available charge of each battery unit on an appropriate interval and makes it available to maintenance personnel before the next flight.

(c) Physical access that allows a maintenance person to measure the battery charge state.

Superseded

The above “means” are acceptable only when the Instructions for Continued Airworthiness (ICA) include a requirement for a person to check the battery charge state within an interval that will ensure sufficient charge for the entire flight and to replace the battery when the charge is not sufficient.

D.1.10 Method of Compliance for Very Small, Button/Coin Non-Rechargeable Lithium Batteries. An acceptable MOC with SCs 1 through 6 for button/coin non-rechargeable lithium battery installations that have less than 2 watt-hours of energy is showing these batteries meet Underwriters Laboratories (UL) 1642.

D.2 Part 25 Compliance

Non-rechargeable lithium battery installations must comply with these SCs and all applicable part 25 and part 26 requirements. The following provides methods of compliance and other information for pertinent part 25 requirements:

D.2.1 System Safety Assessment. Pursuant to 25.1301, 25.1309 and 25.1709, and these SCs requirements for specific functionalities and capabilities, address certain critical failure modes of non-rechargeable lithium batteries and their installations, the applicant must also meet the requirements of 25.1301, 25.1309 and 25.1709, when applicable, in addition to these SCs. To date, in-service experience has shown that non-rechargeable lithium battery thermal/pressure runaway conditions are not extremely improbable. Assume such failures could occur sometime during the life of the battery installation when demonstrating compliance with 25.1309 except for button/coin batteries that have less than 2 watt-hours of energy and meet UL 1642. For button/coin batteries that have less than 2 watt-hours of energy and meet UL 1642, use the data from UL 1642 to support demonstrating compliance with 25.1309. For other non-rechargeable lithium batteries, use the worst case test data from section D.1.1 Method of Compliance for SC 1 and section D.1.2 Method of Compliance for SC 2 to support demonstrating compliance with 25.1309. As part of showing compliance with 25.1309, the applicant is to demonstrate that particular risks, as identified in SAE ARP 4761, Guidelines and Methods for Conducting Safety Assessment Process on Civil Airborne Systems and Equipment, such as an uncontained rotor burst, tire debris, fire, lightning or bird strike, will not compromise continued safe flight and landing. The applicant is to consider the effects of particular risks both internal and external to non-rechargeable lithium battery installations. For example, the applicant is to consider the effects of particular risks on any containment and venting provisions for a non-rechargeable lithium battery.

Application of 25.1309(b) and (c) may result in required periodic maintenance actions or flightcrew alerting features. For example, an over-temperature warning system may be necessary to allow the flightcrew to manage potentially unsafe system operating conditions. Provide rationale for alerting requirements (or for why an alert is not needed) in the system safety assessment of the battery installations to demonstrate compliance with 25.1309(c). Such alerts, when provided, must meet 25.1322. Refer to AC 25.1309-1A, AC 25.1322-1 Flight Crew Alerting, AC 25.1581-1 Airplane Flight Manual, and AC 25.1701-1 Certification of Electrical Wiring Interconnection Systems on Transport Category Airplanes for further guidance.

Venting toxic and explosive gases from a non-rechargeable lithium battery failure through designed ports that lead outside of the airplane is a MOC with SC 3 as discussed in section D.1.4 Method of Compliance for SC 3. Pursuant to 25.1309, consider the hazards of exposure of these gases to ground personnel, air conditioning in-take and engine in-takes.

D.2.2 Section 25.1353 Electrical Equipment and Installations. Pursuant to 25.1353(b) and (c), each SC states that it applies to all non-rechargeable lithium battery installations in lieu of 25.1353(b)(1) through (4) at amendment 25-123 or 25.1353(c)(1) through (4) at earlier amendments. This

Superseded

statement does not relieve an applicant from demonstrating compliance to the other paragraphs of 25.1353.

D.2.3 Section 25.1529 Instruction for Continued Airworthiness (ICA). Pursuant to 25.1529, include in the ICA the following to show compliance with the regulation:

(a) Maintenance requirements to replace each non-rechargeable lithium battery within an interval that will ensure there is sufficient charge to power equipment.

(b) A requirement to only replace non-rechargeable lithium batteries with batteries from the same manufacturer with the same part number or to obtain a new approval for installing a different battery. Refer to the battery original equipment manufacturer maintenance manual.

(c) Procedures to ensure that each non-rechargeable lithium battery has not:

1. Experienced degraded charge retention ability or other damage during storage.

2. Been damaged from environmental or physical impacts such as mechanical shock, vibration, heat and possible abuses encountered during storage, transportation prior to their installation or maintenance activities on or around them.

(d) Precautions to prevent mishandling of replacement non-rechargeable lithium batteries prior to their installation which could result in short-circuit or other unintentional damage.

Acceptable procedures for item 3.b. above may include a quality control process for packaging, storing, maintaining and transporting non-rechargeable lithium batteries, including reporting of dropped or damaged batteries.

D.2.4 Section 25.1729 Electrical Wiring Interconnection Systems (EWISs) ICA. Pursuant to 25.1729, Electrical Wiring Interconnection Systems (EWISs) maintenance and inspection tasks required are to ensure that EWIS components associated with non-rechargeable lithium batteries are sufficient to prevent degradation of any EWIS component that is designed and installed to support compliance with these SCs.

D.2.5 Sections 25.903(d) and 25.1309 Uncontained Engine or Auxiliary Power Unit (APU) Rotor Failures. Pursuant to 25.1309, the applicant is expected to demonstrate that a foreseeable event originating from outside of a non-rechargeable lithium battery, such as an uncontained rotor burst, will not compromise continued safe flight and landing. An applicant may propose fail-safe design features that encase and safely vent the hazardous by-products of a failure originated from within the battery to show compliance with the non-rechargeable lithium battery SCs. However, a rotor failure could defeat such safety features depending on the location of the battery installation. If an applicant proposes to install a non-rechargeable lithium battery in a rotor burst zone, the applicant must ensure the means of compliance to the SCs remain effective considering potential rotor failures that could damage the battery.

Regarding compliance to 25.903(d)(1) turbine engine rotor failures, AC 20-128A Design Considerations for Minimizing Hazards caused by Uncontained Turbine Engine and Auxiliary Power Unit Rotor Failure provides guidance on fragmentation characteristics and the boundaries of the locations in which applicants are expected to evaluate the effects of impact damage following an uncontained rotor burst. If an applicant proposes to install a non-rechargeable lithium battery in a rotor burst zone, the applicant must assess the rotor burst induced damage to the battery to show compliance with 25.903(d)(1) in conjunction with showing compliance with the non-rechargeable lithium battery SCs. In this case, provide a proposed method of compliance to the DASA. Alternatively, locate the battery outside of the rotor burst zone.

Superseded

D.3 Special Condition Applicability Exclusion Criteria

As explained in Appendix C, the FAA determined from non-rechargeable lithium battery incidences that part 25 does not contain adequate safety standards for installing these batteries on transport category airplanes. The FAA addressed this issue on new certification projects for transport category airplanes by requiring changes involving non-rechargeable lithium batteries to comply with special conditions. However, the FAA previously approved many non-rechargeable lithium battery installations that were not shown to comply with special conditions. Therefore, to improve the safety of follow-on airplanes that are delivered with these installations, the FAA included a paragraph in the applicability section of non-rechargeable lithium battery special conditions similar to the following:

These special conditions are not applicable to changes to previously certified non-rechargeable lithium battery installations where the only change is either cosmetic or to relocate the installation to improve the safety of the airplane and occupants. Previously certified non-rechargeable lithium battery installations, as used in this paragraph, are those installations approved for certification projects applied for on or before the effective date of these special conditions. A cosmetic change is a change in appearance only, and does not change any function or safety characteristic of the battery installation. These special conditions are also not applicable to unchanged, previously certified non-rechargeable lithium battery installations that are affected by a change in a manner that improves the safety of its installation. The FAA determined that these exclusions are in the public interest because the need to meet all of the special conditions might otherwise deter these design changes that improve safety.

This statement is intended to allow the Authority or type certificate holders to identify approved lithium battery installations that are a fire safety concern, which are not necessarily unsafe such that the Authority would issue an airworthiness directive, and implement a design change that improves the safety of it on follow-on airplane deliveries without having to show compliance with the special conditions. The FAA considered that requiring new substantiation data for meeting the special conditions may prevent type certificate holders from implementing these improvements.

The special condition applicability exclusion, which relates to improving the safety of previously approved installations, only applies to the below conditions and each condition must be met:

(a) A change to a baseline airplane type certificated on or before the effective date of the special condition. That is, the follow-on airplane change must be compared to a single, baseline airplane (i.e., a distinct serial number airplane). Other changes between the follow-on airplane and baseline airplane may exist, but all of those changes must be approved as part of the follow-on airplane changes. Otherwise, the proposed baseline airplane is not actually the baseline airplane.

(b) Previously approved non-rechargeable lithium battery installations on baseline airplanes where a fire safety concern, which may not be considered unsafe such that the Authority would issue an airworthiness directive, is identified. This exclusion does not cover a situation where a battery is moved to an arguably better location, but either location is considered fine in terms of fire safety.

(c) A change that provides a substantial, fire safety improvement.

(d) For minor software changes to avionics devices that contain non-rechargeable lithium batteries, where the software functional changes have no effect on and are not affected by an existing installed battery. Applicants should demonstrate that the change has no effect on the battery or the associated special conditions.

Superseded

Applicants, who propose to use this special condition applicability exclusion statement, should provide the DASA information to show how their proposal meets each of the above conditions. This includes providing a detailed assessment of the battery installation on the baseline airplane and the improvement due to the proposed change considering a battery thermal runaway failure for both installations. The assessment should:

(a) Consider the battery thermal runaway effects of heat, explosive energy, projecting debris and toxic gases.

(b) Address the proximity of the battery to occupants, critical systems and equipment, structure, and any other installations that could be a hazard if exposed to a battery thermal runaway (e.g., oxygen bottles/lines, fuel lines).

Superseded

SAFETY OBJECTIVES AND MOC FOR INSTALLATION OF NON-RECHARGEABLE LITHIUM BATTERIES ON ROTORCRAFT

This appendix establishes an approach to show compliance for non-rechargeable lithium batteries and their installation to the safety objectives listed in this appendix. It is also intended to ensure, as required by 27/29.601 and 27/29.1309, that the installation does not represent a hazard to the rotorcraft and its occupants.

Regulatory Basis from parts 27 and 29

Pursuant to 27/29.601, the design must not have features or details that experience has shown to be hazardous or unreliable.

Pursuant to 27/29.863, provide a means of minimizing the probability of ignition of flammable fluids or vapours that might leak from flammable liquid sources, and the resultant hazards in the event of ignition.

Pursuant to 27/29.1301, ensure each system is appropriate for its intended function, and is labelled and installed according to its limitations and function.

Pursuant to 29.1309, ensure all systems perform their intended function under any foreseeable operating conditions, systems must be designed to prevent hazards to the rotorcraft in the event of a probable malfunction or failure.

Pursuant to 27.1309, all systems must perform their intended function under any foreseeable operating conditions, systems must be designed to prevent hazards to a multiengine rotorcraft in the event of a probable malfunction or failure and minimize hazards to a single engine rotorcraft. Pursuant to 29/27.1353, storage batteries must be designed and installed to maintain safe cell temperatures and pressures that no explosive or toxic gases can accumulate in hazardous quantities, and that corrosive fluids or gases cannot damage surrounding structures or essential systems.

Pursuant to 27/29.1529, requires that Instructions for Airworthiness be prepared that are acceptable to the Authority.

Advisory Material

RTCA/DO-227A, Minimum Operations Performance Standards (MOPS) for Non-Rechargeable Lithium Batteries.

AC 29-2C, Certification of Transport Category Rotorcraft.

E.1 Safety Objectives (SO's)

Eight Safety Objectives are identified as critical for safe installation of non-rechargeable lithium batteries on rotorcrafts. Each non-rechargeable lithium battery installation must show compliance with the following Safety Objectives:

E.1.1 Safety Objective 1: The battery shall be designed to maintain safe cell temperatures and pressures under all foreseeable operating conditions to prevent fire and explosion.

E.1.2 Safety Objective 2: The battery shall be to prevent the occurrence of self-sustaining, uncontrollable increases in temperature or pressure.

Superseded

E.1.3 Safety Objective 3: The battery shall not emit explosive or toxic gases, either in normal operation or as a result of its failure, that may accumulate in hazardous quantities within the rotorcraft.

E.1.4 Safety Objective 4: The battery must meet the flammable fluid fire protection requirements of 29.863.

E.1.5 Safety Objective 5: The battery and installation must be designed to prevent corrosive fluids or gases that may escape from damaging surrounding structure or adjacent systems, equipment, or electrical wiring.

E.1.6 Safety Objective 6: The battery and installation must be designed to prevent any hazardous effect on rotorcraft structure or systems caused by the maximum amount of heat generated from any battery or individual cell failure.

E.1.7 Safety Objective 7: The battery and installation must have a failure sensing and warning system to alert the flight crew if a failure affects safe operation of the rotorcraft.

E.1.8 Safety Objective 8: The battery and installation must provide a means for the flight crew to determine the battery charge state (for required battery systems).

Note: A battery system consists of individual battery cell(s), a battery assembly, and any protective, monitoring and alerting circuitry or hardware inside or outside of the battery. It may also include vents (when necessary) and packaging. For the purpose of this guidance, a battery and battery system are referred to as a battery. A battery may also be an integral component of an end item assembly. The battery supplies energy to the end item. A battery may also be an end item.

E.2 Method of Compliance (MOC)

The following MOC have been accepted to ensure that the battery meets Safety Objectives 1 through 8 discussed in the paragraphs above. Some failures may still occur due to various factors beyond the control of the battery and battery system OEM; these MOCs are also intended to address the occurrence of these unexpected failures. RTCA/DO-227A provides a MOC acceptable to the DASA for installation of non-rechargeable lithium batteries on rotorcraft. General design and construction requirements necessary to reliably and consistently produce lithium batteries appropriate for installation into the expected rotorcraft environment are found in paragraph 2.1, General Requirements and Design Guidelines. Paragraph 2.2, Functional and Safety Requirements, defines the minimum functional requirements for battery cells, batteries, and end items. Each subparagraph in paragraph 2.2 references a specific test procedure found in paragraph 2.4. Test procedures and evaluation criteria specifically for cells, batteries and end items are outlined in paragraph 2.4 corresponding to each of the functional and safety requirements. Test conditions are defined in paragraph 2.3.

E.2.1 MOC for Safety Objective 1. Show that the individual cells meet the requirements in RTCA/DO-227A, section 2.2.1 by successfully performing the test procedures in section 2.4.1 and judging the test results against the associated evaluation criteria.

E.2.2 MOC for Safety Objective 2. Safety Objective 1 requires that each individual cell within a non-rechargeable lithium battery be designed to maintain safe temperatures and pressures. Safety Objective 2 requires that the battery and end item installation be designed to prevent propagation of a thermal event, such as self-sustained, uncontrollable increases in temperature or pressure from one cell to adjacent cells. Show that the battery installation meets the requirements in RTCA/DO-227A, sections 2.2.2 Battery Functional and Safety Requirements and 2.2.3 End Item Functional and Safety

Superseded

Requirements. Successfully perform the test procedures in sections 2.4.2 and 2.4.3. Judge the test results against the associated evaluation criteria for successful showing.

E.2.3 Safety Objectives 3 through 6. Use the worst case test data from the MOCs for Safety Objectives 1 and 2 to support demonstrating compliance with SO 3 through 6. The DASA considers that the RTCA/DO-227A, section 2.4.3.2.2 End Item Thermal Runaway Containment Test usually provides these worst case data.

1. *E.2.3.1 MOC for Safety Objective 3.* RTCA/DO-227A, appendix A, section A.5 discusses potential gas emissions from batteries and their effects. An acceptable means of complying with Safety Objective 3 includes using the tests required under Safety Objectives 1 and 2 to demonstrate that all emitted gases are contained or vented overboard (i.e., vented outside the rotorcraft) through designed ports. Pursuant to 29.1309, when the design has ports to vent gases overboard, show that there are means to protect ground personnel from exposure to these gases and to prevent re-ingestion, for example through engine in-take or air conditioning in-take. Safety Objective 3 allows explosive and toxic gases to be uncontained and not vented overboard if they do not accumulate in hazardous quantities within the rotorcraft. Consider the gases emitted from not only the cells but also the battery materials (e.g., insulation separators) when demonstrating compliance by this means.

1. *E.2.3.2 MOC for Safety Objective 4.* The amendment level of 25.863 is determined by 14 CFR 21.17 or 21.101, as appropriate. The amendment level is not determined by the issuance or effective date of the special conditions. The Aviation Rulemaking Advisory Committee (ARAC) draft Advisory Circular (AC) 25.863-1, Flammable Fluid Fire Protection gives acceptable guidance on 25.863.

1. *E.2.3.3 MOC for Safety Objective 5.* Show that if fluid escapes the battery, it is not corrosive or it is managed in a way (e.g. contained, isolated, or vented overboard) to protect the surrounding structure and adjacent systems, equipment and electrical wiring.

1. *E.2.3.4 MOC for Safety Objective 6.* Show that the effects of the heat, and any related effects, from the tests performed under Safety Objectives 1 and 2 do not constitute a hazard to the structure or systems of the rotorcraft. If the effects of the heat or any related effects constitute a hazard to the structure or systems of the rotorcraft, design mitigation at the aircraft level may be applied to bring the design into compliance with Safety Objective 6.

E.2.4 MOC for Safety Objective 7. Pursuant to 29.1322, Safety Objective 7 requires flight crew alerting for unsafe operating conditions. Flight crew alerting is required when a battery installation failure affects continued safe flight and landing. The effect of the battery failure on other systems that perform functions required for safe flight and landing must also be considered. The alert must meet the applicable paragraphs of 29.1322. The applicant should refer to the current AC 29-2C for guidance on 29.1322.

E.2.5 MOC for Safety Objective 8. The following are examples of “means” for flight crew or maintenance personnel to determine the battery charge state:

(a) A manually activated system (e.g., push button) that displays the available charge of each battery unit.

(b) An automatic system that records the available charge of each battery unit on an appropriate interval and makes it available to maintenance personnel before the next flight.

Superseded

(c) Physical access that allows a maintenance person to measure the battery charge state.

The above "means" are acceptable only when the Instructions for Continued Airworthiness (ICA) include a requirement for a person to check the battery charge state within an interval that will ensure sufficient charge for the entire flight considering the worst case scenario, and to replace the battery when the charge is not sufficient. After completing all the required test and validation based on the MOC for each safety objectives, provide a summary of all the evaluation criteria and reportable items listed in each test. Compliance to one safety objective does not constitute compliance to any other safety objectives.

E.3 Part 27 and 29 Compliance

Pursuant to part 29, non-rechargeable lithium battery installations should satisfy each of the MOCs identified in this document. The following provides means of compliance and other information on other important part 29 requirements.

E.3.1 System Safety Assessment. Pursuant to 27, 29.1301 and .1309, hazard conditions require specific functionalities and capabilities, and address certain critical failure modes of non-rechargeable lithium batteries and their installations, to date however, in-service experience has shown that non-rechargeable lithium battery thermal/pressure runaway conditions are not extremely improbable. Assuming such failures will occur sometime during the life of the battery installation when demonstrating compliance, periodic maintenance actions or flight crew alerting features such as, an overtemperature warning system may be necessary to allow the flight crew to manage potentially unsafe system operating conditions. Provide rationale for alerting requirements (or for why an alert is not needed) in the system safety assessment of the battery installations to demonstrate compliance with 27.1309 and 29.1309. Such alerts, when provided, must meet 27.1322 and 29.1322.

E.3.2. ICA. The ICA should include the following provisions to comply with 27.1529 and 29.1529:

(a) Maintenance requirements to replace each non-rechargeable lithium battery within an interval that will ensure there is sufficient charge to power equipment.

(b) A requirement to only replace non-rechargeable lithium batteries with batteries from the same manufacturer with the same part number or to obtain a new approval for installing a different battery. Refer to the battery Original Equipment Manufacturer's maintenance manual.

(c) Procedures to ensure that each non-rechargeable lithium battery has not:

1. Experienced degraded charge retention ability or other damage during storage.

2. Been damaged from environmental or physical impacts such as mechanical shock, vibration, heat and possible abuses encountered during storage, transportation prior to their installation or maintenance activities on or around them.

3. Precautions to prevent mishandling of replacement non-rechargeable lithium batteries prior to their installation which could result in short-circuit or other unintentional damage.

Note: Acceptable procedures for paragraph E.3.2-2 above may include a quality control process for packaging, storing, maintaining and transporting non-rechargeable lithium batteries, including reporting of dropped or damaged batteries.

E.3.3 Uncontained Engine or APU Rotor Failures. Sections 27.903(b), 29.903(d) and 27/29.1309. In general, as part of showing compliance with 27/29.1309, the DASA expects the applicant to

Superseded

demonstrate that a foreseeable event originating from outside of a non-rechargeable lithium battery, such as an uncontained rotor burst, will not compromise continued safe flight and landing. While you may use failsafe design features that encase and safely vent the hazardous by-products of a failure originated from within the battery to show compliance with the non-rechargeable lithium battery Safety Objectives, depending on the location of the battery installation, a rotor failure could defeat such safety features. If you propose to install a non-rechargeable lithium battery in a rotor burst zone, you must ensure the means of compliance to the SO's remains effective considering potential rotor failures that could damage the battery. Regarding compliance to 29.903(d)(1) turbine engine rotor failures, AC 20-128A provides guidance on fragmentation characteristics and the boundaries of the locations in which applicants are expected to evaluate the effects of impact damage following an uncontained rotor burst. If you propose to install a non-rechargeable lithium battery in a rotor burst zone, you must assess the rotor burst induced damage to the battery in your plan for showing compliance with 29.903(d)(1) in conjunction with complying with the non-rechargeable lithium battery SO's. Clearly state your method of compliance in your response to this issue paper. Alternatively, the battery is to be located outside of the rotor burst zone.

CERTIFICATION CONSIDERATIONS OF NON-RECHARGEABLE LITHIUM BATTERIES ON SMALL AIRPLANES

F.1 This appendix provides guidance regarding the risk based certification considerations for the installation of non-rechargeable lithium batteries, or equipment that uses non-rechargeable lithium batteries on Title 14 of the Code of Federal Regulations (14 CFR) part 23 airplanes.

F.2 The regulations applicable to the subject include 23.2510 and 23.2525 amendment 23-64, or 23.1309 and 23.1353 with an earlier amendment level.

F.3 Section 23.1309 requires installed equipment perform its intended function and that it is designed to mitigate the hazard severity accordingly.

F.4 Section 23.1353 requires that storage batteries be designed and installed to maintain safe cell temperatures and pressures that no explosive or toxic gases can accumulate in hazardous quantities, and that corrosive fluids or gases cannot damage surrounding structures or essential systems.

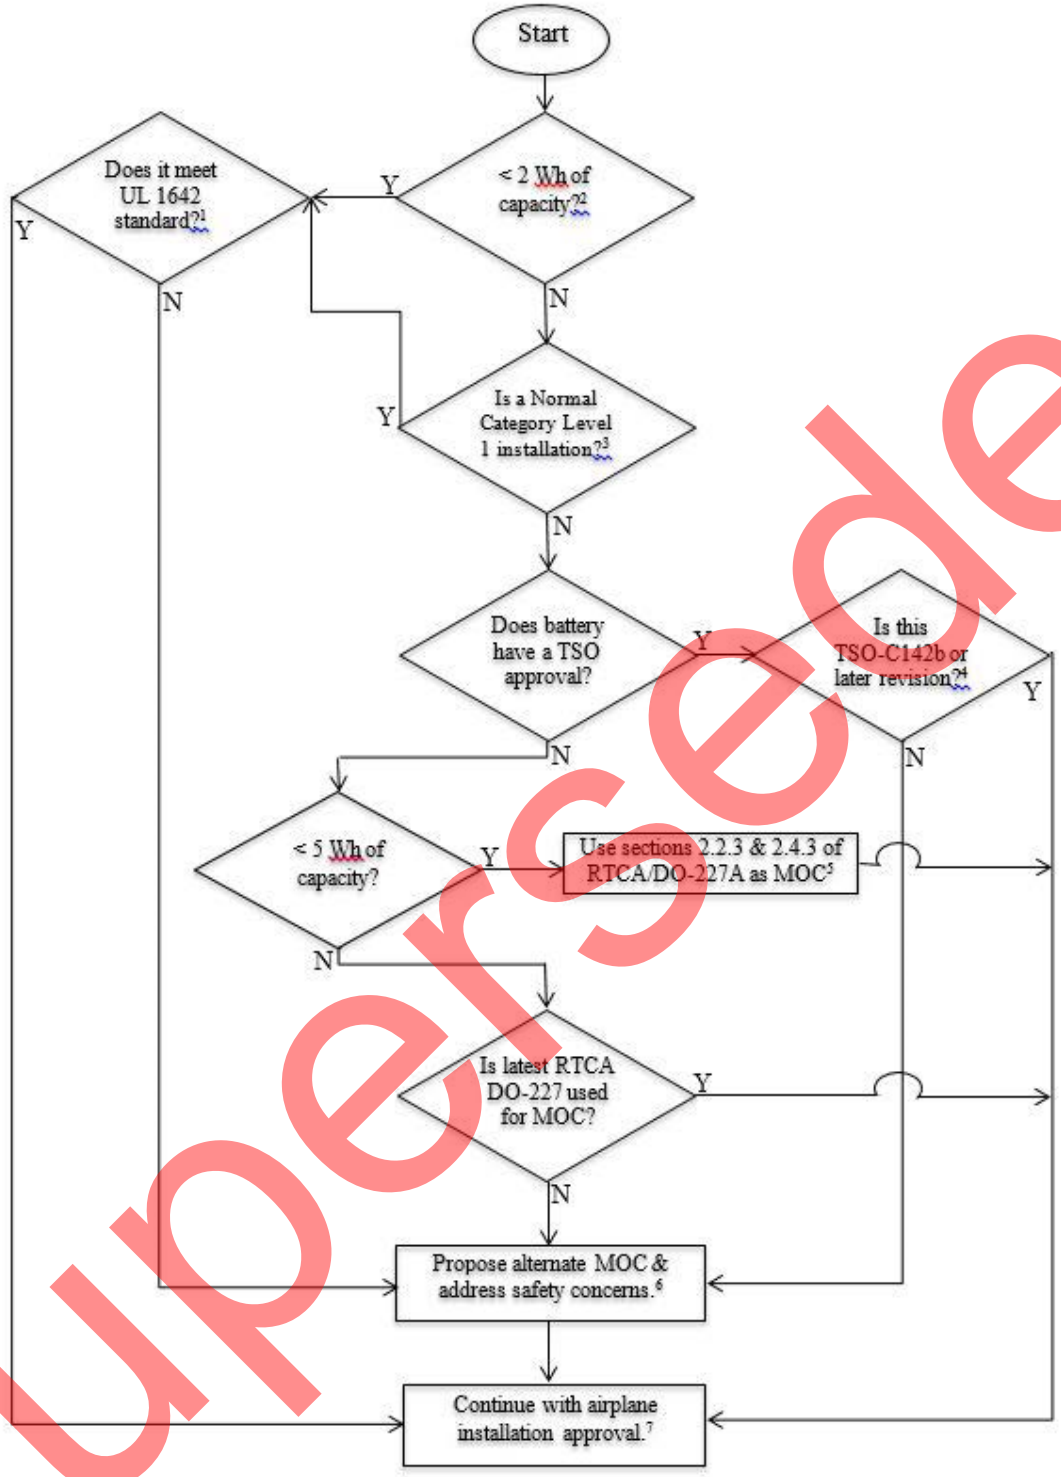
F.5 Section 23.2510 requires the probability and failure conditions of installed system or equipment remain an acceptable inverse relationship.

F.6 Section 23.2525 requires the power supply is adequate for intended operations that a single failure cannot stop power supply to essential loads for safe flight and landing, and has enough power storage capacity of duration to continue safe flight and landing.

F.7 The following depiction, figure 1, identifies applicable evaluations for installing equipment using non-rechargeable lithium batteries in part 23 airplanes.

Superseded

Figure 1. Non-Rechargeable Lithium Battery Certification Considerations



Superseded

Footnotes:

(a) Other than meeting the UL 1642 Standard, the appropriate regulatory authority that governs Hazardous Materials Transportation will regulate the carriage of uninstalled lithium batteries. For example, the UN regulations (e.g., UN 38.3, etc.) established guidance for safe transportation of lithium batteries.

(b) A Watt-hour (Wh) is defined as the rated capacity (in ampere-hours, Ah) times the nominal battery voltage. Evaluate the energy of the entire battery capacity for 2 Wh threshold.

(c) Section 23.2005(b) (1), amendment 23-64, defines a Normal Category Level 1 airplane. Certification basis with earlier amendments should use a Class I airplane, as defined in AC 23.1309-1E for this evaluation.

(d) The following is applicable to this footnote:

1. New installations with TSO-C142a approved articles should present data (e.g., test reports, quantitative and qualitative analysis, etc.) to show that there are no performance gaps in meeting TSO-C142b requirements. One example is substantiation of thermal runaway containment.

2. TSO-C142b-7 marking (i.e., marking requirements of "-7" described in paragraph 4.b of TSO-C142b) is an acceptable means of compliance for installation.

(e) The following items are applicable to this footnote:

1. Battery (or cell) must meet at a minimum UL1642 and UN 38.3 requirements. RTCA document, DO-227A, section 2.2.3 and 2.4.3 can be used as a MOC for the end item that the battery (or cell) provides power to.

2. If RTCA document, DO-227A, sections 2.2.3 and 2.4.3 are not used as a MOC, then the applicant must propose alternate methods to show compliance.

(f) The following items are applicable to this footnote:

1. New installations that use earlier version of RTCA/DO-227 as a MOC must perform adequate analysis and present additional data to meet the latest standards.

2. Coordinate with the small airplane standards branch for proposed alternate MOC, or any analysis used to justify deviations from latest DO-227 required tests.

3. Identified safety concerns must be addressed. Examples are risk assessment and mitigation of internal failures, overheat conditions, flammability, and gas emission.

(g) Continue the certification process. For example, 23.2510 (or 23.1309) compliance includes System Safety Assessment (SSA) process. Location related hazards (e.g. designated fire zones etc.), with respect to where an equipment is to be installed, should be addressed by SSA zonal safety analysis (ZSA), particular risk analysis (PRA), and failure modes and effects analysis (FMEA).

Superseded

ENVIRONMENTAL CONTROL SYSTEMS

INTRODUCTION

9.1 The Environmental Control System (ECS) provides temperature, humidity, ventilation and pressure control to passenger/cargo areas, aircraft systems and equipment. The system must be able to provide this control under any possible role, configuration and environment in which the platform will operate. ECS air may be derived from internal sources (engine or auxiliary power unit), external sources (ram air or air-conditioning cart) or an ECS dedicated compressor. Heat generated by aircraft equipment and occupants is usually dispersed external to the aircraft and needs to be controlled to meet safety and mission requirements. ECS functions and sub-systems may include, but are not limited to: pressurisation, heating, cooling, ventilation, moisture control, pressure and anti-G suit control, defogging, defrosting, anti-icing, rain removal, windshield washing, and electronic and electrical thermal management.

9.2 While compliance with the Authority recognised civil and military Airworthiness Codes described in Section 1 of this manual usually satisfies aircraft ECS safety objectives, the Codes may not account for ECS loads associated with military loads and mission systems. Further, Defence experience with ECS has identified that simple application of the Codes may not adequately account for the Australian operating environment, particularly where ground operations in harsh environmental conditions are expected. Consequently, the Authority prescribes airworthiness design requirements for Defence aircraft ECS to supplement these Airworthiness Codes and support the provision of adequate ECS capability for Defence aircraft operations.

Scope

9.3 This Chapter presents the Authority prescribed airworthiness design requirements for Defence aircraft ECS. Importantly, the airworthiness design requirements in this chapter are not suitable for application in isolation from an Airworthiness Code. The Authority's requirements for the application of recognised Airworthiness Codes are defined in Section 1 of this manual.

ECS DESIGN REQUIREMENTS

9.4 **Design Requirement (Essential).** *Defence aircraft electronic equipment cooling capacity must be evaluated and verified to provide sufficient cooling for safety of flight systems, for both initial aircraft designs and design changes, or additional ECS capacity must be provided.*

9.5 The safety of aircraft designs may be compromised if the ECS is not capable of providing adequate cooling to electrical or electronic equipment. Additionally, changes to ECS ducting or flow paths may impact ECS cooling performance even though capacity remains the same. As part of initial aircraft design certification activities, or during design changes that either add thermal loads to existing ECS demands or change the ECS characteristics, the ECS capacity and performance must be evaluated to verify that it remains adequate for the required load conditions.

Superseded

9.6 **Design Requirement (Essential)**. *Where applicable, Defence aircraft environmental control systems must satisfy the requirements for anti-G suit systems prescribed in MIL-E-18927E(AS), Environmental Control Systems, Aircraft, General Requirements for.*

9.7 Authority recognised civil Airworthiness Codes do not prescribe requirements for anti-G suit supply systems. To support safe anti-G suit operation where a Defence aircraft is to be used in operations requiring anti-G protection, compliance with an appropriate military standard is required.

9.8 **Design Requirement (Recommended).** *Environmental control systems should be capable of maintaining the required temperature, pressure, humidity and ventilation control in the ground environmental conditions for the worst-case duration applicable to the Defence aircraft CRE, described in:*

(a) *MIL-HDBK-310, Global Climatic Data for Developing Military Products*

(b) *DEF(AUST) 5168, The Climatic and Environmental Conditions Affecting the Design of Military Materiel.*

9.9 Compliance with Authority recognised Airworthiness Codes usually satisfies design safety objectives for the purposes of maintaining occupant and aircraft safety during flight (eg pressure and temperature control of occupied spaces and thermal control of aircraft equipment). However, Defence experience in the past, particularly for aircraft that are based on a modified civil variant, has identified that compliance with these Codes may result in an ECS that does not satisfy either occupant or equipment environmental control needs when the aircraft is on the ground. Therefore, the applicable environmental conditions for ground operations should be defined and the ECS evaluated to verify that it can support the associated environmental control requirements, or to identify supplementary ECS capability (eg ground air conditioning systems) if required.

9.10 **Design Requirement (Recommended).** *Cooling for electronic equipment provided by Defence aircraft environmental control systems should allow for 50% greater load capacity than that required for the originally certified aircraft design.*

9.11 Military aircraft operational experience demonstrates that 50% growth capacity from the originally certified design is likely to be sufficient to accommodate future changes in avionics, especially on fighter, bomber and electronically intensive platforms. Additional ECS capacity may be provided through: ECS designs having an electronic heat dissipation load greater than the equipment heat load of the originally certified design; aircraft designs that permit fitment of a larger capacity ECS system; or a combination of these approaches.

ENVIRONMENTAL CONTROL SYSTEMS MANAGEMENT AND PLANNING

9.12 While not essential for the achievement of a safe aircraft design from an ECS perspective, Defence experience has demonstrated that formal ECS management and planning supports the achievement of an appropriate level of ECS capacity and performance. Consequently, the Authority recommends the use of the following two ECS planning documents:

(a) ECS Operating Modes Document (ECSOMD), and

(b) ECS Analysis and Integration Plan (ECSAIP).

9.13 ECS air for Defence aircraft is a resource and, therefore, should be managed in a similar manner to other platform resources such as electrical loads and weight and balance. Critical modes of operation will be present in Defence aircraft ECS, in which the demands on ECS resources may be

Superseded

elevated or where normal ECS resources may be unavailable. These critical modes of operation should be identified during initial aircraft design to establish the required ECS capability, to limit the potential for ECS resources to be compromised throughout the Defence aircraft's service life, and to provide a basis for evaluating the impact of design changes on Defence aircraft ECS.

9.14 One approach to documenting the identification and analysis of ECS modes is an ECS Operating Modes Document (ECSOMD). An ECSOMD should be raised for each defence aircraft acquisition. The SPO responsible for managing the Defence aircraft, should maintain the ECSOMD throughout the aircraft's service life, and update the document for each modification that has an impact on available ECS resources.

ECS Analysis and Integration Plan (ECSAIP)

9.15 Additional oversight of ECS resources during design changes may be required if the ECS:

(a) has an uncertain or undefined spare and/or utilised capacity,

(b) may impose limitations on aircraft operations, or

(c) will be nearing capacity in the immediate future through concurrent or future defined design changes.

9.16 One method of applying this additional oversight is through the use an ECS Analysis and Integration Plan (ECSAIP). An ECSAIP should be developed for all design changes having the potential to significantly impact ECS capabilities. The ECSAIP should build on the ECSOMD, demonstrate that ECS requirements have been adequately identified, and provide a vehicle for ongoing ECS management through the aircraft life of type.

RELATED INFORMATION

9.17 For additional information relating to ECS integration issues, refer to Section 2 Chapter 9, Equipment Environmental Qualification.

ADDITIONAL ENVIRONMENTAL CONTROL SYSTEM DESIGN GUIDANCE

9.18 Further guidance on implementing the ECS design requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

AIR VEHICLE SUBSYSTEMS (MECHANICAL)

INTRODUCTION

10.1 Air vehicle subsystems (mechanical) include: landing, hydraulic power, fuel, aerial refuelling, mechanical, propeller and pneumatic systems, and so on. In Defence aircraft, these subsystems are usually designed to comply with an Authority recognised Airworthiness Code. However, with the increased prevalence of modifying civil-derivative aircraft for military use, there may be occasions where Defence's CRE is different to that which the aircraft was originally certified. Further, the design of some air vehicle subsystems (mechanical) may have an adverse impact on capability and interoperability if Defence's requirements are not considered during design development.

10.2 Nevertheless, Defence's CRE remains a primary consideration when selecting aircraft for Defence use. Any limitations associated with air vehicle subsystems will be comprehensively disclosed in the aircraft's design data and will inform decisions on whether the aircraft can adequately meet Defence's CRE. Consequently, compliance with any of the Authority recognised Airworthiness Codes, detailed in Section 1 Chapter 3 of this manual, is acceptable for air vehicle subsystems, provided that the acquisition organisation has confirmed that the airworthiness design requirements imposed by the Code are compatible with Defence's proposed CRE. Therefore, the DASDRM contains no additional Authority prescribed airworthiness design requirements for air vehicle subsystems.

10.3 For air vehicle subsystems modifications, JSSG-2009 US Department of Defense Joint Service Specification Guide – Air Vehicle Subsystems provides a wealth of information and related standards for guidance.

Capability design requirements

10.4 Defence aircraft designs may adversely impact continued availability for missions if the design does not provide adequate protection of the aircraft while parked. Some Authority recognised Airworthiness Codes may provide design requirements for aircraft picketing, however, these may not be adequate for Defence's role and operating environment.

10.5 While the Authority does not prescribe capability design requirements, the requirement for picketing of Defence aircraft to satisfy the expected ground conditions associated with Defence operations should be considered for aircraft acquisitions.

Interoperability design requirements

10.6 Defence aircraft air vehicle subsystems (mechanical) designs may adversely impact interoperability with other nations and/or continued operational availability, if they are not designed to facilitate interfaces with partner nation assets and support replenishment of fuels, oils and gases at deployed locations. In particular, civil-derivative aircraft may not be designed for interoperability. Section 1 Chapter 4 provides further guidance on interoperability requirements and the application of AFIC standards. The following requirement is not prescribed by the Authority, but should be

Superseded

considered for aircraft acquisitions and modifications to aircraft air vehicle subsystems (mechanical) systems where interoperability is a determining factor.

10.7 **Interoperability design requirement.** *Defence aircraft air vehicle subsystems (mechanical) designs should comply with the requirements defined in AFIC AIR STD ACS 4029 Aircraft Jacking Pads and Clearances, and AFIC AIR STD ACS 4058 Tyre Valve Couplings.*

Superseded

Superseded

10.7 **Interoperability design requirement.** *Defence aircraft air vehicle subsystems (mechanical) designs should comply with the requirements defined in AFIC AIR STD ACS 4029 Aircraft Jacking Pads and Clearances, and AFIC AIR STD ACS 4058 Tyre Valve Couplings.*

Superseded

AIRCRAFT PERFORMANCE AND HANDLING

11.1 Aircraft performance and handling qualities are prescribed in airworthiness design requirements associated with aircraft flight controls and aerodynamics. While the Authority recognised Airworthiness Codes in Section 1 of this manual provide appropriate benchmark standards for Defence aircraft performance and handling qualities, there may be Defence unique role and operating environment considerations that are not adequately accommodated within these Codes. Consequently, Defence conducts comprehensive test programs to ensure that the Defence aircraft's performance, handling qualities and human factors are satisfactory for Defence's intended use.

11.2 The ADF Flight Test Organisations (DASR) retain specialist expertise in the identification of suitable requirements and standards for conducting aircraft performance, handling qualities and human factors assessments, to demonstrate that a Defence aircraft's handling characteristics are acceptable. POs/SPOs intending to acquire a Defence aircraft or implement a modification that could impact the extant handling qualities of a Defence aircraft, should engage with the applicable flight test organisation early in the certification process to obtain advice on appropriate performance and handling qualities design requirements, and suitable verification and test requirements to demonstrate compliance with these requirements.

Superseded

AIRCRAFT STRUCTURES

INTRODUCTION

12.1 This chapter provides airworthiness design requirements for Defence aircraft structures. This chapter is applicable to all certified aircraft types, including crewed fixed-wing and rotary-wing aircraft and certified-category Uncrewed Aircraft Systems (UAS).

12.2 Within the context of the DASR and this chapter, DASA defines the aircraft structure as the aircraft components that are required to carry loads in order to perform their intended functions. The structure of an aircraft includes the fuselage, wing, empennage, landing gear, helicopter rotor and drive systems, control systems and surfaces, engine mounts, radome, nacelles, inlets, store mounts, structural operating mechanisms and other components that perform a structural function.

12.3 The airworthiness codes recognised by DASA (refer Section 1 Chapter 3) provide an appropriate benchmark for establishing and maintaining an adequate level of safety for aircraft structures. However, DASA has identified the following three circumstances where recognised airworthiness codes may require supplementation:

(a) Recognised airworthiness codes not adequately covering the full scope of the proposed Defence Configuration, Role and Environment (CRE).

(b) The nature of proposed military operations typically dictates the need for more complex and proactive in-service structural integrity management (over and above that contained in some airworthiness codes) to ensure risk of failure remains within that inherent in the Type Certification Basis (TCB).

(c) Recognised airworthiness codes vary in terms of design requirements to address the threats associated with ageing of aircraft structures.

12.4 The requirements and guidance in this chapter are framed around these three circumstances. When developing a certification basis for a Military Type Certificate (MTC), Military Supplemental Type Certificate (MSTC) or Major Change, each applicant will need to assess the airworthiness design requirements inherent in the baseline Primary Certification Code (PCC) or standard and supplement or tailor, as required, using the essential requirements in this chapter. Applicants are highly encouraged to engage early with DASA as part of this process. Note that three likely scenarios exist for any given DASDRM requirement:

(a) Intent of DASDRM requirement is not met by any requirement in the underlying PCC / standard. In this case, the applicant would need to supplement the PCC / standard to add a new requirement.

(b) Intent of DASDRM requirement is partially met by an existing requirement in the underlying PCC / standard. In this case, the applicant may tailor the existing requirement so that it meets the full intent of the DASDRM requirement.

Superseded

(c) Intent of DASDRM requirement is fully met by an existing requirement in the PCC / standard. In this case, the applicant may propose to DASA that no supplementation or tailoring is required.

12.5 Separate to the DASA-prescribed airworthiness requirements under the DASR and DASDRM, it is Defence Policy that each Defence-registered aircraft type have an effective and efficient Aircraft Structural Integrity Program (ASIP) to:

(a) ensure, so far as is reasonably practicable, that degradation of integrity does not present risks to health and safety

(b) contribute to delivery and assurance of capability

(c) support cost-effective sustainment of capability.

12.6 Under Defence Policy , the Defence-preferred approach for ASIPs is alignment with MIL-STD-1530; a cradle-to-grave management framework for aircraft structural integrity that encompasses system requirements, design, verification and sustainment. Despite the fact that the ASIP remit and objectives are broader than safety, an effective ASIP is key to supporting the essential design requirements set out in this chapter[1].

12.7 The ASIP for each aircraft type should be documented in an Aircraft Structural Integrity Management Plan (ASIMP). ASIMPs are key documents that assist applicants and the regulated community by maintaining a record of relevant structural certification information and data, and demonstrate how the ASIP complies with the design requirements prescribed in this chapter and supports related DASR obligations[2].

STRUCTURAL TYPE CERTIFICATION

Type Certification Basis

12.8 **TCB Foundation**. As outlined above, the airworthiness codes recognised by DASA provide an appropriate benchmark for developing a TCB for the aircraft structure, subject to supplementation and / or tailoring to address the requirements provided in this chapter and any unique Defence CRE aspects (as discussed below).

12.9 For cases where Defence is acquiring an aircraft where the baseline design requirements are not a recognised airworthiness code, then applicants are recommended to use the European Military Airworthiness Certification Criteria (EMACC) Handbook, in conjunction with this chapter, to develop and propose for DASA approval a comprehensive set of airworthiness design requirements for structural certification. Applicants are highly encouraged to engage early with DASA if this is the case.

12.10 **TCB Supplementation and / or Tailoring.** The requirements related to aircraft structures within the airworthiness codes recognised by DASA often provide enough flexibility to cover the full scope of the proposed Defence CRE.

12.11 Notwithstanding, recognised airworthiness codes (especially civil codes) sometimes do require supplementation and / or tailoring for structural aspects related to military-specific CRE. Examples of areas where structural-related supplementation and / or tailoring has been required in the past include: aerial delivery loads; runway conditions; military-specific system structures and structural loads aspects of crash protection (in accordance with DASDRM Section 2 Chapter 6).

Superseded

12.12 For structural aspects, Defence's type certification approach almost exclusively relies on fully or partially leveraging prior NAA/MAA certification. Performing a CRE Assessment (CREA) is an essential part of this process to ensure the prior certification is applicable for the Defence CRE and the design is safe for the intended Defence use.

12.13 Aircraft Original Equipment Manufacturers (OEMs) design analysis and verification will be conducted using a configuration baseline and usage, loading and environment assumptions that will not always be representative of Defence's intended CRE. Furthermore, structural failure modes (in particular fatigue) can be highly sensitive to small changes in usage, loads and environment. Therefore, CREAs for aircraft structures usually require detailed and quantitative analysis. A particular focus of the CREA should be to quantitatively understand the impact of any CRE differences in the following areas:

(a) structural loads, including means of verification (e.g. flight and ground loads testing)

(b) design and fatigue / durability test spectra

(c) fatigue / durability test interpretation

(d) derivation of structural Airworthiness Limitations (AwLs) (i.e. structural and component life limits and structural inspection requirements)

Critical Parts and Airworthiness Limitations

12.14 The structural critical parts and associated AwLs, consistent with the TCB and the intended Defence CRE, must be identified during type certification (refer DASR AMC 21.A.41).

SUPPLEMENTARY STRUCTURAL DESIGN REQUIREMENTS

Critical Part Life Tracking / Individual Aircraft Tracking (IAT)

12.15 Variations in actual aircraft usage, environment and configuration can have a significant impact on when structural AwL actions (such as component retirement or inspections) need to be performed. This is especially the case for military operations where there is typically a higher variability in mission profiles compared to the civil sector.

12.16 The airworthiness codes recognised by DASA vary in terms of life tracking requirements. For example, civil airworthiness codes require AwLs to be identified[3], however, they do not sufficiently address requirements for tracking life accrual necessary in the military context. DASA therefore prescribes the following essential airworthiness design requirement.

12.17 **Design Requirement (Essential).** *The process for tracking life accrual of structural critical parts must be defined, commensurate with the complexity of the corresponding AwL requirements.*

12.18 AwLs include, and will define, the lifing metric(s) and any algorithm, equation, factor or other engineering data which must be used to calculate life accrual. The complexity of the process for tracking life accrual of structural critical parts will vary based on the complexity of the AwL definition.

Superseded

12.19 In many circumstances, the process for tracking life accrual of structural critical parts will require a dedicated system. In this context, the 'system' will typically comprise on-board and off-board hardware and software for data recording, processing and analysis, as well as the associated procedures[4]. The philosophy and design of the system must be based on the: certification basis; the aircraft type and role; the nature and definition for each AwL; anticipated operational variability (i.e. mission profile and mission mix variability) and uncertainty around ADF CRE. The following considerations should also be taken into account by applicants:

(a) The system must ensure that the accomplishment of AwL actions for individual aircraft or components takes into account the applicable parameters that contribute to life degradation.

(b) The system must have the ability to capture the necessary input data from all ground and flight operations (including development and / or acceptance testing) from the entry into service through to the retirement of each aircraft.

(c) The system must have the ability to identify and appropriately account for any missing or invalid data.

(d) The system must have the ability to track critical part life accrual per individual aircraft or per component as required. The level of component serialisation and tracking fidelity should ensure that individual critical parts do not exceed the underlying basis of AwLs.

(e) Requirements must ensure the system will be validated prior to fielding. Validation should test the entire system (on-board and off-board elements) in an end-to-end fashion (i.e. from raw / input data through to the AwL lifing metric outputs). Validation should ensure that the specified system will produce reliable, repeatable and suitably-conservative outputs so that AwLs are not exceeded in-service. Also within the scope of validation is calibration of all instrumentation (e.g. strain sensors and accelerometers), as required.

12.20 Compliance with this design requirement should be demonstrated through system validation / test report(s), and documentation that defines the process and, where relevant, the dedicated system. These should also be included, either directly or via reference, in the ASIMP.

12.21 Once in-service, the CAMO must maintain a record of the current status of service life-limited components (i.e. track life accrual against AwLs to meet continuing airworthiness obligations - refer DASR M.A.305(d)(4)). Compliance with the essential design requirement above will ensure that the requirements and process for tracking life accrual for structural AwLs are clearly defined up-front as part of type certification.

12.22 Note that the system for Critical Part Life Tracking / IAT may be partially or fully common with the Usage Monitoring system (refer to requirement below). Whilst the systems themselves may have commonality, the outcomes required are separate; therefore, separate sets of requirements must be defined in line with these two essential design requirements.

12.23 The following references also provide useful information on tracking of life accrual for aircraft structures:

(a) MIL-HDBK-516C Change Notice 2[5], section 5.7.3

(b) MIL-STD-1530D Change 1 (Aircraft Structural Integrity Program), sections 5.4.5 and 5.5.2

(c) JSSG-2006 (Joint Service Specification Guide, Aircraft Structures), sections A.3.15 / A.4.15[6].

Superseded

12.24 During design of an aircraft, OEMs demonstrate compliance with airworthiness requirements and develop critical part AwLs based on predicted operational profiles, material behaviour and environment. The OEM's design assumptions are typically based on the intended aircraft role(s) and cannot always specifically account for each operator's individual usage, environment and configuration throughout the entire life-cycle of an aircraft type. This is especially the case for military operations as roles, tactics and operating environments for a given aircraft type can vary significantly between operators and evolve over time. For military aircraft, monitoring accrual of lifing parameters against AwLs alone is insufficient to ensure that aircraft continue to operate within the risk level inherent in the TCB.

12.25 In order to ensure the continued integrity of the aircraft structure, systems and processes for Ongoing Monitoring and Periodic Assessment are required. The purpose of these two facets include:

(a) ongoing monitoring of usage and structural condition in order to collect the data required for, and to determine the periodicity of, assessments

(b) periodic assessment to ensure that the assumptions made during design and certification that could affect the integrity of structural critical parts remain valid for the Defence CRE.

12.26 The airworthiness codes recognised by DASA vary in terms of the requirements for Ongoing Monitoring and Periodic Assessment systems and processes. DASA therefore prescribes the three essential airworthiness design requirements outlined in this sub-section.

12.27 Once in-service, the MTCH must ensure the continued integrity of the aircraft structure through ongoing monitoring and periodic assessment (i.e. as a continued airworthiness obligation - refer DASR 21.A.44(c)). Compliance with the essential design requirements below will ensure that the relevant system and process requirements are clearly defined up-front as part of type certification.

Usage Monitoring (UM) System

12.28 **Design Requirement (Essential).** *A Usage Monitoring system, as necessary to capture the operational data required to ensure the continued integrity of structural critical parts, must be defined.*

12.29 The continued integrity of structural critical parts relies on ensuring the design assumptions (especially the design spectra) are continuously validated, or updated as required, based on actual operational data. Capturing the usage and loads information required to achieve this outcome requires a dedicated UM system. In this context, the 'system' will typically comprise on-board and off-board hardware and software for data recording, processing and analysis, as well as the associated procedures[7].

12.30 The philosophy and design of the system must be based on the aircraft type and role, certification basis and structural design philosophy, anticipated operational variability (i.e. mission profile and mission mix variability) and uncertainty around ADF CRE. The following considerations should also be taken into account by applicants when defining UM system:

(a) The system must have the ability to obtain the operational usage and measured or estimated loads data that will be required to update or confirm the design spectrum, identify when usage changes occur that warrant an update, and provide the data needed to establish or update a design / baseline spectrum.

Superseded

(b) The system must have the ability to capture all usage and operational factors which influence the integrity of structural critical parts. This should include, but is not limited to: all significant sources of repeated loads and other parameters that can influence fatigue cracking; operating location and environment parameters that can influence environmental degradation; and usage parameters that can influence flutter or other aeroelastic instability.

(c) The system must have the ability to measure or estimate structural critical parts loads with sufficient fidelity. The aircraft type and role (and therefore loads that need to be monitored), anticipated operational variability and uncertainty around ADF CRE will dictate the type of monitoring required. For some aircraft types, estimation of structural loads via analytical methods[8] may be sufficient; for others, direct loads measurement (i.e. using strain sensors) will be required. Examples of when a more-comprehensive system for direct loads measurement may be required include:

1. When there is a high degree of uncertainty with regards to the actual in-service loads that may be experienced by structural critical parts.

2. When analytical components of the UM system and / or system for tracking life accrual require ongoing validation with actual loads data.

3. Supporting a major modification or service life extension program.

(d) The system must have the ability to capture the necessary input data from all ground and flight operations (including development and / or acceptance testing) from the entry into service through to the retirement of each aircraft type.

(e) The system must have the ability to capture a representative quantity of valid operational data. An appropriate valid data capture rate should be defined for each aircraft type.

(f) Requirements must ensure the system will be validated prior to fielding. Validation should test the entire system (on-board and off-board elements) in an end-to-end fashion (i.e. from raw / input data through to processed data outputs). Validation should ensure that the system produces reliable, repeatable and accurate outputs. Also within the scope of validation is calibration of all instrumentation (e.g. strain sensors and accelerometers), as required.

12.31 Compliance with this design requirement should be demonstrated through system validation / test report(s) and system definition document(s). These should also be included, either directly or via reference, in the ASIMP.

12.32 Note that the UM system may be partially or fully common with the system for Critical Part Life Tracking / IAT outlined above. Whilst the systems themselves may have commonality, the outcomes required are separate; therefore, separate sets of requirements must be defined in line with these two essential design requirements.

12.33 The following references also provide useful information on UM system requirements:

(a) MIL-HDBK-516C Change Notice 2[9], section 5.7.2

(b) MIL-STD-1530D Change 1 (Aircraft Structural Integrity Program), sections 5.4.4 and 5.5.1

(c) JSSG-2006 (Joint Service Specification Guide, Aircraft Structures), sections A.3.15 / A.4.15[10].

Superseded

12.34 **Design Requirement (Essential).** *A Structural Condition Monitoring system, as necessary to capture the structural condition data required to ensure the continued integrity of structural critical parts, must be defined.*

12.35 Capturing and assessing data describing the actual condition of the aircraft structure is an essential aspect of ensuring the continued integrity of structural critical parts. This allows comparison of actual degradation / damage with that assumed and predicted during design. Capturing the data required to achieve this outcome requires a dedicated SCM system.

12.36 The system should be developed to suit each individual aircraft type, including the certification basis and design philosophy, structural maintenance regime and structure that must be monitored. The following considerations should be taken into account by applicants when defining SCM system:

(a) The system must have the ability to capture the necessary data for all structural critical parts and other significant structure. The definition for what constitutes other significant structure will vary by aircraft type. Other significant structure should be included, as unanticipated degradation or unforeseen failure modes to such structure may warrant re-classification as critical parts.

(b) The system must have the ability to capture the necessary data from production to disposal for each aircraft.

(c) The system must have the ability to capture all structural discrepancies and structural inspection results[11] for the defined scope of structure.

(d) The system must have the ability to capture all the information necessary to enable subsequent assessment to determine the root-cause of discrepancies and impact on continued structural integrity. This should be defined through detailed input data requirements, including data sources and the required fields. Types of information should include (at a minimum) details of the discrepancy, details of the asset, when and how the discrepancy was found, and disposition of discrepancy.

12.37 Compliance with this design requirement should be demonstrated through system definition document(s). These should also be included, either directly or via reference, in the ASIMP.

12.38 The following reference also provide useful information on SCM system requirements:

(a) MIL-STD-1530D Change 1 (Aircraft Structural Integrity Program), sections 5.4.6 and 5.5.12.

Periodic Structural Integrity Assessment

12.39 **Design Requirement (Essential).** *The process for periodic assessment, as necessary to ensure the continued integrity of structural critical parts, must be defined.*

12.40 Periodic structural integrity assessments ensure the MTC (including type design, AwLs and operating limitations) and Instructions for Continuing Airworthiness (ICA) remain compliant with the TCB, and therefore that the risk of structural failure remains within that inherent in the TCB. This is primarily achieved by ensuring the assumptions made during design and certification that could

Superseded

affect the integrity of structural critical parts remain valid in light of actual operational usage and condition.

12.41 The periodic assessment philosophy and details will vary significantly based on the aircraft type and role, anticipated operational variability, certification basis and design philosophy. The following considerations should be taken into account by applicants when defining the periodic structural integrity assessment process:

(a) The process must ensure that detailed and quantitative analysis will be conducted to compare actual ADF usage and condition to design assumptions to ensure that the MTC (including type design, AwLs and operating limitations) remain compliant with the TCB, and that all relevant ICA and monitoring provisions remain appropriate.

(b) The process must define the necessary assessment types and associated frequencies and / or triggers.

12.42 Compliance with this design requirement should be demonstrated by documentation that defines the assessment process. This should also be included, either directly or via reference, in the ASIMP.

12.43 The following reference also provide useful information related to periodic structural integrity assessment:

(a) MIL-STD-1530D Change 1 (Aircraft Structural Integrity Program), sections 5.5.3, 5.5.6, 5.5.7, 5.5.8[12] and 5.5.13.

Ageing Aircraft Structural Requirements

12.44 This is a placeholder for an anticipated Q4 2022 update to this chapter detailing DASA's design requirements related to the threats associated with ageing of aircraft structures.

Superseded

PROPULSION SYSTEMS

INTRODUCTION

13.1 This chapter provides airworthiness design requirements for Defence aircraft propulsion systems. This chapter is applicable to crewed aircraft and certified-category uncrewed aircraft. Within the context of the DASR and this chapter, DASA defines the aircraft propulsion system as including but not limited to the engine and propeller, including sub-systems, accessories and controls. For aircraft powered by reciprocating engines, auxiliary power units, or other turbomachinery, the applicant should seek DASA advice as to whether the content of this chapter is applicable. DASA advice should be sought as to the extent this chapter is applicable to:

(a) aircraft powered by reciprocating engines; or

(b) auxiliary power units and other turbomachinery.

13.2 This chapter is not applicable to propulsion systems fitted to munitions.

13.3 The airworthiness codes recognised by DASA (refer Section 1 Chapter 3) provide an appropriate benchmark for establishing and maintaining an adequate level of safety for aircraft propulsion systems. However, DASA has identified the following three circumstances where recognised airworthiness codes may require supplementation:

(a) Propulsion system environment requirements in some civil airworthiness codes are assessed as inadequate for the Defence CRE.

(b) Novel propulsion system configurations or technologies are used that may not be adequately covered by current recognised airworthiness codes.

(c) The nature of proposed military operations dictates the need for more complex and proactive in-service propulsion system integrity management (over and above that contained in some airworthiness codes) to ensure risk of failure remains within that inherent in the Type Certification Basis (TCB).

13.4 The requirements and associated discussion in this chapter are framed around these circumstances. When developing a certification basis for a Military Type Certificate (MTC), Major Change or Military Supplemental Type Certificate (MSTC), each applicant will need to assess the airworthiness design requirements inherent in the baseline Primary Certification Code (PCC) or standard and supplement or tailor, as required, using the requirements in this chapter. Applicants are highly encouraged to engage early with DASA as part of this process. Note that three likely scenarios exist for any given DASDRM requirement:

(a) Intent of DASDRM requirement is not met by any requirement in the underlying PCC / standard. In this case, the applicant would need to supplement the PCC / standard to add a new requirement.

(b) Intent of DASDRM requirement is partially met by an existing requirement in the underlying PCC / standard. In this case, the applicant may tailor the existing requirement so that it meets the full intent of the DASDRM requirement.

Superseded

(c) Intent of DASDRM requirement is fully met by an existing requirement in the PCC / standard. In this case, the applicant may propose to DASA that no supplementation or tailoring is required.

13.5 Separate to the DASA-prescribed airworthiness requirements under the DASR and DASDRM, it is Defence Policy[1] that each Defence-registered aircraft type have an effective and efficient Propulsion System Integrity Program (PSIP) to:

(a) ensure, so far as is reasonably practicable, that degradation of integrity does not present risks to health and safety

(b) contribute to delivery and assurance of capability

(c) support cost-effective sustainment of capability.

13.6 Under Defence Policy, the Defence-preferred approach for PSIP is alignment with MIL-STD-3024; a cradle-to-grave management framework for propulsion system integrity that encompasses system requirements, design, verification and sustainment. Despite the fact that the PSIP remit and objectives are broader than safety, an effective PSIP is key to supporting the essential design requirements set out in this chapter.

13.7 The PSIP for each aircraft type should be documented in a Propulsion System Integrity Management Plan (PSIMP). PSIMPs are key documents that assist applicants and the regulated community by maintaining a record of relevant propulsion system certification information and data, and demonstrate how the PSIP complies with the design requirements prescribed in this chapter and supports related DASR obligations[2].

PROPULSION SYSTEM TYPE CERTIFICATION

Propulsion System Type Certification Basis

13.8 **TCB Foundation.** As outlined above, the airworthiness codes recognised by DASA provide an appropriate benchmark for developing a TCB for aircraft propulsion systems, subject to supplementation and / or tailoring[3] to address the requirements provided in this chapter and any unique Defence CRE aspects.

13.9 For cases where Defence is acquiring a propulsion system where the baseline design requirements are not a recognised airworthiness code, then applicants are recommended to use the European Military Airworthiness Certification Criteria (EMACC) Handbook, in conjunction with this chapter, to develop and propose for Authority approval a comprehensive set of airworthiness design requirements for propulsion system certification. Applicants are highly encouraged to engage early with DASA if this is the case.

13.10 **Civil-Certified Propulsion Systems.** In some cases, additional design requirements, or additional compliance evidence for existing design requirements, may be required for civil-certified propulsion systems to account for the Defence CRE. For example, this could be applicable for military-specific configuration additions such as engine air particle separators, signature suppression systems or afterburner modules, and military-specific environments such as armament gas ingestion, armament vibration, military threats (e.g. electromagnetic or ballistic) and more severe sand, dust, corrosive and icing conditions.

Superseded

13.11 **Novel Propulsion System Technologies.** The aviation industry is actively pursuing novel propulsion system technologies such as distributed engine configurations, electric and electric-hybrid energy sources and adaptive-cycle turbine engines. Whilst the near-term intended applications for many of these novel technologies is the light and very light aircraft segments, novel technologies will inevitably be used in Defence aircraft. The current airworthiness codes recognised by DASA do not adequately address the full scope of design requirements that would be necessary to certify most of these novel technologies. Whilst some Authorities are working on special conditions, these are mostly for individual applications or may not cover the categories of aircraft that Defence may acquire.

13.12 Therefore, where a novel propulsion system technology is to be employed for a Defence aircraft, suitable design requirements must be identified and proposed to DASA for approval.

Compliance Demonstration and CRE Assessment

13.13 For propulsion system products and their respective systems integration aspects, Defence's type certification approach almost exclusively relies on fully or partially leveraging prior NAA/MAA certification. Performing a CRE Assessment (CREA) is an essential part of this process to ensure the prior certification is applicable for the Defence CRE and the design is safe for the intended Defence use.

13.14 Failure modes for propulsion systems (in particular fatigue) can be highly sensitive to small changes in usage, loads and environment. Therefore, CREAs for propulsion systems usually require detailed and quantitative analysis. Applicants for a MTC who are leveraging prior NAA/MAA certification should undertake an initial 'mission analysis'[4], as described below under the Ongoing Monitoring and Periodic Assessment section, in order to satisfy the propulsion system aspects of the CREA requirement (refer DASR GM 21.A.20).

Critical Parts and Airworthiness Limitations

13.15 The propulsion system critical parts and associated Airworthiness Limitations (AwLs), consistent with the TCB and the intended Defence CRE, must be identified during type certification (refer DASR AMC 21.A.41).

SUPPLEMENTARY PROPULSION SYSTEM DESIGN REQUIREMENTS

Critical Part Life Tracking

13.16 Variations in actual aircraft usage, environment and configuration can have a significant impact on when propulsion system critical part AwL actions (such as component retirement or inspections) need to be performed. This is especially the case for military operations where there is typically higher variability in mission profiles compared to the civil sector.

13.17 The airworthiness codes recognised by DASA vary in terms of life tracking requirements. For example, civil airworthiness codes require AwLs to be identified[5], however, they do not sufficiently address requirements for tracking life accrual necessary in the military context. DASA therefore prescribes the following essential airworthiness design requirement:

Superseded

13.18 **Design Requirement (Essential).** *The process for tracking life accrual of propulsion system critical parts shall be defined, commensurate with the complexity of the corresponding AwL requirements.*

13.19 AwLs include, and will define, the lifing metric(s) and any algorithm, equation, factor(s) or other engineering data, which must be used to calculate life accrual. The complexity of the process for tracking life accrual of propulsion system critical parts will vary based on the complexity of the AwL definition.

13.20 In many circumstances, the process for tracking life accrual of propulsion system critical parts will require a dedicated system. In this context, the 'system' will typically comprise on-board and off-board hardware and software for data recording, processing and analysis, as well as the associated procedures[6]. The philosophy and design of the system must be based on the: certification basis; the propulsion system type and role; the nature and definition for each AwL; anticipated operational variability (i.e. mission profile and mission mix variability) and uncertainty around ADF CRE. The following considerations should also be taken into account by applicants:

(a) The system must ensure that the accomplishment of AwL actions for individual components takes into account the applicable parameters that contribute to life degradation.

(b) The system must have the ability to capture the necessary input data from all ground and flight operations (including development and / or acceptance testing) from the entry into service through to the retirement of each engine or propeller.

(c) The system must have the ability to identify and appropriately account for any missing or invalid data.

(d) The system must have the ability to track critical part life accrual per individual component, per module or per engine as required. The level of tracking and serialisation fidelity must ensure that individual critical parts do not exceed the underlying basis of AwLs.

(e) Requirements must ensure the system will be validated prior to fielding. Validation should test the entire system (on-board and off-board elements) in an end-to-end fashion (i.e. from raw / input data through to the AwL lifing metric outputs). Validation should ensure that the specified system will produce reliable, repeatable and suitably conservative outputs so that AwLs are not exceeded in-service.

13.21 Compliance with this design requirement should be demonstrated through system validation / test report(s), and documentation that defines the process, and where relevant, the dedicated system. These should also be included, either directly or via reference, in the PSIMP.

13.22 Once in-service, the CAMO must maintain a record of the current status of service life limited components (i.e. track life accrual against AwLs to meet continuing airworthiness obligations - refer DASR M.A.305(d)(4)). Compliance with the essential design requirement above will ensure that the requirements and process for tracking life accrual of propulsion system critical parts are clearly defined up-front as part of type certification.

13.23 The following references also provide useful information on propulsion system life tracking requirements:

(a) MIL-HDBK-516C (Airworthiness Certification Criteria), section 7.2.3.6

(b) MIL-HDBK-1783B Change 2 (Engine Structural Integrity Program (ENSIP)), sections A.4.19, A.5.19.c and A.5.19.d.

Superseded

13.24 During design of a propulsion system, OEMs develop critical part AwLs based on predicted engine operation, material behaviour and environment. The OEM's design assumptions[7] are typically based on the intended aircraft role(s) and cannot always specifically account for each operator's individual usage, environment and configuration throughout the entire life-cycle of a propulsion system. This is especially the case for military operations as roles, tactics and operating environments for a given propulsion system can vary significantly between operators and evolve over time. For military aircraft, monitoring accrual of lifing parameters against AwLs alone is insufficient to ensure that engines continue to operate within the risk level inherent in the TCB.

13.25 The term 'mission analysis' is used to describe the process of:

(a) collection of parametric flight data needed to define the operating and environmental conditions that can impact propulsion system critical part AwLs,

(b) periodic assessment of this data to determine if the current critical part AwLs remain valid for the operator, and

(c) as required, calculation of new critical part AwLs based on updated design assumptions that reflect actual and anticipated usage and environment.

13.26 The airworthiness codes recognised by DASA vary in terms of requirements that meet the intent of mission analysis. DASA therefore prescribes the following essential airworthiness design requirement:

13.27 **Design Requirement (Essential).** *A plan for ongoing monitoring and periodic assessment (mission analysis), as necessary to ensure the continued integrity of propulsion system critical parts, shall be documented.*

13.28 The mission analysis philosophy and details will vary significantly based on the propulsion system type and role, anticipated operational variability, certification basis and design philosophy. The following considerations should be taken into account by applicants when documenting the mission analysis plan:

(a) The usage and environmental parameters that need to be monitored in-service, plus any other input data requirements, must be defined. Data requirements should be based on advice from the relevant OEM or organisation capable of conducting the mission analysis.

(b) System requirements must be established to enable collection of the required usage and environmental parameters. Note that there may be a high degree of commonality between the parameters and system required to collect data for mission analysis and that required for critical part life tracking. The system requirements should include mechanisms to ensure that the data collected is:

1. accurate and valid; and

2. representative of all ADF operations and environments (if the entire fleet is not going to be continuously monitored).

(c) The plan must ensure that detailed and quantitative analysis will be conducted to compare actual ADF usage and environment parameters to design assumptions and ensure that any impact(s) on critical part AwLs will be identified. For this reason, the conduct of mission

Superseded

analyses should be undertaken by the OEM, or an appropriately competent and experienced organisation with access to the necessary type design data.

(d) The plan must ensure that all propulsion system critical parts and all AwL aspects will be sufficiently covered, including mandatory life limits and inspection requirements, and any algorithm, equation, factor(s) or other engineering data that is used to calculate life accrual against AwL intervals.

(e) The plan must ensure that mission analysis outputs will either:

1. explicitly confirm that critical part AwLs remain appropriate for the Defence CRE and for preventing occurrence of hazardous propulsion system effects, or

2. as required, provide updated critical part AwLs (including any algorithm, equation, factor(s) or other engineering data to calculate life accrual) along with the substantiation necessary to approve the updated AwLs under DASR 21.

(f) The plan must document the organisational and contractual or international arrangements (including data sharing agreements) that are present to ensure that the plan is implementable.

(g) The plan must ensure that mission analyses will be conducted at a frequency that ensures the effective certified lives / intervals will not be exceeded, even in the case of a significant underestimation of actual usage severity. The frequency of routine mission analysis may need to vary throughout life of the aircraft based on CRE evolution, and dedicated mission analysis should be conducted whenever a significant CRE change is planned. Ongoing monitoring of usage and environment parameters should be conducted to identify any CRE changes that may trigger an amended mission analysis schedule.

13.29 Compliance with this requirement should be demonstrated by documentation that defines the mission analysis plan or statement of work. This should also be included, either directly or by reference, in the PSIMP.

13.30 Once in-service, the MTCH must ensure the continued integrity of the propulsion system through ongoing monitoring and periodic assessment (i.e. as a continued airworthiness obligation - refer DASR 21.A.44(c)). Compliance with the essential design requirement above will ensure that the plan for propulsion system ongoing monitoring and periodic assessment are clearly defined up-front as part of type certification.

13.31 The following references also provide useful information on propulsion system mission analysis (or equivalent terminology) requirements:

(a) MIL-STD-3024 Change 1 (Propulsion System Integrity Program (PSIP)), section 5.1.4.1.6

(b) MIL-HDBK-1783B Change 2 (Engine Structural Integrity Program (ENSIP)), sections A.4.19 and A.5.19.b

(c) EASA AMC E 515 (Engine Critical Parts), section 3(g)

(d) FAA AC 33.70-1 Change 1 (Guidance Material for Aircraft Engine Life Limited Parts Requirements), section 8.g.

Superseded

13.32 Further guidance on implementing the propulsion system requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

AIRBORNE LASERS

INTRODUCTION

14.1 Airborne lasers on Defence aircraft may present a hazard to the safe operation of the host aircraft if the laser is not integrated in a manner that prevents inadvertent exposure of aircrew/ occupants, or aircraft structure and systems, to laser emissions. Further, hazards to other airspace users or people on the ground may result from inappropriate laser design requirements that do not limit the potential for such exposure to occur. Where airborne lasers have a classification that presents personnel exposure hazards, or the laser design is such that contact with the laser beam or by-products of transmission could cause damage to the aircraft, compliance with appropriate design requirements assists to safely integrate the laser into a Defence aircraft. Not all of the Authority recognised Airworthiness Codes in Section 1 of the DASDRM prescribe requirements for the safe integration of airborne lasers. Consequently, the Authority prescribes laser safety, integration and operation design requirements to supplement the civil and military Codes.

Scope

14.2 This chapter of the DASDRM presents Authority prescribed design requirements for Defence aircraft airborne lasers that have the capacity to present a personnel exposure hazard, or pose a hazard to safe aircraft operations through laser beam contact with the aircraft or the generation of by-products.

AIRBORNE LASER DESIGN REQUIREMENTS

14.3 Laser systems fitted to Defence aircraft must not pose a hazard to safe operation of the aircraft through either exposure of aircrew or other aircraft occupants, inadvertent lasing of the aircraft or impact of laser by-products. This section presents the Authority prescribed laser system airworthiness design requirements for Defence aircraft.

Laser personnel safety

14.4 **Design requirement (Essential).** *Aircraft occupants must not be exposed to laser emissions that exceed the thresholds defined in AS/NZS IEC 60825.1 Safety of laser products - Part 1: Equipment classification and requirements.*

14.5 Laser emissions from Defence aircraft may pose hazards to personnel. Designers must ensure that Defence aircraft laser systems do not expose occupants to emission levels that exceed the thresholds defined for laser classifications in AS/NZS IEC 60825.1. Designers must also analyse emissions from Defence aircraft laser systems and establish appropriate safe distances to ensure that persons outside the aircraft are not exposed to emission levels that exceed the safe thresholds and to identify appropriate personnel protective measures where required.

Superseded

14.6 **Design requirement (Essential).** *Defence aircraft lasers must be 'certified' in accordance with the Defence Radiation Safety Manual Chapter 6.*

14.7 Laser certification per the Defence Radiation Safety Manual, Chapter 6, ensures the safe operation of lasers through establishing the applicable laser classification, and the resultant approach to management of associated hazards and risks.

Laser/airframe integration

14.8 **Design requirement (Essential).** *Laser systems must not:*

(a) *induce vibration, acoustic, thermal or structural loads that exceed aircraft limitations*

(b) *create a safety of flight hazard due to chemical by-products and exhaust gasses generated during laser operations.*

14.9 **Design requirement (Essential).** *The laser beam must not contact any part of the aircraft.*

14.10 Laser operation compatibility should be verified by analyses (e.g. structural, stress, mechanical load, electrical load, acoustical), explosive environment test and ground and flight demonstrations/tests. Exhaust gases or chemicals produced by laser operation must not exceed the concentrations defined as safe minimum values in any part of the aircraft or attached structures/ pods. Inadvertent contact with the airframe by either laser by-products or the laser beam may cause damage to critical airframe components. The laser software and/or hardware inhibitor (laser masking) controlling the laser field of regard must be designed so that the beam will not strike any part of the aircraft or any peripherals (i.e. stores, sensors and so on). Laser energy must not be reflected back into the eyes of the pilot, operator, crew, or personnel off any part of the aircraft during laser operations.

Laser operation

14.11 **Design requirement (Essential).** *Airborne laser installations must:*

(a) *only allow operation and direction of the laser beam by the crew (and maintenance personnel)*

(b) *not result in an unsafe (radiating) condition following failure or malfunction*

(c) *allow the crew (and maintenance personnel) to determine when the laser is functioning and to discern the direction of the beam.*

14.12 **Design requirement (Essential).** *The laser system must not be capable of inadvertent lasing when the aircraft is on the ground.*

14.13 Positive control of laser system operation must be provided to the crew (and maintenance personnel) to prevent inadvertent or unintentional operations of the laser during critical flight phases. The laser must be boresighted to the prescribed alignment limit, the sighting display must accurately point the laser to within prescribed limits and the aircraft and/or control station display must indicate clearly when and where the laser is firing. The laser system design must permit the crew or operator to maintain full control of the firing and pointing of the laser at all times. The laser must not fire unless activated by the crew or operator and immediately cease firing at a command from the crew, operator, or by system design. The laser must be controlled during ground operations to preclude inadvertent laser firing. Methods for preventing inadvertent laser firing include, but are not limited

Superseded

to, procedures for ground crew, redundant hardware (e.g. interlocks, interlock switches/weight on wheels), and software (e.g. armament, sensor).

Superseded

INDICATING SYSTEMS

INTRODUCTION

15.1 Aircraft indicating systems provide information to aircrew on the condition of aircraft systems and equipment, the aircraft's flight status and other parameters necessary for safe aircraft operation, and/or to maintain adequate situational awareness. The Authority recognised Airworthiness Codes defined in Section 1 of this manual prescribe requirements for aircraft indicating systems. However, Defence aircraft can utilise indicating systems, such as helmet mounted displays, that are not used in civil aircraft and represent relatively recent advancements in military aircraft technology. Consequently, the civil and military Airworthiness Codes may not prescribe requirements for these systems. Therefore, the Authority prescribes airworthiness design requirements for indicating systems, to supplement the civil and military Airworthiness Codes.

Scope

15.2 This Chapter presents Authority prescribed airworthiness design requirements for Defence aircraft indicating systems.

DEFENCE AIRCRAFT INDICATING SYSTEMS DESIGN REQUIREMENTS

15.3 Defence aircraft indicating systems must conform to standards appropriate to the functions that the instrument or display will perform. Authority recognised civil and military Airworthiness Codes prescribe design requirements that provide a sound foundation for the safe design of common Defence aircraft indicating systems (including those used as a Primary Flight Reference (PFR)). However, indicating systems that are in the early stages of technology development may be proposed for fitment to Defence aircraft to satisfy a capability need and design requirements for such systems may not have been prescribed in Authority recognised Airworthiness Codes. Consequently, applicants for an Australian MTC or MSTC must propose, for Authority approval, airworthiness design requirements based on the intended function and operation of the indicating system.

15.4 **Design Requirement (Essential).** *Where a novel indicating system for which design requirements are not prescribed in Authority recognised Airworthiness Codes is intended for use in a Defence aircraft, airworthiness design requirements for the indicating system must be identified, and proposed for Authority approval.*

15.5 Indicating systems are used for a wide variety of purposes ranging from those having no safety implications to those directly affecting safe flight. The proposed use of novel indicating systems must be clearly understood in order to define suitable design requirements. For example, novel indicating systems may be used to display information to the crew that:

(a) enhances situational awareness or represents mission system status or performance, where the loss or presentation of misleading information does not impact safe flight;

(b) could pose a hazard to safe flight if misleading information was presented to the crew; or

Superseded

(c) represents PFR information.

15.6 For those displays providing mission system status/performance or situational awareness information that does not impact safe flight if the information is lost or is misleading, failure of the equipment/system must not adversely impact other display system functions that present information necessary for safe flight. In these circumstances, the indicating system design requirements need only confirm that the system does not adversely affect other aircraft systems necessary for safe flight.

15.7 Where the presentation of misleading information may pose a hazard to safe flight in a novel display system (eg display of weapons system radar data on a HUD for weather avoidance), an additional level of data assurance is required, commensurate with the impact of the misleading data on safe operations. In these circumstances, the application of design requirements from the Authority recognised Codes for display systems having similar characteristics may be a suitable starting point, but is likely to require supplementation to account for the system's novel features or approach to displaying information.

15.8 The presentation of reliable and accurate PFR information is particularly important due to the data's criticality to safe aircraft operations. Such applications may not be adequately catered for by 'standard' indicating system design requirements prescribed in Authority recognised Codes, and additional design requirements are often necessary to provide the required level of design assurance for these systems. For example, helmet mounted displays (HMD) may provide both flight reference and mission systems information overlayed on the pilot's field of view. Where a HMD is required to function as a PFR, it must satisfy the applicable design requirements prescribed in civil and military Airworthiness Codes as a minimum. However, some unique features of HMD may pose hazards associated with the human machine interface that are not relevant to other types of displays (eg visibility of key flight data at all times may be problematic during head movement). These characteristics may not be adequately accounted for in Authority recognised Airworthiness Codes.

15.9 Where a novel application of an existing indicating system is proposed, airworthiness design requirements must be identified and proposed to the Authority for approval.

ADDITIONAL INDICATING SYSTEMS GUIDANCE

15.10 Further guidance on implementing the indicating systems design requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

SECTION 4 - UNCREWED AIRCRAFT DESIGN REQUIREMENTS

CHAPTER 1 - APPLICATION OF DESIGN REQUIREMENTS TO UAS

APPLICATION OF DESIGN REQUIREMENTS TO UAS

INTRODUCTION

1.1 Defence's regulations for Uncrewed Aircraft Systems (UAS), prescribed within DASR UAS, include three categories of UAS. Only two of these categories relate to the content within Section 4, namely:

(a) **Certified:** Intended for UAS operations where the UAS Operator expects to operate in all classes of airspace for which it is equipped, and over populous areas.

(b) **Specific:** Intended for UAS operations where the UAS is not certified to robust airworthiness standards. Consequently, increased operational limitations and use of risk controls provide for safe UAS operation.

1.2 As stated in Section 1 Chapter 1, the DASDRM prescribes design requirements for aircraft systems and functions that are necessary to achieve safe flight in Defence's proposed configuration, role and operating environment. This sets the scene for Sections 2 and 3 which prescribe additional design requirements particularly aimed at crewed aircraft. However, the UAS context can be somewhat different to crewed aircraft and must be accounted for before these requirements can be applied. The UAS context differences fall into two broad categories:

(a) **Absence of on-board crew.** Crewed aircraft design requirements may contain inherent assumptions that are not valid or appropriate for UAS. For example, Section 2 Chapter 7 Fire Protection includes visual monitoring and smell as legitimate indirect means for fire detection onboard an aircraft. The assumption here is that a crew is onboard the aircraft and will perform certain actions.

(b) **Shifted safety focus.** Crewed aircraft design requirements prescribed in Sections 1 – 3 are predominantly focused on 'safe flight' from the perspective of keeping the aircraft occupants alive, be they crew or passengers. Presently, UAS do not carry passengers or crew therefore 'safe flight' from the perspective of UAS occupants can be discounted. Rather, UAS 'safe flight' occurs when the risk to other airspace users, people on the ground, and critical infrastructure are suitably minimised.

1.3 With the above UAS context in mind, Section 4 presents design requirements for UAS by tailoring requirements in Sections 1-3, or prescribing bespoke UAS design requirements.

1.4 **Nomenclature.** UAS nomenclature varies widely between standards bodies, UAS associations, Aviation Authorities, and even within Defence itself. This chapter employs the UAS nomenclature from ICAO Doc 10019, Manual on Remotely Piloted Aircraft Systems (RPAS), since this will promote nomenclature compatibility with major international Aviation Authorities.

Superseded

1.5 Chapter 2 presents recognised Airworthiness Codes and design requirements for Certified category UAS. Chapter 3 presents criteria for determining the robustness of technical risk controls that can be applied to Specific category UAS.

1.6 Open category UAS, which must operate within Standard Operating Conditions, are not discussed in this manual on the basis of the Authority's assumption that these UAS have no design integrity. Therefore, the safety of Open category UAS operations is reliant primarily on operational risk controls.

Superseded

CERTIFIED CATEGORY UAS

INTRODUCTION

2.1 Certified category Uncrewed Aircraft Systems (UAS) are expected to operate in all classes of airspace for which they are equipped, and over all populous areas. Under such circumstances, certain failures of a Certified category UAS will lead to an increased likelihood of a mid-air collision with other airspace users, serious or fatal injury to people on the ground, or significant damage to critical infrastructure. To account for this, the Authority's approach to initial airworthiness for Certified category UAS is analogous to that adopted for crewed aircraft.

Scope

2.2 This chapter guides applicants in developing a Type Certification Basis (TCB) for a candidate Certified category UAS by prescribing design requirements for a fixed wing Uncrewed Aircraft (UA), be it a Remotely Piloted Aircraft (RPA) or one that flies autonomously, the Remote Pilot Station (RPS), and Command and Control (C2) link(s). Should other components of the UAS be shown by a Functional Hazard Assessment to make a direct contribution to airworthiness, then additional design requirements will be prescribed by the Authority.

RECOGNISED UAS AIRWORTHINESS CODE

2.3 DASDRM Section 1 Chapter 3 articulates the need for robust airworthiness design requirements, usually documented in an Airworthiness Code, to underpin the safe design of Defence crewed aircraft. This need is equally applicable to Certified category UAS.

2.4 The Authority recognises NATO STANAG 4671, Uncrewed Aircraft System Airworthiness Requirements, Edition 3, as an acceptable Airworthiness Code for fixed-wing UAS, provided it is supplemented with the design requirements defined in this chapter. STANAG 4671 was derived from EASA's Certification Specification (CS) 23 for small fixed wing aircraft, and has been accepted as a sufficient UAS Airworthiness Code by Military Airworthiness Authorities (MAAs) of NATO countries, albeit with some reservations.

2.5 The Authority notes that, circa 2021, STANAG 4671 has not yet been well exercised by UAS designers and MAAs, and therefore lacks a proven safety record. It has, however, undergone many years of review by international subject matter experts, and has a sound genesis in EASA's CS-23, and therefore presents a sufficient basis for a Defence Type Certification program provided Defence's design or acquisition organisations remain vigilant for deficiencies in the STANAG when comparing the STANAG's operating context to Defence's unique Configuration, Role, and operating Environment (CRE). Critically, these organisations must ensure a robust system safety program is implemented to identify and address UAS-unique hazards. Furthermore, throughout the life of the platform, continued vigilance will be required to identify early indicators that assumptions are not entirely valid, referenced design standards are not entirely effective, or additional hazards exist that weren't previously considered.

Superseded

2.6 STANAG 4671 assumes a particular context of use for the UAS. This is partly driven by its civil CS-23 genesis and partly by the scope of operations agreed by the STANAG sponsors. For the STANAG to be safely applied to a Defence UAS, the operating context needs to be fully understood, and any limitations addressed where necessary.

2.7 Relevant to what Defence normally considers to be within the scope of 'initial airworthiness' (and therefore requiring coverage in the TCB), STANAG 4671 specifically does not cover:

(a) airspace navigation, integration and segregation requirements (including "sense and avoid")

(b) the type of UAS operation (i.e. the specific military role and operating environment for the UAS)

(c) carriage and release of weapons, pyrotechnics and other functioning or non-functioning stores designed for release during normal operations

(d) non-deterministic flight, in the sense that UA flight profiles are not pre-determined or UA actions are not predictable to the UA crew

(e) piloting from an external or internal control box

(f) supersonic flight

(g) cyber security

(h) engines and propellers

(i) lithium batteries.

2.8 STANAG 4671 also does not cover the following design elements that can affect flight safety, but are not normally covered in TCBs for Defence crewed aircraft:

(a) control station security

(b) security of the command and control data link from wilful interference

(c) frequency spectrum allocation.

2.9 Design requirements for each paragraph 2.7 element are presented in this chapter. While design requirements are not presented for the paragraph 2.8 elements (which normally would not be included in a Defence TCB), Defence's design or acquisition organisations would still be expected to ensure they are robustly addressed.

2.10 This chapter also assumes the UA is not optionally piloted, nor will it carry passengers. A pervasive assumption within STANAG 4671 Edition 3 is that the UA is always uncrewed, and it is impractical to reverse this assumption. Where crew or passenger carriage is required, the Authority would expect a crewed aircraft Airworthiness Code to be used, supplemented to account for the unique UAS context.

2.11 Finally, both STANAG 4671 and this chapter inherently assume the UAS design, role and operating environment will not be excessively novel. However, cognisant of the rapidly evolving nature of UAS designs and their military use, this assumption may not always hold true. Depending on the issue, it may be possible to expand the System Safety Program to identify and manage the

Superseded

resulting unique safety hazards. In other cases, however, the Authority may conclude that STANAG 4671 provides an insufficient basis for a safe UAS design.

2.12 The following sections identify supplementation for STANAG 4671 Edition 3, separated into 'integrated' and 'system' design requirements, aligned respectively to Sections 2 and 3 of this manual.

UAS INTEGRATED DESIGN REQUIREMENTS

2.13 Section 2 of this manual covers engineering disciplines associated with crewed aircraft design that affect multiple aircraft systems or have an impact on most aspects of an aircraft's design. This part of the chapter covers a similar scope, and leverages extensively off Section 2.

2.14 Importantly, Section 2 assumes an Authority-recognised Airworthiness Code underpins the design. Each of the Essential and Recommended design requirements in Section 2 supplement the selected Airworthiness Code, where an aspect of a requirement is judged deficient or to support application to Defence's unique role and operating environment. Unsurprisingly, those same issues will normally be equally relevant to a UAS underpinned by the STANAG 4671 Airworthiness Code, although in some instances the unique UAS context may add or remove some requirements.

System Safety

2.15 STANAG 4671 Edition 3 requires a UAS be designed to reduce risk to a level acceptable to the Certifying Authority, demonstrated through a system safety program that is a core aspect of any given design program (or design change). Cognisant of the significant variations in system safety approaches permitted by international MAAs, Section 2 Chapter 2 presents the Authority prescribed system safety design requirements for crewed aircraft. The essential design requirements in Section 2 Chapter 2 are equally applicable to design activities conducted for new Certified UAS and subsequent design changes, tailored as follows:

(a) Essential requirement 2.15 (single-point failures) is only applicable to Catastrophic consequences for UAS using STANAG 4671 Edition 3 consequence definitions.

(b) UAS using STANAG 4671 Edition 3 Development Assurance Levels and Design Assurance Levels do not need further supplementation through essential requirement 2.30 (software and complex electronic hardware).

2.16 Importantly, STANAG 4671 Edition 3 requires that any special military airworthiness requirements that result in an actual or potential hazard condition that reduces the margin of safety below the levels required by STANAG 4671 Edition 3 paragraph 1309 and its associated Acceptable Means of Compliance (AMC), whether temporary or permanent, will be addressed by suitable operational restrictions.

Aviation Software

2.17 STANAG 4671 Edition 3 requires that software satisfies applicable Design Assurance Levels. In addition to the STANAG 4671 Edition 3 requirements, the Authority guidance and prescribed supplementary aviation software design requirements in Section 2 Chapter 3 are equally applicable to a Certified UAS design.

Superseded

Electromagnetic Environmental Effects

2.18 While STANAG 4671 Edition 3 includes Electromagnetic Environmental Effects (E3) requirements, Australian legislation and Defence Policy, and Defence's intended CRE, necessitate supplementation to the TCB. Section 2 Chapter 4 presents the Authority prescribed design requirements for E3 that are equally applicable to design activities conducted for new Certified UAS and subsequent design changes, tailored as follows:

(a) Essential requirement 4.24 (aircraft occupants) is not applicable to the UA. It is, however, applicable to the occupants of the RPS as C2 link equipment may be located near to or integrated with the RPS.

2.19 Unlike certain crewed aircraft airworthiness design requirements and standards, STANAG 4671 Edition 3 does not include requirements to maintain the E3 hardness levels established by the initial design. Recommended requirement 4.31 (E3 life cycle hardness) seeks to address this by recommending applicants follow the guidance in MIL-STD-464C when determining if additional Instructions for Continuing Airworthiness (ICA) need to be developed. However, note that this recommended 'design requirement' is focused on ICA development rather than E3 design, therefore it does not need to be included in a TCB.

Human Factors Engineering

2.20 STANAG 4671 Edition 3 requires human factors be considered when evaluating failure conditions, however, there is limited guidance material in the STANAG on this crucial engineering discipline. The Authority's guidance and supplementary design requirements for human factors have been collated in Section 2 Chapter 5 and are equally applicable to a Certified UAS design.

Equipment Environmental Qualification

2.21 STANAG 4671 Edition 3 provides equipment environmental qualification design requirements based on a nominal operating environment. Historically, Defence's expected operating environment has often exceeded these nominal requirements. Consequently, the Authority has prescribed equipment environmental qualification design requirements in Section 2 Chapter 9 that are equally applicable to a Certified UAS design.

Aircraft/Stores Compatibility

2.22 STANAG 4671 Edition 3 does not cover UAS designs that allow the carriage and release of aircraft stores. Consequently, the Authority prescribed aircraft/stores compatibility design requirements in Section 2 Chapter 11 are relevant to a Certified UAS design. In applying these design requirements, designers must remain cognisant that for crewed aircraft, the presence of an on-board pilot may be an assumed risk control for a variety of stores-related hazards considered during a system safety program, such as confirmation of safe store carriage/separation through visual means or by on-board indicating systems not subject to datalink uncertainties. Therefore, the demonstration of compliance to Section 2 Chapter 11 requirements must not rely on indications normally received by, or actions performed by, an on-board pilot.

2.23 In complying with the system safety requirements discussed earlier in this chapter, consideration should be given to aircraft/stores compatibility safety hazards that, whilst not always

Superseded

UAS-unique, may create risks of greater likelihood than when those hazards apply to crewed aircraft. In particular, consideration should be given to the:

(a) unavailability of an on-board pilot to identify problems, either visually or through vibration, with uncommanded stores separations, hung stores, UA/stores contact during separation, stores failing to separate or fire when commanded, and damage from bird strikes and lightning strikes

(b) need for additional independent weapon release safety interlocks to account for problems with datalink availability, latency and corruption

(c) need for stores, especially weapons, to transition to a predetermined safe state during lost-link conditions

(d) prevention of unintended weapon arming caused by problems with datalink corruption

(e) means to make armed weapons safe when experiencing problems with datalink availability and corruption

(f) ability of the RP to identify stores' (especially weapons) status when faced with problems with datalink availability, latency and corruption.

2.24 **Design Requirement (Essential).** *Where the UA is to carry and release aircraft stores, the UAS system safety program must account for the lack of an on-board pilot.*

2.25 **Post store separation safety.** The inability to provide effective stores targeting creates safety hazards to the general public either near the stores' flight path or the stores' target area. For crewed aircraft, systems for targeting stores are not subject to datalink uncertainties and the on-board pilot may provide additional risk controls when the target area is visible. To ensure that UAS stores targeting is as effectively performed as for crewed aircraft, consideration should be given during UAS design to the:

(a) unavailability of an on-board pilot to identify problems with weapons targeting, either visually or through vibration, with uncommanded stores separations and UA/stores contact during separation

(b) adequacy of low-integrity GPS systems for weapons targeting in the absence of the visual observation of the target area

(c) problems with weapon targeting created by datalink availability, latency and corruption.

2.26 **Capability Design Requirement.** *Where the UA is to carry and release aircraft stores, the UAS design must consider the hazards to timely and accurate stores targeting created by the lack of an on-board pilot, use of low-integrity GPS systems, as well as datalink availability, latency and corruption.*

Cyber security considerations

2.27 Like most crewed aircraft Airworthiness Codes, STANAG 4671 Edition 3 does not contain cyber security design requirements. For UAS this omission may present an additional risk, given the dislocated nature of the RPS from the UA (which can remove a layer of protection against wilful interference), and the extent of UA control accessible via the C2 link. Consequently, the Authority prescribed cyber security design requirements in Section 2 Chapter 12 are equally applicable to a Certified UAS design.

Superseded

2.28 Where cyber security is identified as a credible threat to aviation safety, in-service management arrangements must also be identified and implemented to maintain the cyber security integrity and minimise risks throughout the UAS life of type.

UAS SYSTEM DESIGN REQUIREMENTS

Introduction

2.29 Section 3 of this manual covers systems on Defence aircraft for which the Authority has historically found Airworthiness Codes to be inadequate for Defence's intended CRE. This part of the chapter covers a similar scope, and leverages extensively off Section 3.

2.30 As with Section 2, Section 3 also assumes an Authority-recognised Airworthiness Code underpins the design and integration of the system onto a Defence aircraft. Each of the Essential and Recommended design requirements in Section 3 supplement the selected Airworthiness Code, where an aspect of a requirement is judged deficient or to support application to Defence's unique role and operating environment. Those same issues will normally be equally relevant to a UAS underpinned by the STANAG 4671 Airworthiness Code, although in some instances the unique UAS context may add or remove some requirements.

Communications Systems

2.31 STANAG 4671 Edition 3 does not prescribe design requirements for the communication systems needed for operations in particular classes of airspace. The design requirements in Section 3 Chapter 2 relevant to the intended classes of airspace are equally applicable to a Certified UAS design.

Flight Recorder and Locating Equipment

2.32 While STANAG 4671 Edition 3 prescribes design requirements for flight recorders and locating equipment, some requirements are open to negotiation with the Certifying Authority and the associated guidance material is generally limited. All essential design requirements in Section 3 Chapter 3 apply to a Certified UAS, but tailored as follows:

(a) Essential requirement 3.6 (flight recorders) is applicable to the UA.

(b) Essential requirement 3.11 (flight recorder power) is not applicable to UAS based on STANAG 4671 Edition 3 as it duplicates the requirements contained in USAR.1459.

(c) Essential requirement 3.16 (Emergency Locator Transmitter) is not applicable to UAS. An Emergency Locator Transmitter's primary purpose is to assist search and rescue to locate a crashed aircraft and provide aid to aircraft occupants as quickly as possible, thus increasing their chances of surviving an accident. Given that Authority prescription of UAS design requirements assumes the UA will not carry any crew or passengers, there is no impetus to carry an ELT. However, Command may choose to require the fitment of an emergency beacon to aid with the recovery of the UA, but this would be determined on the capability need rather than as an 'airworthiness' requirement.

2.33 For crewed aircraft, the placement of flight recorder equipment on-board the aircraft is a logical and practical design solution. For UAS however, the situation is not always as clear. In general, a UAS will have two locations where flight recorder equipment may be fitted; the UA and the RPS.

Superseded

These two locations are connected by a C2 link that can be lost or become degraded during operations. In keeping with crewed aviation principles, the Authority prescribes that flight recorder equipment be fitted on-board the UA as this provides the best opportunity to record all necessary information when the C2 link is lost or degraded. However, there is a view forming worldwide that flight recorder equipment should also be fitted to the RPS to provide complete coverage. While it may be possible to fit flight recorder equipment to the RPS alone and record information via the C2 link, this carries the risk that key information may not be recorded once the C2 link is lost or degraded, or that bandwidth limitations may restrict the information passed to the RPS from the UA. Applicants wishing to explore RPS only design solutions will need to approach the Authority to determine if their proposal will be accepted.

2.34 Finally, while not for inclusion in a TCB, the continuing airworthiness requirements listed in Section 3 Chapter 3 for flight recorder equipment and Emergency Locator Transmitters (where fitted) are equally applicable to Certified UAS.

Navigation Systems

2.35 STANAG 4671 Edition 3 does not prescribe design requirements for navigation systems. Defence UAS can operate in a global airspace environment that includes civil airspace that is subject to prescribed access criteria and adherence to specific Rules of the Air. While International Civil Aviation Organisation (ICAO) rules for civil aviation are not applicable to State registered aircraft, Defence UAS not capable of similar navigation performance to civil aircraft may be subject to civil airspace restrictions and sub-optimal routing. Consequently, the Authority's guidance and supplementary design requirements for navigation systems in Section 3 Chapter 4 are equally applicable to a Certified UAS design.

2.36 Several of the standards in Section 3 Chapter 4 inherently assume the pilot will be on-board the aircraft. In demonstrating compliance to those standards, the unique UAS context where the pilot is separated from the aircraft must be fully accounted for.

Surveillance and Avoidance Systems

2.37 STANAG 4671 Edition 3 does not include design requirements for surveillance and avoidance systems required for airspace integration and aircraft safe separation. While Defence UAS without surveillance and avoidance systems may not necessarily be precluded from operations in civil airspace, without the fitment of such systems sub-optimal routes and additional risk controls may be imposed. In extreme cases, Due Regard operations may end up being the only avenue for Defence to access certain airspace. Therefore, fitment of surveillance and avoidance systems in Defence UAS is, ultimately, a capability decision for the capability manager. The Authority's guidance and supplementary design requirements for surveillance and avoidance systems have been collated in Section 3 Chapter 5 and are equally applicable to a Certified UAS design.

2.38 The lack of on-board crew presents a number of unique challenges for UAS operating in uncontrolled airspace where the ability to 'see and avoid' (also commonly termed 'detect and avoid' when used in the UAS context) other aircraft is a key airspace entry requirement. Several technological solutions are in development worldwide that aim to provide UAS with the ability to detect and avoid other aircraft. STANAG 4671 Edition 3 does not cover 'detect and avoid' designs and the Authority is yet to prescribe associated design requirements. Additionally, care must be taken when considering existing crewed aircraft collision avoidance systems, such as TCAS II, as the underlying algorithms may be based on a defined set of aircraft dynamics that may or may not be

Superseded

applicable to either the UAS or the encounter traffic. It is also worth noting that a 'detect and avoid' system installed onto a UAS would be an item of installed equipment and would need to comply with all relevant STANAG 4671 Edition 3 requirements.

2.39 **Design Requirement (Essential).** *Where a detect and avoid capability is required for airspace access, design requirements for detect and avoid systems must be identified and proposed for Authority approval.*

Lighting Systems

2.40 STANAG 4671 Edition 3 lighting system design requirements may not account for certain military operations, such as external lighting to support air-air refuelling or formation flight. The Authority's guidance and supplementary design requirements for lighting systems in Section 3 Chapter 7 are equally applicable to a Certified UAS design.

Electrical Systems

2.41 Defence experience with electrical systems has shown that simple application of Airworthiness Codes may still pose hazards to safe aircraft operations in Defence's unique CRE, and this is equally relevant to STANAG 4671 Edition 3. All essential design requirements in Section 3 Chapter 8 therefore apply to a Certified UAS, but tailored as follows:

(a) Essential requirement 8.11 (Wiring with PVC) is only a recommended requirement for UAS based on STANAG 4671 Edition 3. Polyvinyl chloride (PVC) releases hydrogen chloride gas when burnt or subject to high temperatures, which transforms into hydrochloric acid on contact with moisture causing sight and breathing impairment. While there are no crew or passengers on-board a STANAG 4671 Edition 3 based UA, designers should confirm the presence of hydrochloric acid generated from electrical system faults will not cause secondary failure modes or longer-term UA degradation.

Environmental Control Systems

2.42 Defence experience with Environmental Control Systems (ECS) has shown that simple application of Airworthiness Codes may not adequately account for the Australian operating environment, particularly where ground operations in harsh environmental conditions are expected, and for some military loads and mission systems. This is equally relevant to STANAG 4671 Edition 3. The Authority's guidance and supplementary design requirements for ECS in Section 3 Chapter 9 are therefore equally applicable to a Certified UAS design.

Aircraft Structural Integrity

2.43 STANAG 4671 Edition 3 does not prescribe an Aircraft Structural Integrity Program be developed for UA. Defence experience is that effective and efficient management of structural integrity is required to ensure ongoing airworthiness, and to preserve the asset to its Planned Withdrawal Date (PWD). The Authority's guidance and supplementary design requirements for aircraft structural integrity in Section 3 Chapter 12 are equally applicable to a Certified UAS design.

Superseded

Propulsion Systems

2.44 STANAG 4671 Edition 3 does not cover engine and propeller design, so bespoke design requirements need to be included in the TCB for the UAS. While an Authority recognised Airworthiness Code for engines and propellers provides a sound basis for these design requirements, from a safety perspective some elements may be excessive and/or insufficient. For example, given the STANAG assumes flight profiles similar to that of General Aviation, UAS designed to perform certain military flight profiles, such as aerobatics or carriage and release of stores, may necessitate additional supplementation to or tailoring of the recognised Airworthiness Code. Additionally, due to the absence of on-board crew and/or passengers, a UA engine failure may not constitute a catastrophic hazard, potentially allowing some relaxation of engine design goals. Conversely, engine design requirements for crewed aircraft may implicitly expect certain observations and actions by on-board crew, and these need to be accounted for in the UAS system safety program.

2.45 Accordingly, while the Authority's guidance and supplementary design requirements in Section 3 Chapter 13 are applicable to a Certified UAS design, there may be room for judicious tailoring or a need for further supplementation.

2.46 **Design Requirement (Essential).** *A relevant Authority-recognised engine Airworthiness Code is to be used for UA engine design, with tailoring and additional requirements identified as necessary, and proposed for Authority approval.*

2.47 **Design Requirement (Essential).** *A relevant Authority-recognised propeller Airworthiness Code is to be used for UA propeller design, with tailoring and additional requirements identified as necessary, and proposed for Authority approval.*

2.48 As UAS designs are still evolving worldwide, novel forms of propulsion will inevitably emerge. Certified UAS employing novel forms of propulsion designs will require the development and inclusion of suitable design requirements.

2.49 **Design Requirement (Essential).** *Where a novel form of propulsion is to be employed, design requirements must be identified and proposed for Authority approval.*

Airborne Lasers

2.50 STANAG 4671 Edition 3 does not include design requirements for airborne lasers that have the capacity to present a personnel exposure hazard, or pose a hazard to safe aircraft operations through laser beam contact with the aircraft or the generation of by-products. All essential design requirements in Section 3 Chapter 14 are equally applicable to a Certified UAS, but tailored as follows:

(a) Essential requirement 14.4 (Aircraft occupant exposure) is not applicable to UAS as there will not be any UA occupants.

(b) Essential requirement 14.8.B (chemical by-products/exhaust gasses) is not applicable to UAS. However, while not an airworthiness issue, designers still have a WHS duty to ensure lingering chemical by-products or exhaust gasses do not pose a hazard to maintenance personnel.

Superseded

Indicating Systems

2.51 As UAS designs are still evolving worldwide, novel forms of indicating systems may emerge. The Authority's guidance and supplementary design requirements for novel indicating systems in Section 3 Chapter 15 are equally applicable to a Certified UAS design.

EMERGING UAS CONSIDERATIONS

Introduction

2.52 STANAG 4671 assumes a particular context of UAS use. Over time, emerging technologies, threats and UAS missions may exceed that context of use. Several potential future issues have been identified in this section, along with Authority-prescribed design requirements. Where these issues are shown to have an effect on airworthiness, the Authority may approve the inclusion of the design requirements into the TCB for the UAS.

Non-deterministic flight

2.53 STANAG 4671 Edition 3 makes provision for automated contingency flight logic and criteria, as the behaviour has generally been pre-programmed for each mission and the resultant actions are predictable. However, STANAG 4671 Edition 3 does not cover 'non-deterministic flight', in the sense that the aircraft's flight profiles are not pre-determined or its actions are not predictable to the Remote Pilot (RP) or Air Traffic Control. Supplementation will therefore be required for Certified UAS that can perform non-deterministic operations. This supplementation need only cover the non-deterministic aspects that have a direct and potentially negative impact on airworthiness.

2.54 **Design Requirement (Essential).** *Where a UAS design will implement a capacity for non-deterministic operation, design requirements must be identified and proposed for Authority approval.*

Unconventional launch and recovery methods

2.55 STANAG 4671 Edition 3 assumes that 'conventional' take-off and landing on paved runways will be utilised by the UA. Where unconventional means of UA launch and/or recovery are to be employed, supplementation to STANAG 4671 Edition 3 may be required. Any supplementation will be limited to those issues where a direct link to aviation safety can be established. For example, a Rocket Assisted Take-Off (RATO) may impose additional airframe stresses, and these must be accounted for in the airframe design. Novel recovery designs may need to account for incorrect operation of the capture mechanism, additional ICA may be required, and so on.

2.56 **Design Requirement (Essential).** *Where unconventional launch and/or recovery is to be employed, design requirements must be identified and proposed for Authority approval.*

Supersonic flight

2.57 STANAG 4671 Edition 3 does not cover supersonic flight profiles and related design considerations. Supersonic flight will require supplementation to STANAG 4671 Edition 3.

Superseded

2.58 **Design Requirement (Essential).** *Where supersonic flight is required, design requirements must be identified and proposed for Authority approval.*

Manual operator control during normal flight operations

2.59 STANAG 4671 Edition 3 excludes UAS designs where a RP must manually control pitch, roll, yaw and/or thrust as part of normal flight operations, which it refers to as “piloting from an external or internal control box”. Supplementation to STANAG 4671 Edition 3 will be required if this method of UA control is to be employed, to account for issues such as the lack of visual cues and haptic feedback an on-board pilot would have received, control latency due to the dislocated state of the RPS and UA, and the potential for a lost or degraded C2 link.

2.60 **Design Requirement (Essential).** *Where manual control of pitch, roll, yaw and/or thrust is required as part of normal operations, design requirements must be identified and proposed for Authority approval.*

Superseded

SPECIFIC CATEGORY UAS

INTRODUCTION

3.1 Specific category UAS rely primarily on the use of technical and operational risk controls to achieve safe operation. Technical risk controls can vary in their applicability, reliability, effectiveness, and demonstrated design integrity, therefore understanding the 'robustness' of implemented technical risk controls is crucial to developing a suite of credible and defensible risk controls to support Specific category UAS operations.

Scope

3.2 This chapter explores how common technical risk controls can be implemented and the resulting contribution provided to the safety of Specific category UAS operations.

TECHNICAL RISK CONTROLS

3.3 This is a placeholder for a future update to this section detailing the Authority's view on the 'robustness' of technical risk controls proposed in support of Specific category UAS operations. In the interim, please contact the chapter Sponsor for the latest guidance.

Superseded

SECTION 5 - AIRCRAFT SUPPORT SYSTEMS

CHAPTER 1 - APPLICATION OF DESIGN REQUIREMENTS TO AIRCRAFT SUPPORT SYSTEMS

APPLICATION OF DESIGN REQUIREMENTS TO AIRCRAFT SUPPORT SYSTEMS

1.1 Safe flight of Defence aircraft may be affected by mission/role equipment, support systems and ground based equipment that interface directly with or are carried on board the aircraft and, therefore, the Authority prescribes airworthiness design requirements for these systems and equipment.

Scope

1.2 Section 5 of the DASDRM presents the prescribed airworthiness design requirements for the following aircraft support systems and ground based, role and/or mission equipment:

(a) aeronautical life support equipment

(b) mission planning systems

(c) electronic flight bags

(d) aerial delivery of materiel

(e) role equipment and portable electronic devices

(f) petroleum, oils, lubricants and allied products.

1.3 For enquiries regarding the content of the chapters in this section, readers should contact the chapter sponsor detailed in Annex A to Section 1 Chapter 1 in the first instance.

AERONAUTICAL LIFE SUPPORT EQUIPMENT (ALSE)

INTRODUCTION

2.1. DASR ORO.40 prescribes the requirements for Military Air Operator (MAO) approval for the carriage and use of Aeronautical Life Support Equipment (ALSE). Under DASR ORO.40, MAO approval of ALSE is supported by a technical assessment that establishes the level of compliance of the ALSE with prescribed design requirements. Compliance may be demonstrated by either the ALSE having been certified as part of the aircraft type design, or by a technical assessment conducted in accordance with the provisions of the regulation.

2.2. The design of ALSE and the interface and interaction between the ALSE and the host aircraft must be comprehensively assessed during Defence aircraft acquisition and/or design changes. Failure to do so can result in ALSE that is not fully compatible with the aircrew/aircraft, or provides an inadequate level of aircrew protection.

2.3. **Role of Aeronautical Life Support Logistics Management Unit (ALSLMU).** ALSLMU is the Defence Subject Matter Expert (SME) for ALSE with respect to all Defence aircraft. The ALSLMU Deputy Senior Design Engineer (DSDE) may be appointed as a Delegate of the Safety Authority as ALSE 'Standards- DoSA (ALSE)' with scope to prescribe, revise and interpret design requirements for ALSE. ALSLMU should be engaged at the earliest opportunity during a new platform procurement, ALSE replacement or design change program to ensure that adequate advice is available to support application of these design requirements during the requirements definition phase and ensure suitability of an ALSE solution as the program matures.

Scope

2.4. This chapter presents the Authority prescribed design requirements, including aircraft integration requirements where applicable, for ALSE. The design and integration requirements provide MAO and CASG System Program Office teams with a basis for establishing that ALSE related risks to safety have been eliminated or otherwise minimised 'So Far as is Reasonably Practicable' (SFARP). The chapter also presents guidance on the technical evaluation of ALSE to support compliance with the prescribed requirements and operational commander decisions on approvals, where required.

DEFINITIONS

2.5. The following definitions are relevant to this chapter:

(a) **ALSE.** ALSE is equipment that supports Defence capability and aircrew in the performance of their duties throughout aircraft operations, including the time during and following a survivable aircraft accident and evacuation. The ALSE may form part of an ensemble or may be fitted as an aircraft store.

Superseded

(b) ALSE can be considered as Safety ALSE (providing aircrew and passengers protection from environmental hazards during flight, survivable accident or incident, evacuation and post evacuation survival) and/or Mission ALSE (providing improved physical performance or functions necessary to support the achievement of an aircrew role). A frequent implementation of ALSE classified as both Mission and Safety is the helmet, which serves as safety equipment in the event of a crash while serving as mission equipment when supporting hearing and eye protection components, Night Vision Goggles (NVG), Lighting and other accessories. The categorisation of ALSE as Safety or Mission does not impact the applicability of standards prescribed within this chapter.

(c) **ALSE Ensemble.** An ALSE Ensemble consists of compatible equipment components that form an integrated ALSE solution that is worn by aircrew or passengers whilst performing duties primarily on-board the aircraft.

2.6. **ALSE Domains.** To support prescription of design requirements for the various types of ALSE, ALSLMU has defined 17 ALSE Domains. The Domains are defined to group similar types of equipment that are divided into 6 overarching categories. The following ALSE Domains are used:

(a) Head Protection

1. Helmets
2. Eye and Face Protection

(b) Inflatables

1. Life Preservers
2. Anti-G Suits
3. Life Rafts

(c) Load Carriage and Restraint

1. Carriers and Ensemble Integration
2. Hoisting Equipment
3. Out of Seat Restraint Systems
4. Ballistic Protection

(d) Post Evacuation Survival

1. Survival Aids
2. Thermal / Immersion Protection
3. Survival Kits and Rescue Packs

(e) Respiration

1. Oxygen / Smoke and Fumes Masks
2. Underwater Emergency Breathing

(f) Sensory Protection

Superseded

1. Hearing Protection

2. Night Vision Systems

3. Chemical, Biological, Radiological and Nuclear (CBRN) Protection.

CERTIFICATION OF ALSE

2.7. As discussed above, Defence manages ALSE within a construct of 'ALSE domains'. To facilitate the technical assessment of ALSE required under ORO.40, these 'domains' have been used to establish which ALSE should be considered under the aircraft's type certification and which should not.

2.8. Note that before approval for use, all ALSE must be subject to technical evaluation to confirm that it meets relevant design requirements and, where applicable, integration requirements, regardless of whether the ALSE is certified as part of the aircraft's type design or not.

2.9. Certification of ALSE can often be a complex undertaking and, therefore, advice on the application of and compliance with design requirements is to be sought from ALSLMU as early as possible within the project lifecycle.

ALSE included within the aircraft's certified type design

2.10. Certification of this ALSE will occur via design approval conducted in accordance with the requirements of DASR 21, to demonstrate that the ALSE complies with the design requirements in this chapter and in other applicable sections of the DASDRM. Relevant ALSE design requirements will be documented in the aircraft's Type Certification Basis (TCB).

2.11. The ALSE domains that are included in the aircraft's certified type design are:

(a) life preservers

(b) life rafts

(c) survival aids

(d) respiratory

(e) night vision systems (integration requirements only)

(f) chemical, biological, radiological and nuclear (CBRN) protection (integration requirements only).

ALSE not included in the aircraft's certified type design

2.12. While only four of the seventeen ALSE domains are included within a Defence aircraft's certified type design (plus the two domains where integration requirements are included), equipment within the remaining domains must still be subject to a robust evaluation of its technical and operational capabilities to ensure that it can safely perform its function when required. Consequently, the Authority also prescribes design requirements for these ALSE domains.

Superseded

2.13. For ALSE not forming part of the aircraft's certified type design, formal confirmation that the ALSE meets the relevant design requirements in this chapter is required to support ALSE approval per ORO.40.

2.14. The ALSE domains that are generally not included in the aircraft's certified type design are:

(a) helmets

(b) eye and face protection

(c) anti-G suits

(d) carriers and ensemble integration

(e) hoisting equipment

(f) out of seat restraint systems

(g) ballistic protection

(h) thermal/immersion protection

(i) underwater emergency breathing

(j) hearing protection

(k) night vision systems (equipment design requirements only)

(l) CBRN protection (equipment/clothing design requirements only).

EXEMPTIONS

2.15. **Flying Clothing.** ALSE has a maintenance policy and requires regular servicing by qualified personnel. Hence flying clothing is not considered ALSE. For information regarding Flying Clothing, contact the Program Manager – Combat Clothing (position number 00460959)

2.16. **Parachute Systems.** The Standards DoSA-ALSE does not hold a delegation for parachutes. The ADF Parachute School should be contacted in the first instance for the design requirements of parachutes.

2.17. **Pyrotechnics.** ALSE Ensembles or survival kits routinely contain pyrotechnic signalling devices. Explosive Materiel Branch (EMB) are the SMEs for this type of equipment. For requirements for pyrotechnic signalling devices refer to the eDEOP101 – Department of Defence Explosives Regulations. For guidance or advice on this topic contact EMB via their group inbox; casglsdembcoordination@dpe.protected.mil.au.

2.18. **Oxygen Systems.** ALSLMU are the SME for oxygen masks, which interface with the aircrew and aircraft oxygen systems, these are covered within this chapter. However, this chapter does not cover aircraft oxygen systems forming part of a particular aircraft design, refer Section 3 Chapter 6 for further guidance.

Superseded

GENERAL CONSIDERATIONS

2.19. ALSLMU is the SME for the scope of ALSE only; aircraft MAOs are responsible for ALSE integration with Defence aircraft. Each Defence aircraft type has been designed to comply with different standards and the integration of ALSE must be undertaken with cognisance of the suite of standards applicable to that type. The following paragraphs provide guidance to MAOs, CAMOs and SPOs on generic considerations for applying the prescribed ALSE design requirements in this chapter, to ensure that the extant aircraft design requirements are not compromised:

(a) **Configuration, Role and operating Environment (CRE).** Changes to a Defence aircraft's CRE can significantly influence the type of ALSE required and the design standards associated with the equipment. The standards prescribed within this chapter need to be applied with caution and tailored to suit the CRE of a particular platform. If any doubt exists the Standards DoSA-ALSE should be consulted for assistance with tailoring the application of standards.

(b) **Crash Protection.** When assessing the suitability of crew-mounted ALSE, evidence of the head and body extremity strike envelopes within the crew stations/cockpits of the aircraft must be sourced. Within these envelopes, the aircraft's design must also identify where suitable energy absorbing padding materials, frangible breakaway panels, smooth contoured surfaces, or ductile materials should or have been used. These intrinsic aircraft design features, if incorporated, provide additional protection to aircrew members in the event of an accident, and may reduce the need to source ALSE designed to further reduce the risk of injury. In cases where a shortfall in the crash protection of a platform is determined, additional ALSE requirements may be defined to treat this shortfall. The ADF aircraft crash protection requirements are prescribed in DASR ARO.40 Aircraft Crash Protection. This requires at AMC ARO.40.A.3.c that ALSE carried by personnel should be risk assessed and treated in the context of Crash Protection (For example: is ALSE adequately restrained under crash loads to prevent it coming lose and injuring aircraft occupants? Does the ALSE impact crashworthy seat restraint systems?). The ADF Contemporary Crash Protection Design Requirements are detailed at Section 2 Chapter 6.

(c) **Evacuation.** The addition/modification of ALSE can influence the ability of survivors to effectively evacuate aircraft and survive post-evacuation. Therefore, when assessing changes to any ALSE ensemble, the effect on both evacuation and survival must be considered. Generally an aircraft's type certification basis will include requirements for emergency evacuation (e.g. FAR25.803) and ALSE should not impact compliance with these requirements.

ALSE DESIGN REQUIREMENTS

2.20. Design requirements for ALSE comprise of Standards and ADF unique requirements. ALSE standards rarely match the context of the proposed design and, consequently, simple compliance with a standard may not be adequate for Defence's intended use of the ALSE. The Defence aircraft's CRE must therefore be considered when evaluating ALSE for suitability and acceptability, as discussed at paragraph 2.19a. The following sections provide for General Requirements and considerations applicable to ALSE as well as Integration Requirements for the integration of ALSE components to form an ALSE Ensemble and the integration of an ALSE ensemble to an aircraft. All ALSE should be assessed against the General and Integration Requirements as well as the specific domain and any other requirements that are relevant from other domains.

Superseded

2.21. In the use of ALSE for Defence service the following requirements and considerations are to be applied:

2.22. **Design Requirement (Essential).** *The maintenance inspection requirements and serviceability limits must be identified and published in relevant maintenance instructions*

2.23. **Key Consideration.** The design and fit of ALSE should consider and meet the needs of the anthropometric measurements of all aviators including females.

Material Properties

2.24. **Design Requirement (Essential).** *Materials used in Carriers or other ensemble components used to secure ALSE in the ensemble (i.e. pouches and straps) must be made of UV light resistant materials. This requirement shall be verified by test of residual strength of materials following accelerated exposure to UV light equivalent to its expected service life.*

(a) **Guidance Material.** Load bearing harness standards have particular requirements related to UV light resistance for primary load bearing webbing, refer to the related Hoisting Equipment or Out of Seat Restraint Systems domains for details. For other materials engage ALSLMU for guidance on the use of an appropriate standard for UV exposure testing.

2.25. **Design Requirement (Essential)**. *ALSE that is worn or stowed within an aircraft must be at least flame resistant.*

(a) **Guidance Material.** Where ALSE components have a similar form to components identified in FAR 25.853 and Appendix F to FAR Part 25 (e.g. ALSE harness or restraint webbing is similar to seat belts and shoulder harnesses) the relevant requirements must be applied. Where components are more similar to aircrew clothing a related standard for flame resistance testing for clothing, such as ISO 15025:2016, may be considered appropriate.

2.26. **Design Requirement (Essential).** All materials used in the manufacture of ALSE must not allow a build-up of static electricity or electrical charge.

(a) **Tailoring Advice.** The 'Material requirements' portion of BS EN 1149-5:2008 - Protective clothing-Electrostatic properties Part 5: Material performance and design requirements (or similar) can be used as guidance for testing if required.

Restraint Requirements

2.27. **Design Requirement (Essential).** *All ALSE components, or their means of restraint (e.g. pouch) to the carrier (or other means of attachment to the wearer) must be of sufficient strength to restrain the component under crashworthiness loads defined in the relevant aircraft(s) type certification basis or derived from the Section 2 Chapter 6 Contemporary Crash Protection Requirements.*

2.28. **Design Requirements (Essential).** *ALSE Ensemble components must remain securely restrained when subject to rotor wash and/or airstream associated with doors open operations.*

(a) **Guidance Material.** It may be suitable to adapt DEF STAN 05-134 Test 19 to apply relevant air blasts equivalent to rotor wash for rotary wing aircraft.

Superseded

2.29. In the production of ALSE designs suitable for Defence service, the equipment must be suitably integrated with the person, the aircraft and the remainder of the aircrew ensemble. ALSLMU are available to provide guidance on the suitability of ALSE and aircrew ensemble integration. The following requirements and considerations are to be applied:

2.30. **Design Requirement (Essential).** *ALSE must be integrated in accordance with DEF STAN 05-134.*

2.31. **Design Requirement (Essential).** *An ALSE Ensemble must be assessed using the test procedures of DEF STAN 05-134 Section 10 as applicable to the aircraft type.*

(a) **Tailoring Advice.** Where an ALSE Ensemble is not intended to be worn for the duration of the flight the assessment of DEF STAN 05-134 para 10.3.1, Test 1: Dressing and Undressing should also be made during flight to ensure the Ensemble can be efficiently donned / doffed during flight.

(b) **Guidance Material.** Other sections of DEF STAN 05-134 are very specific to the UK MoD organisation and should not be applied.

2.32. **Key Consideration.** The ALSE integration testing requirements of DEF STAN 05-134 Issue 1 Paragraph 10 will ensure that the ensemble suitably integrates together and with the aircraft on which it is being used. To ensure a successful outcome it is important that the purpose and assessment criteria of the various testing is understood and applied during the design of the ALSE Ensemble.

2.33. **Key Consideration.** During the assessment of an ALSE Ensemble using the testing program of DEF STAN 05-134 the risk assessment worksheet for Hazardous Manual Tasks from the Workplace Health and Safety (Hazardous Manual Tasks) Code of Practice 2015 should be used to identify any issues where the ALSE Ensemble may contribute to Musculoskeletal Disorders that will need to be managed. This may include identifying changes in design of the ALSE Ensemble to eliminate or mitigate such issues SFARP during its development.

2.34. **Key Consideration.** An ALSE Ensemble should have the ability to adjust the configuration to suit the operational role and environment to balance the hazards associated with weight and bulk of equipment during wear against the threats that the ALSE provides protection against during or following an emergency landing / ditching or crash.

2.35. **Key Consideration.** An ALSE Ensemble and Carrier design should provide for tactile feel for the identification and operation of securing hardware to allow for access to components that are located out of line of sight or in reduced light / visibility environments.

2.36. **Key Consideration.** Prior to ALSE being introduced to service, it should be assessed on each platform for snagging hazards which may cause the wearer to become trapped inside a sinking or burning aircraft. Assessments should consider emergency egress in any direction to and from an emergency exit, as Rotary Wing Aircraft in particular have a tendency to roll inverted following a ditching.

Superseded

DOMAIN REQUIREMENTS

2.37. The following Sections present the prescribed ALSE requirements and Standards for each ALSE Domain.

HEAD PROTECTION DOMAINS

Helmets Domain

2.38. A helmet is usually a safety device to protect the head of aircrew and passengers from dangerous impacts during a potentially survivable crash. The helmet's function is achieved with a combination of materials to both prevent penetration and absorb energy in such a way as to reduce damage from excessive accelerations caused by impacts to the head. Helmets also lower the risk of head injury during ejection and provide protection against windblast, rotor wash and debris in an aircraft during operations. Helmets may also be used as a platform for hearing protection, eye protection, communications equipment and other mission equipment.

2.39. The use of helmets and the selection of impact protection requirements must be done holistically within the aircraft design. Elimination or minimisation of risks so far as is reasonably practicable (SFARP) by means other than a helmet, should be assessed prior to selecting a helmet for use. For example, modification may be possible to the aircraft to prevent head injuries. It should be noted that many fixed and rotary wing aircraft are certified for use without helmets so mission function may be the driving factor in helmet selection.

2.40. A requirement to wear an aviation helmet might conflict with requirements to wear head protection to address different hazards, such as a ground combat ballistic helmet. In such circumstances a decision regarding the wearing of a helmet compliant with the requirements in this chapter, or an alternate helmet, must be guided by the principle of eliminating or otherwise minimising hazards to personnel SFARP.

2.41. The decision to use helmets and the selection of a helmet must be steered by the crash protection properties of the aircraft in which it is employed and the nature of the duties of the wearer. There will always be a trade off with the desirable properties of a helmet. For example, a lightweight helmet is always desired to reduce musculoskeletal (MSK) injuries; however, increased impact or ballistic protection will be accompanied by an increase in helmet mass.

Note

2.42. The requirements in this chapter are applicable to crash helmets only. Currently there are no applicable standards for lower impact head protection. Guidance material for lower impact head protection are mentioned at the end of this document. As of 2021, ALSLMU are investigating requirements of aviation helmets for use as a multi-fit passenger type helmet in collaboration with 5 eye nation's. For additional information contact the ALSLMU head protection SME.

2.43. The helmet section is to be read in conjunction with the General requirements, eye and face protection and Sensory domain's (Hearing protection).

Superseded

2.44. **Design Requirement (Essential).** *The helmet must meet the requirements of AS/NZS 1698:2006, or ECE 22.06.*

2.45. **Tailoring advice.** Amend requirement 5.8 (visors) to read 'eye and face protection section of this DASDRM chapter' in lieu of 'AS 1609'.

2.46. **Tailoring advice.** Requirement 7.1 (test sequence) solvent conditioning must be carried out.

2.47. **Tailoring advice.** Requirement 7.5 (resistance to penetration) test is only required when deemed necessary by the platform MAO.

2.48. **Tailoring advice.** Requirements 8 and 9 (marking and instructions for use and care) must be tailored in conjunction with the acquisition agency prior to introduction to service through the OEM.

2.49. **Design Requirement (Essential).** *The helmet must limit the peak head-form acceleration to 190G when tested IAW AS/NZS 1698:2006 using a flat anvil impact with the centre of the ear cup.*
2.50. **Design Requirement (Essential)**. *The helmet must limit the average head-form acceleration to 175G when tested IAW AS/NZS 1698:2006 using a flat anvil impact with the centre of the ear cup.*

2.51. **Guidance Material.** The previous two requirements are in addition to the testing in section 7.4 of AS/NZS 1698:2006, however the same methodology should be followed.

2.52. **Design Requirement (Essential) – one handed doffing.** *The fitting and retention system of a helmet must be designed such that a wearer can doff the helmet with one hand*.

2.53. **Design Requirement (Recommended).** *The mass of the helmet should be limited to 2.27 kg (5 lb).*

2.54. **Guidance Material.** Helmet weight is a contributing factor to fatigue and MSK injuries. Excessive weight can also increase neck loading and the impact energy of a head impact in a crash event. Care should be taken not to over specify other helmet attributes such as impact protection. A helmet should be selected to be as light as possible while providing the required level of protection. The target maximum mass includes the visors, sound attenuation and communication equipment, NVG's and any accessory to be mounted to the helmet. Consideration should also be given to the frequency and magnitude of high acceleration flight.

2.55. **Guidance Material.** A helmet which is optimised to protect a wearer from an impact of a magnitude which would be expected to cause a concussion or Mild Traumatic Brain Injury (mTBI) must be selected to protect the user from the higher magnitude of potential impacts. Consideration should be given to the CRE and the potential impacts that the helmet is to protect against. Consideration should be given to the member remaining conscious to survive post-crash events (e.g. smoke, fire, sinking aircraft, enemy action), which may occur some distance from emergency services and rescue.

2.56. **Key Consideration – centre of gravity (CoG).** The centre of gravity of a head and helmet is a more significant factor to aircrew fatigue and in flight performance, as well as being a key contributor to neck and back MSK injuries, than helmet weight. The helmet CoG should be as close to the top of the wearer's spine as possible and should be considered in the context of the aircraft's CRE. For example, the frequency and duration of high G loads or personnel moving around the aft of a helicopter while leaning over.

Superseded

2.57. **Key Consideration – rigid protrusions and accessories.** Helmets with rigid protrusions or mounted accessories can impart an angular acceleration to the head in the case of a head impact, increasing the chance of traumatic brain injuries. A large or oddly shaped helmet can also impede emergency egress. Helmets should be as small and as form fitting to the head as can be achieved whilst fulfilling their function. A helmet with a long radius of gyration can also contribute to neck injury, especially during an ejection. Consideration should also be given to external accessories mounted on a helmet causing a force concentration on the helmet during a crash event, with the increased pressure causing the accessory to penetrate the helmet.

2.58. **Key Consideration – helmet penetration and tearing.** An assessment of the crashworthiness of the aircraft and the role of the aircrew within it should be carried out to determine if there is a risk of helmet penetration or tearing during a survivable crash.

2.59. **Key Consideration – environmental qualification.** The operating environment of the aircraft should be used when considering the environmental qualification of the helmet. Consideration should be given to (but not limited to) temperature, humidity, ultraviolet radiation as well as exposure to fresh and salt water, dust and sand. Exposure to variations in environmental conditions may have a significant bearing on the life expectancy and level of protection the helmet affords. The selected temperature ranges should influence the hot and/or cold soaking requirements during testing, as these temperatures may alter the energy attenuation properties of the helmet materials.

2.60. **Key Consideration – helmet coverage and field of view.** The requirement for protection for the entirety of the head, including the face, should be considered when selecting a helmet. The amount of coverage should be balanced with any restrictions to the field of view, which may result in reduced crew situational awareness and increased workload. Restrictions to the field of view are undesirable.

2.61. **Key Consideration – human thermal performance.** The effect of ambient atmospheric conditions on the person wearing the helmet should be considered. This includes the effect of hot and cold injuries through ambient temperature and wind chill e.g. for example flying with open doors.

2.62. **Key Consideration – mission equipment.** Helmets may require incorporation of other features to enhance mission performance. These features should not degrade the crash protection of the helmet unless a safety case shows that a feature of the helmet that impacts crash protection attributes reduces a more serious risk SFARP. Such mission features include a ‘hear through’ function for communicating with persons not connected to communications system e.g. passengers prior to boarding the aircraft or night vision equipment.

2.63. **Key Consideration – ballistic protection.** Consideration should be given to whether the helmet is required to provide ballistic protection. This requirement should be balanced with the risk of MSK injuries from a heavier armoured helmet.

2.64. **Key Consideration – evaluation of aircrew helmets**. Air Standard ASMG 4041 Evaluation Procedures for Flight Helmets provides information on the type of data that should be collected when evaluating candidate aircrew helmets. This may be of use to acquisition projects.

2.65. **Key Consideration – durability.** A helmet which is used in an environment where it is likely to be subjected to many low velocity impacts (minor head knocks or bumps), such as a mobile aircrew’s helmet used in a platform where the wearer is required to stoop to move around a cabin or cargo, should be sufficiently resistant to these impacts to maintain its impact protection properties and/or reduce the mission capabilities of the helmet e.g. damage visors or accessory mounts.

Superseded

2.66. **Key Consideration – crash Protection.** The crashworthiness and inherent crash protection of the aircraft should be considered when identifying head protection to be used. The intrinsic aircraft design features, if incorporated, provide additional protection to aircrew members in the event of an accident, and may reduce the need to source ALSE designed to further reduce the risk of injury.

Additional Fixed Wing Ejection Seat Requirements

2.67. **Design Requirement (Essential).** *The helmet must be capable of maintaining facial and head protection during the ejection sequence.*

2.68. **Design Requirement (Essential).** *The helmet must be tested with all possible equipment configurations, i.e. all accessories/mounted equipment installed.*

2.69. **Guidance Material.** Air Standard ASMG 4041 Evaluation Procedures for Flight Helmets provides guidance on how to conduct ejection seat windblast testing. The velocity of the windblast should be selected based on the operating envelope of the aircraft. Consideration should be applied to unplanned ejections at abnormal e.g. high velocities, not just the aircraft's certified ejection velocities. Facial protection includes protection from windblast and debris produced during the ejection sequence.

Additional Fixed Wing Non-Ejection Seat Mobile Aircrew Considerations

2.70. **Key Consideration.** Consideration should be given in the helmet design for these aircrew to receive low velocity head impacts caused from moving around the aircraft and cargo while in flight. These aircrew may also experience multi axis impacts during survivable crash sequences due to the crew not always being secured in a crashworthy seat.

Additional Rotary Wing Considerations (all helicopter occupants)

2.71. **Key Consideration.** Consideration should be given in the helmet design for occupants to receive low velocity head impacts caused from moving around the aircraft and cargo while in flight. Occupants may also experience multi axis impacts during survivable crash sequences due to the occupants not always being secured in a crashworthy seat. They may also be required to rapidly escape a sinking helicopter.

Utility style Head Protection

2.72. These helmets are typically designed to protect the wearer from non-crash loads e.g. low velocity impacts with cargo and airframe components, while enabling other mission functions e.g. ability to swim or treat patients. These style helmets may be desired when operational risks and functions outweigh the requirement for crash protection. This assessment should be made when holistically assessing the risks associated with the platform and mission e.g. there may be a mission risk that requires minimisation ahead of a more remote risk of aircraft crash. It should be noted that some aircraft are certified to not require helmets for crash protection. In these cases this style of helmet may be sufficient to eliminate or otherwise minimise other mission related risks SFARP.

2.73. **Key Considerations.** The platform CRE must be considered for the application of the passenger helmet to be used. For example, a safety helmet chosen for operations on rotary wing 'down the

Superseded

wire' may be made to a higher specification than a Kevlar/bump style helmet used on fixed wing transportation flights.

2.74. **Guidance Material.** Children may be required to fly on board during Defence assistance to the civil community tasking or 'family day' tasking. Head protection sizes should accommodate children.

Eye and Face Protection Domain

2.75. **General Eye Protection.** Eye and Face Protection provides aircrew with protection from windblast, high light intensity, UV, spall resulting from canopy or windscreen failure, ballistic / fragmentation threats, and dust and debris from rotor or jet wash. The following requirements have been identified as general requirements which are to be applied to all eye and face protection equipment as applicable.

2.76. **Design Requirement (Essential).** *AIR STD ASMG 4079 "The Optical And Material Requirements for Aircrew Helmet Visors" must be met for all visor systems*

2.77. **Design Requirement (Essential).** AIR STD 61/113/14A "The Optical And Material Requirements for Aircrew Plano Sunglasses" must be met for all glasses.

2.78. **Guidance Material.** Spectral transmittance requirements may be difficult to meet, particularly in untinted lenses. Lenses must meet the target values as closely as possible to minimise the chance of eye damage in the long term.

2.79. **Guidance Material.** Impact resistance requirements for "Extra High Impact Resistance" protection contained in AS/NZS AS/NZS 1337.1:2010 may be used in lieu of the requirements outlined in the AIR STDs.

2.80. **Design Requirement (Essential)** *Section 3 of AS/NZS 1337.1:2010 including Amendments 1 and 2, relating to assembled eye and face protectors must be applied to all eye and face protectors.*

(a) **Guidance material.** Special performance requirements as per section 3.3 are to be applied as required dependent on the use case of the protector in question.

(b) **Guidance material.** Where requirements are included in both AS/NZS 1337.1:2010 and the applicable AIR STD, the more stringent of the two must be applied.

2.81. **Key Considerations** The following considerations should be taken into account when assessing any eye and face protection equipment.

(a) Applicable considerations from AS/NZS 1336:2014 should be applied. Particularly advice relating to the management of fogging and perspiration

(b) Various shades of tint are available for both visors and sunglasses, appropriate levels should be assessed where possible in order to maximise user comfort and visibility.

(c) Dual visor systems should be easily switched between a clear and tinted visor with one hand in order to manage changing conditions.

2.82. **Laser Protection.** Laser energy is highly focussed and designed to traverse long distances, and is therefore potentially hazardous to the human eye; more so when emitted at a wavelength invisible to the eye, rendering the eye unable to react normally. Laser protection should be tailored to the application and expected laser threats. Threats range from dazzling through to permanent damage of

Superseded

the eye. The method of eye protection chosen against laser light should not degrade or impact upon the function of other eye related systems therefore all general requirements must be met.

2.83. **Design Requirement (Essential).** *Laser eye protection must limit exposure to known threats to within the Maximum Permitted Exposure limits defined in AS 2211.9:2002 (R2014) for wavelengths between 300nm and 3000nm.*

2.84. **Design Requirement (Recommended).** *Requirements 3.1 through 3.3 of AS 1337.4:2011 should be applied to the maximum possible extent.*

2.85. **Key Considerations.** The following considerations should be taken into account when assessing laser eye protection

(a) Section 6 of AS/NZS 1336:2014 outlines considerations that must be made in order to minimise the risk of laser radiation

(b) Laser protection will generally reduce visible light for the wearer, this may be an issue particularly at night.

(c) Filters designed for protection against laser threats are generally designed in such a way that they only cater to a very narrow selection of wavelengths. These must be selected based on risk analysis of known and probable threats.

2.86. **Face Protection.** Protection for the lower face is also available in the form of a shield that reduces wind on the face and provides impact protection.

2.87. **Design Requirement (Essential).** *The requirements pertaining to "Extra High Impact Resistance" protection contained in AS/NZS 1337.1:2010 must be applied as a minimum to any face shield.*

2.88. **Key Considerations.** The following considerations should be taken into account when assessing face protection:

(a) Face protection should not allow breathing gasses to escape in a manner that causes fogging of any visor or spectacles that are used in conjunction with the face protection.

(b) Face protection must be rapidly removable to allow the use of underwater emergency breathing devices and other safety systems that cover the mouth and face.

Anti-G Suits

2.89. Anti-G Suits are designed to counteract the effects of acceleration on aircrew, which can impact on their survival or ability to perform tasks. The pressurised abdominal and leg bladders aim to support an adequate blood supply to the upper body and head when a person is subject to positive G forces. This counteracts the pooling of the blood from the head and chest into the lower part of the body under high positive G forces which will help preserve circulation, visual acuity and mental alertness until level flight is resumed.

2.90. Some contemporary Anti-G suits incorporate features to assist the wearer in breathing high pressure gasses or to provide protection against exposure to very low air pressure environments. Such features are beyond the scope of this section. Advice should be sought from ALSLMU prior to using such equipment on ADF aircraft.

Superseded

2.91. **Design Requirement (Recommended).** *Anti-G suits should be subjected to scheduled fit checks on the assigned wearer, by a suitably qualified person.*

2.92. **Design Requirements (Recommended).** *Anti-G suits should be subjected to pre-flight functional and/or leak checks.*

(a) **Guidance Material.** The preferred method of compliance is to conduct a functional check which can be conducted in an aircraft with the wearer of the suit strapped in such that the suit is integrated to the aircraft. If a pre-flight check in a carrying aircraft is not feasible, then a functional and/or leak check should be conducted when the suit is donned.

2.93. **Key Considerations.** The following key considerations should be made when introducing Anti-G suits to ADF service:

(a) An Anti-G suit with greater coverage of the wearer will tend to offer superior protection against G forces, whilst an Anti-G suit with a larger total bladder volume will inflate more slowly. High coverage and rapid inflation are both desirable properties of an Anti-G. These characteristics should be considered and optimised for the intended configuration, role and environment of the user.

(b) The use of 'pull away' quick release connectors for the interface between an aircraft and an Anti-G suit are considered desirable for the purpose of rapid emergency egress, but an inadvertent disconnection in flight could contribute to a G Induced Loss of Consciousness (G-LOC) event. The selection of an interface connector should consider both emergency egress and the security of the connection.

(c) The wearer of an Anti-G suit should conduct activities such as the Anti-G Straining Manoeuvre (AGSM) to resist the effects of G forces. Different Anti-G suit designs afford varying levels of protection against G forces and caution should be applied when transitioning from a design with a high level of protection to one with lesser protection. The wearers AGSM activities should be matched to the assistance provided by the suit. Effective conduct of an AGSM with a particular Anti-G suit design requires substantial practice and conditioning. For this reason, care should be taken when considering any finding of equivalence between the function and performance level of different Anti-G suit designs.

(d) The failure of an Anti-G suit could contribute to a G Induced Loss of Consciousness (G-LOC) event. The reliability of an Anti-G suit should be considered in terms of the suit making up part of the carrying aircraft's Anti-G system.

Life Preservers

2.94. Life preservers provide individuals with floatation support whilst in the water following a survivable aircraft ditching. They have inflatable buoyancy chambers to minimise bulk during normal operations and may incorporate survival aid stowage as part of the assembly. The type of life preserver used is highly dependent on the CRE of the host aircraft and the personnel that it is intended for including aircrew and passengers (combat/noncombat).

Constant wear life preservers

2.95. **Design Requirement (Essential).** *Constant wear life preservers must comply with the requirements of DEF(AUST) 9202.*

Superseded

(a) **Tailoring advice.** Replace the second sentence of paragraph 2i of AIR STD ASM 4065 Ed1v3 as follows: “The life preserver must accommodate the full anthropometric range of the user population wearing standard flight clothing and applicable personal survival equipment”.

Non-constant wear life preservers

2.96. **Design Requirement (Essential).** *Non-constant wear life preservers must comply with the requirements of TSO-C13g.*

General life preserver requirements applicable to all life preservers

2.97. **Design Requirement (Essential).** *Life Preservers for Rotary Wing aircraft applications must only use manually activated inflation devices and be inflated by the wearer following egress from the aircraft so that the buoyancy of an inflated life preserver does not trap them within a sinking aircraft.*

2.98. **Design Requirement (Essential).** *Life Preservers for ejection seat aircraft must use automatically activated inflation devices that automatically inflate once in the water to account for the possibility of unconsciousness following the ejection sequence.*

2.99. **Design Requirement (Essential).** *The life preserver must be fitted with a pea-less whistle unless the life preserver is for an infant. The whistle must be secured by a cord to the life preserver.*

2.100. **Design Requirement (Essential).** *The life preserver in the inflated mode must not hamper ingress to single or multi-seat life rafts.*

2.101. **Design Requirement (Essential).** *All inflatable life preservers must use dual chamber buoyancy systems to provide redundancy for damage or failure of one chamber.*

2.102. **Design Requirement (Recommended).** *The buoyancy afforded by a life preserver should consider the additional equipment weight carried by the wearer (e.g. fully loaded combat passengers).*

2.103. **Design Requirement (Recommended).** *Life preservers should be protected against inadvertent inflation.*

2.104. **Design Requirement (Recommended).** *A life line and toggle should be fitted to the life preserver. Where fitted, the life line must have a minimum breaking strain of 45 kg and be approximately 1 metre in length. The life line and toggle are to be stowed within easy reach of the wearer.*

(a) **Guidance Material.** This requirement provides a means for survivors to tether themselves together if they are in the water and do not have a life raft (e.g. survivors could not remove the life raft from a sinking helicopter).

2.105. **Design Requirement (Recommended).** The life preserver should be compatible with helicopter rescue hoisting operations.

2.106. **Key Consideration.** DASDRM Section 2 Chapter 6 Annex A should be referenced for guidance on life preserver stowage on aircraft and quantity of life preservers required.

2.107. **Key Consideration.** The requirement for infant and child life preservers should be assessed during the procurement process based on the expected role of the aircraft.

Superseded

2.108. **Key Consideration.** The MAO should consider if subsurface buoyancy is required for the life preserver application.

2.109. **Key Consideration.** Civilian passengers may not be fluent in English language and/or may not be able to read English which may cause difficulties for the passengers accessing and using the life preserver.

Life Rafts

2.110. Life Rafts provide for survivability of one or more people after an aircraft evacuation over water, or dropping from an aircraft to survivors in the water during Search and Rescue operation. Once boarded, life rafts increase survivability by isolating survivors from the water and providing shelter from the environment. Life raft designs must cater for Defence's survivability needs ranging from hours to days of life support, incorporating communication and rescue aids, rations and water treatment systems where warranted.

2.111. Life Rafts and their components must comply with ALSE General Requirements as well as the following standards as relevant to the specific Defence aircraft installation, considering recommended requirements and guidance material listed.

Life Raft Equipment

2.112. **Design Requirement (Recommended).** The following life raft specific survival aids are strongly recommended as inclusions with all life rafts.

(a) at least one buoyant bailer.

(b) a pair of buoyant paddles (note: not appropriate for larger life rafts).

(c) an efficient radar reflector or a radar transponder.

(d) anti-nausea medication and sick bags for all on board the life raft.

Multi-seat life rafts

2.113. **Design Requirement (Essential).** *Life rafts must comply with TSO-C70b.*

2.114. **Design Requirement (Recommended).** *Life rafts should consider fitment/use of the following recommended features:*

(a) *Life Raft lights should have batteries (or battery and Light units) that are replaceable without the use of adhesives.*

(b) *Attachments should be provided to keep the entrance covers open (the life raft should be packed in this position if a self-erecting canopy is fitted).*

(c) *The total seating space should be insulated by an inflatable floor. When a removable mattress type is supplied, tie down points to attach the mattress to the life raft floor should be added.*

(d) *The floor should be fitted with Inflate/Deflate valves that are compatible with the Life Raft Topping-up valves and the Life Raft Hand pump. When a mattress type inflatable floor is*

Superseded

supplied, the upper side centre of the floor (when installed) should be stencilled with 40 mm high lettering 'INFLATABLE FLOOR'.

(e) *The life raft should provide sufficient air for the occupants at all times, even with the entrances closed.*

(f) *The life raft should contain a viewing port.*

(g) *Where the life raft has multiple entrances, best practice is to have at least one entrance provided with a 'boarding ramp', with other entrances using a 'boarding ladder' style boarding aid. The boarding ramp should not cause life raft deflation if it becomes damaged and the lowest step of the boarding ladder should be .4 m below the life rafts waterline.*

(h) *Have an automatically deploying sea anchor or a labelled reminder for the occupant to deploy the sea anchor.*

2.115. **Design Requirement (Recommended).** *Life rafts which can be externally mounted and deployed remotely should be used in preference to internally installed life rafts which require physical effort to deploy. Internally installed life rafts should have unobstructed access from the inside of the aircraft and that of the ditched position.*

(a) **Guidance Material.** Life rafts should be deployable from three locations being in reach of the flight crew, occupants of the passenger cabin and survivors in the water with the aircraft floating in the ditched/capsized position.

2.116. **Design Requirement (Recommended).** *Life rafts should be equipped with two retaining lines to be used for securing the life raft to the aircraft, one short line and one long.*

(a) **Guidance Material.** A short line holding the life raft close enough for occupants to enter the life raft directly without entering the water which is then cut leaving the life raft attached to the aircraft by the longer retaining line which should allow the life raft to float at a safe distance away from the aircraft.

2.117. **Guidance Material.** Aircraft should have a minimum of two life rafts with sufficient overload capacity to account for the loss of the largest life raft.

2.118. **Guidance Material.** Consideration should be given to whether additional capacity within the life rafts is required to account for operationally kitted aircrew.

2.119. **Guidance Material.** Weight and space permitting, consideration should be given to increasing the puncture resistance of the life raft if it is located in close proximity to an area of the aircraft which is likely to have jagged edges following a water landing/ditching.

2.120. **Guidance Material.** Consideration should be given to whether there are entanglement possibilities from lines/boarding ladders which could trap a person while righting the life raft during a new life rafts introduction to service.

Multi-seat life raft compressed cylinders

2.121. **Design Requirement (Essential).** *Compressed cylinders which have been discharged, immersed in water, visually appear corroded, out of limits or damaged and will (or have) exceeded the 5 years since hydrostatic test must be returned for inspection, testing and refilling. Facilities*

Superseded

conducting the work must satisfy the requirements of AS 2337.1 for Gas Cylinder Test Stations, Part 1: General Requirements, Inspection and Tests–Gas Cylinders.

2.122. **Design Requirement (Essential).** *Recharging and reconditioning, internal and external inspection and testing of Inflation System Compressed Cylinders must comply with AS 2337.1.*

2.123. **Design Requirement (Essential).** *Each cylinder must be charged with the required weight of CO2 and N2 as applicable by the type of cylinder, to within the limits as specified by the manufacturer. CO2 used must conform to BB–C–101, Grade B. Where additional pressure to expel CO2 at lower temperatures is required, cylinders must have added Dry N2 conforming to A–A–59503, Type I, Grade B, Class 1.*

2.124. **Design Requirement (Recommended).** *Painting of the compressed cylinder should be done in accordance with MIL-STD-1411A. The threaded portion of the neck of the cylinder should not be painted.*

2.125. **Design Requirement (Recommended).** *Cylinders fitted with syphon tubes should have the type of syphon tube clearly stencilled in 12 mm lettering, in Black Cellulose Lacquer conforming to A–A–3165, longitudinally on the body of the cylinder, as* applicable.
Single seat life rafts

2.126. **Design Requirement (Essential).** *Life rafts must comply with DEF(AUST) 9203.*

2.127. **Design Requirement (Essential).** *Inflation compressed cylinders must comply with MIL-PRF-25369D(1).*

LOAD CARRIAGE AND RESTRAINT DOMAINS

Carriers

2.128. Carriers form the basis of an ALSE Ensemble in that they provide a platform to which various ALSE can be attached. Carriers take two forms a vest (for non-load bearing applications) or harness (for load bearing applications for restraint / hoisting). Selection of a carrier requires consideration of the requirements of the wider ensemble and the need for restraint/ hoisting capability.

2.129. Design Requirement (Essential). *A carrier must be designed to restrain the load of any ALSE component or combination of components intended to be attached to it simultaneously under relevant crashworthiness loads defined in the relevant aircraft(s) type certification basis or derived from the Section 2 Chapter 6 Contemporary Crash Protection Requirements.*

(a) **Guidance Material.** Where a Harness is required any relevant Out of Seat Restraint or Hoisting Equipment requirements should be applied from the respective Domains.

Hoisting Equipment

2.130. Hoisting Equipment is considered as any equipment that is connected to a rotary wing aircraft's hoist for the purposes of deploying and recovering personnel to/from the aircraft during flight. This ALSE domain includes but is not limited to harnesses, strops, baskets, seats and stretchers. This ALSE domain does not include the aircraft hoist, cable or hoist hook.

2.131. **Design Requirement (Essential).** *Harnesses must meet the requirements of ATSO-C1003 or TSO-C167 as tailored below:*

Superseded

(a) Para 3 (1) of ATSO-C1003 should refer to AS/NZS 1891.1:2020 and use the applicable sections for Full Body Harness.

(b) Para 3 (3) of ATSO-C1003 shall refer to Section 2.2.3 of AS/NZS 1891.1:2020 instead of 4.2.3 of AS/NZS 1891.1:1995.

(c) Para 3 (4) of ATSO-C1003 shall refer to Section 5.1 paragraphs c, f, g, h of AS/NZS 1891.1:2020 instead of 5.1 of AS/NZS 1891.1:1995.

(d) Para 3 (5) of ATSO-C1003 provides dispensation from permanently marking harnesses with a maximum allowable free fall as required by AS/NZS 1891.1:1995. This dispensation still applies to harnesses; however, AS/NZS 1891:2020 does not include this requirement.

(e) Para 3 (6) of ATSO-C1003 refers to Static Tests for Lanyards. These tests are not applicable to harnesses.

(f) Dynamic testing of harnesses must be performed as per AS/NZS 1891.1:2007 Appendix D.

2.132. **Guidance Material.** ATSO-C1003 is no longer a stand-alone document. It was moved to CASR Part 21 Manual of Standards (MOS). Latest revision of MOS is dated 30 Nov 17.

2.133. **Design Requirement (Essential)**. *Rescue Strops must meet the requirements of ATSO-C1003 as tailored below:*

(a) In reference to Para 3 (2) of ATSO-C1003, use the applicable sections in the AS/NZS 1891.1:1995 standard for "Retrieval Strap" testing. General, webbing and attachment hardware requirements used in the Strop shall be as required for harnesses in AS/NZS 1891.1:2020.

(b) Para 3 (3) of ATSO-C1003 shall refer to Section 2.2.3 of AS/NZS 1891.1:2020 instead of 4.2.3 of AS/NZS 1891.1:1995.

(c) Para 3 (4) of ATSO-C1003 shall refer to Section 5.1 paragraphs c, f, g, h of AS/NZS 1891.1:2020 instead of 5.1 of AS/NZS 1891.1: 1995.

(d) Para 3 (5) of ATSO-C1003 shall refer to Section 5.2 of AS/NZS 1891.1:2020 instead of 5.2 of AS/NZS 1891.1:1995.

(e) Para 3 (6) of ATSO-C1003 refers to Static Tests for Lanyards. These tests are not applicable to rescue strops.

2.134. **Guidance Material.** ATSO-C1003 is no longer a stand-alone document. It was moved to CASR Part 21 Manual of Standards (MOS). Latest revision of MOS is dated 30 Nov 2017.

2.135. **Design Requirement (Essential).** *Hoisting equipment other than rescue harness/strops must meet the applicable requirements of NFPA 1983:2017 and ATSO-C1003 Paragraphs 3(8) and 3(9).*

2.136. **Design Requirement (Essential).** *A Rescue Strop must be buoyant for maritime operations.*

2.137. **Design Requirement (Recommended).** *The Rescue Strop should be a bright colour to enhance conspicuity during rescue.*

2.138. **Tailoring Advice.** This requirement is deemed recommended since there may be cases where a strop is required for Combat Search and Rescue (CSAR) operations where bright colours are not suitable.

Superseded

2.139. **Design Requirement (Recommended).** *Where likely to be used for hoisting of hypothermic patients a Rescue Strop should incorporate a Hypothermia strap (a secondary strap placed under the knees of the hoistee for a semi-recumbent position).*

2.140. The current version of FAR 29.865 is Amendment 29-43. Advisory Circular AC29-2C contains detailed guidance at AC29-865B. Within FAR 29.865 Harnesses, Rescue Strops (along with other Personnel carrying devices) are collectively referred to as Personnel Carrying Device Systems (PCDS). The following sections are considered applicable to PCDS:

(a) FAR 29.865(a) The requirement for PCDS to be shown by analysis, test or both to withstand limit static load to a load factor of 3.5 or some lower factor not less than 2.5. AC29.865B provides guidance at paragraph d.(6) and in particular d.(6)(ii)(B) for Human External Cargo. Sub-Para (1) provides for a static analysis to show compliance if a safety factor of 3.0 is applied. Sub-Para (2) identifies use of a conservative load factor of 3.5g or substantiated lower factor not less than 2.5g and Sub-Para (3) identifies the use of a 101kg person as the minimum weight however a note indicates additional equipment weight should be included. In the ADF context it is not uncommon for Aircrewmen with equipment and wet to weigh 150kg. Using these values gives a static load of 150 kg x 9.81 m/s2 x 3.0 x 3.5 = 15.5kN. Given that it is not expected that the helicopter would intentionally operate anywhere near the conservative 3.5g load factor during hoisting operations it is calculated that a load factor of 3.39 (equating to 15kN) would suffice. It is therefore considered that the static load testing of the Harness or Rescue Strop to AS/NZS1891.1 requirement of 15kN will satisfy this requirement.

(b) FAR 29.865(c) (2), these requirements are considered to be satisfied by a Harness or Rescue Strop that meets the tailored requirements of ATSO-C1003 or TSO-C167.

(c) FAR 29.865(c)(3), these requirements for placards/markings for operating, ingress and egress instructions are likely to have been met by requirements of either ATSO-C1003 and AS 1891.1:2007 or TSO-C167 and its reference standards.

(d) FAR 29.865(f), this requirement is for fatigue evaluation in accordance with FAR29.571 to be applied to the PCDS. Guidance at AC29.865B paragraph d.(6)(vi)(B) indicates analysing the PCDS component by component to determine fatigue critical components to be subject to analysis or test to determine fatigue life limits. As it is difficult to analyse the fatigue response of webbing and material type harnesses and strops one approach considered suitable by the Standards DoSA-ALSE would be to conduct cycle testing of the entire PCDS system based on the critical load factors (excluding the safety factor used for ultimate load) and make a determination of the number of hoisting cycles likely to be experienced by the PCDS during its life. Using a weight of 150kg and conservative load factor of 3.5g the fatigue cycle load to be used would be 150kg x 9.81 m/s2 x 3.5) = 5150N. Generally Harnesses and Rescue Strops are have a service life of 10 years (unless otherwise substantiated) so using this and the number of hoisting cycles the equipment is expected to be used (under load) a number of cycles can be determined for testing.

2.141. **Key Considerations.** The following key considerations should be made when introducing hoisting equipment:

(a) Rescue Strops are designed for ease of donning whilst in the water but do not provide the safest option for restraint during hoisting. Strops require the hoistee to hold their arms down to maintain restraint. It is possible if the arms are lifted that the hoistee may fall from the restraint which is known to have occurred in the event of a hoistee becoming unconscious

Superseded

(refer ATSB Aviation Occurrence Investigation Report AO-2013-136). Prior to a Rescue Strop being used the following considerations should be made:

1. whether life is at imminent risk
2. the state of the person to be winched, particularly whether the winchee will remain conscious and coherent during the winch process
3. the potential for the person to remain compliant with winching brief
4. alternative methods and devices to recover the person
5. whether the risk of falling from the device would not result in further serious injury or death.

(b) Rescue Strop design or operating procedures should prevent a survivor from slipping through the rescue strop during winching. It should be considered if any additional design features for a Rescue Strop such as arm straps (to help hold arms down over the strop), crotch straps, self-securing systems and anti-slip materials to prevent slipping from the Rescue Strop are suitable for the application's Configuration, Role and Environment.

(c) Use of a Rescue Strop with hypothermic strap is considered a safer option compared to a single under arm strop, especially with heavier winchee's or those who may have pre-existing heart-related medical conditions, or suffering hypothermia.

(d) Rescue Strops should be chosen as a 'last resort', in favour of using extraction devices which will not allow the winchee to fall out. Additionally, best practice is using strops only over water.

(e) A Rescue Strop should be sufficiently long to fit around the chest of a survivor carrying full aircrew clothing and accoutrements (additional equipment) after immersion in water.

(f) The option of an emergency quick release device fitted between the harness and hoist hook should be considered as part of a safety argument that supports the determination that associated risks have been eliminated or otherwise minimised SFARP. If a quick release is to be used the ATSO-C1003 paragraph 3(7) requirements are considered essential design requirements.

(g) The strop or harness should be adequately comfortable and suitable for the wearer as to not injure the wearer during a lift.

(h) The weight of a rescue strop should be selected to limit flail of an empty strop when attached to a hoist hook and hoisted in the aircraft's rotor wash and this should be assessed by flight test. The weight will need to be balanced with buoyancy of the strop to ensure it floats on the water for ease of use during a water hoisting operation. Alternatively the use of a separate weight attached to the hoist hook to weight the cable and limit movement of an empty strop in the rotor wash could be considered.

(i) Where a Harness is to also be used for restraint whilst out of seat within an aircraft the requirements prescribed for Out of Seat Restraint Systems will also need to be considered and applied to the design.

(j) To prevent a rescue device from spinning, the use of an integrated tagline or litter drag chute should be used to assist in stabilising the equipment and patients during the hoist.

Superseded

(k) Selection of hoisting equipment should be considered in the context of an SFARP solution for the application, configuration, role and environment.

Out of Seat Restraint Systems

2.142. A fall restraint system consist of an anchor point, connectors, full body harness and may include a lanyard, lifeline, or suitable combinations of these. The entire system must be capable of withstanding the impact forces involved in stopping or arresting a fall. When operating out of seat a restraint strap does not provide crashworthy restraint and personnel will be subject to flailing within the extent of the restraint length. When not operationally required to be out of a seat personnel should return to a seat restraint as required by DASR ORO.70(b).

2.143. Restraint systems shall primarily be designed to keep personnel within the designated safe bounds of the aircraft at all times. There may be particular cases however where personnel need a length of restraint to achieve a required positioning where the restraint length could place the personnel at a fall risk position. (For example a helicopter Aircrewman conducting clearances by lying on their stomach to look out the door and underneath an aircraft. In this example when moving from lying to standing position the restraint length could allow the standing Aircrewman to exit the door).

2.144. **Design Requirement (Essential).** *Out of Seat Restraint systems must meet the requirements of the following standards:*

(a) *ATSO-C1001, Dispatcher's Restraint Strap. With the following tailoring:*

1. *Para 3(1) should read: Subject to subclauses (2) to (6), the dispatchers restraint strap must meet the requirements mentioned in AS/NZS 1891.1:2007 relating to lanyards*
2. *Para 3(2) should refer to clause 2.2.1 of AS/NZS 1891.1:2007 instead of 3.2.4 of AS/NZS 1891.1:1995. It is noted that designs incorporating a three ring disconnect include a small eyelet in the load bearing webbing, this may be accepted so long as strength and wear requirements are met*
3. *Para 3(2)b shall refer to the requirements 4.4.1 of AS/NZS 1891.1:2007, tested in accordance with Appendix G of AS/NZS 1891.1:2007*
4. *Para 3(3) should refer to clause 2.3 of AS/NZS 1891.1:2007*
5. *Para 3(6) should refer to the test at Appendix G of AS/NZS 1891.1:2007 instead of Appendix D of AS/NZS 1891.1:1995*
6. *Para 6 should refer to AS/NZS 1891.1:2007 instead of AS/NZS 1891.1:1995*
7. *The ATSO required quick release strap may be optionally omitted for platforms which would not gain significant advantage from the implementation of a quick release device. This is to be determined by the MAO, it is anticipated that all rotorcraft will incorporate a quick release device, whereas large fixed wing aircraft will likely forgo this requirement.*

(b) *AS/NZS 1891.1:2007 Industrial fall-arrest systems and devices – Harnesses and Ancillary Equipment; (As tailored by ATSO-C1001)*

1. *All requirements relating to the use of personal energy absorbers shall also be removed from AS/NZS 1891.1:2007.*

Superseded

2. *The requirements relating to the adjustment of a pole strap found at clause 4.3.2 of AS/NZS 1891.1:2007are deemed as essential, and shall be applied to the lanyard assembly used. The lanyard length must be conveniently adjusted with self-locking connectors that do not cause damage to the lanyard. The release of these connecters must require consecutive deliberate actions in accordance with clause 5.2.1 of AS/NZS 1891.1:2007.*

2.145. **Design Requirement (Recommended).** *All parts of the restraint should be flame resistant in accordance with the general requirements for life support equipment section 2.19 of the DASDRM, therefore the out of seat restraint system should be FAA Part 25.853 compliant.*

2.146. **Key Considerations.** The following key considerations should be made when introducing out of seat restraint equipment:

(a) Platform specific variation will occur. Consideration of the platform specific environment when applying the working at heights code of practice and related standards should be undertaken in each case.

(b) Where working at height standards are used they must be appropriately tailored to an aviation context as aircraft are dynamic platforms and falls can occur in multiple directions and in succession.

(c) A crew member should be able to easily move about the cabin and access all required equipment for their duties, but movement should be restricted beyond the required range of motion to avoid injury under extreme flight conditions or in a crash/hard landing.

(d) Cargo, role equipment and personnel should be appropriately spaced to minimise the likelihood and severity of potential impact should adverse flight conditions be encountered while a user is reliant on out of seat restraints. Consideration should also take place to ensure that adverse reactions such as rubbing and snagging on obstacles so as to avoid minor injuries to personnel or damage to the restraint system. Additionally users operating out of seat should be aware of their surroundings and should have the ability to secure themselves by using hand holds or other means in the event of unexpected turbulence being encountered.

(e) Crew should be able to adjust their lanyards quickly and efficiently, this will assure that they will adjust their lanyards constantly and keep them correctly set as they move about the airframe and conduct varying roles. These mechanisms should not be prone to inadvertent length adjustment. The restraint system should be designed in such a way that it prevents a user from gaining excessive momentum in the event the aircraft accelerates rapidly. This must be balanced with the need to move about the cabin.

(f) As recommended by CASA Airworthiness bulletin 25-007, Restraint straps and harnesses should remain connected to an approved hard point at all times during flight. The use of hard points that are located at height either on a wall or overhead is preferred over the use of a floor based point.

(g) As recommended by the Canada National Defence Airworthiness Design Standards Manual more stringent civilian type “full body’ harnesses incorporating leg and shoulder straps should be used wherever operationally possible as opposed to belt or lower body harnesses.

Superseded

2.147. Aircrew ballistic protection includes protection of crewmembers from weapons such as firearm projectiles, fragmentation, shotgun pellets and sharp edges such as knives and spears. This protection is provided through ballistic armour worn by the crewmember. While the Soldier Modernisation SPO (SMSPO) provides guidance on ballistic protection standards, ALSLMU provides guidance specifically relating to the integration of ballistic protection ALSE within Defence aircraft.

2.148. **Design Requirement (Essential).** *If the ballistic protection ALSE design relies upon rapid removal to assist emergency egress, mitigate negative buoyancy in water, or for Helicopter Under Water Escape (HUET), the rapid removal mechanism must be capable of being activated with one hand.*

2.149. **Design Requirement (Essential).** *The material used for the outer layer of a ballistic protection ALSE garment must comply with the 'Material requirements' portion of BS EN 1149-5:2008 - Protective clothing - Electrostatic properties Part 5: Material performance and design requirements. Pre-test conditioning of the test specimen must be conducted by cleaning the specimen five times in accordance with the manufacturer's cleaning instructions.*

(a) **Tailoring Advice.** The purpose of this design requirement is to ensure that ballistic protection ALSE does not pose a hazard in an aviation environment due to electrical arcing caused by static electricity. An alternate standard may be used if it can be shown to prevent the ballistic protection ALSE from posing a hazard due to static electricity build up or discharge. ALSLMU advice must be sought prior to use of an alternate standard.

2.150. **Key Considerations.** The following key considerations apply when introducing ballistic protection ALSE:

(a) Ballistic protection ALSE tends to be heavy, affect the posture of the wearer and restrict the mobility of the wearer. It should therefore be considered to be a hazard to the wearer and only be used for the purpose of mitigating hazards which are more severe than the hazard it poses.

(b) Requirements for the level and type of protection of ballistic protection ALSE should be based upon assessment of an identified threat such as a defined set of weapon systems and engagement ranges. Such a threat assessment should also consider any protection offered by an aircraft's structure. Land Division of the Defence Science and Technology Group can be engaged to assist in the conduct of such threat assessments.

(c) Soldier Modernisation Systems Program Office (SMSPO) should be consulted regarding the effectiveness of any proposed ballistic protection ALSE system.

POST EVACUATION SURVIVAL DOMAINS

Survival Aids

2.151. Survival aids are required to support the four priorities of survival; Protection (from environment, enemy, propagation of injuries etc.), Location (signalling equipment, locator beacons, radios etc.), Water and Food. Survival aids can be carried in aircrew or passenger ALSE ensembles, within life rafts or specific survival aid packs carried separately on an aircraft. The type and quantity of survival aids required will depend on the CRE for a particular aircraft and may vary from operation to operation depending upon the potential survival environment and expected recovery times.

Superseded

2.152. Five survival environments, identified as Sea, Coastal, Arid, Jungle and Extreme Cold, are taught by Combat Survival Training School and addressed in the Professional ADF Aviators Reference Manual (PAARM) Volume 08 Combat Survival. Where necessary, the survival aid requirements are tailored to each of these environments.

2.153. **Limitations.** The following limitations apply to this Survival Aids section:

(a) The requirements of this section may not need to be applied to ADF transport aircraft that operate similarly to an equivalent civil aircraft type. In such cases DASR AMC ORO.70.A 'Compliance Examples' allow the quantity and type of available survival equipment to meet an acceptable civil standard consistent with a similar aircraft type. When not operated similarly to an equivalent civil aircraft type these requirements will need to be applied to ensure survival equipment appropriate to the task or mission is carried.

(b) Life Raft specific equipment such as pumps to inflate rafts, repair kits, patches, bailing buckets, oars/paddles are not considered within this Domain as it is expected that these will be a defined requirement in the design of a life raft and therefore covered in the Life Raft domain.

(c) First Aid is only considered within scope of this Domain where it is provided within an ALSE ensemble or Survival Kit for the purposes of use following an aircraft emergency landing, ditching or crash. First Aid kits supplied in an aircraft for use in a medical emergency during flight are considered out of scope.

2.154. National Aviation Authorities prescribe operational requirements for operators to have a means for determining suitable survival aids are selected for their particular operations and related environments. As such an exact and standard set of Survival Aids is not be prescribed here. Instead the types of survival aids that are considered essential and recommended for various environments are identified to allow systems project/program offices to work with operators to determine a tailored solution for a particular platform CRE.

2.155. This may be achieved with a standard survival aid suite that is applicable to all aspects of the CRE with supplemental survival aid configurations identified for particular environments/operations that are added or removed as required.

2.156. The selection and quantity of survival aids should be appropriate for the period of time anticipated between an emergency landing or ditching and the location and provision of support or rescue of survivors.

2.157. Tailoring of the survival aid solution to particular environments/operations and expected rescue time may assist in minimising the size and weight of survival aids.

2.158. The use of multi-functioning equipment may assist with the minimisation of size and weight of survival aids.

2.159. **Design Requirement.** *For each of the five key survival environments the following table identifies the minimum Essential (E) and Recommended (R) survival aids to be available in some capacity on the platform. Items that must be carried on the person (aircrew) are identified with an asterisk (*) others may only need to be in a survival kit or life raft. This table does not identify the exact type or quantity of the survival aid that is required, this must be determined on a case by case basis for a particular platform and the intended type of operation and environment and be suitably justified as part of a safety argument that supports a determination that associated risks have been*

Superseded

eliminated or otherwise minimised SFARP. There may be a need for multiple configurations for various operational circumstances.

Table 2-1: Required Survival Aids

Survival Aid	Sea	Coastal	Jungle	Arid	Extreme Cold
Protection					
First Aid					
Wound Dressings (e.g. bandage, gauze, padding, adhesive tape)	E	E	E	E	E
Tourniquet, Non-pneumatic	E*	E*	E*	E*	E*
Gloves, Examination	E	E	E	E	E
Bandage, Gauze, Impregnated (QuikClot)	R	R	R	R	R
Adhesive Bandages	R	R	R	R	R
Alcohol Swabs	R	R	R	R	R
Antiseptic Cream / Betadine	R	R	E	R	R
Sunscreen	E	E	E	E	E
Lip Balm	R	R	R	E	E
Insect Repellent	E	E	E	E	E
Motion Sickness Tablets	E	E			
Anti-Diarrhoea Tablets	R	R	R	R	R
Pain Relief Tablets	R	R	R	R	R
Clothing					
Sun Hat	R	R	R	R	

Superseded

Safety Pins	R	R	R	R	R
Clear Plastic Bags (Transpiration Bags)	R	R	R	R	R
Cord	R	R	R	R	R

Notes:

(a) Dependent on threat environment distress beacons and radios may be either unclassified (for Peace-time Search and Rescue (PSAR)) or encrypted (for Combat Search and Rescue CSAR). Note the current operational solution (PRC-112G) contains both radio and beacon capability along with GPS capability.

(b) IR Glint patch for CSAR applications only

Superseded

(c) Alternative portable water purification devices may be used however these need to be verified to provide a suitable quality of water.

2.160. **Survival Aid General Requirements and Considerations:** The following General requirements and considerations apply to survival aids.

(a) **Design Requirement (Essential).** *Survival Aids that are prone to damage or degradation by water must be contained in waterproof packaging.*

(b) **Design Requirement (Essential).** *Survival Aids with sharp edges must be packaged to prevent injury to personnel or damage to inflatable ALSE which it is packaged with.*

(c) **Design Requirement (Essential).** *Survival Aids must have a means of preventing loss such as a lanyard connecting them to an ALSE Ensemble, life raft or survival kit as applicable.*

(d) **Design Requirement (Essential).** *Where it is not immediately obvious survival aids must be marked for identification and method of operation.*

(e) **Design Requirement (Essential).** *Survival Aid packaging must be able to be opened with chilled and/or gloved hands. This must be demonstrated by the Chilled Hands and Gloved Hands tests of SAE Aerospace Recommended Practice ARP1282 Rev B Survival Kit, Life Rafts and Slide Rafts.*

(f) **Design Requirement (Recommended).** *Metallic survival aid components should be resistant to salt-water corrosion.*

(g) **Key Consideration.** The packaging for Survival Aids needs to be suitably designed to cater for the demands of storage, delivery method and intended use.

(h) **Key Consideration.** Survival Aid documentation should include instructions on the safe use, maintenance and storage of the survival aids. This is particularly important for pyrotechnic devices and bright strobe lights.

(i) **Key Consideration.** When new survival aids are introduced into service, aircrew should be appropriately trained for familiarisation with the equipment and instruction on its' safe use. This is particularly important for pyrotechnic devices, bright strobe lights and the Tourniquet and QuikClot bandage first aid items.

(j) **Guidance Maerial.**

1. Australian Army Land Warfare Procedures – General LWP-G-7-7-6 Environmental Survival identifies general considerations for the development of a survival kit at Chapter 2 paragraphs 2.24 for characteristics of a good survival kit and 2.25 for considerations for optimising the limited space and weight available for survival equipment.

2. In an operational environment it may be necessary to ensure that survival aids are easily concealable.

3. CSTS COMSURV Training identifies the need for carriage of a personal survival kit. ALSE will provide a basic kit. Selection of personal survival kit contents should not duplicate what is provided as ALSE but may supplement it to provide some of the recommended items if they are not able to be accommodated within the ALSE.

Superseded

2.161. **Integration Requirements and Considerations.** The following Integration requirements and considerations apply.

(a) Survival aids will generally be either carried on the person (aircrew ALSE Ensemble), carried within a life raft or separate survival kit. Some items are critical to the highest priorities of survival and are important to be readily available on the person, the method of carriage will be dependent on the aircraft type, its CRE and the type of operations conducted, and may also be limited by the available space on the platform.

(b) **Design Requirement (Essential).** *Where survival aids are integrated into an ALSE Ensemble, the size and weight of the survival aids must be suitable for accommodation by the ensemble.*

(c) Where survival aids are integrated into an ALSE Ensemble:

1. **Guidance Material.** Tailoring of the survival aid solution to particular environments/ operations and expected rescue time may assist in minimising the size and weight of survival aids.

2. **Guidance Material.** Refer to Carriers and Ensemble Integration domain for further requirements and key considerations related to integration with seat and restraint harness systems, the impact on flight controls movement and compatibility with other aspects of the aircraft cockpit and/or cabin.

(d) **Guidance Material.** Where survival aids are integrated into a Survival Kit refer to the Survival Kit and Rescue Pack Domain for further requirements related to the integration into the Survival Kit and to the aircraft.

(e) **Guidance Material.** Where survival aids are stowed in a Survival Kit or life raft, items with limited life or inspection/servicing requirements should be packaged so they are easily accessible for replacement or inspection/servicing.

(f) **Guidance Material.** To limit weight and bulk of survival equipment, duplication across survival aid sources (i.e. carried, survival kit, ditching kit life raft) should be minimised unless deemed necessary for expected survival scenarios.

2.162. **Item Specific Requirements and Considerations.** For a number survival aid types there are some key standards or requirements that must be applied. Where applicable these are prescribed below:

(a) **First Aid**

1. **Guidance Material.** First Aid items should be selected with consideration for injuries that may be sustained from an aviation emergency ditching, landing or crash and the expected survival environment. This should include some combination of bandages, dressings, padding and adhesive tapes. Advice should be sought from Joint Health Command to guide the selection of suitable first aid for a particular application.

(b) **Pyrotechnic Signalling Devices**

1. **Design Requirement (Essential).** *Laser flares must not be used as a substitute for conventional pyrotechnic flares.*

2. **Guidance Material.** Laser flares cannot be considered equivalent to conventional orange smoke flares which provide omnidirectional signalling of location during day conditions. They can be considered as supplemental to pyrotechnic flares only.

Superseded

3. **Guidance Material.** ALSLMU are not the SME for pyrotechnic signalling devices. For advice contact the Explosive Materiel Branch via casglsdembcoordination@dpe.protected.mil.au group inbox. For safety requirements applicable to pyrotechnic signalling devices refer to the eDEOP101 – Department of Defence Explosives Regulations.

(c) **Light Marker Distress (Strobe Light)**

1. **Design Requirement (Essential).** *Where a light marker distress (Strobe Light) is to be integrated with an ALSE Ensemble its intended position during operation must not be in close proximity to the survivor's eye to ensure the bright light does not impact their vision.*

(d) **Distress Beacons**

1. When interpreting Distress Beacon standards and technology, different terminology can be used to describe the type of distress beacon required. A Personal Locator Beacon (PLB) is generally a small, non-buoyant beacon that is easily carried on the person. An Emergency Position Indicating Radio Beacon (EPIRB) is a buoyant beacon generally used on boats and life rafts and designed to float in the water. Distress beacons are sometimes referred to as Electronic Location Transmitters (ELT), this is generally associated with those fitted to an aircraft however it is also sometimes used to include all types. Care should be taken in the selection of each device as the terminology and intended use can often vary from country to country.

2. **Design Requirement (Essential).** *All beacons used by Defence must be 406.025 MHz COSPAS–SARSAT capable unless approved by HQJOC AOC.*

3. **Design Requirement (Essential).** *Distress Beacons for PSAR applications must comply with the Australian Communications and Media Authority (ACMA) Radio communications (406 MHz Satellite Distress Beacons) Standard 2014 and the referenced requirements of AS/NZS 4280.1: 2017 (for EPIRBs) or AS/NZS 4280.2:2017 (For PLBs).*

4. **Design Requirement (Recommended).** *Distress Beacons for PSAR applications should comply with the remaining aspects of either AS/NZS 4280.1: 2017 (for EPIRBs) or AS/NZS 4280.2:2017 (For PLBs).*

5. **Guidance Material.** FAA TSO-C126a or TSO-C126b approved distress beacons are common. These comply with requirements from RTCA DO-204A or RTCA DO-204B respectively. These standards have not yet been assessed for equivalency with the ACMA standard or AS/NZS standards. As such if a TSO approved beacon is proposed to be used it should be assessed against the essential ACMA standard.

6. **Guidance Material.** TSO-C126 refers to distress beacons as Emergency Locator Transmitters of various types. The applicable types are Survival Class A (Buoyant) which is equivalent to an EPIRB and Survival Class B (Non-Buoyant) which is equivalent to a PLB. Other types relate to those ELTs that are installed to the aircraft itself.

7. **Guidance Material.** Distress Beacons must be registered through Headquarters Joint Operations Command (HQJOC) Air and Space Operations Centre (AOC) on the ADF Search and Rescue Beacon Database.

(e) **Compass**

Superseded

1. Most compasses are designed to operate in either the Southern or Northern Hemisphere. They do not function correctly in the opposite hemisphere due to an imbalance in the needle from alignment of the earth's magnetic field. As such it is important that a compass is selected suitable for the hemisphere of operation.

2. **Design Requirement (Recommended).** *Where operations span both hemispheres, or aircraft are routinely expected to operate in either hemisphere, a Dual hemisphere compass should be used.*

(f) **Sunscreen**

1. **Design Requirement (Essential).** *Sunscreen provided as a survival aid must be at least SPF 45+ in accordance with AS/NZS 2604:2012 Sunscreen products – Evaluation and Classification.*

(g) **Water**

1. **Design Requirement (Essential).** *Water used in packaged water must meet the requirements of the FSANZ standard 2.6.2 – Non-Alcoholic Beverages and Brewed Soft Drinks.*

2. **Design Requirement (Essential).** *Packaged water must meet the requirements FSANZ standard 1.6.1 (Microbiological Requirements for Food). Testing for E.coli should be conducted following the procedure listed in AS/NZS 4276.22.*

3. **Design Requirement (Recommended).** *Once filled, the air above the water level in packaged water should be totally displaced.*

4. **Design Requirement (Recommended).** *Packaged water should have the date of filling stamped after the words Date Filled.*

5. **Design Requirement (Recommended).** *Packaged water should have the batch numbers stamped after the words Bag Batch No.*

6. **Key Consideration.** The packaging for water needs to be suitably designed to cater for the demands of storage, delivery method and intended use for the water. For example water carried in a deployable rescue pack may be carried external to the aircraft cabin and be subject to altitude pressure variations, freezing at low temperatures (noting expansion of water on freezing) and being dropped from altitude.

(h) **Food**

1. **Design Requirement (Essential).** *Food sources provided as survival aids must meet the minimum ADF standard for Combat Rations which is prescribed in DEF(AUST) 10374 Food Safety Standard for Manufacturers and Suppliers of Combat Rations and their Components Standard, Issue 1.*

2. **Guidance Material.** One example of suitable food provisions is the Emergency Flying Ration which is a standardised ration in accordance with DEF(AUST) 10655 that can be included in survival kits or life rafts.

(i) **Knives**

1. **Design Requirement (Recommended).** *The considerations of Australian Army Land Warfare Procedures – General LWP-G-7-7-6 Environmental Survival Chapter 2 Section 2-1 should be applied to the selection of pocket and survival knives as applicable.*

Superseded

(j) **Electronic equipment**

1. **Design Requirement (Essential).** *Any electronic survival aids must be evaluated for safe carriage and use in accordance with the requirements for portable electronic devices in DASDRM Section 5 Chapter 6 Role Equipment and Portable Electronic Devices (including Annex A). This will ensure safety of the electrical design in an aviation environment (including batteries) as well as for Electromagnetic Interference and Compatibility (EMI/C).*

2. **Key Consideration.** For battery powered devices where spare batteries are provided they should be compatible with the OEM recommended battery type to ensure performance.

(k) **Other.** Requirements for some survival aid items have not yet been developed. Contact ALSLMU for further information and advice on requirements for other items.

Thermal / Immersion Protection

2.163. The main objective of immersion protective clothing is to limit the rate of heat loss of a survivor in water to avoid death from hypothermia before rescue. This objective is achieved by the provision of thermal insulation, generally provided through insulated undergarments, and outer water resistant layers to ensure the insulation continues to perform satisfactorily post submersion in cold water.

2.164. Two major types of immersion suit exist, quick don and constant wear. Both are used in the ADF in order to ensure that all use cases are catered for. Generally, constant wear suits are used in circumstances where there is inadequate space or time to react in an emergency, while quick don suits may be used on larger aircraft where there may be adequate warning prior to a ditching event.

2.165. **Design Requirement (Essential).** *Constant wear immersion suits must comply with ISO 15027-1:2012.*

(a) *Tailoring. The requirements listed at 4.5 relating to conspicuity are deemed non-essential as a less conspicuous suit may be required for operational reasons or to minimise distracting reflections within the flight deck.*

2.166. **Design Requirement (Essential).** *Quick don immersion suits must comply with ISO 15027-2:2012.*

(a) **Tailoring.** The requirements listed at 4.5 relating to conspicuity are deemed non-essential as a less conspicuous suit may be required for operational reasons or to minimise distracting reflections within the flight deck

2.167. Design Requirement (Essential). All immersion suits must be tested to ISO 15027-3:2012.

(b) **Guidance Material.** The standard gender breakdown for testing assumes 6 personnel of which at least one but no more than three are female. It is recommended that testing be conducted with an equal gender balance where possible.

2.168. **Design Requirement (Recommended).** *Quick don immersion suits should also comply with the illumination resistance requirements outlined at 4.12.2 of ISO 15027-1:2012.*

Superseded

(a) **Guidance Material.** Properly stored quick don immersion suits are not expected to be significantly exposed to light, but it is possible that some may become exposed therefore some resistance to degradation is desired.

2.169. **Design Requirement (Recommended).** *Immersion suits should have an attached sprayhood as per ETSO-2C502 requirement 10 – breathing protection.*

(a) **Guidance Material.** A spray hood can minimise the risk of secondary drowning in rough water. Should a spray hood be impractical other means of limiting secondary drowning should be implemented.

2.170. **Key Considerations.** The following key considerations should be taken into account when introducing immersion suits to service.

(a) There exists several classes of immersion suit, each rated for varied temperatures and durations of immersion. It is important the appropriate class of immersion suit is selected based in the water temperature, likely response time in an emergency and the ambient air temperature. A solution with excessive insulation may lead to heat related injury, insufficient insulation may lead to hypothermia.

(b) Integration of Immersion suits with other ALSE and confined cockpits must be completed to ensure that the immersion suit does not significantly impede the wearer or their equipment

Survival Kits and Rescue Packs

2.171. Survival Kits and Rescue Packs provide a means of holding a range of survival aids for use either following an aircraft emergency or for delivery to survivors as part of a Search and Rescue operation. Guidance relating to the internal contents (life rafts and survival aids) of survival kits and rescue packs can be found separately in the domain in which they belong.

2.172. Survival Kits and Rescue Packs are categorised by the following definitions:

(a) **Survival Kit.** A kit installed or carried on to an aircraft containing survival aids to assist crew and passengers in the event of an emergency landing, ditching or crash.

(b) **Rescue Pack.** An air droppable pack designed to provide assistance to survivors on the land or at sea. This may include survival aids, first aid, medical or other equipment and life rafts as required by the intended application.

2.173. **Design Requirement (Essential).** *When fitted to an aircraft survival kits must be stored in a marked location that is rapidly accessible and does not hinder evacuation.*

2.174. **Design Requirement (Essential).** *Survival kits must meet the fire resistance requirements of Part I of Appendix F to FAR 25 as applicable.*

2.175. **Design Requirement (Essential).** *Battery operated equipment must have sufficient battery capacity available to allow for operation throughout the intended survival duration of the survival kit or rescue pack in which the equipment is contained.*

(a) **Key Consideration.** This requirement may be met though a single large capacity battery, multiple interchangeable batteries or a means to reliably recharge the battery in the field.

2.176. **Design Requirement (Recommended).** *The battery charge at which battery operated equipment will cease to function correctly should be established.*

Superseded

2.177. **Design Requirement (Recommended).** *Rescue Packs should meet the fire resistance requirements of part I of Appendix F to FAR 25 as applicable.*

2.178. **Design Requirement (Recommended).** *Battery expiration dates of included equipment should be marked on the exterior of a survival kit or rescue pack.*

2.179. **Design Requirement (Recommended).** *Survival kits and rescue packs should be designed in a manner such that the probability of any error in configuration of its contents is limited.*

2.180. **Design Requirement (Recommended).** *Survival Kits and Rescue packs should not become damaged in a manner that reduces its function by temperature cycles, pressure cycles, forces or exposure to other environmental conditions placed upon it both during flight and when not in use but fitted to the aircraft on the ground.*

2.181. **Key Considerations.** In addition to the standards and requirements identified the following key considerations should be taken into account in the design of Survival Kits and Rescue Packs.

(a) Components of Survival Kits and Rescue Packs should be generally resistant to wear and tear.

(b) Weight and balance of the rescue pack should be understood and suitably communicated to operators.

(c) Survival Kits and Rescue Packs should be packed in such a manner to minimise the likelihood of damaging survival aids.

(d) Further guidance and test methods are contained in MIL-HDBK-1763 Aircraft Stores Compatibility.

(e) AMTDU's Aerial Delivery Development personnel are the SME's and certifier for load clearance and should be contacted for advice on how to attain and maintain load clearances.

Continuing Airworthiness Requirements

2.182. To ensure that Survival Kit and Rescue Pack functions are not compromised through inadequate continuing airworthiness management systems, the following continuing airworthiness requirements and key considerations apply.

2.183. **Continuing Airworthiness Requirement (Essential).** *All components of Survival Kits and Rescue Packs must be regularly inspected and maintained in accordance with approved Instructions for Continuing Airworthiness. This includes ensuring that batteries are inspected, charged and replaced as required.*

2.184. **Continuing Airworthiness Requirement (Essential).** *Life Support equipment must be inspected, repaired and packed in an approved maintenance facility IAW AAP 7220.001-99 Aeronautical Life Support Instructions.*

2.185. **Continuing Airworthiness Requirement (Essential).** *Crew and maintainers must be trained in the correct procedures for manual handling for the purposes of loading and deploying Survival Kits and Rescue Packs.*

2.186. **Continuing Airworthiness Requirement (Recommended).** *Battery operated equipment should have batteries replaced or recharged once the charge drops below the minimum required for correct functioning.*

Superseded

2.187. DASDRM Section 3 Chapter 6 includes requirements for Aircraft Oxygen Systems. Some of the requirements of that chapter may be considered applicable to oxygen masks as a subset of the oxygen system and should therefore also be considered in addition to the requirements of this section.

2.188. **Design Requirement (Essential).** *Materials used in oxygen / smoke and fumes masks must be assessed as suitably fire resistant, at the intended temperature ranges, and oxygen concentration levels to which the mask will be exposed by applying relevant materials standards and requirements prescribed within S3C6.*

2.189. **Ejection Seat Aircraft.** For ejection seat aircraft the following requirements must be applied for oxygen / smoke and fumes masks.

(a) **Design Requirement (Essential).** *The requirements of Air Force Interoperability Council Air Standard ASM 4068 – Physiological Requirements for Aircrew Oxygen Masks for Use at High Breathing Pressures Ed2 v2.*

(b) **Design Requirement (Essential).** *The mask related requirements in Air Force Space Interoperability Council Air Standard ASMG 4039 – Minimum Physiological Requirements for Aircrew Demand Breathing Systems Ed1 v2.*

(c) **Design Requirement (Essential).** *Inwards relief features, such as an anti-suffocation valve, must be incorporated into oxygen / smoke and fumes masks unless it can be demonstrated that a failure of the breathing air system, that induces suffocation, meets the associated failure probability objective for a catastrophic failure condition. Analysis is one way of demonstrating this compliance.*

2.190. **Non-Ejection Aircraft.** For Non-Ejection aircraft the following requirements apply:

(a) **Design Requirement (Essential).** *For aircraft with type certification based on civilian airworthiness codes the following civilian based requirements of oxygen and smoke and fumes masks must be applied:*

1. *Pilot/Co-Pilot/Other Sedentary Aircrew masks must be of the Quick-Don type and meet the requirements of:*
   - i. *TSO-C99a Flight Deck (Sedentary) Crewmember Protective Breathing Equipment, of 05 Jun 08, or*
   - ii. *ETSO-C99a Flight Deck (Sedentary) Crewmember Protective Breathing Equipment, of 05 Aug 16.*
2. *Mobile Aircrew masks must meet the requirements of:*
   - i. *TSO-C116a Crewmember Portable Protective Breathing Equipment, of 30 Jul 09,or*
   - ii. *ETSO-C116a Crewmember Portable Protective Breathing Equipment, of 05 Aug 16.*
3. *Passengers masks must meet the requirements of:*

Superseded

i. *TSO-C64b Federal Aviation Administration Technical Standard Order: Passenger Oxygen Mask Assembly, Continuous Flow, of 21 May 08, or*

ii. *ETSO-C64b European Technical Standard Order: Oxygen Mask Assembly, Continuous Flow, Passenger, of 19 Dec 16.*

4. *Demand Oxygen Masks must meet the requirements of:*

i. *TSO-C78a Crewmember Demand Oxygen Masks, of 27 May 08, or*

ii. *ETSO-C78a Crewmember Demand Oxygen Masks, of 21 Feb 18.*

5. **Tailoring Advice.** The standards referenced by the TSO documents prescribe particular microphone standards. In the event that the microphone standards are not suitable for integration with the aircraft then alternative microphones may be permitted. In such cases it must be shown that the microphones are safe to operate in the oxygen rich environment with an equivalent level of safety.

6. **Key Consideration.** Oxygen Masks designed under the prescribed Ejection Seat Aircraft requirements can be utilized in Non-Ejection aircraft if the design is deemed suitable to the CRE.

(b) **Design Requirement (Essential).** *For other ADF aircraft the requirements identified above for civil based aircraft at sub-para a must be applied with the following additional considerations:*

1. *Use during periods of intended cabin depressurisation, not just for emergency, must be accounted for. This includes the need to allow the wearer to occlude their nostrils in order to perform the Frenzel and/or Valsalva manoeuvre whilst wearing the mask.*

2. *Operating altitude / cabin altitude requirements for defence aircraft may exceed the requirements of the prescribed standards. In such cases the relevant standard must be tailored to cater for the higher altitudes of a specific aircraft's CRE.*

3. *In some aircraft CRE, passengers may require additional smoke and fumes protection of the eyes. In these cases TSO-C64b / ETSO-C64b will not be suitable. SAE AS8048 Performance Standard for Passenger Smoke and Toxic Fumes Respiratory Protective Equipment or standards for aircrew protective breathing equipment must be applied for passenger applications where protection of the eyes from smoke and fumes is required.*

(c) Where only smoke and fumes protection is required (for example on aircraft operating below the altitudes at which supplementary oxygen is required such as rotary wing aircraft) the following standard may be applied:

1. **Design Requirement (Recommended).** Air Force Interoperability Council Air Standard ASM 4066 Ed 1v4 Smoke Protection Breathing Equipment Used by Mobile Aircrew in Non-Ejection Seat Aircraft at Pressure Altitudes up to 10,000ft.

2. **Design Requirement (Recommended).** In addition to ASM 4066 Ed 1v4 requirements the mask should allow the wearer to occlude their nostrils in order to perform the Frenzel and/or Valsalva manoeuvre whilst wearing the mask.

(d) **Design Requirement (Recommended)** Inwards relief features, such as an anti-suffocation valve, should be incorporated into oxygen / smoke and fumes masks unless analysis

Superseded

demonstrates that a failure of the breathing air system, that induces suffocation, meets the associated failure probability objective for a catastrophic failure condition.

2.191. **Key Considerations**. In addition to the standards and requirements identified the following key considerations should be taken into account in the design of an Oxygen / Smoke and Fumes mask:

(a) Materials should not contaminate breathing gases so as not to irritate the respiratory system or pose long term safety hazards.

(b) Parts of the mask which come into contact with the skin of the head and neck should be made of soft, pliable materials which are non-irritating, non-allergenic, and non-toxic to wet and dry skin.

(c) Masks should not impart an offensive smell or taste to the wearer.

Underwater Emergency Breathing

2.192. Underwater Emergency Breathing Devices (UEBD) consist of a means of storing pressurised air and a regulated delivery system. UEBD are designed for use in rotary wing aircraft to extend the available escape duration should it be rapidly sinking.

2.193. **Design Requirement (Essential).** *The UEBD must meet all requirements of ACS 4043 of 27 Feb 02.*

2.194. **Design Requirement (Essential).** *The UEBD must meet the following requirements from UK CAA draft technical standard CAP 1034 "Development of a Technical Standard for Emergency Breathing Systems" of May 2013.*

(a) *Be simple to deploy and capable of being operated with either hand. The number of deployment actions must be minimised, ideally, with no more than one action being required to activate the system on submersion.*

(b) *Potential snagging hazards must be reduced to a minimum. Any part of the UEBD that might pose a snagging hazard during flight, emergency evacuation, escape or must be suitably covered, protected or restrained.The UEBD design and materials used in its construction must be chosen to have no features which would have a detrimental effect on the performance or operation of other equipment, impair the performance of the seat harness or hinder harness release. UEBD must not impede or prevent escape from a submerged helicopter.*

2.195. **Design Requirement (Essential).** *Requirements 5.7.1 a to f of EN 250:2014 relating to demand regulator performance; work of breathing and respiratory pressure must be met in order to maximise ease of breathing and to minimise the risk of barotrauma.*

2.196. **Design Requirement (Essential).** *Pressure cylinders must meet the requirements of AS 2030.1-2009.*

2.197. **Design Requirement (Recommended).** *The mouthpiece, with the hose and general assembly should withstand a minimum of 1000N as per BS EN 250:2014 requirement 5.8.1 relating to external force on the hose assembly.*

2.198. **Design Requirement (Recommended).** *Head movement should not have any negative effects on the air supply pressure or volume at the mouthpiece.*

Superseded

2.199. **Key considerations.** The following are key considerations that should be considered when introducing underwater emergency breathing devices.

(a) UEBDs are designed to assist with proven existing egress procedures, they are not the only consideration in helicopter underwater escape.

(b) The intent of a UEBD is not as a SCUBA device, UEBD is intended for escape only, users should not attempt to re-enter the aircraft once they have successfully egressed.

(c) Extensive HUET training is required for all users of UEBD, regular training in proper use of the system is required in order to extract maximum benefit from the system should it be required in an emergency.

(d) Breathing air that meets the minimum standards prescribed at paragraph 4.4.2 of AS/NZS 2299.1:2015 should be used to fill the cylinder.

Table 2-2: Breathing air gas composition per 4.4.2 AS/NZS 2299.1:2015

Component	Concentration at 15°C and 101.3 kPa
Oxygen	(21 ±1)% by volume
Carbon Dioxide	≤600 ppm (≤1500mg/m^3)
Carbon Monoxide	≤5 ppm (≤8mg/m^3)
Oil	≤0.5 mg/m^3
Odour	No objectionable odour

(e) The available quantity of breathing air should be maximised while maintaining a form factor with minimal impacts on other ALSE and mobility. For example a 4500psi system is preferred over a comparable 3000psi system.

(f) Integration of UEBDs with clothing should consider the placement of all other equipment. The best overall solution which ensures that the UEBD is readily accessible while providing minimal impact on other equipment should be sought. Placement of the UEBD should also consider the forces of a crash and the potential for injury.

(g) As with any high pressure vessel, dangerous goods considerations are required when transporting UEBDs. This is managed through existing procedures for managing dangerous goods relating to scuba tanks.

(h) Filling procedures should be compliant with AS 2030.5-2009.

(i) Moisture content should be minimised and ideally be less than 100mg/m3 as recommended in AS/NZS 2299.1:2015 paragraph 4.2.4.

Superseded

Hearing Protection

2.200. Noise is a workplace hazard regulated by the WHS Regulations 2011 at Chapter 4, Part 4.1. Regulations 56, 57, 58 and 59. Importantly Regulation 56 defines the exposure standard for noise.

2.201. ADF policy is presented in SafetyMan Noise Management Procedure 04 – Noise Identification Assessment and Monitoring, which identifies that specialist advice is available to support noise assessments.

2.202. CASsafe Requirements for Managing Regulated Hazards, Regulated Hazard 2 - Noise provides relevant CASG policy and identifies that specialist advice is also available from the CASG directorate of Work Health and Safety.

2.203. Hearing protection includes both passive and Active Noise Reduction (ANR) and in some cases includes helmet design as a major contributing design factor. The aircraft platform cockpit and cabin noise profile is required when determining the type of hearing protection necessary. Different hearing protection configurations may be required for each individual aircraft platform. Alternate configurations may also be required to satisfy comfort requirements of individual aircrew and passengers.

2.204. Aircrew hearing protection generally needs to cater for communications and situational awareness of aircraft noises and warning signals. In many cases, Aircrew hearing protection will need to be integrated with a flight helmet. In some cases, passengers may need similar hearing protection solutions to aircrew, in others general Personal Protective Equipment (PPE) type hearing protection may be suitable. Regardless, the process of assessing noise hazards for passengers requires the same level of rigour as for aircrew to ensure adequate protection is provided.

IMPORTANT NOTE

The focus of this section is the identification of standards and requirements for hearing protection equipment selection. Selection of hearing protection lies within the identification of risk control measures phase of a risk assessment process and is considered PPE, the lowest level of control in the hierarchy of controls. Selection of hearing protection can only occur once the sources of noise are identified, the risks associated with the noise are assessed and understood (i.e. noise levels are measured) and the higher controls of elimination, substitution, engineering and administration have been considered and applied where reasonably practicable.

2.205. **Key Considerations.** for this process are provided along with the prescription of standards and requirements for hearing protection due to the importance of first understanding the noise hazard and managing it with a wider application of the hierarchy of controls.

Understanding Noise Hazards

2.206. **Key Consideration.** The Work Health and Safety (WHS) (Managing Noise and Preventing Hearing Loss at Work) Code of Practice 2015 should be applied to the assessment of aircraft noise hazards. (This is an approved code of practice under section 274 of the WHS A) AS/NZS 1269.0:2005(R2016) Occupational Noise Management - Part 0: Overview and General Requirements also provides guidance on adopting an integrated approach to noise management and outlines how the AS/NZS 1269 series of standards can be applied.

Superseded

2.207. **Key Consideration.** The first phase of managing noise is identifying the noise hazards and assessing the risk. This can be achieved by conducting noise surveys to measure and understand the noise aircrew and passengers on aircraft are exposed to. This should include consideration of pre and post-flight noise of the airfield that is routinely encountered. AS/NZS 1269.1:2005 (R2016) Occupational Noise Management – Measurement and Assessment of Noise Immission and Exposure provides suitable requirements and guidance on the types of noise assessment that may be required, the general objectives of an assessment and the instrumentation and procedures needed to carry it out. Of particular interest is Section 6.3 identifying noise assessments required for hearing protector programs and Section 8.5 detailing the measurement procedures required for selecting hearing protectors. Within Defence the following support is available:

(a) The Institute of Aviation Medicine (IAM) may be engaged to support the conduct of noise surveys for ADF aircraft.

(b) Environmental Health Officers (ENVHOs) may be engaged to support the conduct of noise assessments.

(c) CASG Directorate of Work Health and Safety may provide Occupational Medicine and Hygiene specialist advice.

2.208. **Key Consideration.** Once the noise risks are understood, WHS Regulations require them to be eliminated or otherwise minimised SFARP using the hierarchy of controls. AS/NZS 1269.2:2005(R2016) – Occupational Noise Management Part 2 Noise Control Management provides requirements and guidance on the management of noise controls and may be a useful reference for the consideration of higher order risk controls before applying hearing protection as PPE.

2.209. **Key Consideration.** All considerations of Section 5.6 of the WHS (Managing Noise and Preventing Hearing Loss at Work) Code of Practice 2015 are applicable to the selection of hearing protectors.

Hearing Protector Selection Requirements

2.210. **Design Requirement (Essential).** *Where higher order risk controls cannot reduce noise exposure below the exposure standard (LAeq,8h of 85 dB(A), or LC peak of 140 dB(C), WHS Regulation 56) hearing protection solutions must be selected in accordance with AS/NZS 1269.3:2005 (R2016) Occupational Noise Management – Hearing Protector Program Section 6 and appendices A and B. The following ADF policy in SafetyMan must be applied:*

(a) *Both the Classification Method and then Octave-Band Method must be applied for all Red, Black and Extreme hearing protection zones (i.e. continuous noise levels exceed 100 dB(A)).*

(b) *For Earplugs and Earmuffs worn in combination for use in Black and Extreme hearing protection zones (i.e. continuous noise levels exceeding 115 dB(A)) the combined attenuation is calculated by adding 3 dB to the highest noise reduction level of the two personal hearing protectors. This must be considered as information from the relevant authority for the purposes of AS/NZS 1269.3:2005 (R2016) paragraph 6.2.5. At lower noise levels, manufacturer information on combined attenuation is to be used.*

2.211. **Design Requirement (Recommended).** The exposure standard applied for the selection of hearing protection should be reduced (from the regulated LAeq,8h of 85 dB(A) or LC,peak of 140 dB(C)) to an LAeq,8h of 80 dB(A) or LC,peak of 135dB(C) to account for the potential exposure of aircrew to ototoxic chemicals present in aviation fuel as recommended in the WHS (Managing Noise

Superseded

and Preventing Hearing Loss at Work) Code of Practice 2015 and SafetyMan Noise Management Procedure 04.

2.212. **Design Requirement (Recommended).** *The exposure standard applied for the selection of hearing protection should be reduced (from the regulated LAeq,8h of 85 dB(A) or LC,peak of 140 dB(C)) to an LAeq,8h of 80 dB(A) or LC,peak of 135dB(C) for children. For the purpose of this requirement a 'child' is a person under the age of 17, who is too physically small to be fitted with hearing protection which would otherwise be available for use by adults.*

2.213. **Design Requirement (Recommended).** *Efforts should be made to reduce noise exposure below the exposure standard SFARP, cognisant of the following (where applicable):*

(a) Where routine work that requires speed or attentiveness, or where it is important to carry on conversations, the exposure should be kept to LAeq,8h of 70 dB(A) as identified by the WHS (Managing Noise and Preventing Hearing Loss at Work) Code of Practice 2015.

(b) Where sortie durations exceed 10 hours, exposure should be adjusted to account for increased risk of hearing loss in accordance with WHS (Managing Noise and Preventing Hearing Loss at Work) Code of Practice 2015 and SafetyMan Noise Management Procedure 04.

(c) Where aircrew fly more than 5 days a week or more than 8 hours per day, exposure standards should be adjusted as described in SafetyMan Noise Management Procedure 04.

Hearing Protector Design and Performance Requirements

2.214. **Design Requirement (Essential).** *Hearing protectors must comply with the requirements of AS/NZS 1270:2002 (R2014) Acoustics - Hearing Protectors, tailored as follows:*

(a) *The majority of requirements and testing are designed for conventional hearing protectors such as Ear Muffs and Ear Plugs and may not be directly applicable to hearing protection solutions required for aircrew and passengers (e.g. those integrated with aircrew helmets). The contribution of the helmet to attenuation of sound should be considered as part of the hearing protection solution. Such solutions should be considered 'Other Devices' as identified at Section 5, and the clauses for complying with Section 2 general requirements as far as possible and applying testing of Sections 3 and 4 in a way that meaningful comparisons can be made with more conventional hearing protectors, should be applied as in the following examples:*

1. *The low temperature drop test for helmet-mounted earmuffs should not be applied to aircrew helmets where the hearing protectors are contained within the helmet and are unlikely to be damaged by situations that this test represents.*

2. *Aircrew helmets usually achieve fitment of the hearing protector to the ear by custom fitting of the helmet. As such, headband-flexing test would not be applicable. In such cases, an analytical assessment of the hearing protection elements of the helmet to ensure sufficient retention and sealing around the wearers ear can be achieved by the means of fitting and adjustment provided with the helmet.*

(b) *ANR Hearing Protectors are considered 'Specialist Devices' in accordance with clause 1.4.12 and should be treated in accordance with Section 5. Further consideration of ANR and other applicable requirements is provided in a dedicated section below.*

Superseded

(c) *Hearing protection solutions may be assessed/tested to international standards. To cater for these solutions this requirement may, where not deemed reasonably practicable to have the solution tested to this AS/NZS 1270:2002(R2014), be met by suitable analysis to determine that the international standard provides an equivalent level of attenuation.*

Active Noise Reduction Requirements

2.215. ANR technology provides improved attenuation at low frequencies (up to 1000 Hz) and negligible attenuation (and in some cases slightly negative attenuation) at higher frequencies (above 1000 Hz). Any selection of ANR will require detailed understanding of the platform noise profile and the specific performance details of the ANR technology being considered to ensure it provides suitable noise attenuation and its effect on intelligibility of communications is understood. When ANR hearing protection is to be used, the following requirements and considerations apply:

(a) **Key Consideration.** ANR hearing protectors are considered 'Specialist Devices' and should be tested as passive devices in accordance with AS/NZS 1270:2002(R2014), as identified above, for the purposes of a baseline comparison to conventional protectors. This will also provide an assessment of the minimum protection afforded in the event of ANR failure.

(b) **Design Requirement (Recommended).** *Active noise reduction systems used in helmets and headsets should be evaluated in accordance with Advisory Publication (ADV PUB) ASMG 4092 Ed 1 (v1, v2 or v3) – The Evaluation of Active Noise Reduction (ANR) in Flight Helmets and Headsets with the following considerations:*

1. *The Measurement of Sound Pressure Levels at the Ear Canal method should be used as the preferred laboratory method noting it is suitable for ear cup type protectors.*
2. *Other laboratory methods presented in ADV PUB ASMG 4092 Ed 1 (v1, v2 or v3) for assessing attenuation should be considered for the evaluation of in-ear ANR devices where the measurement by microphone is not possible.*
3. *The laboratory method for assessing signal detection presented in ADV PUB ASMG 4092 Ed 1 (v1, v2 or v3) should be used.*
4. *The subjective Modified Rhyme Test method presented in ADV PUB ASMG 4092 Ed 1 (v1, v2 or v3) should be used to assess speech intelligibility.*
5. *The field assessment of attenuation inflight by measuring the Ear Canal sound pressures by microphone and comparing with measurements outside of the helmet/ headset should also be used noting this is limited to assessment of ear cup type protectors. Where used in combination with earplugs or for in-ear ANR systems, additional assessment is required. Subjective assessment via questionnaire is also identified and considered suitable to form part of an evaluation of ANR systems.*
6. *The method of field assessment for improvement in signal detection by introducing tones through the ICS during flight/operating profiles and comparing the volume settings required with ANR OFF and ON to provide a measure of improved signal detection should be applied.*
7. *Subjective Field Speech intelligibility assessment methods should be used to evaluate ANR improvements in speech intelligibly.*

Superseded

(c) Some international standards for Active Noise Reduction have been identified by ALSLMU but are yet to be fully considered. Contact ALSLMU to discuss ANR requirements.

General requirements and considerations for hearing protection solutions

2.216. **Design Requirement (Essential).** *Aircraft warning tones and annunciations must remain audible to aircrew whilst wearing the hearing protection.*

2.217. **Design Requirement (Essential).** *Speech communications over radio and intercommunications systems must remain audible and intelligible to aircrew whilst wearing the hearing protection.*

2.218. **Key Consideration.** The effect of hearing protection on direct voice communications should be evaluated where required. The safety of personnel will need to be prioritised to ensure exposure standards are not exceeded. This may necessitate additional communications equipment where such communication is deemed essential and cannot be achieved directly with necessary hearing protection in place.

2.219. **Design Requirement (Essential).** *Where rapid altitude pressure changes are possible (e.g. fast jet applications) hearing protectors that effectively seal the ear canal must allow for equalisation of pressure across the protector between the inner ear and surrounding environment to prevent ear damage. E.g. when an individually moulded Communication Earplug (CEP) is used a vented CEP transducer is required.*

2.220. **Key Considerations.** Hearing protection to be used with aviation helmets should not adversely impact other requirements of the helmet, particularly the provision of impact, penetration and/or ballistic protection. This is especially important when fitting new hearing protection to an existing helmet, and less so when being considered as an integrated part of the helmet design. The following should be considered as applicable:

(a) When fitting new hearing protection to an existing helmet the impact on the compliance of a helmet to its specification should be assessed.

(b) When implementing a new integrated helmet and hearing protection solution the impact of the hearing protection elements on the requirements prescribed for the Helmet Domain in this chapter of the DASDRM should be considered.
2.221. Key Consideration. Where moulded Earplug or CEP are used the application of lubricant can achieve increased attenuation along with improved ease of insertion and comfort. If lubricant is required to achieve improved attenuation, assessment should consider whether the lubricant will persist in the ear for the duration of noise exposure.

2.222. **Key Consideration.** Where hearing protection solutions allow use of ancillary connected devices (such as Bluetooth connected mobile phones and media players) the sound levels of ancillary audio media play back will contribute to the noise exposure and will need to be considered in noise assessments. Guidance on appropriate use of ancillary devices and the contribution to noise levels should be provided in associated Orders, Instructions and Procedures (OIP).

Related considerations

2.223. When introducing hearing protection solutions the following related key considerations apply:

Superseded

(a) **Key Consideration.** Hearing protectors should be adequately managed and supported by a hearing protector program to ensure their full effectiveness is achieved. AS/NZS 1269.3:2005 (R2016) Occupational Noise Management Part 3 Hearing Protector Program Section 4 identifies necessary Management Responsibilities whilst Sections 7 through 13 provide guidance that will support the development of a robust program that supports issue, fitting, cleaning, maintenance, training and effective use of hearing protectors.

(b) **Key Consideration.** When providing hearing protection solutions the provision of suitable instructions and training in the OEM's recommended use of the protection to users is essential. The level of protection provided can be significantly reduced if not used correctly for the entire duration of noise exposure, leading to hearing loss or tinnitus. This is particularly important for foam earplug type protection which can provide little to none of the intended attenuation if not inserted correctly. SafetyMan Noise Management Procedure 07 Education, Training and Instruction provides ADF policy on Noise training and provision of promulgation of instructions in OIP.

(c) **Key Consideration.** The WHS (Managing Noise and Preventing Hearing Loss at Work) Code of Practice 2015 and SafetyMan Noise Management Procedure 04 provides guidance on the ongoing monitoring of noise hazards and reviewing control.

(d) **Key Consideration.** Whilst the purpose of hearing protection ALSE is to eliminate or reduce the exposure of personnel to aircraft noise, crew being able to hear the operation of aircraft systems contributes to situational awareness. Crew being able to hear the functioning or malfunctioning or aircraft systems at moderate sound levels through hearing protection is considered desirable.

Night Vision Systems

2.224. Aviation Night Vision Imaging Systems (ANVIS) are helmet mounted goggle assemblies that provide aircrew with night vision capabilities to support the conduct of flying operations at night. The goggles come in a binocular configuration and are powered by battery. There are currently two types of ANVIS goggles approved for Defence use: the AN/AVS-6 and AN/AVS-9. Within these types, there are different configurations that relate to the type of objective lens and type of Image Intensifier Tube (IIT). RTCA DO-275 contains the minimum operational performance standards (MOPS) for aviation night vision imaging systems (NVIS).

2.225. **Design Requirement (Essential).** *NVG technologies must comply with STANAG-7042 ED.2 Image Intensifying Night Vision Devices for Aircraft.*

2.226. **Key Considerations.** When introducing new NVG technologies or modifying extant configurations the following considerations apply:

(a) Institute of Aviation Medicine (IAM) should be engaged to assess physiological effects of significant changes to NVG technologies, such as change in phosphor colour (white vs green) or large changes in performance levels compared with in service NVGs.

(b) Ground based assessment of NVGs should be made prior to progressing to flight testing. (Defence Science and Technology Group have NVG test facilities available).

(c) NVGs should be assessed for compatibility with Aircraft Lighting (additional information and standards for Aircraft Lighting and Night Vision Imaging Systems can be found in Section 3 Chapter 7).

Superseded

(d) NVGs should be assessed for compatibility with Aircraft Head Up Display (HUD) systems where applicable.

(e) NVGs should be assessed for compatibility with aerodrome lighting and obstacle lighting, Noting there are known issues with LED based obstacle lighting not being visible through NVGs, the risk associated with any non-compatibility should be identified and eliminated or otherwise minimised SFARP.

CBRN Protection

2.227. CBRN protection ALSE consists of body covering garments, masks, and equipment to supply uncontaminated breathing air. The body covering garments can be worn under, over, or in lieu of other ALSE or flying clothing. Masks can be half face oronasal types, or full face masks which can also be incorporated in a hood.

2.228. **Design Requirement (Essential).** *An assessment of the effectiveness of a CBRN ALSE countermeasure in a CBRN threat environment for which it is intended to be used must be conducted in consultation with applicable subject matter experts.*

(a) **Guidance Material.** Subject matter experts should belong to the Department of Defence, or be otherwise endorsed by applicable agencies in the Department of Defence. As an example the Chemical Biological Defence Branch of the Defence Science and Technology Group would be suitable for consultation regarding chemical or biological threat environments.

2.229. **Design Requirement (Essential).** *Any part of CBRN ALSE which covers the face must facilitate one handed doffing.*

2.230. **Design Requirements (Essential).** *CBRN ALSE must facilitate the wearer drinking without compromising CBRN protection.*

2.231. **Design Requirement (Essential).** *CBRN ALSE must protect the wearer from hypoxia as per paragraph 4c of Air Force Interoperability Council Air Standard ASM 4067 Ed1 v2.*

2.232. **Design Requirement (Essential).** *A CBRN ALSE mask must allow the wearer to eliminate mucus and vomitus from the mask as per paragraph 4i of Air Force Interoperability Council Air Standard ASM 4067 Ed1 v2.*

2.233. **Design Requirement (Essential).** *CBRN ALSE must facilitate donning and doffing contaminated CRBN ALSE as per paragraph 9 of Air Force Interoperability Council Air Standard ASM 4067 Ed1 v2.*

2.234. **Design Requirement (Essential).** *CBRN ALSE which incorporates an oronasal mask must seal per paragraph 12a of Air Force Interoperability Council Air Standard ASM 4067 Ed1 v2.*

2.235. **Design Requirement (Essential).** *A CBRN ALSE mask must facilitate the equalisation of inner ear pressure as per paragraph 13 of Air Force Interoperability Council Air Standard ASM 4067 Ed1 v2.*

2.236. **Design Requirement (Essential).** *A CBRN ALSE mask which incorporates optical transparencies must incorporate anti-mist/anti-fogging features as per paragraph 17 of Air Force Interoperability Council Air Standard ASM 4067 Ed1 v2.*

Superseded

2.237. **Design Requirement (Essential).** *If CBRN ALSE displaces eye and face protection ALSE, the CBRN ALSE must be assessed for suitability as eye and face protection as per the eye and face protection domain portion of this chapter.*

2.238. **Design Requirement (Essential).** *The material used for any item of CBRN ALSE which is worn as the outer layer of clothing must comply with the 'Material requirements' portion of BS EN 1149-5:2008 - Protective clothing - Electrostatic properties Part 5: Material performance and design requirements. Pre-test conditioning of the test specimen by laundering is not required.*

(a) **Tailoring Advice.** The purpose of this design requirement it to ensure that CBRN ALSE does not pose a hazard in an aviation environment due to electrical arcing caused by static electricity. An alternate standard may be used if it can be shown to prevent the CBRN ALSE from posing a hazard due to static electricity build up or discharge.

2.239. **Design Requirement (Essential).** *The material making up the outer layer of CBRN ALSE which is worn as the outer layer of clothing must be subject to Test Procedure A – Surface Ignition of ISO 15025:2016. Pre-test conditioning of the test specimen by laundering is not required. Adherence to the following criteria must be assessed for a material or garment passing this test:*

(a) *No specimen shall give flaming to the top or either side edge.*

(b) *No specimen shall give hole formation.*

(c) *No specimen shall give molten or flaming debris.*

(d) *The mean value of the after flame time shall be equal to or less than 2 seconds.*

(e) *The mean value of the afterglow time shall be equal to or less than 2 seconds.*

2.240. **Design Requirement (Essential).** *The material making up the outer layer of CBRN ALSE which is worn as the outer layer of clothing must be subject to Test Procedure B – Bottom Edge Ignition of ISO 15025:2016. Pre-test conditioning of the test specimen by laundering is not required. Adherence to the following criteria must be assessed for a material or garment passing this test:*

(a) *No specimen shall give flaming to the top or either side edge.*

(b) *No specimen shall give hole formation.*

(c) *No specimen shall give molten or flaming debris.*

(d) *The mean value of the after flame time shall be equal to or less than 2 seconds.*

(e) *The mean value of the afterglow time shall be equal to or less than 2 seconds.*

2.241. **Design Requirement (Essential).** *The weight, size and materials of a CBRN ALSE mask must comply with paragraph 8 of Air Force Interoperability Council Air Standard ASM 4067 Ed1 v2.*

2.242. **Design Requirement (Essential).** *Integration of CBRN ALSE must be conducted in accordance with the instructions contained in Air and Space Interoperability Council - ADV PUB ASM 4084 Methodology for Integration Testing of Aircrew Clothing and Equipment.*

(a) **Tailoring Advice.** ADV PUB ASM 4084 uses non proscriptive language such as 'should' rather than terms such as 'must' or 'shall'. This design requirement mandates that all portions of ADV PUB ASM 4084 must be considered, but compliance findings of 'not applicable' can be assessed as acceptable.

Superseded

2.243. **Design Requirement (Essential).** *CBRN ALSE must facilitate the elimination of bodily waste.*

(a) **Tailoring Advice.** CBRN ALSE intended for short term wear must facilitate urination. Failing to do so is likely to result in wearers self-restricting fluid intake which could lead to dehydration. CBRN ALSE intended for longer term wear must accommodate defecation and the management of menstrual blood flow.

(b) **Guidance Material.** Management of diet and use of medication, both under the supervision of an aviation medical officer, can assist in managing the requirement for defecation and managing menstrual blood flow.

2.244. **Design Requirement (Essential).** *CBRN ALSE masks must either interface with existing ICS equipment or contain ICS equipment with an equivalent level of performance.*

2.245. **Design Requirement (Essential).** *If a CBRN mask is to be used with supplemental oxygen, materials used in the mask must be assessed as suitably fire resistant, at the intended temperature ranges, and oxygen concentration levels to which the mask will be exposed by applying relevant materials standards and requirements prescribed within Section 3 Chapter 6.*

2.246. **Design Requirement (Recommended).** *CBRN ALSE should incorporate anti-suffocation and anti-drown protection as described by paragraph 11e of Air Force Interoperability Council Air Standard ASM 4067 Ed1 v2.*

2.247. **Key Considerations.** The following key considerations should be taken into account when introducing CBRN ALSE to ADF service:

(a) CBRN ALSE forms part of a CBRN protection capability. It cannot be effective without other elements of such a capability such as decontamination.

(b) CBRN ALSE can be used in a 'quick don' configuration. This could be used in the use cases of don prior to emergency egress from a CBRN protected platform, don for only part of a mission, or don in response to a detected CBRN threat. In the use case of don for part of a mission, a capability to confirm the absence of contamination prior to doffing is required. In the use case don in response to a detected CBRN threat, a CBRN threat warning mechanism is required.

(c) The user of CBRN ALSE intended for use in a 'quick don' role will require the ability to rapidly don and doff the equipment without assistance in the intended use environment. CBRN ALSE intended for permanent wear during missions can reasonably require the assistance of ALSE tradesmen or other crew members for donning and doffing.

(d) Exposure to foreign object contamination such as dust, sea spray, water or large amounts of sweat can reduce the effectiveness or useful life of CBRN ALSE.

(e) Unaided speech communications with ground crew or passengers is expected to be difficult in some aviation environments. The use of CBRN ALSE can further hinder such communication. Features in a CBRN ALSE system to aid the ability of wearers to participate in unaided voice communications are desirable.

ADDITIONAL ALSE GUIDANCE

2.248. ALSLMU review and amend the ALSE Standards prescribed in this chapter on an ongoing basis with the aim to maintain contemporary and traceable design requirements for each ALSE

Superseded

Domain. Before applying ALSE standards prescribed in this chapter, ALSLMU must be engaged for the latest advice as published requirements may become obsolete as a result of these reviews.

2.249. Contact ALSLMU for advice or assistance in accessing referenced standards via ALSLMU.DeskOfficer@defence.gov.au.

Superseded

INTRODUCTION

SYSTEM SAFETY

INTRODUCTION

2.1 Hazards in aircraft design are largely managed by employing aerospace design standards, since these standards represent many years of experience in the identification, analysis and control of hazards. However, while a system may be comprised of individual components that meet relevant reliability, safety or performance benchmarks on their own, the integration of these sub-systems can give rise to hazards at the system level. System safety is an engineering discipline that encompasses safety as a core aspect of any given system design (or design change). System safety comprises a number of tools and techniques to identify aircraft hazards and implement controls for those hazards to satisfy prescribed safety objectives. The application of these tools and techniques is an essential adjunct to a standards based approach to design, noting that design standards may:

(a) not apply to a whole system, merely elements of the system

(b) not be relevant for novel applications, which can pose novel hazards

(c) not keep up with technology advances, since standards often have review and update cycles that span many years

(d) allow different options depending on the system's criticality.

2.2 The implementation of a robust and effective system safety approach to Defence aircraft design is prescribed by the Authority. As system safety involves a whole-of-system approach to design, achievement of safety objectives requires the application of the system safety tools and techniques during aircraft design activities, normally through the adoption of a formal System Safety Program. The framework and processes under which system safety is applied for Defence aircraft designs may be articulated in a dedicated artefact (for example via a System Safety Program Plan) or inherently included in a design organisation's design processes.

2.3 **Other National Airworthiness Authority (NAA)/Military Airworthiness Authority (MAA) approaches to system safety.** The Authority has evaluated recognised NAA and MAA approaches to implementing system safety, and the associated aviation system safety standards, and concluded that intelligent application and in some cases expansion is required to satisfy Defence's regulatory and statutory requirements. For example, system safety standards may not account for Defence's obligations under the WHS legislation, since they may permit 'risk acceptance' once a specified risk level has been achieved. To promote the 'intelligent application' of system safety standards, this chapter adopts a different structure to other DASDRM chapters. Here, the chapter first defines the outcomes that are needed for a robust system safety program. The chapter then identifies where recognised NAA/MAA approaches to system safety require particular attention if they are to meet the Authority's prescribed outcomes. This approach provides design organisations with guidance to embed robust system safety practices into their engineering procedures.

Scope

2.4 This chapter presents Authority prescribed system safety design requirements that are applicable to design activities conducted for new aircraft and design changes. The Authority's prescribed design requirements for software safety are provided at Section 2 Chapter 3.

Superseded

2.5 The application of system safety to Defence aircraft designs achieves three key outcomes:

(a) Design safety objectives are:

1. defined, and

2. agreed by the Authority.

(b) Design hazards[1] are identified and controlled.

(c) Hazards identified during design, and associated controls, are documented.

2.6 Authority prescribed system safety design requirements that support the achievement of each of these outcomes are defined in the following paragraphs.

Defining safety objectives

2.7 The establishment of safety objectives for the particular aircraft type, cognisant of Defence's role and operating environment, is fundamental to the implementation of a robust system safety program and represents good aviation engineering design practice. Over many decades of aviation operations, these safety objectives have been demonstrated to achieve safe aircraft design. Consequently, the defined safety objectives represent the point at which further elimination or minimisation of identified hazards is unlikely to be reasonably practicable.

2.8 Safety objectives may be articulated as specific outcomes to be achieved (eg no single point failures having a catastrophic severity) or through objective safety criteria applicable to a particular hazard severity (eg Failure Probability Objectives (FPOs) and Design Assurance Levels (DALs)).

2.9 **SS Requirement (Essential) (Aircraft Acquisitions).** *Applicants for a Military Type Certificate must establish the quantitative safety criteria to be applied to the aircraft design (eg FPOs, catastrophic failure rate, and so on).*

2.10 A design organisation's design processes must describe how the organisation will ensure that quantitative safety criteria applicable to the Defence aircraft are identified and met for new aircraft designs. Prior to adopting the quantitative criteria as a basis for Defence aircraft certification, the design organisation must seek Authority agreement that the quantitative criteria represent an appropriate basis for safe aircraft operations and aircraft certification. The approved quantitative safety criteria will form an integral element of a Defence aircraft's Type Certification Basis.

2.11 **SS Requirement (Essential) (Aircraft Design Changes).** *Aircraft design changes must comply with the quantitative safety criteria from the initial aircraft design (ie the original aircraft design FPOs, catastrophic failure rate, and so).*

2.12 Once the quantitative safety criteria have been agreed by the Authority, they must be applied to all design changes unless prior agreement to adopt amended safety criteria has been obtained from the Authority. Any proposal to adopt amended safety criteria will represent a change to the approved TCB and, therefore, a Military Certification Review Item (MCRI) must be raised and submitted to the Authority for approval, regardless of whether the design is a Major or Minor change.

2.13 **SS Requirement (Essential)**. Applicants for a Military Type Certificate or Major Change approval must seek Authority agreement where reduced 'at risk' time is proposed to be accounted for in satisfying prescribed safety objectives.

Superseded

2.14 The use of limited exposure intervals (eg 'at risk' time) to justify a reduction in safety objectives for aircraft systems could lead designers into error. For example, it would be inappropriate to use a limited exposure interval for reducing safety objectives for a safety-critical system, where the adverse consequences of system failure cannot be clearly linked to a specific stage of flight or set of flight conditions (eg when establishing safety objectives for ejection seats). Where the use of 'at risk' time is proposed in support of meeting FPOs for a specific aircraft system, a determination on the adequacy of the proposed approach must be sought from the Authority.

2.15 **SS Requirement (Essential).** *The design or design change must not permit a single-point failure, or permit a combination of independent failures (including human errors associated with the human machine interface) involving safety-critical functions, which have a consequence of catastrophic, critical (MIL-STD-882 definition) or hazardous (FAR/CS 2x.1309 definition) severity.*

2.16 Safety-critical systems must be "fail-safe", such that any single failure will cause the system to revert to a state which will not result in an unsafe condition. Independent system failures and human machine interface errors that have a consequence of catastrophic, critical (MIL-STD-882 definition) or hazardous (FAR/CS 2x.1309 definition) severity must be eliminated through design.

2.17 When establishing compliance with this requirement, the failure of any single element, component or connection in a system or sub-system during any one flight must be assumed regardless of its probability, and such failures should not be catastrophic. Subsequent failures during the same flight, whether detected or latent, must also be assumed unless the joint probability of such failure conditions satisfies the relevant catastrophic, critical or hazardous FPO.

2.18 Compliance with this requirement must be demonstrated through a thorough safety assessment, including both qualitative and quantitative assessment of the design for each catastrophic, critical or hazardous failure condition identified by a Functional Hazard Assessment (FHA).

2.19 Redundant subsystems may also be implemented as a hazard mitigation strategy for safety-critical systems. These systems are used when the primary system fails and the function of that system is required to maintain continued safe flight and landing. The separation or shielding of redundant subsystems from damage, adverse operating effects of neighbouring systems/components, common cause faults and other environmental factors is essential for a safe design.

2.20 **SS Requirement (Essential).** *Information concerning unsafe system operating conditions must be provided to the crew to enable them to take appropriate corrective action.*

2.21 **SS Requirement (Essential).** *Systems and controls, including indications and annunciations, must be designed to minimise crew errors, which could create additional hazards.*

2.22 **SS Requirement (Essential).** *A 'safe' indication must not be presented to the crew when an 'unsafe' condition exists.*

2.23 Where analysis identifies that some action by the crew is required to achieve safety objectives, the designer must verify that:

(a) any identified indications are actually provided by the system

(b) any identified indications will actually be recognised

(c) any actions required have a reasonable expectation of being accomplished successfully and in a timely manner.

Superseded

2.24 When failure monitoring and indication are provided by a system, its reliability must be compatible with the safety objectives associated with the system function for which it provides the indication. In the case of aircraft conditions requiring immediate crew action, a suitable warning indication must be provided to the crew, if not provided by inherent aircraft characteristics.

2.25 Defence aircraft designs must also account for potential human error in interpretation of system operations and controls, or warnings, indications or annunciations, which could result in crew actions that introduce hazards. In particular, no probable system failure is to result in a 'safe' indication of an 'unsafe' condition so that the crew would incorrectly assume the system is available or functional. When an unsafe condition is annunciated or detected, the flying instructions must have clear and precise corrective procedures for handling the failure without an excessive increase in workload.

2.26 **SS Requirement (Essential).** *The design of a safety-critical system must prevent the inadvertent initiation by human error of a catastrophic failure condition.*

2.27 Defence aircraft designs must account for, and where reasonably practicable eliminate, potential impacts of human error in the design of safety-critical systems as a result of human machine interface issues. For example, the addition of a throttle lever detent prevents an inadvertent selection of reverse thrust without the conscious lifting of the throttle levers over the detent. Similarly, a guarded switch for activation of engine fire extinguishers prevents inadvertent switch selection.

2.28 **SS Requirement (Essential).** *The operation of non-required equipment (eg mission systems), must not interfere with the proper functioning of safety-critical systems or present a hazard themselves.*

2.29 Non-required systems do not need to perform their function throughout the entire aircraft operating and environmental conditions. However, in situations where the non-required equipment is to be operated, both normal operations and operation under failure conditions must not adversely affect safe aircraft operations, safety-critical systems or aircraft occupants. Hazardous conditions associated with normal operations, malfunction and erroneous behaviour of non-required equipment must be identified through FHAs.

Hazard identification and control

2.30 Robust hazard identification and control is a cornerstone of safe aircraft design. Design organisations must implement processes that support effective hazard identification and control that accounts for Defence's role and operating environment, and achieves the applicable safety objectives for each failure condition and associated hazard. Where safety objectives are not initially achieved, additional controls must be identified and implemented (using the hierarchy of controls) to meet the prescribed safety objectives.

2.31 **SS Requirement (Essential).** *Systematic techniques must be implemented for identifying credible hazards attributable to hardware, software and human system integration.*

2.32 System safety tools and techniques provide a robust means of hazard identification. These tools and techniques expose failure conditions where required safety criteria are not met or where integrated system hazards exist that have not been identified via compliance with design standards. For aircraft design changes, the existing aircraft Hazard Log (or similar) may also assist in identifying relevant hazards.

2.33 A design organisation's design processes must describe the application of formal hazard identification techniques and any tailoring to suit the specific design activity being undertaken. In particular, the processes should describe how the design organisation intends to apply system safety

Superseded

tools and techniques defined in aerospace system safety standards, including for those hazards applicable to complex system interactions, such as formal Functional Hazard Assessment/Analysis and/or System/Sub-System Hazard Analyses.

2.34 **SS Requirement (Essential).** *Identified hazards must be analysed to verify the achievement of safety objectives, or additional controls must be identified and implemented to achieve safety objectives.*

2.35 Robust analysis of hazards identified during design activities is an essential contributor to aviation safety. A design organisation's design processes must therefore describe the application of formal hazard analysis techniques and any tailoring to suit the specific design activity being undertaken. Hazard analysis techniques, commensurate with the scope of the design and potential impact on aviation safety must be employed to identify potential controls. For example, Fault Tree Analyses, Common Cause Analyses, Zonal Safety Analyses, Particular Risk Analyses and so on should be adopted where the design is complex and/or the consequences of failure are severe.

2.36 **SS Requirement (Essential).** Hazard controls must be implemented in accordance with the hierarchy of risk controls.

2.37 As discussed at paragraph 2.8, good practice in the aviation industry requires the identification of hazards and the implementation of controls to achieve prescribed safety objectives. However, where prescribed safety objectives are not met, and therefore the design falls outside of this good practice, any residual hazards must be robustly addressed through the implementation of additional controls. Implementation of controls must be undertaken with an appropriate understanding and application of the hierarchy of risk controls. The hierarchy of controls, per Regulation 36 of the WHS legislation, requires:

(a) implementing one or more of: substitution of the hazardous design with something safer; isolation of the hazard from people; and reducing the risk through engineering controls (eg use of mechanical guards or circuit isolation devices)

(b) if a risk remains, implementing administrative controls (ie procedures and training)

(c) if a risk remains, implementing the use of PPE.

2.38 The System Safety Design Order of Precedence, described in MIL-STD-882, needs intelligent application to fully satisfy the hierarchy of controls. Importantly, the effectiveness of procedures and training as a sole treatment strategy for hazards is unreliable as the primary control over the system life cycle. Warnings, cautions or other written advisory notifications must not be used as the only risk reduction method for hazards having catastrophic, critical (MIL-STD-882) or hazardous (FAR/CS 2x.1309) severities.

2.39 **SS Requirement (Essential).** *Consultation, co-operation and co-ordination between stakeholders must ensure all potential risk controls are identified and assessed for implementation.*

2.40 Consultation, co-operation and co-ordination frameworks enable robust hazard identification and analysis, and the identification and assessment of reasonably practicable controls, both design/technical and operational in nature. A design organisation's design processes must include the means by which stakeholder consultation, co-operation and co-ordination will be achieved. Operational stakeholder engagement is essential to evaluate potential operational controls for hazards when the design cannot meet prescribed safety criteria due to an adverse impact on Defence capability. Importantly, the framework must ensure that proposed design changes do not invalidate or impact extant controls for hazards that may not be related to the design under consideration.

Superseded

2.41 One framework under which consultation, co-operation and co-ordination can be enacted is through an established System Safety Group (SSG) or equivalent body, which is responsible for reviewing identified hazards and associated controls. If employed, the SSG should be structured to optimise timely and effective consultation, co-ordination and co-operation between technical, operational and maintenance subject matter experts, and other relevant specialists and stakeholders.

2.42 A key outcome of consultation, co-operation and co-ordination is the identification of and commitment to the means by which controls will be implemented, reviewed and maintained. Clear responsibilities for confirming that controls have been implemented and are being monitored for effectiveness must be established within the adopted framework.

2.43 **SS Requirement (Essential).** *Where meeting design safety objectives would have an unacceptable adverse effect on capability, the non-compliance must be approved by the Authority.*

2.44 Occasionally, compliance with design safety objectives may unacceptably impact Defence's required capability outcomes. Where prescribed safety objectives cannot be met, the applicant must submit for Authority consideration and agreement any proposal to amend safety objectives. The proposal to amend the safety objectives must be supported by clear risk characterisation associated with the amended safety objectives and confirmation by the relevant operational commander that the operational impact of compliance with the prescribed safety objectives is unacceptable. Only where the Authority concludes that the risk has been appropriately characterised, the operational commander has made an informed determination that the risk has been minimised so far as is reasonably practicable and residual risk retention is appropriate, will the Authority approve the amended safety objectives via a Military Certification Review Item (MCRI).

Documenting hazards

2.45 To ensure that all controls necessary to achieve prescribed safety objectives are effectively captured and monitored, and will be considered during future design activities, robust hazard documentation is required.

2.46 **SS Requirement (Essential).** *Hazards identified during design activities, and associated controls, must be documented.*

2.47 While the identification of hazards and associated controls through a robust system safety program will result in the achievement of safety objectives, the continued safety of the design will only be achieved if any controls associated with identified hazards are implemented and remain effective. Hazard documentation also assists designers to ensure that future design activities do not introduce changes that either remove an existing hazard control or impact the effectiveness of a control. Consequently, hazard documentation is required to provide a safety baseline for the design and to support future design activities.

2.48 One means of documenting hazards and controls is via a Hazard Log. If employed, a Hazard Log should be updated during the aircraft's service life whenever:

(a) previously unidentified hazards, or new hazards introduced as part of a design change, are identified

(b) new controls for an already identified hazard are implemented, or already implemented controls are removed/changed.

2.49 A Hazard Log (or equivalent) is a key artefact that supports the Military Type Certificate Holder to satisfy their obligations under DASR 21.A.44, regarding the in-service management of product hazards, and to support the outcomes required of organisational Safety Management Systems for the

Superseded

Defence aircraft. Where the relevant operational commander has agreed to retention of any safety risk that may be posed by hazards remaining after implementation of controls, a Hazard Log (or equivalent) may also be used to record risk retention details, including the criteria for review of control effectiveness and risk retention decision validity.

AUTHORITY RECOGNISED NAA/MAA APPROACHES TO SYSTEM SAFETY

2.50 As previously discussed the common civil and military system safety standards require intelligent application and in some cases expansion if they are to meet Authority prescribed system safety requirements. Where the application of these standards is subject to oversight by an Authority recognised NAA/MAA, and within the framework and scope of that authority's regulatory approach, application of the standards may entirely satisfy the Authority prescribed system safety requirements. However, where the standards are applied outside of the regulatory system of the relevant NAA/MAA, tailoring of the standards may result in the Authority prescribed requirements no longer being met.

2.51 This section describes how the adoption of common system safety standards, under Authority recognised NAA/MAA oversight, contributes to meeting the Authority prescribed system safety requirements in this chapter. This section also provides designers with guidance on the intelligent application of the common system safety standards, where a Defence aircraft design is not subject to oversight by an Authority recognised NAA/MAA.

Civil system safety approach

2.52 Common civil system safety standards applicable to aviation consist of the FAR/CS 2x.1309, the associated Acceptable Means of Compliance (AMC) (eg AC25.1309 and AMJ 25-1309), and the SAE standards ARP4754 Guidelines for Development of Civil Aircraft and Systems, and ARP4761 Guidelines and Methods for Conducting the Safety Assessment Process on Civil Airborne Systems and Equipment. The civil standards describe methodologies and processes to establish safety objectives (both quantitative and qualitative) for the aircraft design, and to identify and control hazards. Indeed, the civil approach to system safety in aircraft design is closely aligned with Defence's approach to system safety.

2.53 **Designs certified by an Authority recognised NAA.** For new aircraft or modifications to existing aircraft, the extant civil certification applies where the Defence aircraft design meets the configuration, role and operating environment (CRE) approved by the certifying authority. Application of the civil system safety standards in this case will achieve compliance with all Authority prescribed system safety requirements, since:

(a) the role and operating environment of the aircraft is known and accounted for, by both the designer and certifying NAA, in the civil certification program

(b) risk retention due to shortfalls against the prescribed safety objectives is not permitted by Authority recognised NAAs

(c) there is a well-established history of designers enacting system safety programs that meet recognised NAA requirements for the development of safe aircraft designs using appropriate hazard controls

(d) hazards will have been documented, and controls established and published in relevant OIP to ensure safety objectives continue to be met.

Superseded

2.54 However, designs certified under a civil certification framework may not provide clear disclosure of all hazards and associated controls (per paragraphs 2.47 through 2.51), which is an important contributor to the MTCH meeting their DASR obligations. Consequently, additional insight into these hazards and implemented controls, or the ability to access this information where required, should be arranged.

2.55 **Designs developed using civil system safety standards, but not certified by an Authority recognised NAA.** As discussed above, application of the civil system safety standards within a civil regulatory context will satisfy the Authority's system safety requirements. Similarly, where the civil system safety standards are faithfully applied to designs that are not certified by an Authority recognised NAA, the design should also satisfy the Authority's prescribed safety objectives. However, where the prescribed safety objectives are not met, or the Defence aircraft CRE is outside of the scope of the CRE approved by the original certifying NAA, additional analysis of hazards that may be impacted will be required.

2.56 For all Defence aircraft designs where the civil system safety standards are adopted, the designer must ensure that the civil standards are rigorously applied. In particular, all prescribed safety objectives must be met, and the hierarchy of controls, per paragraphs 2.38 and 2.39, must be applied to those design elements where safety objectives cannot be met. Where the Defence CRE is outside of the scope of the CRE approved for the extant civil certification, designers must ensure that the CRE deltas are assessed to confirm that prescribed safety objectives are still met for the Defence CRE, or that additional controls are implemented where required. Finally, any identified hazards must be documented per paragraphs 2.47 through 2.51 to support in-service hazard management.

US Military system safety approach

2.57 MIL-HBK-516 Airworthiness Certification Criteria and MIL-STD-882 Department of Defense Standard Practice – System Safety define the US DoD system safety requirements for military systems. MIL-STD-882 describes methodologies and processes to establish safety objectives (both quantitative and qualitative) for the aircraft design, and to identify and control hazards.

2.58 **Designs certified by an Authority recognised US MAA.** US militaries have a well-established history of producing safe aircraft designs under their regulatory systems, which includes application of MIL-STD-882 and the adoption of system safety requirements prescribed in MIL-HDBK-516. Therefore, for new aircraft or modifications to existing aircraft, where the Defence configuration, role and operating environment (CRE) is consistent with that assumed for the US certification, application of MIL-STD-882 will achieve compliance with the majority of Authority prescribed system safety requirements.

2.59 However, a key aspect of the MIL-STD-882 approach to system safety is the ability for the 'program executive' to accept residual risk associated with hazards where the quantitative safety criteria (established per paragraphs 2.9 and 2.11 of this chapter) have not been met. This acceptance of residual risk may be inconsistent with both theDASRs and WHS legislation obligations. Therefore, any hazards 'accepted' under the MIL-STD-882 system safety approach will need to subsequently be evaluated by Defence, and additional controls implemented if reasonably practicable, to satisfy Defence regulatory and statutory requirements.

2.60 Finally, designs certified under a recognised US MAA certification framework may not provide clear disclosure of all hazards and associated controls (per paragraphs 2.47 through 2.51), which is an important contributor to the MTCH meeting their DASR obligations. Consequently, additional insight into these hazards and implemented controls, or the ability to access this information where required, should be arranged.

Superseded

2.61 **Designs developed and certified outside of an Authority recognised US MAA's regulatory system.** When employed outside of the context of a recognised US MAA's regulatory approach, MIL-HBK-516 and MIL STD-882 require considerable intelligent application if the Authority requirements for identification and control of hazards are to be met. The following issues may result in non-compliance with Authority prescribed system safety requirements:

(a) The specific system safety activities (ie 'tasks') described in MIL-STD-882 are intended to be tailored, such that only those relevant to the particular design under consideration are conducted. Therefore, intelligent selection of relevant 'tasks' is required if Authority prescribed safety outcomes are to be met.

(b) The MIL-STD-882 approach to documenting and characterising risk associated with hazards may lead to the definition of 'acceptable' risk levels, which is inconsistent with the DASR approach to hazard management and Australian WHS legislation.

(c) The adoption of a purely MIL-STD-882 system safety program may lead a designer into error since it does not require that all safety objectives are met and therefore implies that the designer has some discretion in terms of compliance.

(d) The MIL-STD-882 approach to identifying hazards may not be undertaken using formal system safety tools and techniques that are commensurate with the degree of criticality and/or complexity of the design under consideration.

(e) MIL-STD-882 does not explicitly include considerations for fail safe design (noting that fail safe design is included in MIL-HBK-516C Airworthiness Certification Criteria, although not all US military aircraft designs adopt this Airworthiness Code) or for establishing safety criteria for systems with limited at risk exposure times.

2.62 Where a designer proposes to adopt MIL-HBK-516 and MIL-STD-882 for Defence-unique designs that will be certified outside of a recognised US MAA regulatory approach, all of the potential shortfalls at paragraph 2.63 will need to be resolved through intelligent application of the standard. In all cases, the Authority prescribed system safety requirements detailed in the preceding sections of this chapter must be met.

UK Military system safety approach

2.63 DEF STAN 00-056 Safety Requirements for Defence Systems describes the generic UK MoD approach to implementing system safety for Defence systems, including aircraft designs. DEF STAN 00-056 is primarily a risk management standard that describes the process by which military equipment can be verified to have satisfied the UK safety legislation requirements. Without considerable intelligent application, the standard's 'risk management' approach is incompatible with the DASR approach to type certification/design approval and is inconsistent with Australian WHS legislation. As a result, DEF STAN 00-056 can only be used as the system safety standard for Defence aircraft design activities where agreement with the Authority has been reached on how the perceived deficiencies in the standard can be resolved.

SYSTEM SAFETY GUIDANCE

2.64 Further guidance on implementing the system safety requirements prescribed in this chapter can be provided by the chapter sponsor.

Superseded

DEFINITIONS

AERONAUTICAL LIFE SUPPORT EQUIPMENT (ALSE)

INTRODUCTION

2.1. DASR ORO.40 prescribes the requirements for Military Air Operator (MAO) approval for the carriage and use of Aeronautical Life Support Equipment (ALSE). Under DASR ORO.40, MAO approval of ALSE is supported by a technical assessment that establishes the level of compliance of the ALSE with prescribed design requirements. Compliance may be demonstrated by either the ALSE having been certified as part of the aircraft type design, or by a technical assessment conducted in accordance with the provisions of the regulation.

2.2. The design of ALSE and the interface and interaction between the ALSE and the host aircraft must be comprehensively assessed during Defence aircraft acquisition and/or design changes. Failure to do so can result in ALSE that is not fully compatible with the aircrew/aircraft, or provides an inadequate level of aircrew protection.

2.3. **Role of Aeronautical Life Support Logistics Management Unit (ALSLMU).** ALSLMU is the Defence Subject Matter Expert (SME) for ALSE with respect to all Defence aircraft. The ALSLMU Deputy Senior Design Engineer (DSDE) may be appointed as a Delegate of the Safety Authority as ALSE 'Standards- DoSA (ALSE)' with scope to prescribe, revise and interpret design requirements for ALSE. ALSLMU should be engaged at the earliest opportunity during a new platform procurement, ALSE replacement or design change program to ensure that adequate advice is available to support application of these design requirements during the requirements definition phase and ensure suitability of an ALSE solution as the program matures.

Scope

2.4. This chapter presents the Authority prescribed design requirements, including aircraft integration requirements where applicable, for ALSE. The design and integration requirements provide MAO and CASG System Program Office teams with a basis for establishing that ALSE related risks to safety have been eliminated or otherwise minimised 'So Far as is Reasonably Practicable' (SFARP). The chapter also presents guidance on the technical evaluation of ALSE to support compliance with the prescribed requirements and operational commander decisions on approvals, where required.

DEFINITIONS

2.5. The following definitions are relevant to this chapter:

(a) **ALSE.** ALSE is equipment that supports Defence capability and aircrew in the performance of their duties throughout aircraft operations, including the time during and following a survivable aircraft accident and evacuation. The ALSE may form part of an ensemble or may be fitted as an aircraft store.

(b) ALSE can be considered as Safety ALSE (providing aircrew and passengers protection from environmental hazards during flight, survivable accident or incident, evacuation and post evacuation survival) and/or Mission ALSE (providing improved physical performance or functions necessary to support the achievement of an aircrew role). A frequent

Superseded

implementation of ALSE classified as both Mission and Safety is the helmet, which serves as safety equipment in the event of a crash while serving as mission equipment when supporting hearing and eye protection components, Night Vision Goggles (NVG), Lighting and other accessories. The categorisation of ALSE as Safety or Mission does not impact the applicability of standards prescribed within this chapter.

(c) **ALSE Ensemble.** An ALSE Ensemble consists of compatible equipment components that form an integrated ALSE solution that is worn by aircrew or passengers whilst performing duties primarily on-board the aircraft.

2.6. **ALSE Domains.** To support prescription of design requirements for the various types of ALSE, ALSLMU has defined 17 ALSE Domains. The Domains are defined to group similar types of equipment that are divided into 6 overarching categories. The following ALSE Domains are used:

(a) Head Protection

1. Helmets
2. Eye and Face Protection

(b) Inflatables

1. Life Preservers
2. Anti-G Suits
3. Life Rafts

(c) Load Carriage and Restraint

1. Carriers and Ensemble Integration
2. Hoisting Equipment
3. Out of Seat Restraint Systems
4. Ballistic Protection

(d) Post Evacuation Survival

1. Survival Aids
2. Thermal / Immersion Protection
3. Survival Kits and Rescue Packs

(e) Respiration

1. Oxygen / Smoke and Fumes Masks
2. Underwater Emergency Breathing

(f) Sensory Protection

1. Hearing Protection
2. Night Vision Systems
3. Chemical, Biological, Radiological and Nuclear (CBRN) Protection.

Superseded

2.7. As discussed above, Defence manages ALSE within a construct of 'ALSE domains'. To facilitate the technical assessment of ALSE required under ORO.40, these 'domains' have been used to establish which ALSE should be considered under the aircraft's type certification and which should not.

2.8. Note that before approval for use, all ALSE must be subject to technical evaluation to confirm that it meets relevant design requirements and, where applicable, integration requirements, regardless of whether the ALSE is certified as part of the aircraft's type design or not.

2.9. Certification of ALSE can often be a complex undertaking and, therefore, advice on the application of and compliance with design requirements is to be sought from ALSLMU as early as possible within the project lifecycle.

ALSE included within the aircraft's certified type design

2.10. Certification of this ALSE will occur via design approval conducted in accordance with the requirements of DASR 21, to demonstrate that the ALSE complies with the design requirements in this chapter and in other applicable sections of the DASDRM. Relevant ALSE design requirements will be documented in the aircraft's Type Certification Basis (TCB).

2.11. The ALSE domains that are included in the aircraft's certified type design are:

(a) life preservers

(b) life rafts

(c) survival aids

(d) respiratory

(e) night vision systems (integration requirements only)

(f) chemical, biological, radiological and nuclear (CBRN) protection (integration requirements only).

ALSE not included in the aircraft's certified type design

2.12. While only four of the seventeen ALSE domains are included within a Defence aircraft's certified type design (plus the two domains where integration requirements are included), equipment within the remaining domains must still be subject to a robust evaluation of its technical and operational capabilities to ensure that it can safely perform its function when required. Consequently, the Authority also prescribes design requirements for these ALSE domains.

2.13. For ALSE not forming part of the aircraft's certified type design, formal confirmation that the ALSE meets the relevant design requirements in this chapter is required to support ALSE approval per ORO.40.

2.14. The ALSE domains that are generally not included in the aircraft's certified type design are:

(a) helmets

(b) eye and face protection

(c) anti-G suits

Superseded

(d) carriers and ensemble integration

(e) hoisting equipment

(f) out of seat restraint systems

(g) ballistic protection

(h) thermal/immersion protection

(i) underwater emergency breathing

(j) hearing protection

(k) night vision systems (equipment design requirements only)

(l) CBRN protection (equipment/clothing design requirements only).

EXEMPTIONS

2.15. **Flying Clothing.** ALSE has a maintenance policy and requires regular servicing by qualified personnel. Hence flying clothing is not considered ALSE. For information regarding Flying Clothing, contact the Program Manager – Combat Clothing (position number 00460959)

2.16. **Parachute Systems.** The Standards DoSA-ALSE does not hold a delegation for parachutes. The ADF Parachute School should be contacted in the first instance for the design requirements of parachutes.

2.17. **Pyrotechnics.** ALSE Ensembles or survival kits routinely contain pyrotechnic signalling devices. Explosive Materiel Branch (EMB) are the SMEs for this type of equipment. For requirements for pyrotechnic signalling devices refer to the eDEOP101 – Department of Defence Explosives Regulations. For guidance or advice on this topic contact EMB via their group inbox; casglsdembcoordination@dpe.protected.mil.au.

2.18. **Oxygen Systems.** ALSLMU are the SME for oxygen masks, which interface with the aircrew and aircraft oxygen systems, these are covered within this chapter. However, this chapter does not cover aircraft oxygen systems forming part of a particular aircraft design, refer Section 3 Chapter 6 for further guidance.

GENERAL CONSIDERATIONS

2.19. ALSLMU is the SME for the scope of ALSE only; aircraft MAOs are responsible for ALSE integration with Defence aircraft. Each Defence aircraft type has been designed to comply with different standards and the integration of ALSE must be undertaken with cognisance of the suite of standards applicable to that type. The following paragraphs provide guidance to MAOs, CAMOs and SPOs on generic considerations for applying the prescribed ALSE design requirements in this chapter, to ensure that the extant aircraft design requirements are not compromised:

(a) **Configuration, Role and operating Environment (CRE).** Changes to a Defence aircraft's CRE can significantly influence the type of ALSE required and the design standards associated with the equipment. The standards prescribed within this chapter need to be applied with caution and tailored to suit the CRE of a particular platform. If any doubt exists the Standards DoSA-ALSE should be consulted for assistance with tailoring the application of standards.

Superseded

(b) **Crash Protection.** When assessing the suitability of crew-mounted ALSE, evidence of the head and body extremity strike envelopes within the crew stations/cockpits of the aircraft must be sourced. Within these envelopes, the aircraft's design must also identify where suitable energy absorbing padding materials, frangible breakaway panels, smooth contoured surfaces, or ductile materials should or have been used. These intrinsic aircraft design features, if incorporated, provide additional protection to aircrew members in the event of an accident, and may reduce the need to source ALSE designed to further reduce the risk of injury. In cases where a shortfall in the crash protection of a platform is determined, additional ALSE requirements may be defined to treat this shortfall. The ADF aircraft crash protection requirements are prescribed in DASR ARO.40 Aircraft Crash Protection. This requires at AMC ARO.40.A.3.c that ALSE carried by personnel should be risk assessed and treated in the context of Crash Protection (For example: is ALSE adequately restrained under crash loads to prevent it coming lose and injuring aircraft occupants? Does the ALSE impact crashworthy seat restraint systems?). The ADF Contemporary Crash Protection Design Requirements are detailed at Section 2 Chapter 6.

(c) **Evacuation.** The addition/modification of ALSE can influence the ability of survivors to effectively evacuate aircraft and survive post-evacuation. Therefore, when assessing changes to any ALSE ensemble, the effect on both evacuation and survival must be considered. Generally an aircraft's type certification basis will include requirements for emergency evacuation (e.g. FAR25.803) and ALSE should not impact compliance with these requirements.

ALSE DESIGN REQUIREMENTS

2.20. Design requirements for ALSE comprise of Standards and ADF unique requirements. ALSE standards rarely match the context of the proposed design and, consequently, simple compliance with a standard may not be adequate for Defence's intended use of the ALSE. The Defence aircraft's CRE must therefore be considered when evaluating ALSE for suitability and acceptability, as discussed at paragraph 2.19a. The following sections provide for General Requirements and considerations applicable to ALSE as well as Integration Requirements for the integration of ALSE components to form an ALSE Ensemble and the integration of an ALSE ensemble to an aircraft. All ALSE should be assessed against the General and Integration Requirements as well as the specific domain and any other requirements that are relevant from other domains.

GENERAL REQUIREMENTS

2.21. In the use of ALSE for Defence service the following requirements and considerations are to be applied:

2.22. **Design Requirement (Essential).** *The maintenance inspection requirements and serviceability limits must be identified and published in relevant maintenance instructions*

2.23. **Key Consideration.** The design and fit of ALSE should consider and meet the needs of the anthropometric measurements of all aviators including females.

Material Properties

2.24. **Design Requirement (Essential).** *Materials used in Carriers or other ensemble components used to secure ALSE in the ensemble (i.e. pouches and straps) must be made of UV light resistant materials. This requirement shall be verified by test of residual strength of materials following accelerated exposure to UV light equivalent to its expected service life.*

Superseded

(a) **Guidance Material.** Load bearing harness standards have particular requirements related to UV light resistance for primary load bearing webbing, refer to the related Hoisting Equipment or Out of Seat Restraint Systems domains for details. For other materials engage ALSLMU for guidance on the use of an appropriate standard for UV exposure testing.

2.25. **Design Requirement (Essential)**. *ALSE that is worn or stowed within an aircraft must be at least flame resistant.*

(a) **Guidance Material.** Where ALSE components have a similar form to components identified in FAR 25.853 and Appendix F to FAR Part 25 (e.g. ALSE harness or restraint webbing is similar to seat belts and shoulder harnesses) the relevant requirements must be applied. Where components are more similar to aircrew clothing a related standard for flame resistance testing for clothing, such as ISO 15025:2016, may be considered appropriate.

2.26. **Design Requirement (Essential).** All materials used in the manufacture of ALSE must not allow a build-up of static electricity or electrical charge.

(a) **Tailoring Advice.** The 'Material requirements' portion of BS EN 1149-5:2008 - Protective clothing-Electrostatic properties Part 5: Material performance and design requirements (or similar) can be used as guidance for testing if required.

Restraint Requirements

2.27. **Design Requirement (Essential).** *All ALSE components, or their means of restraint (e.g. pouch) to the carrier (or other means of attachment to the wearer) must be of sufficient strength to restrain the component under crashworthiness loads defined in the relevant aircraft(s) type certification basis or derived from the Section 2 Chapter 6 Contemporary Crash Protection Requirements.*

2.28. **Design Requirements (Essential).** *ALSE Ensemble components must remain securely restrained when subject to rotor wash and/or airstream associated with doors open operations.*

(a) **Guidance Material.** It may be suitable to adapt DEF STAN 05-134 Test 19 to apply relevant air blasts equivalent to rotor wash for rotary wing aircraft.

INTEGRATION REQUIREMENTS

2.29. In the production of ALSE designs suitable for Defence service, the equipment must be suitably integrated with the person, the aircraft and the remainder of the aircrew ensemble. ALSLMU are available to provide guidance on the suitability of ALSE and aircrew ensemble integration. The following requirements and considerations are to be applied:

2.30. **Design Requirement (Essential).** *ALSE must be integrated in accordance with DEF STAN 05-134.*

2.31. **Design Requirement (Essential).** *An ALSE Ensemble must be assessed using the test procedures of DEF STAN 05-134 Section 10 as applicable to the aircraft type.*

(a) **Tailoring Advice.** Where an ALSE Ensemble is not intended to be worn for the duration of the flight the assessment of DEF STAN 05-134 para 10.3.1, Test 1: Dressing and Undressing should also be made during flight to ensure the Ensemble can be efficiently donned / doffed during flight.

(b) **Guidance Material.** Other sections of DEF STAN 05-134 are very specific to the UK MoD organisation and should not be applied.

Superseded

2.32. **Key Consideration.** The ALSE integration testing requirements of DEF STAN 05-134 Issue 1 Paragraph 10 will ensure that the ensemble suitably integrates together and with the aircraft on which it is being used. To ensure a successful outcome it is important that the purpose and assessment criteria of the various testing is understood and applied during the design of the ALSE Ensemble.

2.33. **Key Consideration.** During the assessment of an ALSE Ensemble using the testing program of DEF STAN 05-134 the risk assessment worksheet for Hazardous Manual Tasks from the Workplace Health and Safety (Hazardous Manual Tasks) Code of Practice 2015 should be used to identify any issues where the ALSE Ensemble may contribute to Musculoskeletal Disorders that will need to be managed. This may include identifying changes in design of the ALSE Ensemble to eliminate or mitigate such issues SFARP during its development.

2.34. **Key Consideration.** An ALSE Ensemble should have the ability to adjust the configuration to suit the operational role and environment to balance the hazards associated with weight and bulk of equipment during wear against the threats that the ALSE provides protection against during or following an emergency landing / ditching or crash.

2.35. **Key Consideration.** An ALSE Ensemble and Carrier design should provide for tactile feel for the identification and operation of securing hardware to allow for access to components that are located out of line of sight or in reduced light / visibility environments.

2.36. **Key Consideration.** Prior to ALSE being introduced to service, it should be assessed on each platform for snagging hazards which may cause the wearer to become trapped inside a sinking or burning aircraft. Assessments should consider emergency egress in any direction to and from an emergency exit, as Rotary Wing Aircraft in particular have a tendency to roll inverted following a ditching.

DOMAIN REQUIREMENTS

2.37. The following Sections present the prescribed ALSE requirements and Standards for each ALSE Domain.

HEAD PROTECTION DOMAINS

Helmets Domain

2.38. A helmet is usually a safety device to protect the head of aircrew and passengers from dangerous impacts during a potentially survivable crash. The helmet's function is achieved with a combination of materials to both prevent penetration and absorb energy in such a way as to reduce damage from excessive accelerations caused by impacts to the head. Helmets also lower the risk of head injury during ejection and provide protection against windblast, rotor wash and debris in an aircraft during operations. Helmets may also be used as a platform for hearing protection, eye protection, communications equipment and other mission equipment.

2.39. The use of helmets and the selection of impact protection requirements must be done holistically within the aircraft design. Elimination or minimisation of risks so far as is reasonably practicable (SFARP) by means other than a helmet, should be assessed prior to selecting a helmet for use. For example, modification may be possible to the aircraft to prevent head injuries. It should be noted that many fixed and rotary wing aircraft are certified for use without helmets so mission function may be the driving factor in helmet selection.

Superseded

2.40. A requirement to wear an aviation helmet might conflict with requirements to wear head protection to address different hazards, such as a ground combat ballistic helmet. In such circumstances a decision regarding the wearing of a helmet compliant with the requirements in this chapter, or an alternate helmet, must be guided by the principle of eliminating or otherwise minimising hazards to personnel SFARP.

2.41. The decision to use helmets and the selection of a helmet must be steered by the crash protection properties of the aircraft in which it is employed and the nature of the duties of the wearer. There will always be a trade off with the desirable properties of a helmet. For example, a lightweight helmet is always desired to reduce musculoskeletal (MSK) injuries; however, increased impact or ballistic protection will be accompanied by an increase in helmet mass.

Note

2.42. The requirements in this chapter are applicable to crash helmets only. Currently there are no applicable standards for lower impact head protection. Guidance material for lower impact head protection are mentioned at the end of this document. As of 2021, ALSLMU are investigating requirements of aviation helmets for use as a multi-fit passenger type helmet in collaboration with 5 eye nation's. For additional information contact the ALSLMU head protection SME.

2.43. The helmet section is to be read in conjunction with the General requirements, eye and face protection and Sensory domain's (Hearing protection).

General requirements that apply to all helmets

2.44. **Design Requirement (Essential).** *The helmet must meet the requirements of AS/NZS 1698:2006, or ECE 22.06.*

2.45. **Tailoring advice.** Amend requirement 5.8 (visors) to read 'eye and face protection section of this DASDRM chapter' in lieu of 'AS 1609'.

2.46. **Tailoring advice.** Requirement 7.1 (test sequence) solvent conditioning must be carried out.

2.47. **Tailoring advice.** Requirement 7.5 (resistance to penetration) test is only required when deemed necessary by the platform MAO.

2.48. **Tailoring advice.** Requirements 8 and 9 (marking and instructions for use and care) must be tailored in conjunction with the acquisition agency prior to introduction to service through the OEM.

2.49. **Design Requirement (Essential).** *The helmet must limit the peak head-form acceleration to 190G when tested IAW AS/NZS 1698:2006 using a flat anvil impact with the centre of the ear cup.*

2.50. **Design Requirement (Essential)**. *The helmet must limit the average head-form acceleration to 175G when tested IAW AS/NZS 1698:2006 using a flat anvil impact with the centre of the ear cup.*

2.51. **Guidance Material.** The previous two requirements are in addition to the testing in section 7.4 of AS/NZS 1698:2006, however the same methodology should be followed.

2.52. **Design Requirement (Essential) – one handed doffing.** *The fitting and retention system of a helmet must be designed such that a wearer can doff the helmet with one hand*.

2.53. **Design Requirement (Recommended).** *The mass of the helmet should be limited to 2.27 kg (5 lb).*

2.54. **Guidance Material.** Helmet weight is a contributing factor to fatigue and MSK injuries. Excessive weight can also increase neck loading and the impact energy of a head impact in a crash event. Care should be taken not to over specify other helmet attributes such as impact protection. A

Superseded

helmet should be selected to be as light as possible while providing the required level of protection. The target maximum mass includes the visors, sound attenuation and communication equipment, NVG's and any accessory to be mounted to the helmet. Consideration should also be given to the frequency and magnitude of high acceleration flight.

2.55. **Guidance Material.** A helmet which is optimised to protect a wearer from an impact of a magnitude which would be expected to cause a concussion or Mild Traumatic Brain Injury (mTBI) must be selected to protect the user from the higher magnitude of potential impacts. Consideration should be given to the CRE and the potential impacts that the helmet is to protect against. Consideration should be given to the member remaining conscious to survive post-crash events (e.g. smoke, fire, sinking aircraft, enemy action), which may occur some distance from emergency services and rescue.

2.56. **Key Consideration – centre of gravity (CoG).** The centre of gravity of a head and helmet is a more significant factor to aircrew fatigue and in flight performance, as well as being a key contributor to neck and back MSK injuries, than helmet weight. The helmet CoG should be as close to the top of the wearer's spine as possible and should be considered in the context of the aircraft's CRE. For example, the frequency and duration of high G loads or personnel moving around the aft of a helicopter while leaning over.

2.57. **Key Consideration – rigid protrusions and accessories.** Helmets with rigid protrusions or mounted accessories can impart an angular acceleration to the head in the case of a head impact, increasing the chance of traumatic brain injuries. A large or oddly shaped helmet can also impede emergency egress. Helmets should be as small and as form fitting to the head as can be achieved whilst fulfilling their function. A helmet with a long radius of gyration can also contribute to neck injury, especially during an ejection. Consideration should also be given to external accessories mounted on a helmet causing a force concentration on the helmet during a crash event, with the increased pressure causing the accessory to penetrate the helmet.

2.58. **Key Consideration – helmet penetration and tearing.** An assessment of the crashworthiness of the aircraft and the role of the aircrew within it should be carried out to determine if there is a risk of helmet penetration or tearing during a survivable crash.

2.59. **Key Consideration – environmental qualification.** The operating environment of the aircraft should be used when considering the environmental qualification of the helmet. Consideration should be given to (but not limited to) temperature, humidity, ultraviolet radiation as well as exposure to fresh and salt water, dust and sand. Exposure to variations in environmental conditions may have a significant bearing on the life expectancy and level of protection the helmet affords. The selected temperature ranges should influence the hot and/or cold soaking requirements during testing, as these temperatures may alter the energy attenuation properties of the helmet materials.

2.60. **Key Consideration – helmet coverage and field of view.** The requirement for protection for the entirety of the head, including the face, should be considered when selecting a helmet. The amount of coverage should be balanced with any restrictions to the field of view, which may result in reduced crew situational awareness and increased workload. Restrictions to the field of view are undesirable.

2.61. **Key Consideration – human thermal performance.** The effect of ambient atmospheric conditions on the person wearing the helmet should be considered. This includes the effect of hot and cold injuries through ambient temperature and wind chill e.g. for example flying with open doors.

2.62. **Key Consideration – mission equipment.** Helmets may require incorporation of other features to enhance mission performance. These features should not degrade the crash protection of the

Superseded

helmet unless a safety case shows that a feature of the helmet that impacts crash protection attributes reduces a more serious risk SFARP. Such mission features include a 'hear through' function for communicating with persons not connected to communications system e.g. passengers prior to boarding the aircraft or night vision equipment.

2.63. **Key Consideration – ballistic protection.** Consideration should be given to whether the helmet is required to provide ballistic protection. This requirement should be balanced with the risk of MSK injuries from a heavier armoured helmet.

2.64. **Key Consideration – evaluation of aircrew helmets**. Air Standard ASMG 4041 Evaluation Procedures for Flight Helmets provides information on the type of data that should be collected when evaluating candidate aircrew helmets. This may be of use to acquisition projects.

2.65. **Key Consideration – durability.** A helmet which is used in an environment where it is likely to be subjected to many low velocity impacts (minor head knocks or bumps), such as a mobile aircrew's helmet used in a platform where the wearer is required to stoop to move around a cabin or cargo, should be sufficiently resistant to these impacts to maintain its impact protection properties and/or reduce the mission capabilities of the helmet e.g. damage visors or accessory mounts.

2.66. **Key Consideration – crash Protection.** The crashworthiness and inherent crash protection of the aircraft should be considered when identifying head protection to be used. The intrinsic aircraft design features, if incorporated, provide additional protection to aircrew members in the event of an accident, and may reduce the need to source ALSE designed to further reduce the risk of injury.

Additional Fixed Wing Ejection Seat Requirements

2.67. **Design Requirement (Essential).** *The helmet must be capable of maintaining facial and head protection during the ejection sequence.*

2.68. **Design Requirement (Essential).** *The helmet must be tested with all possible equipment configurations, i.e. all accessories/mounted equipment installed.*

2.69. **Guidance Material.** Air Standard ASMG 4041 Evaluation Procedures for Flight Helmets provides guidance on how to conduct ejection seat windblast testing. The velocity of the windblast should be selected based on the operating envelope of the aircraft. Consideration should be applied to unplanned ejections at abnormal e.g. high velocities, not just the aircraft's certified ejection velocities. Facial protection includes protection from windblast and debris produced during the ejection sequence.

Additional Fixed Wing Non-Ejection Seat Mobile Aircrew Considerations

2.70. **Key Consideration.** Consideration should be given in the helmet design for these aircrew to receive low velocity head impacts caused from moving around the aircraft and cargo while in flight. These aircrew may also experience multi axis impacts during survivable crash sequences due to the crew not always being secured in a crashworthy seat.

Additional Rotary Wing Considerations (all helicopter occupants)

2.71. **Key Consideration.** Consideration should be given in the helmet design for occupants to receive low velocity head impacts caused from moving around the aircraft and cargo while in flight. Occupants may also experience multi axis impacts during survivable crash sequences due to the occupants not always being secured in a crashworthy seat. They may also be required to rapidly escape a sinking helicopter.

Utility style Head Protection

Superseded

2.72. These helmets are typically designed to protect the wearer from non-crash loads e.g. low velocity impacts with cargo and airframe components, while enabling other mission functions e.g. ability to swim or treat patients. These style helmets may be desired when operational risks and functions outweigh the requirement for crash protection. This assessment should be made when holistically assessing the risks associated with the platform and mission e.g. there may be a mission risk that requires minimisation ahead of a more remote risk of aircraft crash. It should be noted that some aircraft are certified to not require helmets for crash protection. In these cases this style of helmet may be sufficient to eliminate or otherwise minimise other mission related risks SFARP.

2.73. **Key Considerations.** The platform CRE must be considered for the application of the passenger helmet to be used. For example, a safety helmet chosen for operations on rotary wing 'down the wire' may be made to a higher specification than a Kevlar/bump style helmet used on fixed wing transportation flights.

2.74. **Guidance Material.** Children may be required to fly on board during Defence assistance to the civil community tasking or 'family day' tasking. Head protection sizes should accommodate children.

Eye and Face Protection Domain

2.75. **General Eye Protection.** Eye and Face Protection provides aircrew with protection from windblast, high light intensity, UV, spall resulting from canopy or windscreen failure, ballistic / fragmentation threats, and dust and debris from rotor or jet wash. The following requirements have been identified as general requirements which are to be applied to all eye and face protection equipment as applicable.

2.76. **Design Requirement (Essential).** *AIR STD ASMG 4079 "The Optical And Material Requirements for Aircrew Helmet Visors" must be met for all visor systems*

2.77. **Design Requirement (Essential).** AIR STD 61/113/14A "The Optical And Material Requirements for Aircrew Plano Sunglasses" must be met for all glasses.

2.78. **Guidance Material.** Spectral transmittance requirements may be difficult to meet, particularly in untinted lenses. Lenses must meet the target values as closely as possible to minimise the chance of eye damage in the long term.

2.79. **Guidance Material.** Impact resistance requirements for "Extra High Impact Resistance" protection contained in AS/NZS AS/NZS 1337.1:2010 may be used in lieu of the requirements outlined in the AIR STDs.

2.80. **Design Requirement (Essential)** *Section 3 of AS/NZS 1337.1:2010 including Amendments 1 and 2, relating to assembled eye and face protectors must be applied to all eye and face protectors.*

(a) **Guidance material.** Special performance requirements as per section 3.3 are to be applied as required dependent on the use case of the protector in question.

(b) **Guidance material.** Where requirements are included in both AS/NZS 1337.1:2010 and the applicable AIR STD, the more stringent of the two must be applied.

2.81. **Key Considerations** The following considerations should be taken into account when assessing any eye and face protection equipment.

(a) Applicable considerations from AS/NZS 1336:2014 should be applied. Particularly advice relating to the management of fogging and perspiration

Superseded

(b) Various shades of tint are available for both visors and sunglasses, appropriate levels should be assessed where possible in order to maximise user comfort and visibility.

(c) Dual visor systems should be easily switched between a clear and tinted visor with one hand in order to manage changing conditions.

2.82. **Laser Protection.** Laser energy is highly focussed and designed to traverse long distances, and is therefore potentially hazardous to the human eye; more so when emitted at a wavelength invisible to the eye, rendering the eye unable to react normally. Laser protection should be tailored to the application and expected laser threats. Threats range from dazzling through to permanent damage of the eye. The method of eye protection chosen against laser light should not degrade or impact upon the function of other eye related systems therefore all general requirements must be met.

2.83. **Design Requirement (Essential).** *Laser eye protection must limit exposure to known threats to within the Maximum Permitted Exposure limits defined in AS 2211.9:2002 (R2014) for wavelengths between 300nm and 3000nm.*

2.84. **Design Requirement (Recommended).** *Requirements 3.1 through 3.3 of AS 1337.4:2011 should be applied to the maximum possible extent.*

2.85. **Key Considerations.** The following considerations should be taken into account when assessing laser eye protection

(a) Section 6 of AS/NZS 1336:2014 outlines considerations that must be made in order to minimise the risk of laser radiation

(b) Laser protection will generally reduce visible light for the wearer, this may be an issue particularly at night.

(c) Filters designed for protection against laser threats are generally designed in such a way that they only cater to a very narrow selection of wavelengths. These must be selected based on risk analysis of known and probable threats.

2.86. **Face Protection.** Protection for the lower face is also available in the form of a shield that reduces wind on the face and provides impact protection.

2.87. **Design Requirement (Essential).** *The requirements pertaining to "Extra High Impact Resistance" protection contained in AS/NZS 1337.1:2010 must be applied as a minimum to any face shield.*

2.88. **Key Considerations.** The following considerations should be taken into account when assessing face protection:

(a) Face protection should not allow breathing gasses to escape in a manner that causes fogging of any visor or spectacles that are used in conjunction with the face protection.

(b) Face protection must be rapidly removable to allow the use of underwater emergency breathing devices and other safety systems that cover the mouth and face.

Anti-G Suits

2.89. Anti-G Suits are designed to counteract the effects of acceleration on aircrew, which can impact on their survival or ability to perform tasks. The pressurised abdominal and leg bladders aim to support an adequate blood supply to the upper body and head when a person is subject to positive G forces. This counteracts the pooling of the blood from the head and chest into the lower part of the

Superseded

body under high positive G forces which will help preserve circulation, visual acuity and mental alertness until level flight is resumed.
