
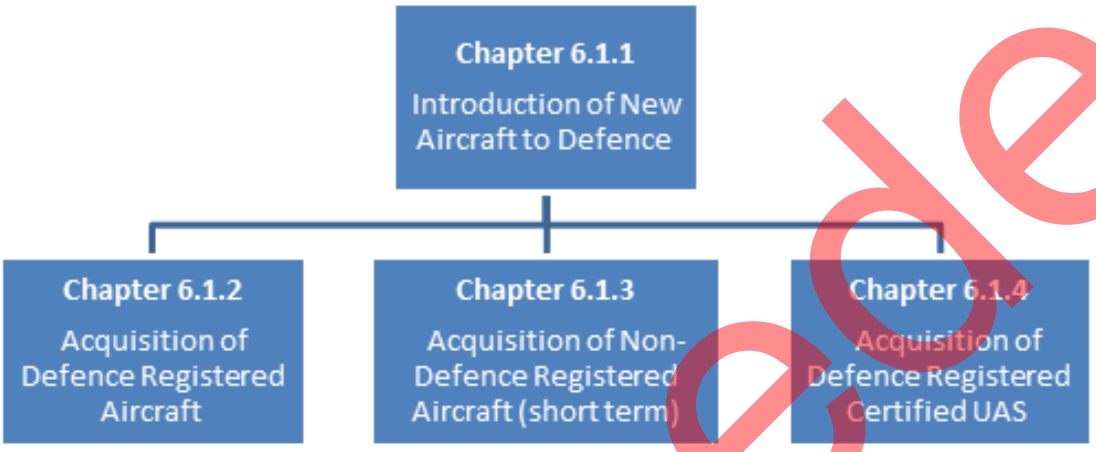

Figure 1: Chapter 6.1 structure

6.1.1.9 This chapter will also provide content that is common to the next four chapters, to avoid duplication.

Aircraft Registration

6.1.1.10 All Defence aircraft, apart from some non-certified UAS, must be included on the Register of a military or civil aviation authority. DASR separates these registrations into two categories; Defence registered aircraft and non-Defence registered aircraft. The latter are almost universally regulated by CASA. While other registrations are occasionally employed, they are always transitory arrangements[1].

6.1.1.11 A Defence registered aircraft is subject to Defence Aviation Safety Regulations (DASR) and DASA safety assurance oversight. An Australian civil registered aircraft, on the other hand, is subject to Civil Aviation Safety Regulations (CASR) and CASA safety assurance oversight as well as some limited DASA oversight.

6.1.1.12 When Defence is procuring an aircraft type that is also used under the civil regulatory framework, an important decision by the Capability Manager, required early in the acquisition process, is to determine whether the Defence aircraft will be Defence registered or civil[2] registered. This registration can have an enduring effect on Defence aviation capability, as summarised below:

1. **Defence registration.** Defence registration ensures the aircraft is within the exclusive jurisdiction of the DASR, which make specific allowance for:

   i. uniquely military roles, including weapons carriage and deployment, low flying, aerial delivery, clandestine flying, formation flying, transporting

Superseded

hazardous materials and dangerous goods etc — types of operations that may be heavily restricted or unsupportable under civil regulatory requirements

ii. flexibility in the approach to achieving compliance with the DASR

iii. the application of risk management where DASR compliance cannot be shown, provided a credible and defensible level of aviation safety performance is achieved

iv. Commanders to deviate from requirements (2) and (3) above in the event of compelling operational imperatives or emergencies.

DASA is experienced in regulating for the unique military operational context. Consequently, DASA is well-placed to advise Commanders on military aviation safety issues and to provide tailored independent safety assurance of military organisations and products.

2. **Civil registration.** Civil registration can initially be attractive to Capability Managers and acquisition organisations due to the simplicity of contractual and ongoing management, and potential faster introduction of the aircraft into service. However civil registration should only be considered for short term arrangements, or where an aircraft will not be considered a continuous 'State' aircraft. Complicating factors include that:

i. it can bind Defence to civil aviation safety regulations for design, maintenance and operation, and these regulations have not been customised to the unique military aviation context

ii. there may be a lack of risk-managed operational flexibility, which is the hallmark of Defence's aviation safety regulations

iii. it can bind Defence to the potential inflexibilities of the civil regulator

iv. there may be adverse diplomatic and security implications of Defence operating a non-Defence registered aircraft overseas.

6.1.1.13 Where a Capability Manager is considering civil registration for a temporary Defence aircraft, DASA should be engaged at the earliest practicable opportunity for consultation. Annex A presents a list of issues that should be explored during this engagement, to assist the Capability Manager in making an informed decision on Defence registration versus civil registration.

6.1.1.14 Annex B presents guidance on the structure and administration of the Defence Register.

Aviation Safety Responsibilities

6.1.1.15 DASP Manual Volume 1 states that aviation safety is a command responsibility, so commanders and managers are accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

6.1.1.16 The responsibility for ensuring (ie making sure) a new Defence aircraft is safe for flight falls directly on the Defence acquisition organisations and the relevant in-service support organisations. This includes, amongst other things, ensuring:

1. the aircraft design is safe for flight in the intended role and operating environment (ie aircraft design and certification)

Superseded

2. the physical aircraft standard of construction meets that design (ie aircraft production)

3. arrangements are in place to ensure the design remains safe (ie continued airworthiness)

4. arrangements are in place to ensure the aircraft remains in a condition for safe operation (ie continuing airworthiness)

5. arrangements are in place to design future changes and repairs (ie aircraft design)

6. operators are able to safely operate the aircraft (ie flight operations).

6.1.1.17 The role of DASA, on the other hand, is to gain assurance that the above elements have been executed effectively.

Aviation safety authorisations

6.1.1.18 When assured of safety, the relevant military or civil aviation safety authority (whether DASA or CASA) may issue a range of authorisations, often in the form of certificates, permits, approvals or licenses. For Defence registered aircraft, the list of authorisations is expansive, potentially comprising up to 12 different types of organisational, product and personnel authorisations. For civil registered aircraft, CASA will issue the civil equivalents to some or many of these 12 authorisations. Chapters 6.1.2 to 6.1.5 explore the Aviation Safety authorisations that may be issued by DASA and CASA for each acquisition category.

6.1.1.19 While DASA does not issue authorisations for civil registered aircraft, DASA may require that the aircraft are included within the scope of the Military Air Operator (MAO), issue a relevant Operations Specification (OpSpec) and conduct limited safety assurance oversight.

6.1.1.20 **Planning and coordination.** Aviation Safety authorisations issued by DASA or CASA are a major milestone in the aircraft acquisition process. Establishing the contracts, systems and people to merit each authorisation is usually complex, with considerable potential to waste time and resources. Effective engagement with the appropriate Aviation Safety authority (DASA for Defence registered aircraft, and both CASA and DASA for civil registered aircraft) is therefore in the best interests of all parties.

6.1.1.21 Engagement should ideally commence as soon as the Defence acquisition organisation has a reasonable view on the candidate aircraft, the need for Defence-unique design changes, and the probable operating and support constructs[3]. Engagement should be well advanced before Defence publishes any tender documents (eg Requests for Tender, Foreign Military Sales requests, etc) that may later affect an authorisation.

6.1.1.22. For civil registered aircraft, CASA will provide guidance on how to achieve the civil authorisations that will be required. DASA will do likewise for the new OpSpec, if one is to be published. This development of this DASA authorisation is far from a trivial endeavour. Not only does it cover the flying management of the MAO and other operational systems for the new aircraft, it also assesses whether the entire aviation safety construct (inclusive of all CASA authorisations) is likely to support safe Defence aviation.

6.1.1.23 For Defence registered aircraft, DASA will provide guidance on how to achieve the required DASA authorisations. Some additional guidance is available through DASA-sponsored courses and website resources.

Superseded

6.1.1.24 Chapters 6.1.2 to 6.1.4 provide tailored guidance on how engage with the relevant Aviation Safety authorities, since this varies widely between civil and Defence registered aircraft, and crewed and uncrewed aircraft.

6.1.1.25 **Documented agreements.** DASRs do not mandate any formal plans or agreements for achieving DASA authorisations. However, it is a practice that DASA highly recommends, given the substantial complexities in establishing the organisations and systems to manage Aviation Safety, and therefore the potential impacts (both positive and negative) on cost and schedule - and ultimately Defence capability.

6.1.1.26 For both Defence and civil registered aircraft, DASA advocates the production of an Aviation Safety Acquisition Management Plan (ASAMP). The ASAMP is an iterative agreement between applicants and DASA on the path to achieving DASA authorisations, and supports commanders and managers in accounting for parallel lines of effort and cross-regulation dependencies. It describes, amongst other things, the overarching acquisition strategy in the context of Aviation Safety and brings together the planned outcomes of the operational, technical, logistical and safety management activities.

6.1.1.27 The ASAMP should be drafted after the acquisition strategy solidifies, nominally following government acquisition approval, but before RFTs (or equivalent) are released. While ASAMPs have previously been drafted before initial contact with DASA has been made, this is rarely an efficient approach. The ideal time to draft the ASAMP is soon after the initial meeting with DASA, given that meeting will influence much of the ASAMP content. The ASAMP would normally be updated after contracts and agreements are signed, since this is the stage where the scope of most authorisations should be clear.

6.1.1.28 Chapters 6.1.2 to 6.1.5 provide guidance on the production of ASAMPs, tailored to the particular acquisition arrangement. ASAMP content varies widely between civil and Defence registered aircraft, with the latter including plans for achieving up to 12 different DASA authorisations. While the differences between crewed and uncrewed aircraft ASAMPs are less significant, the latter will focus on the unique challenges of separating the crew from the aircraft and the additional transitional authorisations that may be available for certified UAS.

Common Concepts

6.1.1.29 The next four chapters are dedicated to the four acquisition arrangements listed at Paragraph 6.1.1.6. To avoid duplication in those chapters, the remainder of this chapter will introduce several concepts that are likely to be common to each acquisition arrangement.

Recognition

6.1.1.30 Aviation Safety authority may acknowledge that products, services and data received from another Aviation Safety authority and the respective system they oversight are compatible within their own Aviation Safety framework. This concept, known as ‘recognition’, is extensively employed for new Defence aircraft acquisitions. Regardless of whether a new aircraft is Defence registered or not, recognition will almost certainly be applied for aircraft design and production. For non-Defence registered aircraft, recognition will also contribute to Defence’s confidence in aircraft maintenance and operation. DASP Manual Volume 3 Chapter 6.5, Recognition of Other Aviation Safety Authorities, provides further guidance on the application of recognition.

6.1.1.31 Where recognition is being considered for a certified UAS, DASA advice should be sought. Certified UAS are not yet commonplace, so the competence and capability of international Aviation Safety authorities in regulating and oversighting certified UAS is still evolving.

Superseded

Statement of Operating Intent and Usage (SOIU)

6.1.1.32 DASRs require all Defence registered aircraft and certified UAS (and certain other UAS when directed by the Authority) to have a Statement of Operating Intent (SOIU) that has been approved by the relevant Environmental Commander and DASA. The SOIU describes the approved roles, operating envelope, usage spectrum and operating environment for a particular aircraft type.

6.1.1.33 Development of an SOIU is not mandatory for a non-Defence registered aircraft, but may assist MAOs with establishing the operational context of their intended operations, to assist with identification of any additional safety controls required to provide an equivalent level of safety to that of Defence registered aircraft.

6.1.1.34 Annex C presents further information and development guidance for SOIUs.

Independent Review of Aviation Safety

6.1.1.35 DASP Manual Volume 3 Chapter 6, Independent Review of Aviation Safety, provides information on the scope and role of Airworthiness Boards (AwBs) within the framework of capability acquisition.

6.1.1.36 Historically, AwBs were identified as a 'gate' for issuance of some DASA authorisations. The contemporary role of the AwB in the acquisition process is to complement the role of the regulator in addressing parts of the 'system of systems' that are not adequately covered through regulatory oversight activity. DASA identifies that this increases flexibility and reduces the impost on the regulated community.

6.1.1.37 Chapters 6.1.2 to 6.1.4 provide guidance on the documentation package provided to Introduction into Service (IIS) AwBs for each acquisition type. The documentation will commonly consist of:

1. the extant submissions for the relevant DASA authorisations
2. an updated ASAMP which reflects the status of the acquisition program, details and plans for outstanding activities, and impact statements and associated risk management for outstanding activities
3. checklists and other artefacts.

6.1.1.38 An AwB is commonly convened prior to the first operation of a Defence registered aircraft, due to the often complex nature of organisational, risk management and other elements. Notwithstanding the aforementioned, there is no regulatory impediment to commencing limited operations, commensurate with risk, prior to the conduct and reporting of an IIS AwB. Progressive AwBs may be convened as the organisations and operational capabilities evolve.

6.1.1.39 An IIS AwB may be less common for non-Defence registered aircraft given that Defence aircraft that are continuous 'State' aircraft should be Defence registered. When determining whether an AwB is required, the Defence AA may take into account the complexity of support arrangements, whether Defence's operations are closely aligned to civil norms, and other similar factors.

6.1.2 Acquisition of (Crewed) Defence Registered Aircraft

Introduction

6.1.2.1 Aviation safety is a command and management responsibility. Commanders and senior managers are accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

6.1.2.2 Provided the aircraft and its support and operating arrangements meet the relevant Defence Aviation Safety Regulation (DASR) requirements, DASA may issue a range of 'authorisations', in the form of certificates, permits, approvals or licenses. These authorisations provide confidence to both the Capability Manager and the Australian Government that the aircraft is capable of safe flight.

6.1.2.3 While the respective DASRs define the required safety outcomes for these DASA authorisations, history has shown that additional guidance is needed if safety risks are to be efficiently and effectively eliminated or otherwise minimised so far as is reasonably practicable.

Purpose

6.1.2.4 This chapter guides Defence's aircraft acquisition organisations, relevant in-service organisations and Defence industry partners through the aviation safety requirements and recommended practices during the acquisition (whether through purchase, lease or other arrangement) of crewed aircraft that will be Defence registered.

Regulatory outcomes from the acquisition process

6.1.2.5 For a new Defence registered aircraft to operate, Command must ensure it is safe for flight. Command achieves this by ensuring the aircraft are designed, constructed, maintained and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation. In turn, if suitably assured of safety, DASA may issue a range of authorisations. Depending on the acquisition and support arrangements, this can extend to 12 different types of organisational, product and personnel authorisations, as follows:

1. organisational authorisations:
    i. Military Air Operator (MAO)
    ii. Military Design Organisation (MDO)
    iii. Military Production Organisation (MPO)
    iv. Approved Maintenance Organisation (AMO)
    v. Continuing Airworthiness Management Organisation (CAMO)
    vi. Maintenance Training Organisation (MTO)
    vii. Military Type Certificate Holder (MTCH) (currently an implicit authorisation)
2. product authorisations:

Superseded

i. Military Type Certificate (MTC) and associated Type Certificate Data Sheet (TCDS)

ii. Military Permit to Fly (MPTF)

iii. Aircraft Management Programme (AMP)

iv. Military Certificate of Airworthiness (CoA)

Note: *In addition, it may include a range of niche authorisations, for example a product conformity agreement, master minimum equipment list, and so on.*

3. personnel authorisations:

i. Military Aircraft Maintenance Licence (MAML)

Note: *DASA directly authorises certain management personnel within approved organisations. However, those authorisations are considered to be part of the organisational approval process in this chapter, so they are not separately listed here.*

6.1.2.6 Figure 1 summarises the range of DASA authorisations that are usually relevant to a new aircraft acquisition, grouped according to their relevance to aircraft design, construction, maintenance or operation. The subsequent paragraphs separately explore each group.

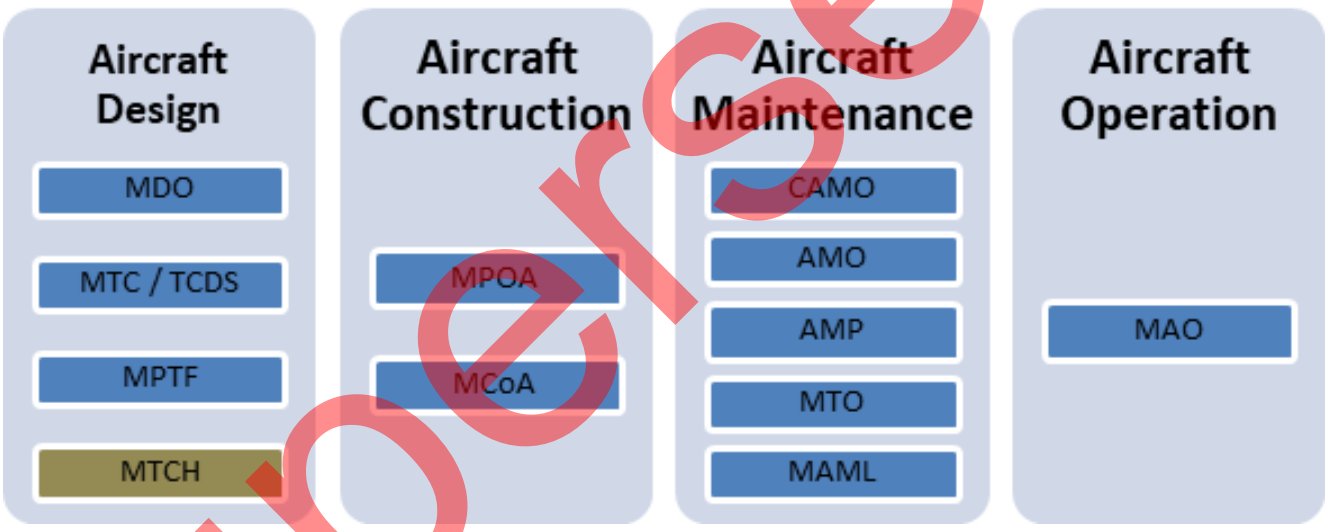

Figure 1: DASA authorisations relevant to Defence aircraft acquisitions[4]

Aircraft design (and certification)

6.1.2.7 New Defence crewed aircraft will normally be civil or military 'off-the-shelf' aircraft that are subsequently modified to meet Defence's capability requirements. Ensuring the final aircraft design is safe for flight in Defence's intended Configuration, Role and Environment (CRE) is a critical step in the acquisition process. Four separate DASA authorisations are relevant to this process, design, construction, maintenance or operation.

6.1.2.8 **Military Design Organisation (for initial aircraft design).** An organisation that has been approved by DASA to provide aircraft design services for a new Defence aircraft is termed a Military Design Organisation (MDO). These MDOs may be a military or industry organisation, and may be located in Australia or overseas. MDOs are often required for the design of new Defence aircraft,

Superseded

although as explored in the next four paragraphs, this requirement can be reduced, or even eliminated, in some circumstances.

6.1.2.9 **Military Type Certificate.** The Defence type certification process is central to confirming that the aircraft design is safe for Defence's intended Configuration, Role and Configuration (CRE) for the aircraft. At its core is the Type Certification Basis (TCB), which is a DASA-agreed set of airworthiness design requirements, including an airworthiness code and other standards, and tailoring to both as required.

6.1.2.10 At its extreme, type certification requires a DASA-approved MDO to create an aircraft design that complies with the TCB, and to produce evidence that demonstrates this compliance. In turn, DASA examines the evidence on a non-exhaustive basis, and if assured of safety, issues a Military Type Certificate (MTC)[5] and associated TCDS.

6.1.2.11 There is, however, a shortcut to the above approach that is employed for most Defence aircraft acquisitions. When Defence is procuring off-the-shelf aircraft or equipment, the Applicant[6] may seek relief from the need to develop new compliance demonstration evidence, to the extent an extant certification by a recognised National or Military Aviation Authority (NAA/MAA) is relevant to Defence's CRE. This is known as 'recognition of prior certification'. In rare circumstances, DASA can certify an entire new aircraft based solely on the prior certification of another NAA/MAA.

6.1.2.12 More commonly, however, Defence aircraft acquisitions employ a combination of the above two processes. That is, recognition of prior certification is used to cover the design of the off-the-shelf aircraft, and a DASA-approved MDO designs the Defence-unique modifications and produces the requisite compliance demonstration evidence. Sometimes another NAA/MAA may agree to certify some or all of the Defence-unique modifications, which may reduce or even remove the need for a DASA-approved MDO.

6.1.2.13 **Military Type Certificate Holder.** The MTC for a new Defence aircraft is issued by DASA to the Military Type Certificate Holder (MTCH), who takes on responsibility for ensuring the 'continued airworthiness' of the design[7]. This role is normally assigned to the relevant Defence SPO, who will implement standing arrangements with other Defence organisations, industry partners, and perhaps other militaries, to support the function. Amongst other things, the MTCH organisation is responsible for implementing systems for collecting, investigating and analysing aircraft occurrences which may affect its airworthiness, and holding (or providing access to) aircraft design information.

6.1.2.14 Note that DASA does not currently issue an explicit organisational approval for MTCHs, although this may change. Instead, the proposed MTCH arrangement is evaluated by DASA as part of its deliberations on whether to issue a MTC.

6.1.2.15 **Military Permit to Fly.** It is possible for DASA to issue a MTC for a new aircraft type immediately upon its addition to the Defence Register. More likely, however, there will be a period where the aircraft is not yet ready for a MTC because, for example:

1. the aircraft design is still under development
2. compliance demonstration evidence is still being created or compiled
3. Defence's MTC will leverage off the certification of another NAA/MAA, which is yet to be finalised

Superseded

6.1.2.16 DASA can issue a Military Permit to Fly (MPTF) to a MAO[8] in advance of the MTC if satisfied the aircraft design substantially complies with its agreed TCB, the configuration of the subject aircraft is clearly defined, the aircraft is capable of safe flight under defined conditions and for specified purposes, and any elevated risk has been justifiably retained. However, since the MPTF will usually impose (often significant) risk controls that limit the operation of the aircraft, extended operations under an MPTF are not common.

6.1.2.17 **Military Design Organisations (for in-service support).** Finally, throughout an aircraft's operational life, design changes are inevitable to remedy design defects, address obsolescence issues, design repairs, implement capability enhancements, and so on. These design changes will often be the purview of one or more DASA-approved MDOs, which are typically (but not essentially) the same as the MDOs that support the MTCH function.

6.1.2.18 Ultimately, both the MTCH and Continuing Airworthiness Management Organisation (CAMO – see below) must be able to demonstrate that sufficient design support arrangements are in place to maintain the safety of the aircraft[9], before a new aircraft is operated on the Defence Register. Depending on the aircraft acquisition contract, this design support function might initially be provided by the aircraft Original Equipment Manufacturer (OEM); if so, the in-service MDOs might not be needed immediately.

6.1.2.19 **Summary.** Summarised, the four DASA design-related authorisations that are usually relevant to aircraft acquisitions are presented in Figure 2. The MTCH is depicted in a different colour, to show that DASA does not (yet) directly issue an MTCH approval.

Figure 2: DASA authorisations related to aircraft design

6.1.2.20 DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MDOs, MTCs, MPTFs and MTCHs.

Aircraft production (or construction)

6.1.2.21 A MTC focuses on the safety of an aircraft's design. It does not consider the subsequent manufacture and assembly of the design, which is the purview of aircraft production (or

Superseded

'construction' in historic Defence parlance). The two DASA authorisations relevant to new aircraft production are Military Production Organisations and Military Certificates of Airworthiness.

6.1.2.22 **Military Production Organisation.** A Military Production Organisation (MPO) is a DASA-approved organisation that can manufacture and assemble parts, appliances, aircraft, engines or propellers to approved design data[10]. In the context of a Defence aircraft acquisition, MPOs can manufacture and assemble both the baseline aircraft (often called the 'green' aircraft) and the Defence-unique modifications to the green aircraft. They may be the same organisation, or there may be multiple different MPOs.

6.1.2.23 More commonly for new aircraft, however, Defence leverages the oversight provided by a DASA-recognised NAA/MAA of certain production organisations. This can reduce, or even eliminate, the need for DASA-approved MPOs.

6.1.2.24 **Military Certificate of Airworthiness.** As noted previously, a MTC is issued for an aircraft type. A separate DASA authorisation needs to subsequently be issued for each aircraft tail, namely the Military Certificate of Airworthiness (MCoA)[11], once DASA is satisfied the produced aircraft conforms to the design covered by the MTC. Central to DASA issuance of a MCoA is evidence that each product, part or appliance conforms to the approved design data and is in condition for safe operation.

6.1.2.25 A MCoA cannot be issued prior to the MTC. Where a new Defence aircraft is to be flown under a MPTF prior to the issue of a MTC, the MPTF effectively provides the function of the MCoA. As part of the process for seeking a MPTF, an applicant will need to demonstrate that the produced aircraft does indeed conform to the currently approved design data.

6.1.2.26 **Summary.** Summarised, the two DASA production-related authorisations that are usually relevant to new aircraft acquisitions are presented in Figure 3.

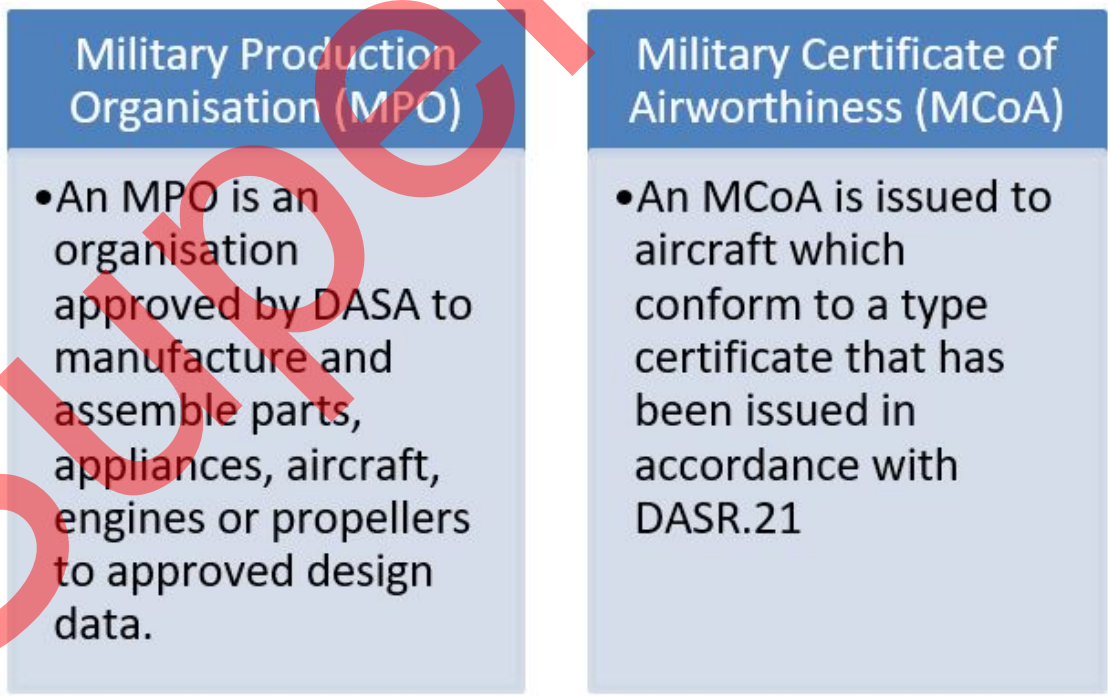

Figure 3: DASA authorisations related to production

6.1.2.27 DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MPOs and MCoAs.

Superseded

Aircraft maintenance (continuing airworthiness)

6.1.2.28 While Defence has long used the colloquial term of 'aircraft maintenance' to cover airworthiness activities beyond aircraft design and production, the DASRs purposely use the more expansive term of 'continuing airworthiness'. Aircraft maintenance is any one or combination of overhaul, repair, inspection, replacement, modification or defect/fault rectification of an aircraft or component. Continuing airworthiness encompasses this, plus maintenance management, maintenance training and maintenance licensing. For completeness, this section will use the term 'continuing airworthiness'.

6.1.2.29 Robust continuing airworthiness arrangements must be in place prior to the operation of a new Defence aircraft. Once assured of the sufficiency of these arrangements, DASA may issue three relevant organisational approvals, namely Continuing Airworthiness Management Organisations, Approved Maintenance Organisations and Maintenance Training Organisations. DASA may also approve Aircraft Maintenance Programmes and issue Military Aircraft Maintenance Licences to eligible personnel.

6.1.2.30 **Continuing Airworthiness Management Organisation.** Continuing Airworthiness covers all processes that ensure an aircraft continues to comply with initial airworthiness requirements and supports the ongoing validity of the aircraft's MCoA. The Continuing Airworthiness Management Organisation (CAMO), while not directly responsible for actual aircraft maintenance, is responsible for engaging organisations to conduct design and maintenance services. The CAMO will:

1. engage MDO(s) for design services as required
2. engage the MTCH for any matters that impact the aircraft's type design and type certification under MTC or an individual aircraft's CoA]
3. task AMOs to maintain products (aircraft, engines and propellers), parts and appliances and
4. provide governance and oversight to organisations performing DASR M functions on its behalf.

6.1.2.31 In most cases, the acquisition of a new aircraft type will not result in the creation of a new CAMO; rather, the scope of an extant CAMO will be expanded to include the new aircraft type. The presence of a suitable CAMO is integral to DASA's approval of a new MAO, or adding an additional aircraft to an extant MAO's scope.

6.1.2.32 **Aircraft Maintenance Organisations.** DASR provides two avenues for the maintenance of an aircraft and its components. The first is a DASA-approved Approved Maintenance Organisation (AMO), and the second is 'another maintenance organisation accepted by DASA'. A combination of both is usually employed for Defence aircraft.

6.1.2.33 An AMO is an organisation approved by DASA to conduct aircraft maintenance activities. This includes all actions required for restoring and maintaining an item in a serviceable condition including servicing, repair, modification, overhaul, inspection and determination of condition to maintain aircraft safety and airworthiness. AMOs may be a military or Defence Industry organisation, may be located in Australia or overseas, and may encompass one or multiple aircraft types. New Defence aircraft may be supported by one or several AMOs.

6.1.2.34 DASR Part M makes provision for maintenance services to be consumed from other maintenance organisations that are accepted by DASA. While the regulation infers that DASA explicitly accepts each of these maintenance organisations, this is not normally the case. Rather,

Superseded

DASA will automatically accept a maintenance organisation provided it is oversighted by a NAA/MAA that is 'recognised' as competent by DASA, and provided the CAMO ensures the conditions and caveats on the relevant 'recognition certificate' are met. Recognition certificates for each NAA/MAA recognised by DASA are available on DASA's website.

6.1.2.35 Prior to operation of a new Defence aircraft, the CAMO must demonstrate that arrangements are in place to maintain the aircraft in an airworthy condition. In limited circumstances, DASA may agree to the temporary absence of some maintenance arrangements, but only where this does not affect the near-term support of the aircraft.

6.1.2.36 **Aircraft Maintenance Programme.** An Aircraft Maintenance Programme (AMP) describes the scheduled maintenance tasks, their frequency of completion, the associated maintenance procedures, and so on, necessary to preserve the airworthiness of the aircraft. For aircraft acquisition projects, an initial AMP must be approved by DASA prior to the conduct of any maintenance activities. Maintenance activities can in some cases pre-date flying operations on the Defence Register, since they include aircraft preservation and other maintenance tasks required to prepare the aircraft for operation.

6.1.2.37 **Military Aircraft Maintenance Licenses.** AMOs require some personnel to hold particular categories of Military Aircraft Maintenance Licences (MAMLs). Furthermore, in order to be entitled to exercise certification privileges on a specific aircraft type, the holder of a MAML requires their licence to be endorsed with the relevant aircraft type ratings. As part of the AMO approval process for a new aircraft, the AMO will need to demonstrate that its personnel hold sufficient and applicable MAMLs.

6.1.2.38 **Maintenance Training Organisation.** A Maintenance Training Organisation (MTO) conducts training and examinations for maintenance personnel as specified in DASR 66. While a new MTO would rarely be required for a new Defence aircraft, an extant MTO would need to demonstrate its competence to conduct the type/task training and assessments for the new aircraft.

6.1.2.39 **Summary.** Summarised, the five DASA authorisations related to continuing airworthiness (of which maintenance is a component) of Defence aircraft acquisitions are presented in Figure 4.

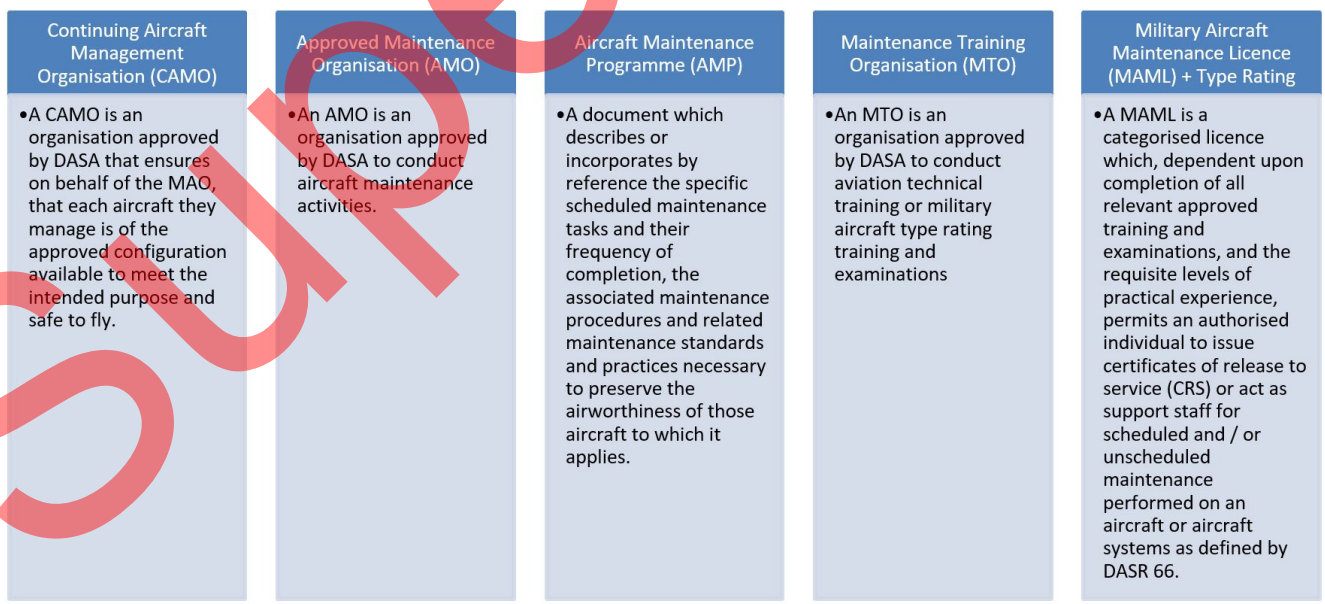

Figure 4: DASA continuing airworthiness-related authorisations

Superseded

6.1.2.40 DASPMAN Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into CAMOs, AMOs, AMPs, MTOs and MAMLs.

Aircraft operation

6.1.2.41 A Military Air Operator Certificate (MAOC) is the principal authorisation granted by DASA to conduct military air activities. Each aircraft type operated by the MAO is authorised by a separate DASA-issued Operations Specification (OpSpec) annex. The OpSpec annex details, amongst other things, key positions of the MAO, operating provisions, roles and tasks, specific approvals, and any limitations or conditions imposed by DASA.

6.1.2.42 The relevant OpSpec annex is required before first flight of the aircraft by the MAO[12]. DASA will issue the OpSpec annex once assured that the necessary Fundamental Inputs to Capability (FIC) elements, as well as quality and safety management systems, are in place to support intended operations.

6.1.2.43 Preparing a MAO to take on a new Defence aircraft can be a substantial undertaking. Amongst other things, for the new aircraft type the MAO will need to:

1. define the operating intent and usage for the aircraft through an approved Statement of Operating Intent and Usage (SOIU)
2. ensure arrangements are in place for maintaining the airworthiness of the aircraft through a CAMO and AMOs
3. implement the multitude of systems needed to manage Operations personnel and Air operations
4. produce/accept Orders, Instructions and Publications (OIP)[13]
5. establish an Aviation Safety Management System (ASMS).

6.1.2.44 Implementing these requirements, even for an existing MAO, is likely to require considerable planning and effort. Consequently, DASA recognises that a graduated capability growth plan for operational authorisations may be required. The Aviation Safety Acquisition Management Plan (ASAMP - see Chapter 6.1.1 and later in this chapter) is a suitable repository for reflecting the status of the acquisition program, including details of work completed, re-programing of remaining activities and risk management for the incomplete tasks.

6.1.2.45 **Summary.** Summarised, the singe DASA flight operations-related authorisation relevant to aircraft acquisitions is presented in Figure 5.

Superseded

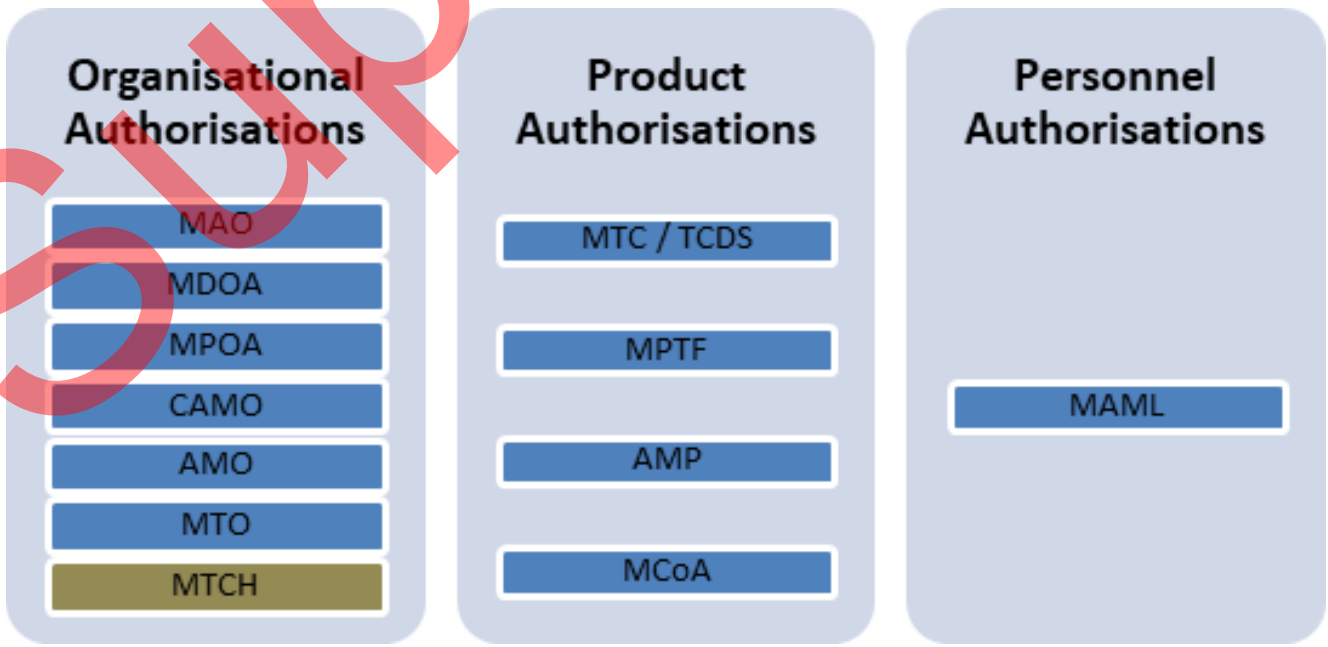
Figure 5: DASA authorisations related to aircraft operations

6.1.2.46 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MAOs.

Summary

6.1.2.47 This section has presented an overview of the DASA authorisations that may be relevant to new aircraft design, construction, maintenance and operation. Depending on the acquisition arrangements and the aircraft role, some authorisations might not be required.

6.1.2.48 The diagram at the start of this section (Figure 1) summarised all of the possible DASA authorisations according to whether they were relevant to new aircraft design, construction, maintenance or operation. However, another way of grouping them is according to whether they are organisational, product or personnel authorisations, as shown in Figure 6.



Superseded

Figure 6: DASA authorisations for new aircraft (grouped by category)

6.1.2.49 This grouping has the advantage that the eight organisational authorisations all use substantially the same processes for application and approval, and the three product authorisations have strong synergies. Consequently, for simplicity, this grouping will be used in the next section.

Processes, Plans and DASA Interaction

6.1.2.50 The previous section presented an overview of the DASA authorisations that may be relevant to new aircraft acquisitions. While the respective DASRs define the required safety outcomes for these DASA authorisations, history has shown that achieving the authorisations can be a complex and protracted journey. This section guides the reader though the process of achieving these DASA authorisations.

6.1.2.51 Figure 7 shows how the various DASA authorisations usually fit onto a project timeline. The vertical stripes present four significant milestones for introducing a new aircraft to Defence, the items above the dashed line show DASP-related project and Command activities, and the items below the line show the DASA authorisations. A time scale has purposely not been included, because this can vary enormously between aircraft acquisitions.

Superseded

Figure 7: Common project timeline for DASA authorisations

6.1.2.52 The elements below the dashed line can broadly be grouped into five activities, as shown in Figure 8. With the exception of Activity 1, the remaining activities are rarely sequential; more often than not Activities 2 and 3 are executed concurrently, and several activities may be cyclic.

Superseded

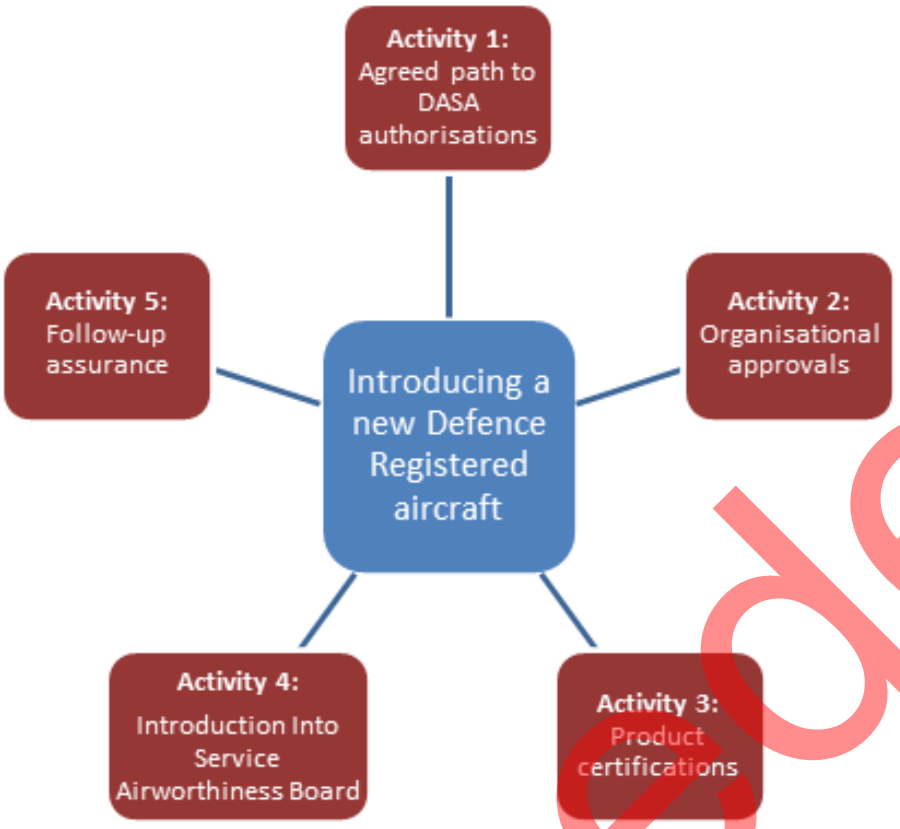


Figure 8: Activities in introducing a new Defence aircraft

6.1.2.53 Each of these five activities from Figure 8 is explored below.

Activity 1: Agreed path to authorisations

6.1.2.54 A major milestone in the aircraft acquisition process is the achievement of a range of DASA authorisations. However, establishing the contracts, systems and people to merit each authorisation is usually complex, with considerable potential to waste time and resources. Effective engagement with DASA is therefore in the best interests of all parties.

6.1.2.55 **Initial engagement.** Engagement should ideally commence as soon as Defence's acquisition organisation has a reasonable view on the candidate aircraft, the need for Defence-unique design changes, and the probable operating and support constructs[14]. Engagement should be well-advanced before Defence issues any tender documents (eg Requests for Tender, Foreign Military Sales Letter of Requests, etc) that may later affect an authorisation.

6.1.2.56 The initial engagement should involve DASA specialists, the Defence acquisition organisation, and capability manager representatives. If known, the Defence and industry organisations that will support the aircraft could also participate. Key outcomes will be:

1. a shared understanding of the project scope and schedule, candidate aircraft and the likely scope of Defence-unique design changes

Superseded

2. initial views on which of the seven DASA organisational approvals are likely to be needed and, for those that may not be needed, agree on the alternative means of achieving the same safety outcomes

3. initial views on how the aircraft might achieve an MTC, including how current or future certifications by DASA-recognised national or military airworthiness authorities (NAA/ MAAs) might contribute

4. initial views on whether an MPTF might be required to allow for test and other flying prior to the issue of an MTC

5. DASA should provide a management overview of each likely DASA authorisation, including: key milestones, common approval timeframes, recommended DASA collaboration, availability of training and other guidance material, and so on.

6.1.2.57 Annex A presents an expanded version of the above list, which can be used as a set of talking points for this initial engagement. Depending on the acquisition strategy, some of the details may initially be sparse. If so, further engagement should be scheduled for when the information is likely to become available, but still before releasing RFTs or equivalent documents.

6.1.2.58 **Documented agreement.** As noted in Chapter 6.1.1, DASRs do not mandate a plan or agreement for achieving DASA authorisations. It is, however, a practice that DASA highly recommends, given the substantial complexities in establishing the organisations and systems to manage aviation safety, and therefore the potential impacts (both positive and negative) on cost and schedule - and ultimately Defence capability.

6.1.2.59 DASA advocates the production of an Aviation Safety Acquisition Management Plan (ASAMP). The ASAMP is an iterative agreement between Applicants and DASA on the path to achieving DASA authorisations, and supports commanders and managers in accounting for parallel lines of effort and cross-regulation dependencies.

6.1.2.60 Annex B presents the suggested content and management arrangements for an ASAMP. Summarised, it suggests the main body of the ASAMP should describe the overarching aviation safety acquisition strategy and bring together the planned outcomes of the operational, technical, logistical and safety management activities. It should also describe the management of flight operations during acquisition, particularly if operations are to commence under an MPTF.

6.1.2.61 Annex B also suggests the ASAMP should include a series of annexes, with individual annexes dedicated to each DASA authorisation. Each annex could be sponsored by the relevant Applicant for the DASA authorisation, and could form an agreement between DASA and the Applicant on the path to the particular authorisation. For simple acquisitions, the annexes might directly present the information[15]. For more complex acquisitions, particularly where there are a range of Applicants for the various DASA authorisations, the annexes might merely contain a link to a planning document that is drafted and managed by the respective Applicant. Either way, the annexes should be 'modular', whereby each annex is configuration managed and approved separately to the main body of the ASAMP.

Superseded

6.1.2.62 The ASAMP should be drafted after the acquisition strategy solidifies (usually post Government approval), but before RFTs (or equivalent) are released. The ideal time to draft the ASAMP is usually soon after the initial engagement with DASA, and in fact that engagement will influence much of the ASAMP content. The ASAMP would normally be updated after contracts and agreements are signed, since the path to most DASA authorisations should be clear.

6.1.2.63 Once contracts and agreements are signed, the main body of the ASAMP need only be updated when there is a marked change in the acquisition strategy or high-level schedule for the project. The annexes, on the other hand, will probably be updated more frequently, particularly in the earlier stages of the project as knowledge and plans evolve.

6.1.2.64 **Ongoing engagement.** DASA's experience is that three forms of engagement should be maintained throughout the project lifecycle, as follows:

1. Periodic major stakeholder engagements, expanding on the initial engagement suggested previously in this section. This should occur throughout the acquisition project lifecycle, usually when significant milestones are approaching

2. Frequent coordination and status updates between senior project management staff (commonly the CASG Project Engineering Manager, the CM Transition Team lead, etc), and DASA's operational and technical leads for the acquisition

3. Engagement as required between each of the Applicants for a DASA authorisation and the respective DASA specialist.

6.1.2.65 **DASA assistance with contract reviews.** There is no DASR requirement for DASA to be engaged in seeking offers (eg RFT or equivalent), selecting the successful tenderer, negotiating the contract, and signing the contract. However, where a contract element may one day affect a DASA authorisation, prudent DASA involvement can reduce project cost and schedule risk. Areas where DASA can contribute include:

1. Prior to RFT (or equivalent) issue:

    i. confirming the RFT requirements for organisational approvals are appropriate for aircraft acquisition and/or in-service support

    ii. confirming the RFT airworthiness design requirements (including airworthiness codes and other standards), and proposed approach to aircraft certification, present a suitable pathway to MTC

    iii. confirming the RFT aircraft production arrangements present a suitable pathway to issue of MCoA

    iv. confirming aircraft registration pathways, particularly for significant modifications to a green aircraft by a third party

Superseded

v. providing expert input to specialist aircraft design technology requirements, such as aircraft structural integrity (ASI) design and in-service management systems.

2. For RFT assessment:

i. If any of the above RFT items seek preliminary plans for DASA organisational approvals or product certifications, then DASA can participate in the assessment of those plans

ii. otherwise, while the Defence acquisition organisation will conduct the tender evaluation, DASA staff are available for on-call advice and assistance as required[16]

3. For contract negotiation: DASA staff would rarely be directly involved in contract negotiations, but are available for on-call advice and assistance as required.

4. Final contract review: DASA does not review the mature contract prior to signature, but is available for advice and assistance as required.

6.1.2.66 **Delegations.** During the project lifecycle, organisations may elect to delegate their Command responsibilities, for example the appointment of the senior operator within the project transition team to make operational decisions in relation to the project. Once notified of the delegation, DASA will treat the decisions and approvals of the delegate as if the accountable manager had issued them.

6.1.2.67 Later in the project lifecycle, usually just before MTC issue, a 'Platform DoSA' will need to be appointed by DASA. The Platform DoSA role is normally delegated to the incumbent Defence CENGR of the platform MTCH organisation, and is responsible for assurance of MTCH actions with respect to reportable occurrences, issue of MCoAs, approval of flight conditions and issue of Airworthiness Directives. DASP Manual Volume 3 Chapter 4.3, Delegates of the Safety Authority, provides additional information.

Activity 2: Organisational approvals

6.1.2.68 Professional aircraft design, construction, maintenance and operation organisations are cornerstone to aviation safety. Implementing the required organisations for a new aircraft, and obtaining DASA approval of each organisation, is usually a significant activity for both the Applicants and DASA. This section explores the planning, establishment and assessment of new DASA-approved organisations.

6.1.2.69 **Planning.** As noted in Activity 1, the ASAMP should include a planning annex for each organisational approval. The ASAMP should plan for the organisational approvals to be achieved well prior to their need date, which are likely to be as follows:

Superseded

1. MAO: DASA authorisation is required prior to the first operation of the aircraft by the MAO[17]. This authorisation is reflected in DASA's issue of an OpSpec annex for the new aircraft

2. MDO:

   i. (for initial aircraft design): Required prior to design changes to the green aircraft, if those changes are not to be certified by a recognised NAA/MAA

   ii. (for in-service support): Required prior to first flight on the Defence Register, unless DASA has agreed to an alternative interim support arrangement

3. MTCH: Implementation of suitable MTCH arrangements are a prerequisite for issue of an MTC. However, depending on the acquisition arrangement, some of these functions may need to be in place earlier to support the initial MPTF

4. MPO: Required prior to any aircraft production activity, unless an alternative production approval path has been agreed by DASA

5. CAMO: Required prior to first flight of the aircraft on the Defence Register

6. AMO: Required prior to first flight of the aircraft on the Defence Register[19], unless an alternative interim maintenance arrangement has been agreed by DASA. AMOs will need MAMLs in sufficient numbers to meet AMO needs, relevant to the scope of operations and numbers of aircraft

7. MTO: Agreed in consultation with DASA.

6.1.2.70 Note that while DASA agreement to the above authorisation plans is not a regulatory requirement, it is encouraged by DASA. As Figure 9 shows, the time needed to implement a new organisation and then achieve a DASA organisational approval can be substantial, so careful management is needed to minimise Defence's schedule risk.

Superseded

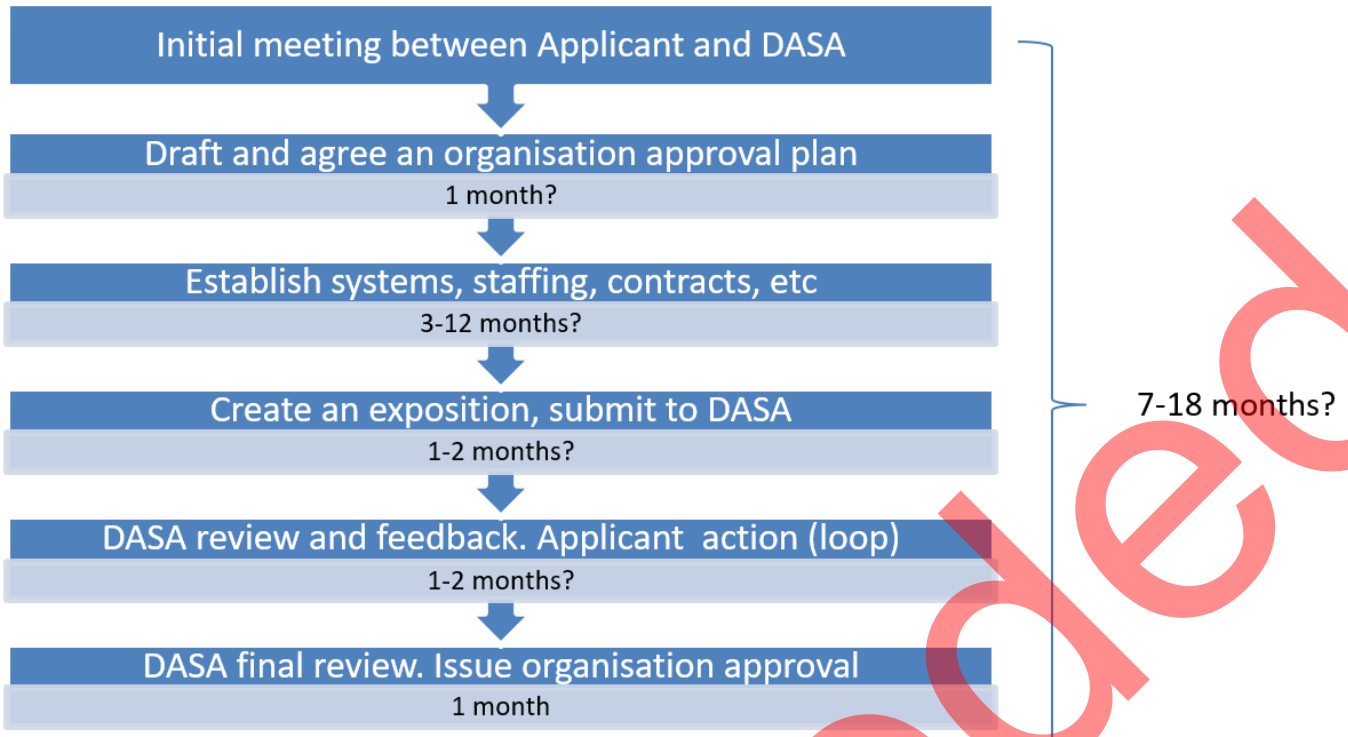

Figure 9: Timeline for DASA organisational approvals

6.1.2.71 **Establishing organisations.** DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, presents a description of each DASA organisational approval, including the key artefact(s) needed to show regulatory compliance - for example, the MDO's design organisation handbook, the AMO's Maintenance Organisation Exposition (MOE), the MAO's Operations Compliance Statement (OCS), and so on. Each of these artefacts will help guide the Applicant's efforts to establish an organisation that professionally supports Defence aviation safety, as will the Acceptable Means of Compliance (AMC) and Guidance Material (GM) accompanying the relevant DASRs. DASA-sponsored education courses and DASA website material also offer useful information.

6.1.2.72 However, Applicants must bear in mind that such guidance may be incomplete, or not entirely relevant to the local context. Consequently, DASA cannot overstate the importance of the Applicant's role in refining the organisation beyond DASR (and DASA) requirements. This might include, for example:

1. learning from other Defence organisations
2. learning from comparable civil organisations[20]
3. exploring the (often extensive) guidance material released by other NAA/MAAs[21]
4. consulting with staff and others with relevant domain expertise.

6.1.2.73 A robust and evolving Aviation Safety Management System (ASMS) is pivotal to establishing an organisation that optimises its contribution to Defence aviation safety. An ASMS utilises a systematic

Superseded

approach to managing aviation safety, including organisational structures, accountabilities, policies and procedures. An effective ASMS continuously improves an organisation's safety performance through pro-actively collecting and analysing safety data to predict, prevent and treat aviation hazards and risks. DASP Manual Volume 3 Chapter 6.2, Safety Management, provides further guidance.

6.1.2.74 **DASA assessment.** The annexes in Chapter 5.3 provide insight into DASA's approach to assessing, and ultimately approving, a new or expanded organisational approval. Most approvals follow a similar process, namely:

1. the Applicant drafts an 'Exposition' or similar document, as key evidence that their organisation has implemented the systems and processes needed to comply with the relevant DASRs

2. the applicant submits the relevant DASR Form to seek an organisational approval

3. DASA conducts an assessment of the Exposition and the documents it references, often as a desktop activity for new organisations; on occasion DASA may do an on-site assessment

4. if needed, the applicant remedies any deficiencies that preclude DASA's approval of the organisation

5. DASA issues an organisational approval, perhaps initially limited in scope

6. once the aircraft is operating and the organisation has the opportunity to exercise its approval, DASA will conduct a deeper assessment, usually including an on-site visit, placing particular emphasis on the effectiveness of the ASMS and system monitoring.

6.1.2.75 Figure 10 summarises the path through to DASA approval for the seven organisations common to new aircraft acquisitions.

Superseded

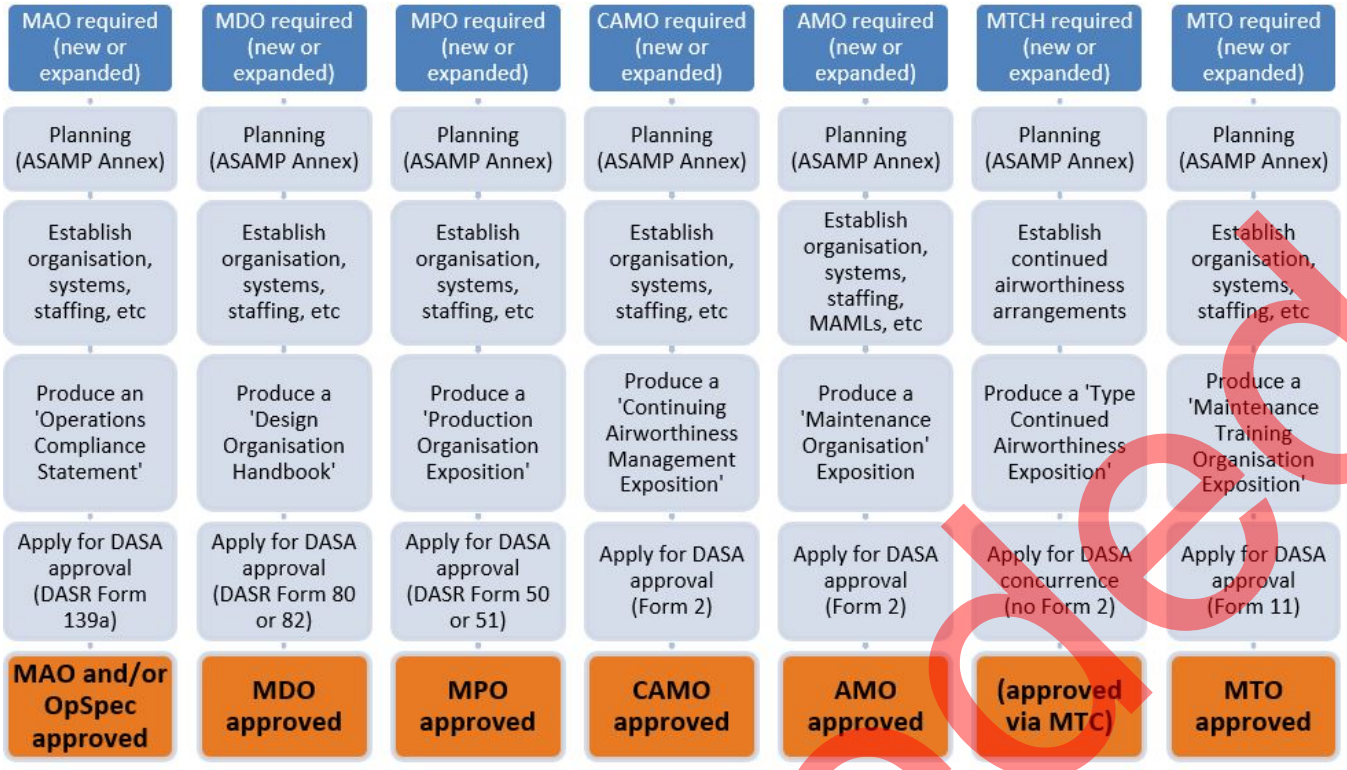

Figure 10: Path to DASA organisational approvals

Activity 3: Product authorisations

6.1.2.76 The four common product authorisations for new aircraft are the MTC, MCoA, MPTF and AMP. While an MPTF will often be issued prior to an MTC and MCoA, preparatory work on the other two will usually precede and support the issue of the MPTF. Hence, this section will consider the MPTF last.

6.1.2.77 Before exploring the four product authorisations, some brief discussion on safety risk management is warranted. Risk management is almost always a contributor to MTC and MPTF authorisations, so all stakeholders need to be conversant with Defence's 7-step risk management approach, as explained in the DASA Advisory Circular 003/2018, Risk Management in the DASP. Furthermore, DASA's experience is that this risk management is most effective when all parties robustly consult, cooperate and coordinate with each other. Critically, this must occur across organisational boundaries, and across specialisations (most notably between operators and engineers).

6.1.2.78 **MTC.** Achieving an MTC for a new aircraft is a significant milestone for an aircraft acquisition project, and one that commonly takes substantial planning and effort. While the path to an MTC is explored in DASP Manual Volume 3 Chapter 7.2, Certification, for the benefit of readers not needing that depth of information, a brief description of the process is included here.

Superseded

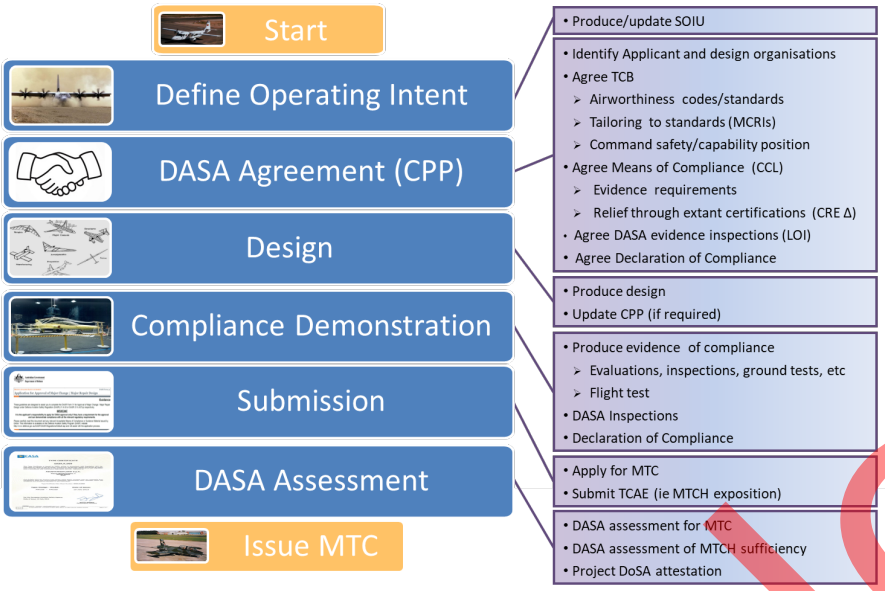

Figure 11: Path to issue of an MTC

6.1.2.79 An overview of the type certification process, culminating in an MTC, is shown in Figure 11. The first step, defining the operating intent for the aircraft, is pivotal to designers producing a design that is safe for Defence's intended Configuration, Role and Environment (CRE). A poorly-developed operating intent, or one developed late in the design lifecycle, can (and previously has) resulted in:

1. additional cost to re-design elements of the aircraft
2. operational limitations to eliminate the elevated risk, or
3. management and retention of elevated risk, often for the life of the aircraft.

6.1.2.80 The second step shows the Applicant and DASA agreeing on a Certification Program Plan (CPP). While a CPP is not explicitly required by DASR, it is inconceivable that Defence would pursue a certification program without an agreed CPP, since it imposes obligations on both the Applicant and DASA. Critically, the CPP:

1. agrees on the Type Certification Basis (TCB) for the new aircraft, which comprises the airworthiness requirements (inclusive of tailoring) that the design must meet
2. agrees on the evidence that will be produced by the design organisation(s) to demonstrate the design complies with the TCB
3. agrees on the application of 'recognition of prior acceptance', where existing product certifications by DASA-recognised NAA/MAAs will contribute to the certification of Defence's new aircraft [22]
4. defines the extent of DASA's inspections of compliance demonstration evidence.

Superseded

6.1.2.81 The tailoring of the TCB, mentioned in the first sub-paragraph above, is accomplished using one of five types of Military Certification Review Item (MCRI)[23]. Four of these MCRIs either maintain or improve the safety of the aircraft design, while the fifth, the 'Exception MCRI', can approve a reduction in the safety of the aircraft design. This reduction is only justifiable where requiring compliance with a TCB requirement would adversely affect Defence capability. While DASA ultimately approves the Exception MCRI, it is based heavily on Command's confirmation that a capability imperative exists, and that the risks due to the TCB non-compliance have been eliminated or otherwise minimised SFARP. The document used to communicate and record these Command risk decisions is normally the Airworthiness Issue Paper (AwIP). Guidance for AwIPs is provided at annex C.

6.1.2.82 The third step in the certification process is where the design organisation produces the design. For new Defence-unique designs, this often requires a DASA-approved MDO unless the design will be certified by a DASA-recognised NAA/MAA, as explained earlier in this chapter. The MDO must be in place before the design effort commences.

6.1.2.83 The fourth step, Compliance Demonstration, is where the MDO produces evidence that their design meets the DASA-agreed TCB. This step may require DASA approval of an MPTF to enable flight testing if the aircraft is already on the Defence Register. The MPTF is explored later in this section.

6.1.2.84 The fifth and six steps wrap up the certification process, and are largely self-explanatory. It is worth noting that while an Airworthiness Board (AwB) is not a prerequisite for DASA issue of an MTC, if the Defence Aviation Authority (Defence AA) elects to convene an AwB near to the MTC issue date, then DASA may wait until after that event to issue the MTC. AwBs are explored later in this chapter.

6.1.2.85 **MCoA.** As noted previously, an MCoA cannot be issued prior to the MTC. However, it is normal practice for the Defence acquisition organisation to be prepared in advance, so DASA[24] can issue MCoAs for the delivered fleet directly following the issue of the MTC. DASPMAN Volume 3 Chapter 5.3 presents the conditions and processes for MCoA issue.

6.1.2.86 **MPTF.** Once a new aircraft type has been added to the Defence Register, but prior to issue of the MTC, MAOs may need to operate the aircraft. For example, the flight test MAO may need to conduct flight tests to generate compliance demonstration evidence, and to contribute to operational test and evaluation (OT&E). The operational MAO may need to maintain crew currency, evolve OIP, conduct OT&E, and so on.

6.1.2.87 DASA can issue an MPTF if the aircraft design has been shown to substantially comply with its TCB, the configuration of the aircraft is clearly defined, the aircraft is capable of safe flight under defined conditions, and any elevated risk has been justifiably retained. An MPTF is effectively reliant on both the MTC and the MCoA processes being well-advanced.

6.1.2.88 The initial MPTF will usually constrain the MAO's operation of the aircraft. After all, the type certification program is still incomplete so there will be areas of the design that are known to be deficient or where uncertainty still remains, and hence the MPTF will impose commensurate risk controls. DASPMAN Volume 3 Chapter 7.5, Flight Conditions and MPTFs, explores MPTFs and their associated flight conditions, including risk management, the application process, periods of validity, and so on. The MAO will often self-impose additional constraints on flight operations, and will ease these constraints as the systems and personnel skills mature.

Superseded

6.1.2.89 **AMP.** CASG's Reliability and Aircraft Maintenance Program (RAMP) team, which is collocated with DASA's Melbourne office, provides Defence's centre of expertise for AMPs, and advises DASA on whether an AMP should be approved[25]. Both DASA and the RAMP team should be engaged early in the acquisition phase for guidance on AMP requirements.

Activity 4: Convene an Airworthiness Board

6.1.2.90 As discussed in Chapter 6.1.1, the Defence AA would normally require that an AwB be convened prior to operation of a new aircraft on the Defence Register[26]. The Introduction into Service AwB, normally held immediately prior to the commencement of flight operations, complement regulatory activities conducted by the DASA and build on the confidence of DASA authorisations. This AwB is underpinned by progressive check-ins by the board members with both DASA and the regulated community, focussing on:

1. understanding the status of DASA assurance of relevant products and organisations
2. safety assurance of the collective enterprise (CM, CASG, Industry) introducing the new platform;
3. potential organisational culture hazards; and
4. transition safety risks associated with the introduction of the capability through to reaching initial operational capability milestones.

6.1.2.91 The artefacts submitted by Applicants to the AwB would predominantly consist of already produced project documentation and attestations that collectively summarise the readiness to commence Flight Operations:

1. Airworthiness Plans, Artefacts, Approvals and Authorisations
2. FIC Status and Capability Realisation
3. Integrated Airworthiness System Assessment
4. MAO Risk Management and OIP

6.1.2.92 The Defence AA would normally require progressive AwBs during the initial operating period for a new aircraft, most likely aligned with key Operational Capability milestones. Hence the AwB can explore whether the operational and support systems are maturing commensurately. Periodicity might be influenced by the severity of organisational and/or product deficiencies noted during DASA assurance activities and/or a previous AwB.

6.1.2.93 Annex D presents additional guidance on the submissions, requirements and conduct of an AwB for a new aircraft type.

Superseded

Activity 5: Follow-up DASA assessments

6.1.2.94 The organisational and product authorisation requirements presented in this chapter are seldom wholly implemented when the Applicants apply for the relevant DASA authorisations. Provided DASA is satisfied the safety risks due to the deficiencies can be robustly managed, this may not preclude DASA from issuing the authorisation, as explored in the following paragraphs.

6.1.2.95 **Organisational approvals.** When DASA initially issues an organisational approval, the processes and people may not yet have been exercised for the new aircraft type. For example, an MDO may not have produced designs, the MAO may not have exercised its ASMS, organisational deficiencies may have been identified by DASA, and so on. Equally, the organisation may self-identify temporary deficiencies in their own processes and people.

6.1.2.96 These issues may not preclude DASA from issuing the organisational approval if satisfied the organisation has the ability to safely operate and support the aircraft. DASA may elect to moderate this risk through, amongst other things:

1. placing limitations on operations, initially via the initial MPTF and later via the OpSpec
2. initially constraining the 'privileges' that are available to organisations under some regulations
3. re-visiting the organisation soon after their systems and processes have been exercised.

6.1.2.97 Over time, once DASA is assured the deficiencies or lack of experience have been addressed, the constraints may be eased. The Defence AA may convene AwBs to provide additional confidence.

6.1.2.98 **Product authorisations.** As a matter of pragmatism, a MTC can be issued before compliance with the TCB has been entirely demonstrated. As a result, the MTC may include temporary limitations, or the TCB may include temporary Exception MCRIs (with supporting AwIPs documenting essential risk management), pending resolution of the outstanding design issues. Once evidence of TCB compliance is provided to DASA's satisfaction, the limitations or other risk management measures can be progressively removed.

Project completion

6.1.2.99 Even after the above five activities have been substantially completed, residual issues may still be outstanding. Provided these issues are sufficiently few in number and complexity[27], they have been professionally transitioned to the running system, and any associated risks are being managed in the relevant ASMS, DASA will in due course consider the acquisition project to be closed.

6.1.2.100 The residual issues will be monitored by DASA through normal compliance assurance activities.

Niche Applications

Superseded

6.1.2.101 So far, this chapter has focused on new aircraft types being acquired by Defence. This final section will explore three niche applications of the information presented in this chapter, namely fleet additions, acquisition of used aircraft, and Major design changes to in-service aircraft.

Fleet addition aircraft

6.1.2.102 When additional aircraft are to be added to an extant Defence fleet, the guidance presented earlier in this chapter is still mostly relevant, although it can be applied in a substantially abbreviated form. An assessment of each of the five activities from the previous section is presented below.

6.1.2.103 **Activity 1: Agreement on DASA authorisations.** The information presented in the previous section is entirely relevant. That is, the acquisition organisation should engage with DASA before contracts and other agreements are signed, and an agreed path to DASA approvals should be documented in an ASAMP. The ASAMP will be much abbreviated compared to the acquisition of a new aircraft type, and some of the ASAMP annexes will not be required.

6.1.2.104 **Activity 2: Organisational approvals.** Each of the organisational approvals will likely be in place, so this activity is limited to ensuring those organisations can manage the additional workload and (where applicable) the configuration differences of the new aircraft.

6.1.2.105 **Activity 3: Product certifications.** If the new aircraft are precisely the same configuration as the extant fleet, they can simply be listed on the MTC and individual MCoAs then issued for each new aircraft. More likely, however, there will be configuration differences. While other avenues may be acceptable, most often the new aircraft are added to the MTC mirroring the configuration of the extant fleet, and the configuration deltas for the new aircraft are processed as design changes (Major and Minor) to the common type design. If there will be a delay in completing this activity, an MPTF can be used to cover the configuration differences of the additional aircraft.

6.1.2.106 If there are substantial configuration differences to the extant fleet, perhaps even with changes to the TCB, the new aircraft might need to undergo a targeted type certification program that focuses on the configuration deltas. DASA's approval may be reflected as a separate model number on the MTC, or the deltas might be encompassed in a Military Supplemental Type Certificate (MSTC).

6.1.2.107 **Activity 4:** AwB. AwB independent review of additional aircraft would normally be considered as part of the next scheduled sustainment AwB. In exceptional circumstances, a separate AwB may be convened if the acquisition of additional aircraft requires appreciable changes to extant FIC arrangements.

6.1.2.108 **Activity 5:** Follow-up DASA assessments. The information on product deficiencies presented in the previous section is equally relevant to fleet addition aircraft. The information on organisational deficiencies, on the other hand, is unlikely to be applicable; rather, the next routine compliance assurance activity would check how the organisation is coping with the extra workload.

Used aircraft

Superseded

6.1.2.109 Where Defence elects to acquire used aircraft, the guidance presented earlier in this chapter is entirely relevant. However, there are additional actions that will need to be undertaken for Activity 3: Product Certification, namely the provision of additional documentation and the completion of additional inspections to support the issue of an MCoA.

6.1.2.110 **Documentation.** DASR 21.A.174 presents a list of the additional documentation needed for a used aircraft, namely:

1. (if the aircraft originates from a foreign military applying an EMAR based regulations): a Military Airworthiness Review Certificate;

2. (if the aircraft originates from a civil state of registry that is recognised by DASA): an export certificate of airworthiness from the recognised CAA;

3. (if the aircraft originates from elsewhere):

    i. a statement by the Authority of the State where the aircraft is, or was, registered, reflecting the airworthiness status of the aircraft on its register at time of transfer

    ii. a weight and balance report with a loading schedule

    iii. the flight manual and any other manuals required by the Authority of the State of registry

    iv. historical records to establish the production, modification, and maintenance standard of the aircraft, including all limitations associated with a restricted certificate of airworthiness

    v. a recommendation for the issuance of a certificate of airworthiness or restricted certificate of airworthiness and a Military Airworthiness Review Certificate following an airworthiness review in accordance with DASR M.

6.1.2.111 **Inspections.** Used aircraft require a more stringent inspection than new build aircraft, and must be performed by an appropriately qualified, independent and experienced organisation. The inspecting organisation is to conduct a comprehensive review of the aircraft design, maintenance and operational documentation, verified by a physical inspection of the airframe structure, engines and other systems.

6.1.2.112 The inspecting organisation is to provide inspection reports detailing the airworthiness inspection result. As a minimum, reports should include the following:

1. details of the aircraft inspected, including registration number, manufacturer, serial number, model designation, and Certificate of Airworthiness number

2. last known inspected configuration of the aircraft

Superseded

3. a summary of the usage and maintenance history of the aircraft, engines and propellers, including current maintenance, weight and balance, and lifed component status

4. details of any major structural and life-limited component changes made to items such as wings and tailplane, and a summary of the individual histories of such components, unless new when fitted

5. details of any accidents or incidents in which the aircraft has been involved

6. details of any major repairs or modifications performed on the aircraft, engines and propellers and verification that they have been properly approved and incorporated

7. details of any applicable aircraft-general, type-specific, engine or equipment airworthiness directives or service bulletins and verification that the aircraft complies

8. a condition assessment of flight safety critical components and fatigue-sensitive structure

9. recommendations for the resolution of any airworthiness deficiencies or concerns arising as a result of the airworthiness inspection

10. flight manuals and any other manuals.

6.1.2.113 Should Defence be contemplating the acquisition of used aircraft, DASA should be contacted early in the decision process. DAVENG staff in particular will provide the acquisition project with useful guidance.

Major design changes

6.1.2.114 This chapter has so far focused on aircraft acquisitions. However, the content can be extensively applied to particularly complex Major design changes to in-service aircraft. A Major design change is one that has an appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product .

6.1.2.115 Defence currently conducts around 70 Major design changes to its fleet each year. Most of these design changes have little if any significant impact on the aircraft operator or support organisations. Occasionally, however, Defence undertakes a Major design change whose effects pervade the DASP.

6.1.2.116 An example might be an extensive mid-life cockpit upgrade, which will not only challenge the design organisation, it can extensively affect MAO OIP, require simulator upgrades, change the aircrew training curriculum, allow new Performance Based Navigation approvals, require additional maintenance equipment and training, require new production organisations, require parallel operations of two different aircraft configurations for extended periods, and so on. An extensive flight test program to explore human factors and other certification issues might also be required.

Superseded

6.1.2.117 Making such pervasive changes to the aircraft and supporting systems can be a complex undertaking that requires coordination and often robust risk management across multiple organisational boundaries. While it perhaps does not have the complexities of introducing a new aircraft into service, it is far from straightforward and can introduce elevated safety risks if not executed well. In such circumstances, increased independent assurance from DASA is likely to benefit aviation safety.

6.1.2.118 Where DASA, in consultation with the MAO and CASG, identifies a Major design change that warrants this expanded DASA independent assurance, DASA will treat the project similarly to an aircraft acquisition. This may include, for example, increased scrutiny of organisational approvals, a closer assessment of how the new configuration is introduced into service (including, if necessary, imposing temporary operating constraints), greater assurance of risk management decisions, and so on. The Defence AA may require an AwB to be convened to provide an independent review of how well the new configuration has been integrated into Defence.

6.1.2.119 For these Major design changes, the guidance in the previous section is applicable almost in its entirety. Notably, an ASAMP should be raised, albeit some elements will self-evidently either be of limited scope or not applicable. An SOIU update may be required, organisational approvals may need to be expanded, and so on. The only element that is unchanged is the type certification process, since DASA certification oversight is always implemented commensurate with risk, and this is unaffected by the additional DASA scrutiny outlined in this section.

Annexes:

1. Project Initiation Meeting
2. ASAMP Guidance
3. Airworthiness Issue Papers
4. Airworthiness Board Guidance

6.1.3 Acquisition of Non-Defence-Registered Aircraft

Introduction

6.1.3.1 Civil registration of a Defence aircraft may be attractive to Capability Managers (CMs) and acquisition organisations. It may provide contractual and ongoing management simplicity, and sometimes lower costs and result in a faster introduction into service.

6.1.3.2 Regardless of the registration arrangement, Command retains the responsibility for ensuring the safety of aircraft occupants, other aircraft, people, and facilities on the ground. However, in the case of non-Defence-Registered (NDR) aircraft, DASA has a comparatively lesser role in guiding and assisting Command in meeting these obligations.

Purpose

Superseded

6.1.3.3 This chapter guides Defence's aircraft acquisition organisations and Military Air Operators through the aviation safety requirements and recommended practices during the acquisition of an NDR aircraft, but only to the extent, that DASA is involved in the process.

CONTENT UNDER REVIEW

Circa 2023, DASA is currently conducting a major review of the DASA approach and regulations for non-Defence Registered (NDR) aircraft. The review will assess, amongst other things, the legal implications of a State aircraft being regulated by a civil regulator, the need (if any) for DASR regulations to supplement the civil regulations, the role of DASA (if any) in aviation safety assurance, and so on.

Once the review is completed, DASR.NDR and this DASPMAN chapter will be updated. In the meantime, Defence organisations considering the acquisition of a NDR aircraft should contact DASA for advice.

Superseded

6.1.1. Introduction

6.1 Introduction of New Defence Aircraft Capabilities

6.1.1 Introduction

Background

6.1.1.1 Defence periodically adds aircraft to its inventory to meet a capability need. The aircraft may be purchased or leased, crewed or uncrewed, Defence or civil registered. An essential prerequisite for Defence operation of a new aircraft, regardless of the acquisition arrangement, is for Defence to confirm that it is safe for flight. This encompasses the safety of aircraft occupants, other airspace users, and overflown people and facilities.

6.1.1.2 The acquisition process for a new aircraft begins during the capability development phase of the life cycle, where operational requirements are defined and potential solutions investigated. The Aviation Safety management process commences concurrently with the acquisition process, and remains inextricably linked. Decisions made early in the acquisition process can have an enduring effect on Aviation Safety.

6.1.1.3 For a Defence aircraft to be safe for flight, the aircraft to be appropriately designed, constructed, maintained and operated, as explained in DASP Manual Volume 3 Chapter 3, The Defence Aviation Safety Program. It is the responsibility of aircraft acquisition organisations in Defence, relevant in-service organisations and Defence industry partners, to ensure a Defence aircraft is safe for flight, both from the initial design and throughout its Defence lifecycle. In turn, the relevant Aviation Safety authorities need to gain assurance that the aircraft is safe for flight. If suitably assured, the Aviation Safety authorities can issue a range of 'authorisations', usually in the form of certificates, permits, approvals or licenses.

Purpose

6.1.1.4 This series of chapters aims to guide Defence aircraft acquisition organisations, relevant in-service organisations and Defence industry partners through the aviation safety requirements and recommended practices during the aircraft acquisition process.

6.1.1.5 This first chapter provides a general introduction to acquiring new Defence aircraft, including registration requirements, Aviation Safety responsibilities, engagement with Aviation Safety authorities and other common concepts.

Applicability

6.1.1.6 This chapter is applicable to the acquisition (whether through purchase, lease or other arrangement) of the following Defence aircraft:

1. Defence registered crewed aircraft
2. Non-Defence registered crewed aircraft (short term)
3. Defence registered certified uncrewed aircraft systems (UAS)

Superseded

6.1.1.7 While the concepts in this chapter are also broadly applicable to Open and Specific category (ie non-certified) UAS, the regulatory approaches for these UAS are substantially different to certified aircraft, so DASP Manual Volume 3 Chapter 10, Uncrewed Aircraft Systems, separately covers their acquisition.

Structure

6.1.1.8 This chapter will provide context for the next four chapters, which will individually cover the three different arrangements for Defence aircraft acquisitions listed in paragraph 6, and as shown in Figure 1.

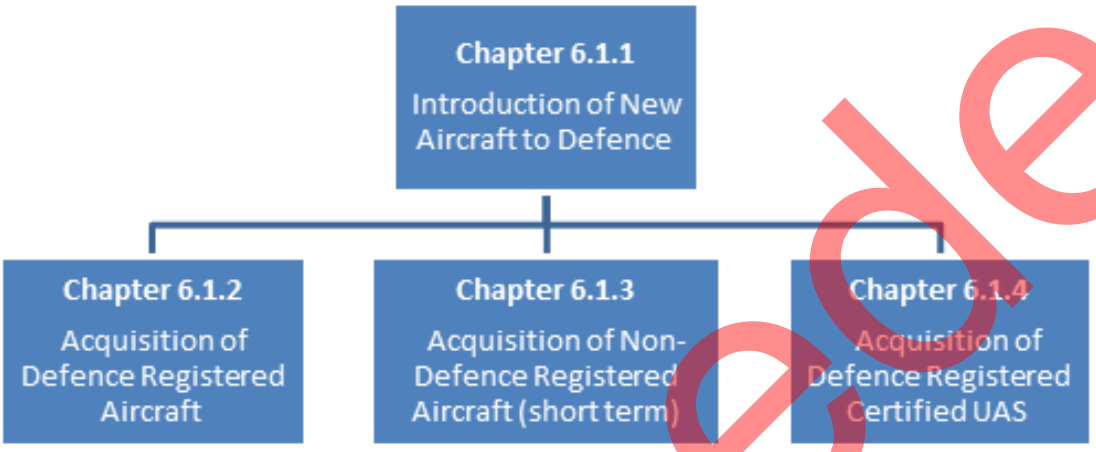

Figure 1: Chapter 6.1 structure

6.1.1.9 This chapter will also provide content that is common to the next four chapters, to avoid duplication.

Aircraft Registration

6.1.1.10 All Defence aircraft, apart from some non-certified UAS, must be included on the Register of a military or civil aviation authority. DASR separates these registrations into two categories; Defence registered aircraft and non-Defence registered aircraft. The latter are almost universally regulated by CASA. While other registrations are occasionally employed, they are always transitory arrangements[1].

6.1.1.11 A Defence registered aircraft is subject to Defence Aviation Safety Regulations (DASR) and DASA safety assurance oversight. An Australian civil registered aircraft, on the other hand, is subject to Civil Aviation Safety Regulations (CASR) and CASA safety assurance oversight as well as some limited DASA oversight.

6.1.1.12 When Defence is procuring an aircraft type that is also used under the civil regulatory framework, an important decision by the Capability Manager, required early in the acquisition process, is to determine whether the Defence aircraft will be Defence registered or civil[2] registered. This registration can have an enduring effect on Defence aviation capability, as summarised below:

1. **Defence registration.** Defence registration ensures the aircraft is within the exclusive jurisdiction of the DASR, which make specific allowance for:

   i. uniquely military roles, including weapons carriage and deployment, low flying, aerial delivery, clandestine flying, formation flying, transporting

Superseded

hazardous materials and dangerous goods etc — types of operations that may be heavily restricted or unsupportable under civil regulatory requirements

ii. flexibility in the approach to achieving compliance with the DASR

iii. the application of risk management where DASR compliance cannot be shown, provided a credible and defensible level of aviation safety performance is achieved

iv. Commanders to deviate from requirements (2) and (3) above in the event of compelling operational imperatives or emergencies.

DASA is experienced in regulating for the unique military operational context. Consequently, DASA is well-placed to advise Commanders on military aviation safety issues and to provide tailored independent safety assurance of military organisations and products.

2. **Civil registration.** Civil registration can initially be attractive to Capability Managers and acquisition organisations due to the simplicity of contractual and ongoing management, and potential faster introduction of the aircraft into service. However civil registration should only be considered for short term arrangements, or where an aircraft will not be considered a continuous 'State' aircraft. Complicating factors include that:

i. it can bind Defence to civil aviation safety regulations for design, maintenance and operation, and these regulations have not been customised to the unique military aviation context

ii. there may be a lack of risk-managed operational flexibility, which is the hallmark of Defence's aviation safety regulations

iii. it can bind Defence to the potential inflexibilities of the civil regulator

iv. there may be adverse diplomatic and security implications of Defence operating a non-Defence registered aircraft overseas.

6.1.1.13 Where a Capability Manager is considering civil registration for a temporary Defence aircraft, DASA should be engaged at the earliest practicable opportunity for consultation. Annex A presents a list of issues that should be explored during this engagement, to assist the Capability Manager in making an informed decision on Defence registration versus civil registration.

6.1.1.14 Annex B presents guidance on the structure and administration of the Defence Register.

Aviation Safety Responsibilities

6.1.1.15 DASP Manual Volume 1 states that aviation safety is a command responsibility, so commanders and managers are accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

6.1.1.16 The responsibility for ensuring (ie making sure) a new Defence aircraft is safe for flight falls directly on the Defence acquisition organisations and the relevant in-service support organisations. This includes, amongst other things, ensuring:

1. the aircraft design is safe for flight in the intended role and operating environment (ie aircraft design and certification)

Superseded

2. the physical aircraft standard of construction meets that design (ie aircraft production)

3. arrangements are in place to ensure the design remains safe (ie continued airworthiness)

4. arrangements are in place to ensure the aircraft remains in a condition for safe operation (ie continuing airworthiness)

5. arrangements are in place to design future changes and repairs (ie aircraft design)

6. operators are able to safely operate the aircraft (ie flight operations).

6.1.1.17 The role of DASA, on the other hand, is to gain assurance that the above elements have been executed effectively.

Aviation safety authorisations

6.1.1.18 When assured of safety, the relevant military or civil aviation safety authority (whether DASA or CASA) may issue a range of authorisations, often in the form of certificates, permits, approvals or licenses. For Defence registered aircraft, the list of authorisations is expansive, potentially comprising up to 12 different types of organisational, product and personnel authorisations. For civil registered aircraft, CASA will issue the civil equivalents to some or many of these 12 authorisations. Chapters 6.1.2 to 6.1.5 explore the Aviation Safety authorisations that may be issued by DASA and CASA for each acquisition category.

6.1.1.19 While DASA does not issue authorisations for civil registered aircraft, DASA may require that the aircraft are included within the scope of the Military Air Operator (MAO), issue a relevant Operations Specification (OpSpec) and conduct limited safety assurance oversight.

6.1.1.20 **Planning and coordination.** Aviation Safety authorisations issued by DASA or CASA are a major milestone in the aircraft acquisition process. Establishing the contracts, systems and people to merit each authorisation is usually complex, with considerable potential to waste time and resources. Effective engagement with the appropriate Aviation Safety authority (DASA for Defence registered aircraft, and both CASA and DASA for civil registered aircraft) is therefore in the best interests of all parties.

6.1.1.21 Engagement should ideally commence as soon as the Defence acquisition organisation has a reasonable view on the candidate aircraft, the need for Defence-unique design changes, and the probable operating and support constructs[3]. Engagement should be well advanced before Defence publishes any tender documents (eg Requests for Tender, Foreign Military Sales requests, etc) that may later affect an authorisation.

6.1.1.22. For civil registered aircraft, CASA will provide guidance on how to achieve the civil authorisations that will be required. DASA will do likewise for the new OpSpec, if one is to be published. This development of this DASA authorisation is far from a trivial endeavour. Not only does it cover the flying management of the MAO and other operational systems for the new aircraft, it also assesses whether the entire aviation safety construct (inclusive of all CASA authorisations) is likely to support safe Defence aviation.

6.1.1.23 For Defence registered aircraft, DASA will provide guidance on how to achieve the required DASA authorisations. Some additional guidance is available through DASA-sponsored courses and website resources.

Superseded

6.1.1.24 Chapters 6.1.2 to 6.1.4 provide tailored guidance on how engage with the relevant Aviation Safety authorities, since this varies widely between civil and Defence registered aircraft, and crewed and uncrewed aircraft.

6.1.1.25 **Documented agreements.** DASRs do not mandate any formal plans or agreements for achieving DASA authorisations. However, it is a practice that DASA highly recommends, given the substantial complexities in establishing the organisations and systems to manage Aviation Safety, and therefore the potential impacts (both positive and negative) on cost and schedule - and ultimately Defence capability.

6.1.1.26 For both Defence and civil registered aircraft, DASA advocates the production of an Aviation Safety Acquisition Management Plan (ASAMP). The ASAMP is an iterative agreement between applicants and DASA on the path to achieving DASA authorisations, and supports commanders and managers in accounting for parallel lines of effort and cross-regulation dependencies. It describes, amongst other things, the overarching acquisition strategy in the context of Aviation Safety and brings together the planned outcomes of the operational, technical, logistical and safety management activities.

6.1.1.27 The ASAMP should be drafted after the acquisition strategy solidifies, nominally following government acquisition approval, but before RFTs (or equivalent) are released. While ASAMPs have previously been drafted before initial contact with DASA has been made, this is rarely an efficient approach. The ideal time to draft the ASAMP is soon after the initial meeting with DASA, given that meeting will influence much of the ASAMP content. The ASAMP would normally be updated after contracts and agreements are signed, since this is the stage where the scope of most authorisations should be clear.

6.1.1.28 Chapters 6.1.2 to 6.1.5 provide guidance on the production of ASAMPs, tailored to the particular acquisition arrangement. ASAMP content varies widely between civil and Defence registered aircraft, with the latter including plans for achieving up to 12 different DASA authorisations. While the differences between crewed and uncrewed aircraft ASAMPs are less significant, the latter will focus on the unique challenges of separating the crew from the aircraft and the additional transitional authorisations that may be available for certified UAS.

Common Concepts

6.1.1.29 The next four chapters are dedicated to the four acquisition arrangements listed at Paragraph 6.1.1.6. To avoid duplication in those chapters, the remainder of this chapter will introduce several concepts that are likely to be common to each acquisition arrangement.

Recognition

6.1.1.30 Aviation Safety authority may acknowledge that products, services and data received from another Aviation Safety authority and the respective system they oversight are compatible within their own Aviation Safety framework. This concept, known as ‘recognition’, is extensively employed for new Defence aircraft acquisitions. Regardless of whether a new aircraft is Defence registered or not, recognition will almost certainly be applied for aircraft design and production. For non-Defence registered aircraft, recognition will also contribute to Defence’s confidence in aircraft maintenance and operation. DASP Manual Volume 3 Chapter 6.5, Recognition of Other Aviation Safety Authorities, provides further guidance on the application of recognition.

6.1.1.31 Where recognition is being considered for a certified UAS, DASA advice should be sought. Certified UAS are not yet commonplace, so the competence and capability of international Aviation Safety authorities in regulating and oversighting certified UAS is still evolving.

Superseded

Statement of Operating Intent and Usage (SOIU)

6.1.1.32 DASRs require all Defence registered aircraft and certified UAS (and certain other UAS when directed by the Authority) to have a Statement of Operating Intent (SOIU) that has been approved by the relevant Environmental Commander and DASA. The SOIU describes the approved roles, operating envelope, usage spectrum and operating environment for a particular aircraft type.

6.1.1.33 Development of an SOIU is not mandatory for a non-Defence registered aircraft, but may assist MAOs with establishing the operational context of their intended operations, to assist with identification of any additional safety controls required to provide an equivalent level of safety to that of Defence registered aircraft.

6.1.1.34 Annex C presents further information and development guidance for SOIUs.

Independent Review of Aviation Safety

6.1.1.35 DASP Manual Volume 3 Chapter 6, Independent Review of Aviation Safety, provides information on the scope and role of Airworthiness Boards (AwBs) within the framework of capability acquisition.

6.1.1.36 Historically, AwBs were identified as a 'gate' for issuance of some DASA authorisations. The contemporary role of the AwB in the acquisition process is to complement the role of the regulator in addressing parts of the 'system of systems' that are not adequately covered through regulatory oversight activity. DASA identifies that this increases flexibility and reduces the impost on the regulated community.

6.1.1.37 Chapters 6.1.2 to 6.1.4 provide guidance on the documentation package provided to Introduction into Service (IIS) AwBs for each acquisition type. The documentation will commonly consist of:

1. the extant submissions for the relevant DASA authorisations
2. an updated ASAMP which reflects the status of the acquisition program, details and plans for outstanding activities, and impact statements and associated risk management for outstanding activities
3. checklists and other artefacts.

6.1.1.38 An AwB is commonly convened prior to the first operation of a Defence registered aircraft, due to the often complex nature of organisational, risk management and other elements. Notwithstanding the aforementioned, there is no regulatory impediment to commencing limited operations, commensurate with risk, prior to the conduct and reporting of an IIS AwB. Progressive AwBs may be convened as the organisations and operational capabilities evolve.

6.1.1.39 An IIS AwB may be less common for non-Defence registered aircraft given that Defence aircraft that are continuous 'State' aircraft should be Defence registered. When determining whether an AwB is required, the Defence AA may take into account the complexity of support arrangements, whether Defence's operations are closely aligned to civil norms, and other similar factors.

6.1.2 Acquisition of (Crewed) Defence Registered Aircraft

Introduction

6.1.2.1 Aviation safety is a command and management responsibility. Commanders and senior managers are accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

6.1.2.2 Provided the aircraft and its support and operating arrangements meet the relevant Defence Aviation Safety Regulation (DASR) requirements, DASA may issue a range of 'authorisations', in the form of certificates, permits, approvals or licenses. These authorisations provide confidence to both the Capability Manager and the Australian Government that the aircraft is capable of safe flight.

6.1.2.3 While the respective DASRs define the required safety outcomes for these DASA authorisations, history has shown that additional guidance is needed if safety risks are to be efficiently and effectively eliminated or otherwise minimised so far as is reasonably practicable.

Purpose

6.1.2.4 This chapter guides Defence's aircraft acquisition organisations, relevant in-service organisations and Defence industry partners through the aviation safety requirements and recommended practices during the acquisition (whether through purchase, lease or other arrangement) of crewed aircraft that will be Defence registered.

Regulatory outcomes from the acquisition process

6.1.2.5 For a new Defence registered aircraft to operate, Command must ensure it is safe for flight. Command achieves this by ensuring the aircraft are designed, constructed, maintained and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation. In turn, if suitably assured of safety, DASA may issue a range of authorisations. Depending on the acquisition and support arrangements, this can extend to 12 different types of organisational, product and personnel authorisations, as follows:

1. organisational authorisations:
    i. Military Air Operator (MAO)
    ii. Military Design Organisation (MDO)
    iii. Military Production Organisation (MPO)
    iv. Approved Maintenance Organisation (AMO)
    v. Continuing Airworthiness Management Organisation (CAMO)
    vi. Maintenance Training Organisation (MTO)
    vii. Military Type Certificate Holder (MTCH) (currently an implicit authorisation)
2. product authorisations:

Superseded

i. Military Type Certificate (MTC) and associated Type Certificate Data Sheet (TCDS)

ii. Military Permit to Fly (MPTF)

iii. Aircraft Management Programme (AMP)

iv. Military Certificate of Airworthiness (CoA)

Note: *In addition, it may include a range of niche authorisations, for example a product conformity agreement, master minimum equipment list, and so on.*

3. personnel authorisations:

i. Military Aircraft Maintenance Licence (MAML)

Note: *DASA directly authorises certain management personnel within approved organisations. However, those authorisations are considered to be part of the organisational approval process in this chapter, so they are not separately listed here.*

6.1.2.6 Figure 1 summarises the range of DASA authorisations that are usually relevant to a new aircraft acquisition, grouped according to their relevance to aircraft design, construction, maintenance or operation. The subsequent paragraphs separately explore each group.

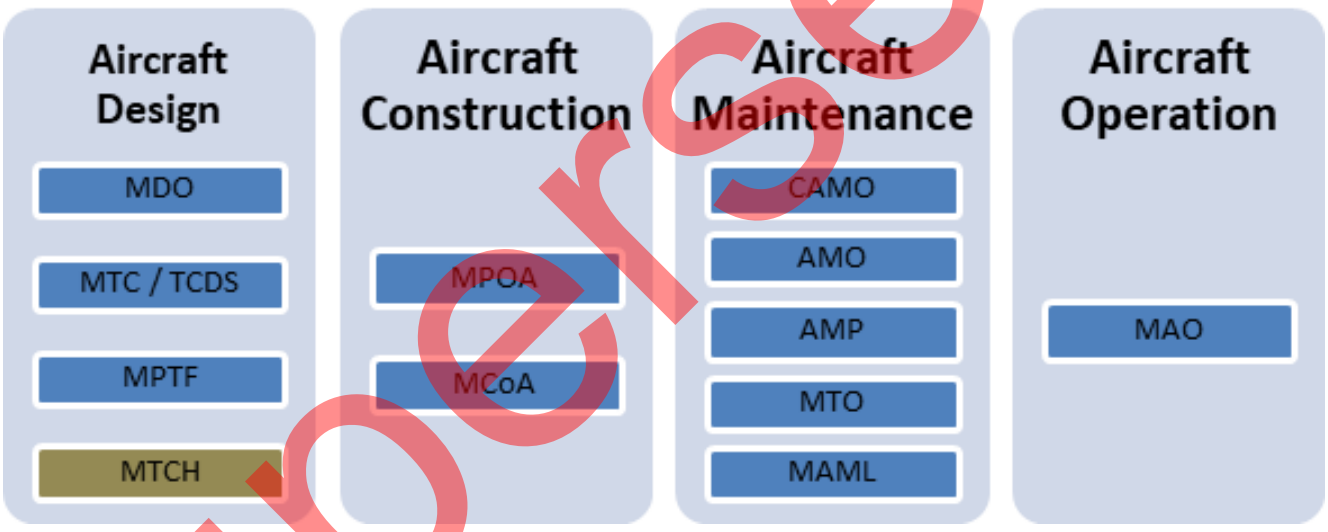

Figure 1: DASA authorisations relevant to Defence aircraft acquisitions[4]

Aircraft design (and certification)

6.1.2.7 New Defence crewed aircraft will normally be civil or military 'off-the-shelf' aircraft that are subsequently modified to meet Defence's capability requirements. Ensuring the final aircraft design is safe for flight in Defence's intended Configuration, Role and Environment (CRE) is a critical step in the acquisition process. Four separate DASA authorisations are relevant to this process, design, construction, maintenance or operation.

6.1.2.8 **Military Design Organisation (for initial aircraft design).** An organisation that has been approved by DASA to provide aircraft design services for a new Defence aircraft is termed a Military Design Organisation (MDO). These MDOs may be a military or industry organisation, and may be located in Australia or overseas. MDOs are often required for the design of new Defence aircraft,

Superseded

although as explored in the next four paragraphs, this requirement can be reduced, or even eliminated, in some circumstances.

6.1.2.9 **Military Type Certificate.** The Defence type certification process is central to confirming that the aircraft design is safe for Defence's intended Configuration, Role and Configuration (CRE) for the aircraft. At its core is the Type Certification Basis (TCB), which is a DASA-agreed set of airworthiness design requirements, including an airworthiness code and other standards, and tailoring to both as required.

6.1.2.10 At its extreme, type certification requires a DASA-approved MDO to create an aircraft design that complies with the TCB, and to produce evidence that demonstrates this compliance. In turn, DASA examines the evidence on a non-exhaustive basis, and if assured of safety, issues a Military Type Certificate (MTC)[5] and associated TCDS.

6.1.2.11 There is, however, a shortcut to the above approach that is employed for most Defence aircraft acquisitions. When Defence is procuring off-the-shelf aircraft or equipment, the Applicant[6] may seek relief from the need to develop new compliance demonstration evidence, to the extent an extant certification by a recognised National or Military Aviation Authority (NAA/MAA) is relevant to Defence's CRE. This is known as 'recognition of prior certification'. In rare circumstances, DASA can certify an entire new aircraft based solely on the prior certification of another NAA/MAA.

6.1.2.12 More commonly, however, Defence aircraft acquisitions employ a combination of the above two processes. That is, recognition of prior certification is used to cover the design of the off-the-shelf aircraft, and a DASA-approved MDO designs the Defence-unique modifications and produces the requisite compliance demonstration evidence. Sometimes another NAA/MAA may agree to certify some or all of the Defence-unique modifications, which may reduce or even remove the need for a DASA-approved MDO.

6.1.2.13 **Military Type Certificate Holder.** The MTC for a new Defence aircraft is issued by DASA to the Military Type Certificate Holder (MTCH), who takes on responsibility for ensuring the 'continued airworthiness' of the design[7]. This role is normally assigned to the relevant Defence SPO, who will implement standing arrangements with other Defence organisations, industry partners, and perhaps other militaries, to support the function. Amongst other things, the MTCH organisation is responsible for implementing systems for collecting, investigating and analysing aircraft occurrences which may affect its airworthiness, and holding (or providing access to) aircraft design information.

6.1.2.14 Note that DASA does not currently issue an explicit organisational approval for MTCHs, although this may change. Instead, the proposed MTCH arrangement is evaluated by DASA as part of its deliberations on whether to issue a MTC.

6.1.2.15 **Military Permit to Fly.** It is possible for DASA to issue a MTC for a new aircraft type immediately upon its addition to the Defence Register. More likely, however, there will be a period where the aircraft is not yet ready for a MTC because, for example:

1. the aircraft design is still under development
2. compliance demonstration evidence is still being created or compiled
3. Defence's MTC will leverage off the certification of another NAA/MAA, which is yet to be finalised

Superseded

6.1.2.16 DASA can issue a Military Permit to Fly (MPTF) to a MAO[8] in advance of the MTC if satisfied the aircraft design substantially complies with its agreed TCB, the configuration of the subject aircraft is clearly defined, the aircraft is capable of safe flight under defined conditions and for specified purposes, and any elevated risk has been justifiably retained. However, since the MPTF will usually impose (often significant) risk controls that limit the operation of the aircraft, extended operations under an MPTF are not common.

6.1.2.17 **Military Design Organisations (for in-service support).** Finally, throughout an aircraft's operational life, design changes are inevitable to remedy design defects, address obsolescence issues, design repairs, implement capability enhancements, and so on. These design changes will often be the purview of one or more DASA-approved MDOs, which are typically (but not essentially) the same as the MDOs that support the MTCH function.

6.1.2.18 Ultimately, both the MTCH and Continuing Airworthiness Management Organisation (CAMO – see below) must be able to demonstrate that sufficient design support arrangements are in place to maintain the safety of the aircraft[9], before a new aircraft is operated on the Defence Register. Depending on the aircraft acquisition contract, this design support function might initially be provided by the aircraft Original Equipment Manufacturer (OEM); if so, the in-service MDOs might not be needed immediately.

6.1.2.19 **Summary.** Summarised, the four DASA design-related authorisations that are usually relevant to aircraft acquisitions are presented in Figure 2. The MTCH is depicted in a different colour, to show that DASA does not (yet) directly issue an MTCH approval.

Figure 2: DASA authorisations related to aircraft design

6.1.2.20 DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MDOs, MTCs, MPTFs and MTCHs.

Aircraft production (or construction)

6.1.2.21 A MTC focuses on the safety of an aircraft's design. It does not consider the subsequent manufacture and assembly of the design, which is the purview of aircraft production (or

Superseded

'construction' in historic Defence parlance). The two DASA authorisations relevant to new aircraft production are Military Production Organisations and Military Certificates of Airworthiness.

6.1.2.22 **Military Production Organisation.** A Military Production Organisation (MPO) is a DASA-approved organisation that can manufacture and assemble parts, appliances, aircraft, engines or propellers to approved design data[10]. In the context of a Defence aircraft acquisition, MPOs can manufacture and assemble both the baseline aircraft (often called the 'green' aircraft) and the Defence-unique modifications to the green aircraft. They may be the same organisation, or there may be multiple different MPOs.

6.1.2.23 More commonly for new aircraft, however, Defence leverages the oversight provided by a DASA-recognised NAA/MAA of certain production organisations. This can reduce, or even eliminate, the need for DASA-approved MPOs.

6.1.2.24 **Military Certificate of Airworthiness.** As noted previously, a MTC is issued for an aircraft type. A separate DASA authorisation needs to subsequently be issued for each aircraft tail, namely the Military Certificate of Airworthiness (MCoA)[11], once DASA is satisfied the produced aircraft conforms to the design covered by the MTC. Central to DASA issuance of a MCoA is evidence that each product, part or appliance conforms to the approved design data and is in condition for safe operation.

6.1.2.25 A MCoA cannot be issued prior to the MTC. Where a new Defence aircraft is to be flown under a MPTF prior to the issue of a MTC, the MPTF effectively provides the function of the MCoA. As part of the process for seeking a MPTF, an applicant will need to demonstrate that the produced aircraft does indeed conform to the currently approved design data.

6.1.2.26 **Summary.** Summarised, the two DASA production-related authorisations that are usually relevant to new aircraft acquisitions are presented in Figure 3.

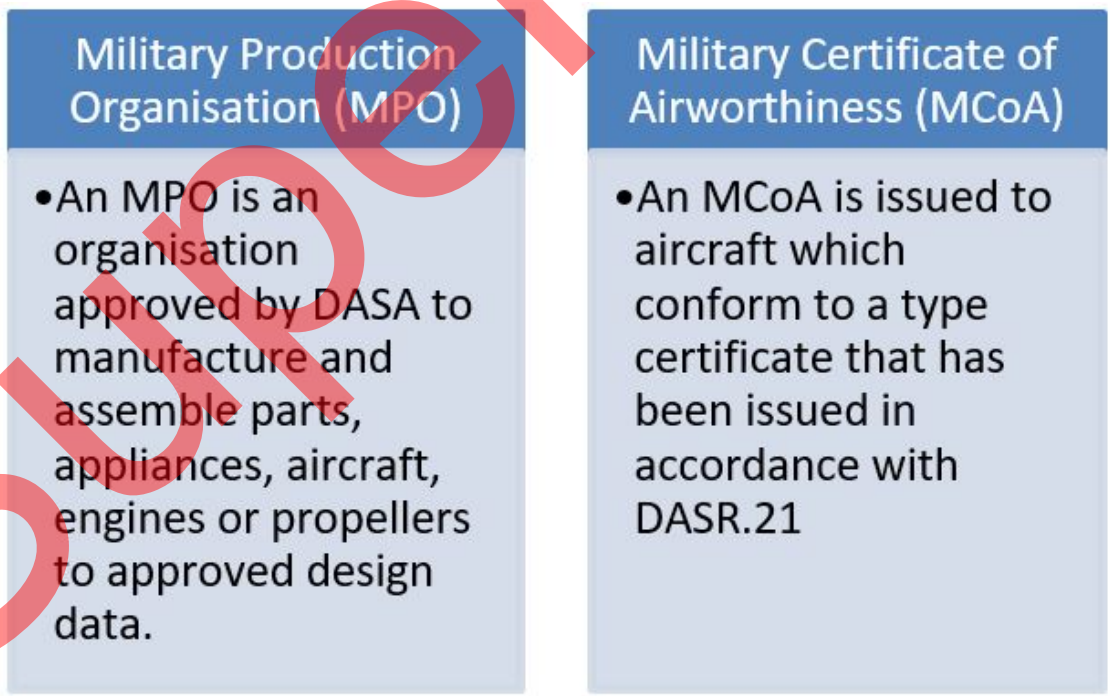

Figure 3: DASA authorisations related to production

6.1.2.27 DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MPOs and MCoAs.

Superseded

Aircraft maintenance (continuing airworthiness)

6.1.2.28 While Defence has long used the colloquial term of 'aircraft maintenance' to cover airworthiness activities beyond aircraft design and production, the DASRs purposely use the more expansive term of 'continuing airworthiness'. Aircraft maintenance is any one or combination of overhaul, repair, inspection, replacement, modification or defect/fault rectification of an aircraft or component. Continuing airworthiness encompasses this, plus maintenance management, maintenance training and maintenance licensing. For completeness, this section will use the term 'continuing airworthiness'.

6.1.2.29 Robust continuing airworthiness arrangements must be in place prior to the operation of a new Defence aircraft. Once assured of the sufficiency of these arrangements, DASA may issue three relevant organisational approvals, namely Continuing Airworthiness Management Organisations, Approved Maintenance Organisations and Maintenance Training Organisations. DASA may also approve Aircraft Maintenance Programmes and issue Military Aircraft Maintenance Licences to eligible personnel.

6.1.2.30 **Continuing Airworthiness Management Organisation.** Continuing Airworthiness covers all processes that ensure an aircraft continues to comply with initial airworthiness requirements and supports the ongoing validity of the aircraft's MCoA. The Continuing Airworthiness Management Organisation (CAMO), while not directly responsible for actual aircraft maintenance, is responsible for engaging organisations to conduct design and maintenance services. The CAMO will:

1. engage MDO(s) for design services as required
2. engage the MTCH for any matters that impact the aircraft's type design and type certification under MTC or an individual aircraft's CoA]
3. task AMOs to maintain products (aircraft, engines and propellers), parts and appliances and
4. provide governance and oversight to organisations performing DASR M functions on its behalf.

6.1.2.31 In most cases, the acquisition of a new aircraft type will not result in the creation of a new CAMO; rather, the scope of an extant CAMO will be expanded to include the new aircraft type. The presence of a suitable CAMO is integral to DASA's approval of a new MAO, or adding an additional aircraft to an extant MAO's scope.

6.1.2.32 **Aircraft Maintenance Organisations.** DASR provides two avenues for the maintenance of an aircraft and its components. The first is a DASA-approved Approved Maintenance Organisation (AMO), and the second is 'another maintenance organisation accepted by DASA'. A combination of both is usually employed for Defence aircraft.

6.1.2.33 An AMO is an organisation approved by DASA to conduct aircraft maintenance activities. This includes all actions required for restoring and maintaining an item in a serviceable condition including servicing, repair, modification, overhaul, inspection and determination of condition to maintain aircraft safety and airworthiness. AMOs may be a military or Defence Industry organisation, may be located in Australia or overseas, and may encompass one or multiple aircraft types. New Defence aircraft may be supported by one or several AMOs.

6.1.2.34 DASR Part M makes provision for maintenance services to be consumed from other maintenance organisations that are accepted by DASA. While the regulation infers that DASA explicitly accepts each of these maintenance organisations, this is not normally the case. Rather,

Superseded

DASA will automatically accept a maintenance organisation provided it is oversighted by a NAA/MAA that is 'recognised' as competent by DASA, and provided the CAMO ensures the conditions and caveats on the relevant 'recognition certificate' are met. Recognition certificates for each NAA/MAA recognised by DASA are available on DASA's website.

6.1.2.35 Prior to operation of a new Defence aircraft, the CAMO must demonstrate that arrangements are in place to maintain the aircraft in an airworthy condition. In limited circumstances, DASA may agree to the temporary absence of some maintenance arrangements, but only where this does not affect the near-term support of the aircraft.

6.1.2.36 **Aircraft Maintenance Programme.** An Aircraft Maintenance Programme (AMP) describes the scheduled maintenance tasks, their frequency of completion, the associated maintenance procedures, and so on, necessary to preserve the airworthiness of the aircraft. For aircraft acquisition projects, an initial AMP must be approved by DASA prior to the conduct of any maintenance activities. Maintenance activities can in some cases pre-date flying operations on the Defence Register, since they include aircraft preservation and other maintenance tasks required to prepare the aircraft for operation.

6.1.2.37 **Military Aircraft Maintenance Licenses.** AMOs require some personnel to hold particular categories of Military Aircraft Maintenance Licences (MAMLs). Furthermore, in order to be entitled to exercise certification privileges on a specific aircraft type, the holder of a MAML requires their licence to be endorsed with the relevant aircraft type ratings. As part of the AMO approval process for a new aircraft, the AMO will need to demonstrate that its personnel hold sufficient and applicable MAMLs.

6.1.2.38 **Maintenance Training Organisation.** A Maintenance Training Organisation (MTO) conducts training and examinations for maintenance personnel as specified in DASR 66. While a new MTO would rarely be required for a new Defence aircraft, an extant MTO would need to demonstrate its competence to conduct the type/task training and assessments for the new aircraft.

6.1.2.39 **Summary.** Summarised, the five DASA authorisations related to continuing airworthiness (of which maintenance is a component) of Defence aircraft acquisitions are presented in Figure 4.

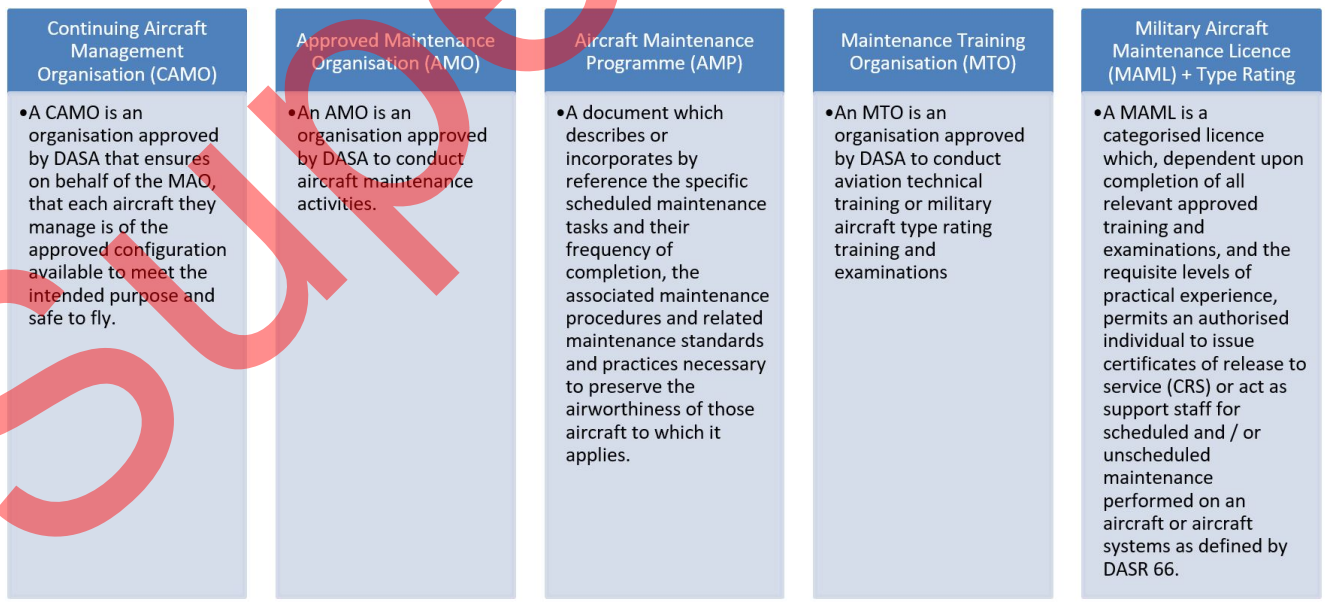

Figure 4: DASA continuing airworthiness-related authorisations

Superseded

6.1.2.40 DASPMAN Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into CAMOs, AMOs, AMPs, MTOs and MAMLs.

Aircraft operation

6.1.2.41 A Military Air Operator Certificate (MAOC) is the principal authorisation granted by DASA to conduct military air activities. Each aircraft type operated by the MAO is authorised by a separate DASA-issued Operations Specification (OpSpec) annex. The OpSpec annex details, amongst other things, key positions of the MAO, operating provisions, roles and tasks, specific approvals, and any limitations or conditions imposed by DASA.

6.1.2.42 The relevant OpSpec annex is required before first flight of the aircraft by the MAO[12]. DASA will issue the OpSpec annex once assured that the necessary Fundamental Inputs to Capability (FIC) elements, as well as quality and safety management systems, are in place to support intended operations.

6.1.2.43 Preparing a MAO to take on a new Defence aircraft can be a substantial undertaking. Amongst other things, for the new aircraft type the MAO will need to:

1. define the operating intent and usage for the aircraft through an approved Statement of Operating Intent and Usage (SOIU)
2. ensure arrangements are in place for maintaining the airworthiness of the aircraft through a CAMO and AMOs
3. implement the multitude of systems needed to manage Operations personnel and Air operations
4. produce/accept Orders, Instructions and Publications (OIP)[13]
5. establish an Aviation Safety Management System (ASMS).

6.1.2.44 Implementing these requirements, even for an existing MAO, is likely to require considerable planning and effort. Consequently, DASA recognises that a graduated capability growth plan for operational authorisations may be required. The Aviation Safety Acquisition Management Plan (ASAMP - see Chapter 6.1.1 and later in this chapter) is a suitable repository for reflecting the status of the acquisition program, including details of work completed, re-programing of remaining activities and risk management for the incomplete tasks.

6.1.2.45 **Summary.** Summarised, the singe DASA flight operations-related authorisation relevant to aircraft acquisitions is presented in Figure 5.

Superseded

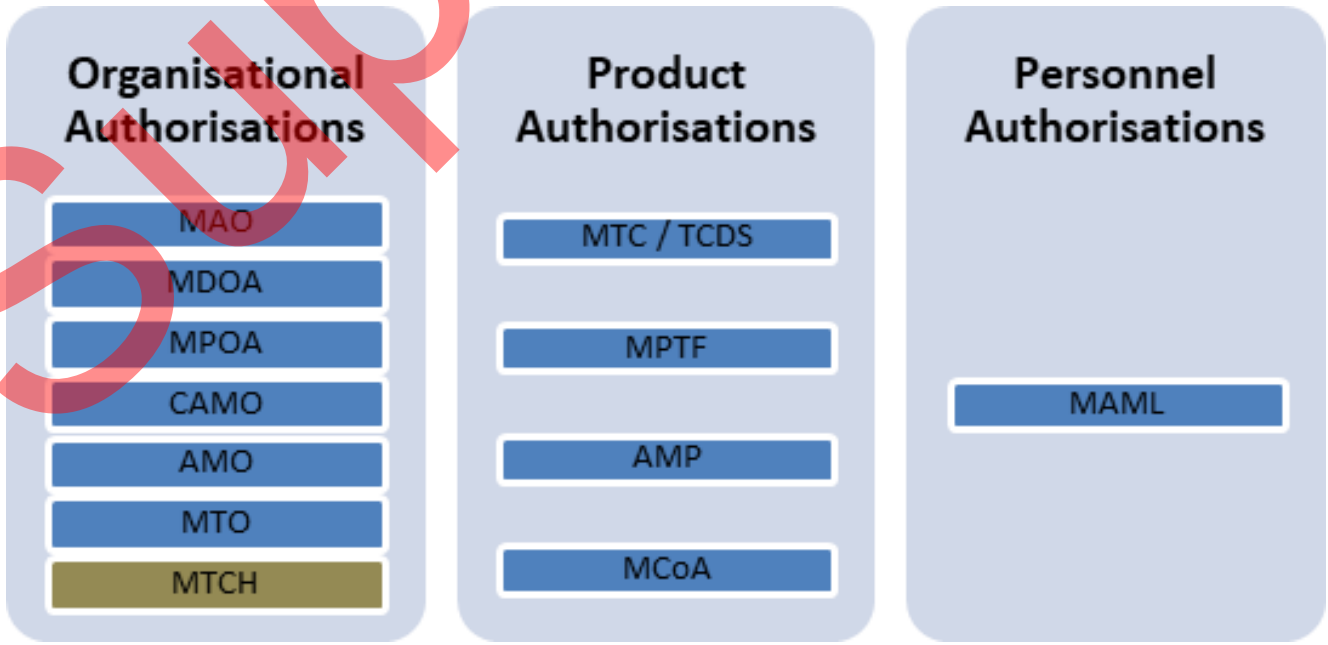
Figure 5: DASA authorisations related to aircraft operations

6.1.2.46 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MAOs.

Summary

6.1.2.47 This section has presented an overview of the DASA authorisations that may be relevant to new aircraft design, construction, maintenance and operation. Depending on the acquisition arrangements and the aircraft role, some authorisations might not be required.

6.1.2.48 The diagram at the start of this section (Figure 1) summarised all of the possible DASA authorisations according to whether they were relevant to new aircraft design, construction, maintenance or operation. However, another way of grouping them is according to whether they are organisational, product or personnel authorisations, as shown in Figure 6.



Superseded

Figure 6: DASA authorisations for new aircraft (grouped by category)

6.1.2.49 This grouping has the advantage that the eight organisational authorisations all use substantially the same processes for application and approval, and the three product authorisations have strong synergies. Consequently, for simplicity, this grouping will be used in the next section.

Processes, Plans and DASA Interaction

6.1.2.50 The previous section presented an overview of the DASA authorisations that may be relevant to new aircraft acquisitions. While the respective DASRs define the required safety outcomes for these DASA authorisations, history has shown that achieving the authorisations can be a complex and protracted journey. This section guides the reader though the process of achieving these DASA authorisations.

6.1.2.51 Figure 7 shows how the various DASA authorisations usually fit onto a project timeline. The vertical stripes present four significant milestones for introducing a new aircraft to Defence, the items above the dashed line show DASP-related project and Command activities, and the items below the line show the DASA authorisations. A time scale has purposely not been included, because this can vary enormously between aircraft acquisitions.

Superseded

Figure 7: Common project timeline for DASA authorisations

6.1.2.52 The elements below the dashed line can broadly be grouped into five activities, as shown in Figure 8. With the exception of Activity 1, the remaining activities are rarely sequential; more often than not Activities 2 and 3 are executed concurrently, and several activities may be cyclic.

Superseded

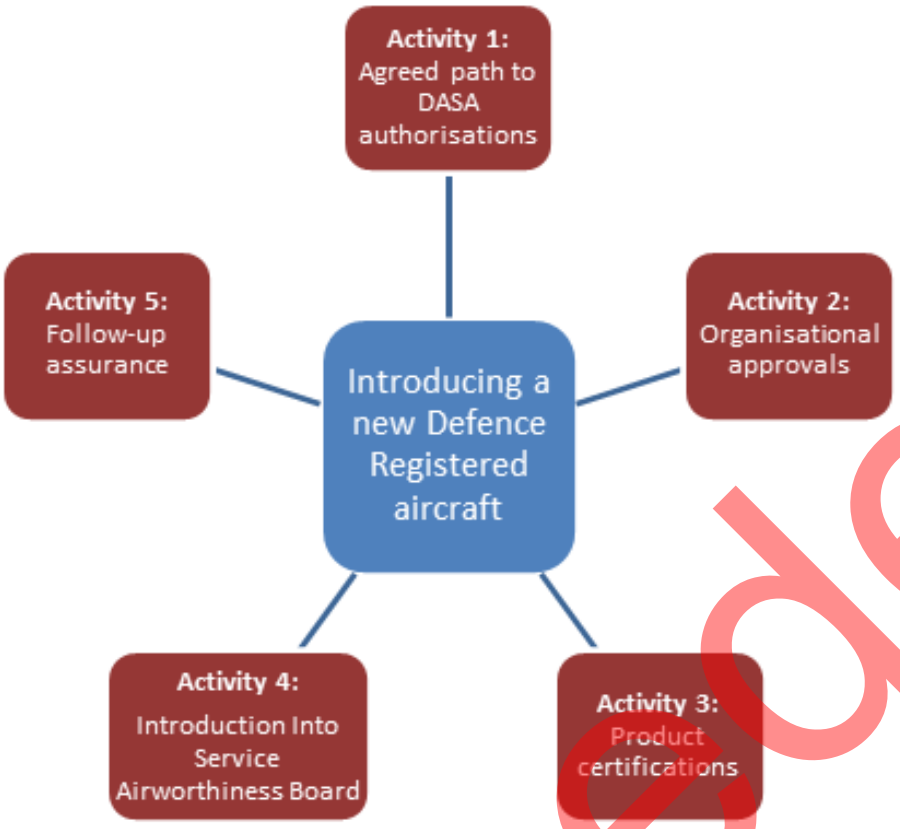


Figure 8: Activities in introducing a new Defence aircraft

6.1.2.53 Each of these five activities from Figure 8 is explored below.

Activity 1: Agreed path to authorisations

6.1.2.54 A major milestone in the aircraft acquisition process is the achievement of a range of DASA authorisations. However, establishing the contracts, systems and people to merit each authorisation is usually complex, with considerable potential to waste time and resources. Effective engagement with DASA is therefore in the best interests of all parties.

6.1.2.55 **Initial engagement.** Engagement should ideally commence as soon as Defence's acquisition organisation has a reasonable view on the candidate aircraft, the need for Defence-unique design changes, and the probable operating and support constructs[14]. Engagement should be well-advanced before Defence issues any tender documents (eg Requests for Tender, Foreign Military Sales Letter of Requests, etc) that may later affect an authorisation.

6.1.2.56 The initial engagement should involve DASA specialists, the Defence acquisition organisation, and capability manager representatives. If known, the Defence and industry organisations that will support the aircraft could also participate. Key outcomes will be:

1. a shared understanding of the project scope and schedule, candidate aircraft and the likely scope of Defence-unique design changes

Superseded

2. initial views on which of the seven DASA organisational approvals are likely to be needed and, for those that may not be needed, agree on the alternative means of achieving the same safety outcomes

3. initial views on how the aircraft might achieve an MTC, including how current or future certifications by DASA-recognised national or military airworthiness authorities (NAA/ MAAs) might contribute

4. initial views on whether an MPTF might be required to allow for test and other flying prior to the issue of an MTC

5. DASA should provide a management overview of each likely DASA authorisation, including: key milestones, common approval timeframes, recommended DASA collaboration, availability of training and other guidance material, and so on.

6.1.2.57 Annex A presents an expanded version of the above list, which can be used as a set of talking points for this initial engagement. Depending on the acquisition strategy, some of the details may initially be sparse. If so, further engagement should be scheduled for when the information is likely to become available, but still before releasing RFTs or equivalent documents.

6.1.2.58 **Documented agreement.** As noted in Chapter 6.1.1, DASRs do not mandate a plan or agreement for achieving DASA authorisations. It is, however, a practice that DASA highly recommends, given the substantial complexities in establishing the organisations and systems to manage aviation safety, and therefore the potential impacts (both positive and negative) on cost and schedule - and ultimately Defence capability.

6.1.2.59 DASA advocates the production of an Aviation Safety Acquisition Management Plan (ASAMP). The ASAMP is an iterative agreement between Applicants and DASA on the path to achieving DASA authorisations, and supports commanders and managers in accounting for parallel lines of effort and cross-regulation dependencies.

6.1.2.60 Annex B presents the suggested content and management arrangements for an ASAMP. Summarised, it suggests the main body of the ASAMP should describe the overarching aviation safety acquisition strategy and bring together the planned outcomes of the operational, technical, logistical and safety management activities. It should also describe the management of flight operations during acquisition, particularly if operations are to commence under an MPTF.

6.1.2.61 Annex B also suggests the ASAMP should include a series of annexes, with individual annexes dedicated to each DASA authorisation. Each annex could be sponsored by the relevant Applicant for the DASA authorisation, and could form an agreement between DASA and the Applicant on the path to the particular authorisation. For simple acquisitions, the annexes might directly present the information[15]. For more complex acquisitions, particularly where there are a range of Applicants for the various DASA authorisations, the annexes might merely contain a link to a planning document that is drafted and managed by the respective Applicant. Either way, the annexes should be 'modular', whereby each annex is configuration managed and approved separately to the main body of the ASAMP.

Superseded

6.1.2.62 The ASAMP should be drafted after the acquisition strategy solidifies (usually post Government approval), but before RFTs (or equivalent) are released. The ideal time to draft the ASAMP is usually soon after the initial engagement with DASA, and in fact that engagement will influence much of the ASAMP content. The ASAMP would normally be updated after contracts and agreements are signed, since the path to most DASA authorisations should be clear.

6.1.2.63 Once contracts and agreements are signed, the main body of the ASAMP need only be updated when there is a marked change in the acquisition strategy or high-level schedule for the project. The annexes, on the other hand, will probably be updated more frequently, particularly in the earlier stages of the project as knowledge and plans evolve.

6.1.2.64 **Ongoing engagement.** DASA's experience is that three forms of engagement should be maintained throughout the project lifecycle, as follows:

1. Periodic major stakeholder engagements, expanding on the initial engagement suggested previously in this section. This should occur throughout the acquisition project lifecycle, usually when significant milestones are approaching

2. Frequent coordination and status updates between senior project management staff (commonly the CASG Project Engineering Manager, the CM Transition Team lead, etc), and DASA's operational and technical leads for the acquisition

3. Engagement as required between each of the Applicants for a DASA authorisation and the respective DASA specialist.

6.1.2.65 **DASA assistance with contract reviews.** There is no DASR requirement for DASA to be engaged in seeking offers (eg RFT or equivalent), selecting the successful tenderer, negotiating the contract, and signing the contract. However, where a contract element may one day affect a DASA authorisation, prudent DASA involvement can reduce project cost and schedule risk. Areas where DASA can contribute include:

1. Prior to RFT (or equivalent) issue:

    i. confirming the RFT requirements for organisational approvals are appropriate for aircraft acquisition and/or in-service support

    ii. confirming the RFT airworthiness design requirements (including airworthiness codes and other standards), and proposed approach to aircraft certification, present a suitable pathway to MTC

    iii. confirming the RFT aircraft production arrangements present a suitable pathway to issue of MCoA

    iv. confirming aircraft registration pathways, particularly for significant modifications to a green aircraft by a third party

Superseded

v. providing expert input to specialist aircraft design technology requirements, such as aircraft structural integrity (ASI) design and in-service management systems.

2. For RFT assessment:

i. If any of the above RFT items seek preliminary plans for DASA organisational approvals or product certifications, then DASA can participate in the assessment of those plans

ii. otherwise, while the Defence acquisition organisation will conduct the tender evaluation, DASA staff are available for on-call advice and assistance as required[16]

3. For contract negotiation: DASA staff would rarely be directly involved in contract negotiations, but are available for on-call advice and assistance as required.

4. Final contract review: DASA does not review the mature contract prior to signature, but is available for advice and assistance as required.

6.1.2.66 **Delegations.** During the project lifecycle, organisations may elect to delegate their Command responsibilities, for example the appointment of the senior operator within the project transition team to make operational decisions in relation to the project. Once notified of the delegation, DASA will treat the decisions and approvals of the delegate as if the accountable manager had issued them.

6.1.2.67 Later in the project lifecycle, usually just before MTC issue, a 'Platform DoSA' will need to be appointed by DASA. The Platform DoSA role is normally delegated to the incumbent Defence CENGR of the platform MTCH organisation, and is responsible for assurance of MTCH actions with respect to reportable occurrences, issue of MCoAs, approval of flight conditions and issue of Airworthiness Directives. DASP Manual Volume 3 Chapter 4.3, Delegates of the Safety Authority, provides additional information.

Activity 2: Organisational approvals

6.1.2.68 Professional aircraft design, construction, maintenance and operation organisations are cornerstone to aviation safety. Implementing the required organisations for a new aircraft, and obtaining DASA approval of each organisation, is usually a significant activity for both the Applicants and DASA. This section explores the planning, establishment and assessment of new DASA-approved organisations.

6.1.2.69 **Planning.** As noted in Activity 1, the ASAMP should include a planning annex for each organisational approval. The ASAMP should plan for the organisational approvals to be achieved well prior to their need date, which are likely to be as follows:

Superseded

1. MAO: DASA authorisation is required prior to the first operation of the aircraft by the MAO[17]. This authorisation is reflected in DASA's issue of an OpSpec annex for the new aircraft

2. MDO:

   i. (for initial aircraft design): Required prior to design changes to the green aircraft, if those changes are not to be certified by a recognised NAA/MAA

   ii. (for in-service support): Required prior to first flight on the Defence Register, unless DASA has agreed to an alternative interim support arrangement

3. MTCH: Implementation of suitable MTCH arrangements are a prerequisite for issue of an MTC. However, depending on the acquisition arrangement, some of these functions may need to be in place earlier to support the initial MPTF

4. MPO: Required prior to any aircraft production activity, unless an alternative production approval path has been agreed by DASA

5. CAMO: Required prior to first flight of the aircraft on the Defence Register

6. AMO: Required prior to first flight of the aircraft on the Defence Register[19], unless an alternative interim maintenance arrangement has been agreed by DASA. AMOs will need MAMLs in sufficient numbers to meet AMO needs, relevant to the scope of operations and numbers of aircraft

7. MTO: Agreed in consultation with DASA.

6.1.2.70 Note that while DASA agreement to the above authorisation plans is not a regulatory requirement, it is encouraged by DASA. As Figure 9 shows, the time needed to implement a new organisation and then achieve a DASA organisational approval can be substantial, so careful management is needed to minimise Defence's schedule risk.

Superseded

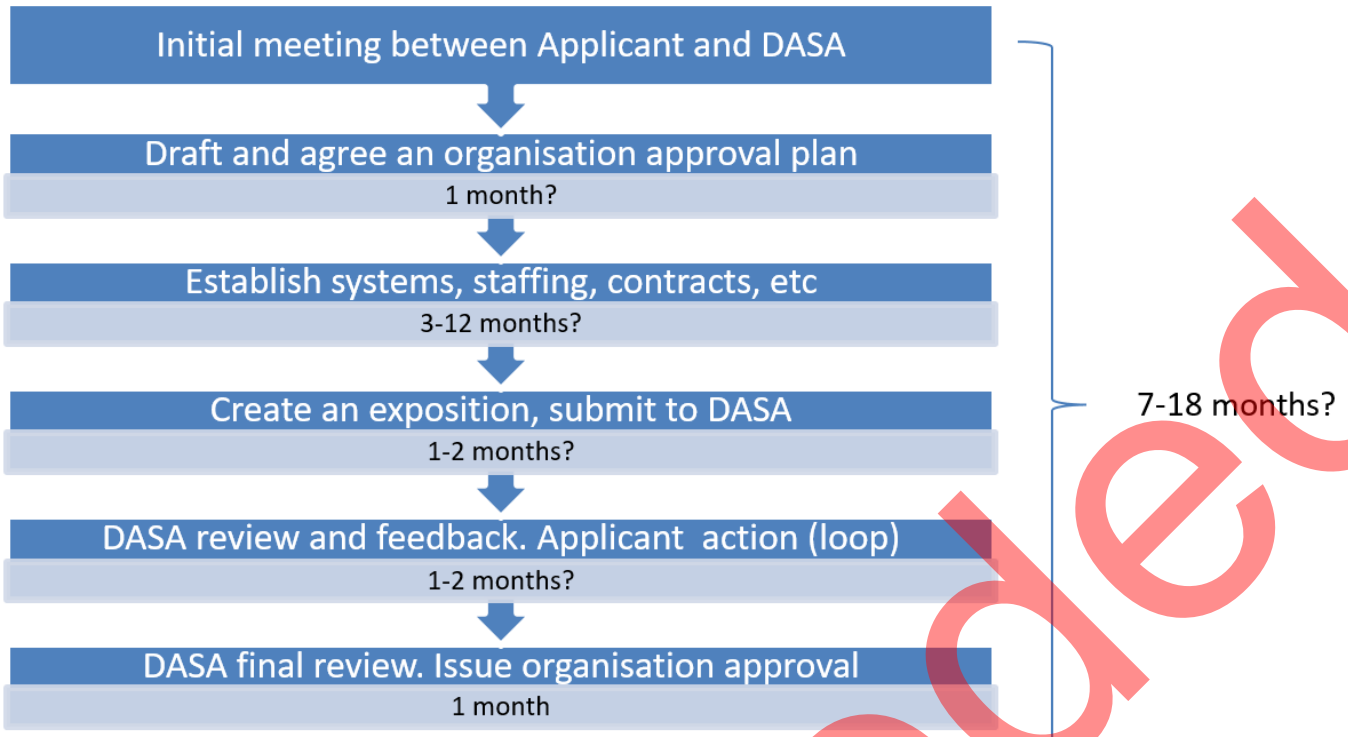

Figure 9: Timeline for DASA organisational approvals

6.1.2.71 **Establishing organisations.** DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, presents a description of each DASA organisational approval, including the key artefact(s) needed to show regulatory compliance - for example, the MDO's design organisation handbook, the AMO's Maintenance Organisation Exposition (MOE), the MAO's Operations Compliance Statement (OCS), and so on. Each of these artefacts will help guide the Applicant's efforts to establish an organisation that professionally supports Defence aviation safety, as will the Acceptable Means of Compliance (AMC) and Guidance Material (GM) accompanying the relevant DASRs. DASA-sponsored education courses and DASA website material also offer useful information.

6.1.2.72 However, Applicants must bear in mind that such guidance may be incomplete, or not entirely relevant to the local context. Consequently, DASA cannot overstate the importance of the Applicant's role in refining the organisation beyond DASR (and DASA) requirements. This might include, for example:

1. learning from other Defence organisations
2. learning from comparable civil organisations[20]
3. exploring the (often extensive) guidance material released by other NAA/MAAs[21]
4. consulting with staff and others with relevant domain expertise.

6.1.2.73 A robust and evolving Aviation Safety Management System (ASMS) is pivotal to establishing an organisation that optimises its contribution to Defence aviation safety. An ASMS utilises a systematic

Superseded

approach to managing aviation safety, including organisational structures, accountabilities, policies and procedures. An effective ASMS continuously improves an organisation's safety performance through pro-actively collecting and analysing safety data to predict, prevent and treat aviation hazards and risks. DASP Manual Volume 3 Chapter 6.2, Safety Management, provides further guidance.

6.1.2.74 **DASA assessment.** The annexes in Chapter 5.3 provide insight into DASA's approach to assessing, and ultimately approving, a new or expanded organisational approval. Most approvals follow a similar process, namely:

1. the Applicant drafts an 'Exposition' or similar document, as key evidence that their organisation has implemented the systems and processes needed to comply with the relevant DASRs

2. the applicant submits the relevant DASR Form to seek an organisational approval

3. DASA conducts an assessment of the Exposition and the documents it references, often as a desktop activity for new organisations; on occasion DASA may do an on-site assessment

4. if needed, the applicant remedies any deficiencies that preclude DASA's approval of the organisation

5. DASA issues an organisational approval, perhaps initially limited in scope

6. once the aircraft is operating and the organisation has the opportunity to exercise its approval, DASA will conduct a deeper assessment, usually including an on-site visit, placing particular emphasis on the effectiveness of the ASMS and system monitoring.

6.1.2.75 Figure 10 summarises the path through to DASA approval for the seven organisations common to new aircraft acquisitions.

Superseded

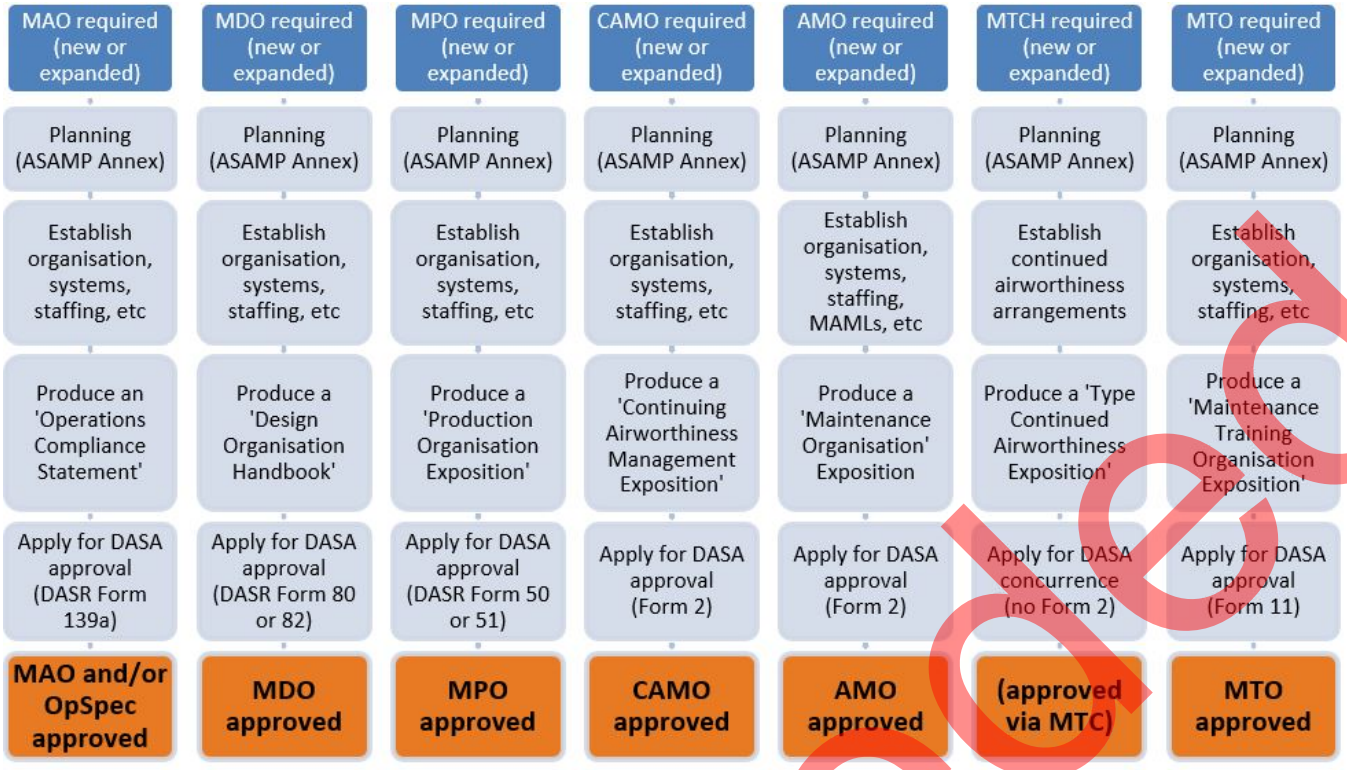

Figure 10: Path to DASA organisational approvals

Activity 3: Product authorisations

6.1.2.76 The four common product authorisations for new aircraft are the MTC, MCoA, MPTF and AMP. While an MPTF will often be issued prior to an MTC and MCoA, preparatory work on the other two will usually precede and support the issue of the MPTF. Hence, this section will consider the MPTF last.

6.1.2.77 Before exploring the four product authorisations, some brief discussion on safety risk management is warranted. Risk management is almost always a contributor to MTC and MPTF authorisations, so all stakeholders need to be conversant with Defence's 7-step risk management approach, as explained in the DASA Advisory Circular 003/2018, Risk Management in the DASP. Furthermore, DASA's experience is that this risk management is most effective when all parties robustly consult, cooperate and coordinate with each other. Critically, this must occur across organisational boundaries, and across specialisations (most notably between operators and engineers).

6.1.2.78 **MTC.** Achieving an MTC for a new aircraft is a significant milestone for an aircraft acquisition project, and one that commonly takes substantial planning and effort. While the path to an MTC is explored in DASP Manual Volume 3 Chapter 7.2, Certification, for the benefit of readers not needing that depth of information, a brief description of the process is included here.

Superseded

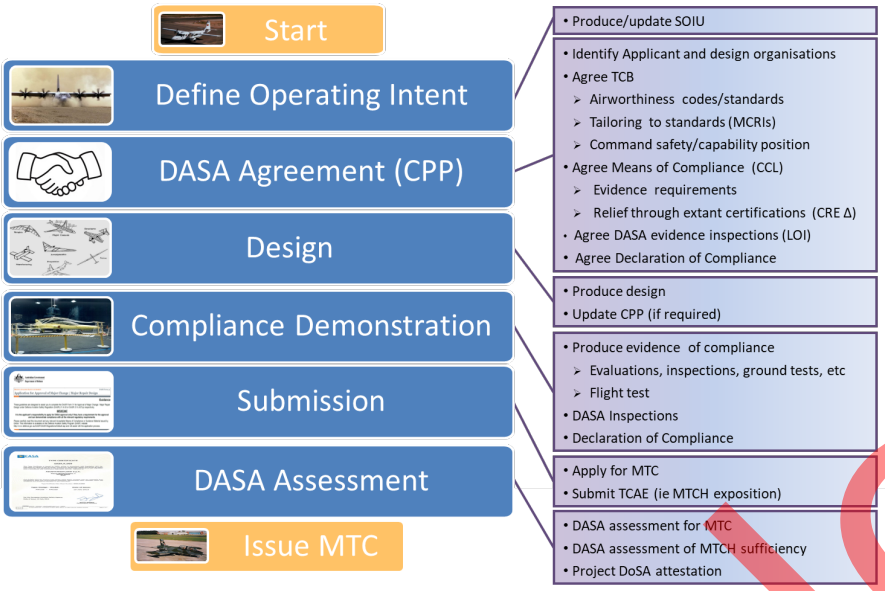

Figure 11: Path to issue of an MTC

6.1.2.79 An overview of the type certification process, culminating in an MTC, is shown in Figure 11. The first step, defining the operating intent for the aircraft, is pivotal to designers producing a design that is safe for Defence's intended Configuration, Role and Environment (CRE). A poorly-developed operating intent, or one developed late in the design lifecycle, can (and previously has) resulted in:

1. additional cost to re-design elements of the aircraft
2. operational limitations to eliminate the elevated risk, or
3. management and retention of elevated risk, often for the life of the aircraft.

6.1.2.80 The second step shows the Applicant and DASA agreeing on a Certification Program Plan (CPP). While a CPP is not explicitly required by DASR, it is inconceivable that Defence would pursue a certification program without an agreed CPP, since it imposes obligations on both the Applicant and DASA. Critically, the CPP:

1. agrees on the Type Certification Basis (TCB) for the new aircraft, which comprises the airworthiness requirements (inclusive of tailoring) that the design must meet
2. agrees on the evidence that will be produced by the design organisation(s) to demonstrate the design complies with the TCB
3. agrees on the application of 'recognition of prior acceptance', where existing product certifications by DASA-recognised NAA/MAAs will contribute to the certification of Defence's new aircraft [22]
4. defines the extent of DASA's inspections of compliance demonstration evidence.

Superseded

6.1.2.81 The tailoring of the TCB, mentioned in the first sub-paragraph above, is accomplished using one of five types of Military Certification Review Item (MCRI)[23]. Four of these MCRIs either maintain or improve the safety of the aircraft design, while the fifth, the 'Exception MCRI', can approve a reduction in the safety of the aircraft design. This reduction is only justifiable where requiring compliance with a TCB requirement would adversely affect Defence capability. While DASA ultimately approves the Exception MCRI, it is based heavily on Command's confirmation that a capability imperative exists, and that the risks due to the TCB non-compliance have been eliminated or otherwise minimised SFARP. The document used to communicate and record these Command risk decisions is normally the Airworthiness Issue Paper (AwIP). Guidance for AwIPs is provided at annex C.

6.1.2.82 The third step in the certification process is where the design organisation produces the design. For new Defence-unique designs, this often requires a DASA-approved MDO unless the design will be certified by a DASA-recognised NAA/MAA, as explained earlier in this chapter. The MDO must be in place before the design effort commences.

6.1.2.83 The fourth step, Compliance Demonstration, is where the MDO produces evidence that their design meets the DASA-agreed TCB. This step may require DASA approval of an MPTF to enable flight testing if the aircraft is already on the Defence Register. The MPTF is explored later in this section.

6.1.2.84 The fifth and six steps wrap up the certification process, and are largely self-explanatory. It is worth noting that while an Airworthiness Board (AwB) is not a prerequisite for DASA issue of an MTC, if the Defence Aviation Authority (Defence AA) elects to convene an AwB near to the MTC issue date, then DASA may wait until after that event to issue the MTC. AwBs are explored later in this chapter.

6.1.2.85 **MCoA.** As noted previously, an MCoA cannot be issued prior to the MTC. However, it is normal practice for the Defence acquisition organisation to be prepared in advance, so DASA[24] can issue MCoAs for the delivered fleet directly following the issue of the MTC. DASPMAN Volume 3 Chapter 5.3 presents the conditions and processes for MCoA issue.

6.1.2.86 **MPTF.** Once a new aircraft type has been added to the Defence Register, but prior to issue of the MTC, MAOs may need to operate the aircraft. For example, the flight test MAO may need to conduct flight tests to generate compliance demonstration evidence, and to contribute to operational test and evaluation (OT&E). The operational MAO may need to maintain crew currency, evolve OIP, conduct OT&E, and so on.

6.1.2.87 DASA can issue an MPTF if the aircraft design has been shown to substantially comply with its TCB, the configuration of the aircraft is clearly defined, the aircraft is capable of safe flight under defined conditions, and any elevated risk has been justifiably retained. An MPTF is effectively reliant on both the MTC and the MCoA processes being well-advanced.

6.1.2.88 The initial MPTF will usually constrain the MAO's operation of the aircraft. After all, the type certification program is still incomplete so there will be areas of the design that are known to be deficient or where uncertainty still remains, and hence the MPTF will impose commensurate risk controls. DASPMAN Volume 3 Chapter 7.5, Flight Conditions and MPTFs, explores MPTFs and their associated flight conditions, including risk management, the application process, periods of validity, and so on. The MAO will often self-impose additional constraints on flight operations, and will ease these constraints as the systems and personnel skills mature.

Superseded

6.1.2.89 **AMP.** CASG's Reliability and Aircraft Maintenance Program (RAMP) team, which is collocated with DASA's Melbourne office, provides Defence's centre of expertise for AMPs, and advises DASA on whether an AMP should be approved[25]. Both DASA and the RAMP team should be engaged early in the acquisition phase for guidance on AMP requirements.

Activity 4: Convene an Airworthiness Board

6.1.2.90 As discussed in Chapter 6.1.1, the Defence AA would normally require that an AwB be convened prior to operation of a new aircraft on the Defence Register[26]. The Introduction into Service AwB, normally held immediately prior to the commencement of flight operations, complement regulatory activities conducted by the DASA and build on the confidence of DASA authorisations. This AwB is underpinned by progressive check-ins by the board members with both DASA and the regulated community, focussing on:

1. understanding the status of DASA assurance of relevant products and organisations
2. safety assurance of the collective enterprise (CM, CASG, Industry) introducing the new platform;
3. potential organisational culture hazards; and
4. transition safety risks associated with the introduction of the capability through to reaching initial operational capability milestones.

6.1.2.91 The artefacts submitted by Applicants to the AwB would predominantly consist of already produced project documentation and attestations that collectively summarise the readiness to commence Flight Operations:

1. Airworthiness Plans, Artefacts, Approvals and Authorisations
2. FIC Status and Capability Realisation
3. Integrated Airworthiness System Assessment
4. MAO Risk Management and OIP

6.1.2.92 The Defence AA would normally require progressive AwBs during the initial operating period for a new aircraft, most likely aligned with key Operational Capability milestones. Hence the AwB can explore whether the operational and support systems are maturing commensurately. Periodicity might be influenced by the severity of organisational and/or product deficiencies noted during DASA assurance activities and/or a previous AwB.

6.1.2.93 Annex D presents additional guidance on the submissions, requirements and conduct of an AwB for a new aircraft type.

Superseded

Activity 5: Follow-up DASA assessments

6.1.2.94 The organisational and product authorisation requirements presented in this chapter are seldom wholly implemented when the Applicants apply for the relevant DASA authorisations. Provided DASA is satisfied the safety risks due to the deficiencies can be robustly managed, this may not preclude DASA from issuing the authorisation, as explored in the following paragraphs.

6.1.2.95 **Organisational approvals.** When DASA initially issues an organisational approval, the processes and people may not yet have been exercised for the new aircraft type. For example, an MDO may not have produced designs, the MAO may not have exercised its ASMS, organisational deficiencies may have been identified by DASA, and so on. Equally, the organisation may self-identify temporary deficiencies in their own processes and people.

6.1.2.96 These issues may not preclude DASA from issuing the organisational approval if satisfied the organisation has the ability to safely operate and support the aircraft. DASA may elect to moderate this risk through, amongst other things:

1. placing limitations on operations, initially via the initial MPTF and later via the OpSpec
2. initially constraining the 'privileges' that are available to organisations under some regulations
3. re-visiting the organisation soon after their systems and processes have been exercised.

6.1.2.97 Over time, once DASA is assured the deficiencies or lack of experience have been addressed, the constraints may be eased. The Defence AA may convene AwBs to provide additional confidence.

6.1.2.98 **Product authorisations.** As a matter of pragmatism, a MTC can be issued before compliance with the TCB has been entirely demonstrated. As a result, the MTC may include temporary limitations, or the TCB may include temporary Exception MCRIs (with supporting AwIPs documenting essential risk management), pending resolution of the outstanding design issues. Once evidence of TCB compliance is provided to DASA's satisfaction, the limitations or other risk management measures can be progressively removed.

Project completion

6.1.2.99 Even after the above five activities have been substantially completed, residual issues may still be outstanding. Provided these issues are sufficiently few in number and complexity[27], they have been professionally transitioned to the running system, and any associated risks are being managed in the relevant ASMS, DASA will in due course consider the acquisition project to be closed.

6.1.2.100 The residual issues will be monitored by DASA through normal compliance assurance activities.

Niche Applications

Superseded

6.1.2.101 So far, this chapter has focused on new aircraft types being acquired by Defence. This final section will explore three niche applications of the information presented in this chapter, namely fleet additions, acquisition of used aircraft, and Major design changes to in-service aircraft.

Fleet addition aircraft

6.1.2.102 When additional aircraft are to be added to an extant Defence fleet, the guidance presented earlier in this chapter is still mostly relevant, although it can be applied in a substantially abbreviated form. An assessment of each of the five activities from the previous section is presented below.

6.1.2.103 **Activity 1: Agreement on DASA authorisations.** The information presented in the previous section is entirely relevant. That is, the acquisition organisation should engage with DASA before contracts and other agreements are signed, and an agreed path to DASA approvals should be documented in an ASAMP. The ASAMP will be much abbreviated compared to the acquisition of a new aircraft type, and some of the ASAMP annexes will not be required.

6.1.2.104 **Activity 2: Organisational approvals.** Each of the organisational approvals will likely be in place, so this activity is limited to ensuring those organisations can manage the additional workload and (where applicable) the configuration differences of the new aircraft.

6.1.2.105 **Activity 3: Product certifications.** If the new aircraft are precisely the same configuration as the extant fleet, they can simply be listed on the MTC and individual MCoAs then issued for each new aircraft. More likely, however, there will be configuration differences. While other avenues may be acceptable, most often the new aircraft are added to the MTC mirroring the configuration of the extant fleet, and the configuration deltas for the new aircraft are processed as design changes (Major and Minor) to the common type design. If there will be a delay in completing this activity, an MPTF can be used to cover the configuration differences of the additional aircraft.

6.1.2.106 If there are substantial configuration differences to the extant fleet, perhaps even with changes to the TCB, the new aircraft might need to undergo a targeted type certification program that focuses on the configuration deltas. DASA's approval may be reflected as a separate model number on the MTC, or the deltas might be encompassed in a Military Supplemental Type Certificate (MSTC).

6.1.2.107 **Activity 4:** AwB. AwB independent review of additional aircraft would normally be considered as part of the next scheduled sustainment AwB. In exceptional circumstances, a separate AwB may be convened if the acquisition of additional aircraft requires appreciable changes to extant FIC arrangements.

6.1.2.108 **Activity 5:** Follow-up DASA assessments. The information on product deficiencies presented in the previous section is equally relevant to fleet addition aircraft. The information on organisational deficiencies, on the other hand, is unlikely to be applicable; rather, the next routine compliance assurance activity would check how the organisation is coping with the extra workload.

Used aircraft

Superseded

6.1.2.109 Where Defence elects to acquire used aircraft, the guidance presented earlier in this chapter is entirely relevant. However, there are additional actions that will need to be undertaken for Activity 3: Product Certification, namely the provision of additional documentation and the completion of additional inspections to support the issue of an MCoA.

6.1.2.110 **Documentation.** DASR 21.A.174 presents a list of the additional documentation needed for a used aircraft, namely:

1. (if the aircraft originates from a foreign military applying an EMAR based regulations): a Military Airworthiness Review Certificate;

2. (if the aircraft originates from a civil state of registry that is recognised by DASA): an export certificate of airworthiness from the recognised CAA;

3. (if the aircraft originates from elsewhere):

    i. a statement by the Authority of the State where the aircraft is, or was, registered, reflecting the airworthiness status of the aircraft on its register at time of transfer

    ii. a weight and balance report with a loading schedule

    iii. the flight manual and any other manuals required by the Authority of the State of registry

    iv. historical records to establish the production, modification, and maintenance standard of the aircraft, including all limitations associated with a restricted certificate of airworthiness

    v. a recommendation for the issuance of a certificate of airworthiness or restricted certificate of airworthiness and a Military Airworthiness Review Certificate following an airworthiness review in accordance with DASR M.

6.1.2.111 **Inspections.** Used aircraft require a more stringent inspection than new build aircraft, and must be performed by an appropriately qualified, independent and experienced organisation. The inspecting organisation is to conduct a comprehensive review of the aircraft design, maintenance and operational documentation, verified by a physical inspection of the airframe structure, engines and other systems.

6.1.2.112 The inspecting organisation is to provide inspection reports detailing the airworthiness inspection result. As a minimum, reports should include the following:

1. details of the aircraft inspected, including registration number, manufacturer, serial number, model designation, and Certificate of Airworthiness number

2. last known inspected configuration of the aircraft

Superseded

3. a summary of the usage and maintenance history of the aircraft, engines and propellers, including current maintenance, weight and balance, and lifed component status

4. details of any major structural and life-limited component changes made to items such as wings and tailplane, and a summary of the individual histories of such components, unless new when fitted

5. details of any accidents or incidents in which the aircraft has been involved

6. details of any major repairs or modifications performed on the aircraft, engines and propellers and verification that they have been properly approved and incorporated

7. details of any applicable aircraft-general, type-specific, engine or equipment airworthiness directives or service bulletins and verification that the aircraft complies

8. a condition assessment of flight safety critical components and fatigue-sensitive structure

9. recommendations for the resolution of any airworthiness deficiencies or concerns arising as a result of the airworthiness inspection

10. flight manuals and any other manuals.

6.1.2.113 Should Defence be contemplating the acquisition of used aircraft, DASA should be contacted early in the decision process. DAVENG staff in particular will provide the acquisition project with useful guidance.

Major design changes

6.1.2.114 This chapter has so far focused on aircraft acquisitions. However, the content can be extensively applied to particularly complex Major design changes to in-service aircraft. A Major design change is one that has an appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product .

6.1.2.115 Defence currently conducts around 70 Major design changes to its fleet each year. Most of these design changes have little if any significant impact on the aircraft operator or support organisations. Occasionally, however, Defence undertakes a Major design change whose effects pervade the DASP.

6.1.2.116 An example might be an extensive mid-life cockpit upgrade, which will not only challenge the design organisation, it can extensively affect MAO OIP, require simulator upgrades, change the aircrew training curriculum, allow new Performance Based Navigation approvals, require additional maintenance equipment and training, require new production organisations, require parallel operations of two different aircraft configurations for extended periods, and so on. An extensive flight test program to explore human factors and other certification issues might also be required.

Superseded

6.1.2.117 Making such pervasive changes to the aircraft and supporting systems can be a complex undertaking that requires coordination and often robust risk management across multiple organisational boundaries. While it perhaps does not have the complexities of introducing a new aircraft into service, it is far from straightforward and can introduce elevated safety risks if not executed well. In such circumstances, increased independent assurance from DASA is likely to benefit aviation safety.

6.1.2.118 Where DASA, in consultation with the MAO and CASG, identifies a Major design change that warrants this expanded DASA independent assurance, DASA will treat the project similarly to an aircraft acquisition. This may include, for example, increased scrutiny of organisational approvals, a closer assessment of how the new configuration is introduced into service (including, if necessary, imposing temporary operating constraints), greater assurance of risk management decisions, and so on. The Defence AA may require an AwB to be convened to provide an independent review of how well the new configuration has been integrated into Defence.

6.1.2.119 For these Major design changes, the guidance in the previous section is applicable almost in its entirety. Notably, an ASAMP should be raised, albeit some elements will self-evidently either be of limited scope or not applicable. An SOIU update may be required, organisational approvals may need to be expanded, and so on. The only element that is unchanged is the type certification process, since DASA certification oversight is always implemented commensurate with risk, and this is unaffected by the additional DASA scrutiny outlined in this section.

3. Airworthiness Issue Papers
4. Airworthiness Board Guidance

6.1.3 Acquisition of Non-Defence-Registered Aircraft

Introduction

6.1.3.1 Civil registration of a Defence aircraft may be attractive to Capability Managers (CMs) and acquisition organisations. It may provide contractual and ongoing management simplicity, and sometimes lower costs and result in a faster introduction into service.

6.1.3.2 Regardless of the registration arrangement, Command retains the responsibility for ensuring the safety of aircraft occupants, other aircraft, people, and facilities on the ground. However, in the case of non-Defence-Registered (NDR) aircraft, DASA has a comparatively lesser role in guiding and assisting Command in meeting these obligations.

Purpose

Superseded

6.1.3.3 This chapter guides Defence's aircraft acquisition organisations and Military Air Operators through the aviation safety requirements and recommended practices during the acquisition of an NDR aircraft, but only to the extent, that DASA is involved in the process.

CONTENT UNDER REVIEW

Circa 2023, DASA is currently conducting a major review of the DASA approach and regulations for non-Defence Registered (NDR) aircraft. The review will assess, amongst other things, the legal implications of a State aircraft being regulated by a civil regulator, the need (if any) for DASR regulations to supplement the civil regulations, the role of DASA (if any) in aviation safety assurance, and so on.

Once the review is completed, DASR.NDR and this DASPMAN chapter will be updated. In the meantime, Defence organisations considering the acquisition of a NDR aircraft should contact DASA for advice.

Superseded

Annex A - Aircraft Registration Discussion Points

(a) This annex is intended to guide discussions between the Capability Manager representative, the Defence acquisition organisation and DASA, to help the Capability Manager make an informed decision whether a new aircraft should be Defence or civil registered.

Capability Requirement

(b) To the extent of current knowledge, the Capability Manager representative should provide insight into the following:

1. Will the candidate aircraft be a continuous 'state' aircraft, and if so, what is the duration of the capability requirement?
2. What are the candidate aircraft type(s)?
3. What is the likely scope of operations for the aircraft?
4. Of these operations, which are not normally associated with civil aircraft? Examples may include weapons carriage and deployment, low flying, aerial delivery, clandestine flying, formation flying, transporting hazardous materials and dangerous goods, etc
5. Is the operating environment for the aircraft likely to exceed civil norms? Examples include hostile electromagnetic environments, harsh physical environments, etc

Discussion

(c) With the context provided by the above information, discuss the following:

1. If the procured aircraft are to be continuously 'State' aircraft, what extenuating circumstances would support continued operation on the civil register?
2. Would any of the proposed military roles be precluded under civil regulations? If they are not precluded, might any be heavily restricted?
3. How much flexibility does the MAO require in the employment of risk management to meet regulatory requirements?
4. Will Commanders need the ability to deviate from regulatory requirements in the event of compelling operational imperatives or emergencies? Examples may include flying aircraft with design or maintenance deficiencies that present elevated levels of risk, flying 'due regard', etc.
5. What are the implications of Defence being bound to civil aviation safety regulations for design, maintenance and operation?
6. What are the diplomatic and security implications of Defence operating a non-Defence registered aircraft overseas?

(d) The preceding discussion will assist the Capability Managers representative to identifying the potential drawbacks of civil registration. Where implications may be unclear, expert advice from CASA should be sought.

Superseded

Introduction

(a) Defence aircraft can be categorised by registration type into either Defence Registered, or Non-Defence Registered Aircraft. Categorisation by registration type is important because it determines which DASR parts apply to operation of the aircraft. In compliance with ICAO Article 18, aircraft will not be on more than one register at any time. Aircraft may transfer between registers.

(b) In Australia, the two Authorities that maintain aircraft registers are the Civil Aviation Safety Authority (CASA) and the Defence Aviation Safety Authority (DASA). The terminology for equivalent overseas authorities is Civil Aviation Authority (CAA) for a civil authority and Military Aviation Authority (MAA) for a Military Authority. A nation is not likely to have more than one civil authority although there may be multiple military authorities as is the case in the USA.

(c) A Defence UAS that is not held on the Defence Register must be recorded on a local register in accordance with DASR UAS.10 (d) and (e)—with the exception of UAS operated under DASR NDR. Refer to DASPMAN Vol 3 UAS Part 2 Chapter 2 for local registration of UAS.

Purpose

(d) This chapter provides guidance on how MAOs and Project Offices (POs) request allocation of an Application Identifier (AI), request Defence registration of an aircraft, and request removal of an aircraft from the Defence Register. DASR ARO.60 is applicable to this chapter.

Defence Registration

(e) An aircraft owned or leased by Defence and that continuously operates as a State Aircraft should be Defence registered. Defence registration allows the full flexibility of the DASP to apply to an aircraft. It enables DASA authorisation of military roles, including the release of ordnance, low flying, and formation flying—types of operations that may be heavily restricted or unsupportable under civil regulatory requirements (applicable to civil registered Defence aircraft through DASR NDR.05(a)). Defence registration ensures the aircraft is within the exclusive jurisdiction of the DASR.

The Defence Register

(f) DASA publishes the list of registered aircraft on the DASA website. For each aircraft on the Defence Register the following information is recorded:

1. an Application Identifier (AI) unique to the aircraft type
2. an aircraft tail number
3. an aircraft model number
4. the manufacturer’s serial number of the aircraft
5. the aircraft delivery date
6. the Defence registration date
7. reference to DASA approval documentation

Superseded

8. the operating MAO.

Inclusion of aircraft on the Defence Register

(g) This section describes how MAOs (and SPOs on behalf of a MAO) request DASA to add or remove aircraft from the Defence Register.

(h) Defence Registration is a two-stage process. The first stage is allocation of an Application Identifier (AI) for each aircraft type. The second stage is the addition of each aircraft to the Defence Register following delivery and acceptance.

Application for aircraft type Application Identifier assignment

(i) DASA assigns an AI to aircraft types as a unique identifier. This AI appears on many DASA authorisations including the Military Type Certificate (MTC) and OpSpec. The AI also forms the first component of the registration markings of each aircraft (eg for AI 'A44' the tail numbers will be A44-nnn, where 'nnn' is the individual aircraft's unique registration number).

(j) A MAO (or their representative) may apply to DASA for issue of an AI. Ideally, this occurs after the government has provided acquisition approval for the aircraft. The application is normally via minute and should include evidence of government approval and details of the acquisition program including the:

1. make and manufacturer of the aircraft
2. number of aircraft sought
3. anticipated entry-into-service date.

(k) Following receipt of an application for an AI, DASA will review the application. If complete, DASA will allocate the next available AI, and create a record for the new aircraft type in the Defence Register. The MAO will then be notified of their assigned AI.

(l) **Assignment methodology.** DASA assign all Defence registered aircraft an AI. The first AI assigned A[1] was to DH9A in the early 1920s. DASA assigns AI's sequentially from A1 through to A99. When the allocation reaches A99, DASA starts a new series and issues AI from A1. Army and Air Force aircraft are assigned AI with the prefix 'A' whilst Navy aircraft numbering using the prefix 'N'.

Application for aircraft registration

(m) The second stage of aircraft registration is an application to DASA for registration of each aircraft tail. As aircraft registration is a pre-requisite for the issue of a Military Certificate of Airworthiness (MCoA), normal practice is for the MAO or PO to apply for registration immediately following delivery of each aircraft from the manufacturer.

(n) The application may take the form of a Minute, or by prior agreement with DASA, another document. The application must provide the following information and be supported with evidence:

1. the desired tail number
2. evidence that Defence has control of the specific aircraft, through either ownership or lease
3. evidence that the aircraft is not on another CAA/MAA register.

Superseded

(o) An applicant may prove control over an aircraft through evidence of ownership such as SG-01, DD1149 or DD-250 forms. For a leased aircraft, an extract from the lease agreement or form where Defence has accepted custody of the aircraft is sufficient.

(p) Prior to delivery, aircraft are usually subject to acceptance flight test activities. Generally, to conduct these activities the manufacturer has to comply with local registry requirements of their national MAA or CAA. For DASA to add the aircraft to the Defence Register, the applicant must provide evidence that the aircraft is not on any other register.

(q) Following receipt of an application for registration, DASA will review the application. If complete, DASA will add the new tail number to the Defence Register. Following registration, DASA will send a letter to the applicant, relevant MAO-AM, Environmental Commander and the CASA Registrar – Civil Register of Aircraft. DASA will send relevant aircraft identification information to Airservices Australia.

Removal of aircraft from the Defence Register

(r) A MAO or SPO must apply to DASA to remove an aircraft from the Defence Register. The application must contain the following:

1. the reason the aircraft is being removed from the register
2. confirmation that Defence Registration markings have been removed[2]
3. reference to the approved aircraft disposal plans or agreement
4. where applicable, details for the subsequent owner and registrar.

Following receipt of an application to remove aircraft from the Defence Register, DASA will review the application. If the application is complete, DASA will annotate the Defence Register with removal. Following de-registration, DASA will send a letter to the applicant, relevant MAO-AM, Environmental Commander and CASA Registrar – Civil Register to confirm aircraft removal from the Defence Register.

Superseded

Introduction

(a) Statements of Operating Intent and Usage (SOIU) must effectively describe the intended roles, usage and operating environment for a particular Defence aircraft type. This chapter expands on multiple DASR policy areas to present coherent guidance to Capability Managers (CM), Military Air Operators (MAO) and Project Offices (PO) on producing SOIUs.

(b) The SOIU requirements for an aircraft are derived from a series of capability requirements documents. The SOIU provides the broad operating parameters within which the aircraft type can safely operate. The SOIU must have sufficient detail to support identification of system requirements for a Defence aircraft type under acquisition or modification via a Major Change to Type Design. Accordingly, the SOIU is a key document in developing the Type Certification Basis (TCB) for new Defence aircraft or Major Changes to Type Design. In addition, the SOIU defines the intended scope of employment of an aircraft by a Military Air Operator (MAO) during flight operations.

Purpose

(c) This chapter describes the lifecycle of an SOIU for Defence certified aircraft (including certified UAS). Development of an SOIU is not mandatory for a Non-Defence Registered Aircraft (NDRA), but may assist a MAO to establish the operational context of their intended NDRA operations to assist with identification of any additional safety controls required in order to eliminate or minimise risks SFARP. This chapter describes the relationship between the SOIU and other key project documents and DASR authorisations. For non-certified UAS refer to DASPMAN Volume 3 Part 2 Chapter 3.

SOIU Relationship to Capability Strategy, Plans and Policy

(d) The SOIU synthesises the capability requirements into intended functional, enabling and sustainment requirements for a Defence aircraft system. Capability requirements may stem from Defence strategic policy (such as the Defence Strategic Review), Service capability plans/ strategies, and aircraft platform Operations Concept Documents (OCDs) and Capability Realisation Plans (CRPs). They may include interoperability, force generation and preparedness outcomes. Thus, the SOIU is subordinate to these capability documents and (together with the Integrated Program Management Plan (IPMP)) establishes the concept of operations and system level requirements to support safe introduction into service (and subsequent sustainment) of an aircraft type. In turn, the SOIU plays a foundational role within the system of DASR authorisations for an aircraft platform. Figure 1 shows the synthesis of platform capability requirements into the SOIU. A depiction of the DASR artefacts that are dependent on the SOIU is contained at DASPMAN Vol 3 ASAMP Chapter N Annex A.

Superseded

Figure 1: Capability Requirement Inputs to SOIU Development

DASR Requirements

(e) The SOIU enables identification of aviation system requirements that underpin Initial Airworthiness certification activities and Flight Operations authorisations regulated under DASR. The following DASR, associated Guidance Material (GM) and Acceptable Means of Compliance (AMC) applicable to this chapter are:

1. DASR ARO.50
2. DASR 21.A.15
3. DASR 21.A.17
4. DASR ARO.100
5. DASR ORO.05
6. DASR ORO.10
7. DASR UAS.20 (a)

Uses of the SOIU by various stakeholders

(f) Due to the prevalence of the SOIU in multiple DASR policy areas, different stakeholders use the SOIU for differing purposes. A PO (or Military Type Certificate Holder (MTCH)) uses an initial SOIU to determine an appropriate Certification Basis for a Type. The initial SOIU also documents the intended aircraft usage spectrum, which underpins the aircraft and engine structural certification requirements. MAO use initial SOIU to inform the intended bounds of aircraft operations. This supports a MAO in establishing a Flying Management System (FMS) for an Aircraft Type. In sustainment, the SOIU is used to communicate how the MAO-AM is currently operating, and how they intend to operate the platform in the future. As a result, variation of the SOIU will have an impact across multiple stakeholders and previously issued DASR authorisations.

SOIU Lifecycle

(g) The SOIU is subject to regular variation, due to changes in intended aircraft capability, usage or operating environment. Amendment of the SOIU triggers a cascade of stakeholder actions to implement revised capability and seek a range of DASR authorisations. Figure 2 depicts the SOIU lifecycle.

Superseded

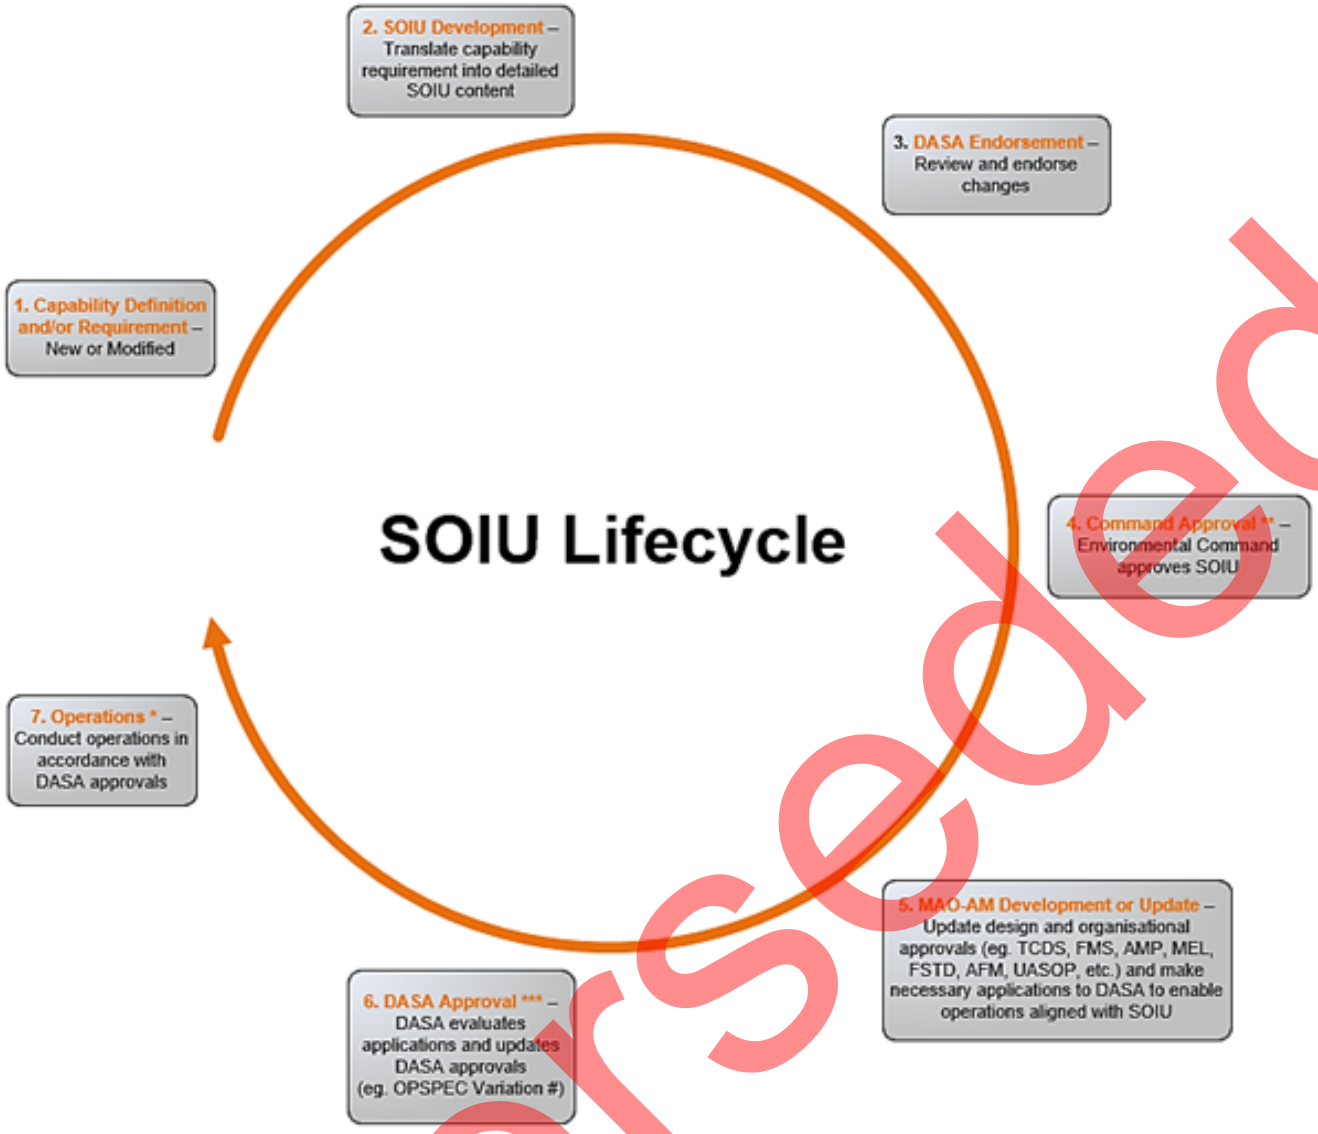

Figure 2: Depiction of the SOIU Lifecycle within DASR

(h) **Step 1 – Capability Definition and/or requirement.** The decision of when to develop an initial SOIU for Defence aircraft or capability may vary across the One Defence Capability System (ODCS) (formerly known as the Capability Life Cycle (CLC)) dependent on the scope and complexity of the project. Usually, development of an initial SOIU occurs post Gate 0, to support the risk mitigation and requirements setting phase of the ODCS. At the very latest, an approved SOIU must be in place to support commencement of acquisition activities (Investment Committee Gate 2 decision). SOIU development is one of the first planning milestones within an Aviation Safety Acquisition Management Plan (ASAMP). Following Introduction Into Service (IIS), emerging capability needs may necessitate variation of the SOIU, if they substantially alter the intended aircraft role, usage or operating environment of the subject aircraft.

(i) **Step 2 – SOIU Development.** The acquisition PO initially develops the SOIU as a joint operational and technical document. At this stage, the SOIU must have sufficient information to inform type certification activities and support identification of anticipated organisational approval and authorisation requirements. The MAO is responsible for in-service management of the SOIU, supported by the Continuing Airworthiness Management Organisation (CAMO) and MTCH (or delegate). The MTCH should ensure that the proposed SOIU is compatible with the Type Certification Basis.

Superseded

(j) There should be sufficient detail in an SOIU to articulate intended aircraft system roles, tasks, functional requirements, operating environments and anticipated aircraft usage. DASR ARO.50 does not mandate further detailed SOIU content requirements. DASA has developed an SOIU template (on the DASA website) as per DASR ARO.50.a (GM), based upon observed regulated community best practice. Further guidance on suggested SOIU content is in paragraph 16.

(k) **Step 3 – DASA Endorsement.** DASR ARO.50 requires that DASA endorse SOIU for Defence registered aircraft. DASA endorsement will be scaled based on program maturity and recognising that further maturation of the SOIU will occur during early phases of acquisition. All applications for DASA endorsement of an SOIU need PD/MTCH and operator evidentiary statements to confirm the engagement of relevant stakeholders during the development of the SOIU. DASA endorses the SOIU as an appropriate input to Initial Airworthiness approvals. In providing endorsement of the SOIU, DASA assures the MAO arrangements underpinning the MAOC Operations Compliance Statement (OCS) are consistent with the SOIU scope of intended current operations. This endorsement does not approve any role or usage stated within the SOIU. Where necessary, DASA staff will identify caveats to endorsement, which may include Specific Limitations against the affected aircraft type within the MAOC OpSpec. Particularly, staff from each of the DASA Directorates (Initial Airworthiness, Continuing Airworthiness, Aviation Engineering and Aviation Operations) will assure the SOIU is sufficiently detailed to:

1. establish and maintain the Type Design of the aircraft
2. ascertain whether or not any changes to the CRE alter the validity of the MAOC OpSpec
3. ascertain whether any Human Factors/Human Machine Interface (HF/HMI) requirements, performance and handling qualities impacts have been identified
4. ascertain whether the SOIU (mainly Flight Profiles, Mission Mix and Rate of Effort) provide sufficient detail to manage aircraft and propulsion system structural life-limits and management.

(l) **Step 4 – Command Approval.** The Environmental Commander (COMAUSFLT/ COMD AVNCOMD/ ACAUST) approves the SOIU for their respective services, following endorsement by the Defence Aviation Authority's airworthiness delegate (DG DASA). SOIU approval represents:

1. confirmation that the SOIU meets capability requirements as laid out in platform Operational Concept Documents and Joint / Service Capability Strategies
2. approval of the intended scope of aircraft operations and environment
3. commitment of resourcing to meet intended ROE (and force generation requirements)
4. part of the direction for the MAO and MTCH to proceed with developing applications for necessary changes to DASA organisational approvals and authorisations.

(m) **Step 5 – MAO-AM Development or Update.** Upon receipt of an approved SOIU, the MAO (supported by the MTCH, CAMO and PO) should undertake a program of work to develop submissions to DASA for Type Certification, Organisational Approvals and other required DASA Authorisations that will underpin implementation of the SOIU intent. These submissions are ensure actions as shown at DASPMAN Vol 3 Chap 6.2.1 Annex A. For initial SOIU (or major changes in capability), this will likely involve development of planning documentation such as

Superseded

the Aviation Safety Acquisition Management Plan (ASAMP), Certification Program Plan (CPP) and Organisational Approvals and Authorisations Plan (OAAP) (if not already developed at Step 1). SOIU variations involving Major Changes to Type Design will follow the Type Certification process under DASR 21.A.17. Concurrently, the MAO will develop updates to Orders, Instructions and Publications (OIP), establish training, and pursue all other necessary changes in order to support variation of the MAO OCS per DASR ARO.100. This step will culminate in the MAO application to the Authority for issue of (or variation to) a MAOC OpSpec commensurate with the new or modified SOIU (including the SOIU version number and approval date), citing evidence of changes underpinning the revised MAOC OCS.

(n) **Step 6 – DASA Approval.** DASA directorates provide independent assurance to support the issue of changes to Type Design and DASA Authorisations. DASA bases these activities on objective evidence accompanying submissions. DASA only considers an SOIU authoritative when the MAOC OpSpec reflects the authorised version.

(o) **Step 7 – Operations.** Per DASR ARO.100, ORO.05, and ORO.10, the intended scope of operations are within the SOIU and authorised by the MAOC OpSpec. For an aircraft system in being there will always be an authorised SOIU annotated on the MAOC OpSpec Type Annex. Other draft SOIU variations may be in development and progressing along the SOIU lifecycle.

SOIU Content Guidance

(p) The MAO/PO routinely updates the SOIU to distinguish between the intended scope of current operations from potential future capabilities. DASA has developed an SOIU template based upon observed best practice in the regulated community. The following SOIU topics are applicable to all new or modified aircraft types:

1. **Description of Aircraft Roles.** Describe the aircraft role in terms of the predominant operations the aircraft will undertake. This is usually in terms of the operational effect associated with conduct of the role, such as Offensive Counter Air, Anti-submarine Warfare or Air Logistics Support. An aircraft may undertake several different roles. The level of detail in the description for each role must be commensurate with the need to define those roles for which the aircraft is authorised and inform the definition of associated tasks, flight profiles and operating environment. While the role of the aircraft is a sub-element and intrinsic attribute of capability, the MAO/PO should not include the capability objectives that the aircraft supports.

2. **Description of Aircraft Tasks.** Aircraft tasks are subordinate elements (or discrete activities) that are necessary in order to fulfil an aircraft role. These can relate directly to the conduct of operations or considered as force enabling tasks. Examples of role related tasks for an aircraft might include Humanitarian Aid and Disaster Relief, Aerial Delivery, Search and Rescue or Passenger Transport. Enabling tasks may include Aircraft Initial and Conversion Training, Flight Test activities, Flypast and Flying Displays or Air to Air Refuelling. Task descriptions should discuss particular aircraft configuration requirements (such as enabling role or mission equipment) or intended operating environment factors (such as for embarked helicopter operations and sustainment) that are unique to the conduct of the task. The formulation of flight profiles uses this detail.

3. **Flight Profiles.** Depending on the number of intended tasks, Flight profiles may be included in the main body of the SOIU or as annexes. Flight profiles should have sufficient detail to establish aircraft usage monitoring programs, enable generation of training packages and development of MAO OIP. Flight profiles should be compiled

Superseded

into logical groups such as 'Common Profiles', 'Ground Attack', 'Air-to-Air', 'Aeromedical Evacuation' and similar logical groupings. There may be benefit to include a short discussion of intended aircraft configurations for each flight profile, including intended role equipment and Minimum Equipment List (MEL) impacts (if applicable). A list of suggested parameters, graphics and tabulated manoeuvre depictions to include in flight profiles is contained within the DASA SOIU template.

4. **Physical Operating Environment.** Usually, the physical operating environment is broken into the airborne physical environment and ground physical environment. The intended physical operating environment will have bearing on the aircraft limitations documented within the TCDS (and in turn the Aircraft Flight Manual) and will inform the aircraft usage monitoring, engine and structural integrity programs. A list of suggested operating environment parameters is contained within the DASA SOIU template.

5. **Functional Operating Environment.** The functional environment should describe the intended flight operation considerations associated with airspace access regulations (e.g. Communication, Navigation, Surveillance / Air Traffic Management (CNS/ATM)), operations in electromagnetic (EM) and threat environments, or where compliance provides desired safety enhancements for certain niche activities (e.g. frequent operations close to the ground or prolonged overwater). The functional environment section should also articulate the intended applicability of Specific Purpose Approvals under DASR SPA. For items that are potentially classified above OFFICIAL: Sensitive, a reference to the applicable document that contains the required information is appropriate.

6. **Intended Rate of Effort and Planned Withdrawal Date.** The intended rate of effort and planned withdrawal date should align with ADF capability strategies and the aircraft's OCD.

7. **Consideration of ADF unique policy and procedural impacts.** There may be ADF policies and procedures (eg Aviation Safety Design Requirements Manual), or Australian legislative requirements (eg Work Health and Safety Act 2011) that could affect Defence aircraft design, type certification or intended operations. This section of the SOIU should capture the unique Australian requirements to inform Type Certification requirement setting or the need for MAOC OpSpec Specific Limitations. Therefore, this section should describe any unique ADF policy and procedures that could influence the Defence aircraft operations, as well as identify any Australian legislation that must be complied with that could affect the aircraft design or operations.

8. **Clearly segregated discussion of anticipated future capabilities or changes.** The anticipated future capabilities or changes section is to segregate any anticipated change in the aircraft Configuration, Role and Environment (CRE), which deviates from the stated intent of current operations in the main body of the SOIU. This segregation is imperative to understand the approved scope of current aircraft operations implemented via the TCB and MAOC OpSpec and for the MAO to maintain compliance with DASR ORO.05 and ORO.10. This definition of future intended capabilities or changes may be used to support requirement setting activities.

(q) **SOIU Terminology.** As the SOIU defines an intent, the drafter should utilise words like 'intends', 'plans', 'anticipates' and 'expects' in preference to words like 'approved', 'capable', and 'certified'. This is to clarify that the document is a statement of intent only and with

Superseded

implementation recommendations. The authoritative documents that limit aircraft operations are comprised of the Type Certificate Data Sheet (TCDS) (for aircraft limitations and environmental limitations) and the MAOC OpSpec (for task related Specific Approvals and Limitations).

Superseded

6.1.2. Acquisition of (Crewed) Defence Registered Aircraft

6.1 Introduction of New Defence Aircraft Capabilities

6.1.1 Introduction

Background

6.1.1.1 Defence periodically adds aircraft to its inventory to meet a capability need. The aircraft may be purchased or leased, crewed or uncrewed, Defence or civil registered. An essential prerequisite for Defence operation of a new aircraft, regardless of the acquisition arrangement, is for Defence to confirm that it is safe for flight. This encompasses the safety of aircraft occupants, other airspace users, and overflown people and facilities.

6.1.1.2 The acquisition process for a new aircraft begins during the capability development phase of the life cycle, where operational requirements are defined and potential solutions investigated. The Aviation Safety management process commences concurrently with the acquisition process, and remains inextricably linked. Decisions made early in the acquisition process can have an enduring effect on Aviation Safety.

6.1.1.3 For a Defence aircraft to be safe for flight, the aircraft to be appropriately designed, constructed, maintained and operated, as explained in DASP Manual Volume 3 Chapter 3, The Defence Aviation Safety Program. It is the responsibility of aircraft acquisition organisations in Defence, relevant in-service organisations and Defence industry partners, to ensure a Defence aircraft is safe for flight, both from the initial design and throughout its Defence lifecycle. In turn, the relevant Aviation Safety authorities need to gain assurance that the aircraft is safe for flight. If suitably assured, the Aviation Safety authorities can issue a range of 'authorisations', usually in the form of certificates, permits, approvals or licenses.

Purpose

6.1.1.4 This series of chapters aims to guide Defence aircraft acquisition organisations, relevant in-service organisations and Defence industry partners through the aviation safety requirements and recommended practices during the aircraft acquisition process.

6.1.1.5 This first chapter provides a general introduction to acquiring new Defence aircraft, including registration requirements, Aviation Safety responsibilities, engagement with Aviation Safety authorities and other common concepts.

Applicability

6.1.1.6 This chapter is applicable to the acquisition (whether through purchase, lease or other arrangement) of the following Defence aircraft:

1. Defence registered crewed aircraft
2. Non-Defence registered crewed aircraft (short term)
3. Defence registered certified uncrewed aircraft systems (UAS)

Superseded

6.1.1.7 While the concepts in this chapter are also broadly applicable to Open and Specific category (ie non-certified) UAS, the regulatory approaches for these UAS are substantially different to certified aircraft, so DASP Manual Volume 3 Chapter 10, Uncrewed Aircraft Systems, separately covers their acquisition.

Structure

6.1.1.8 This chapter will provide context for the next four chapters, which will individually cover the three different arrangements for Defence aircraft acquisitions listed in paragraph 6, and as shown in Figure 1.

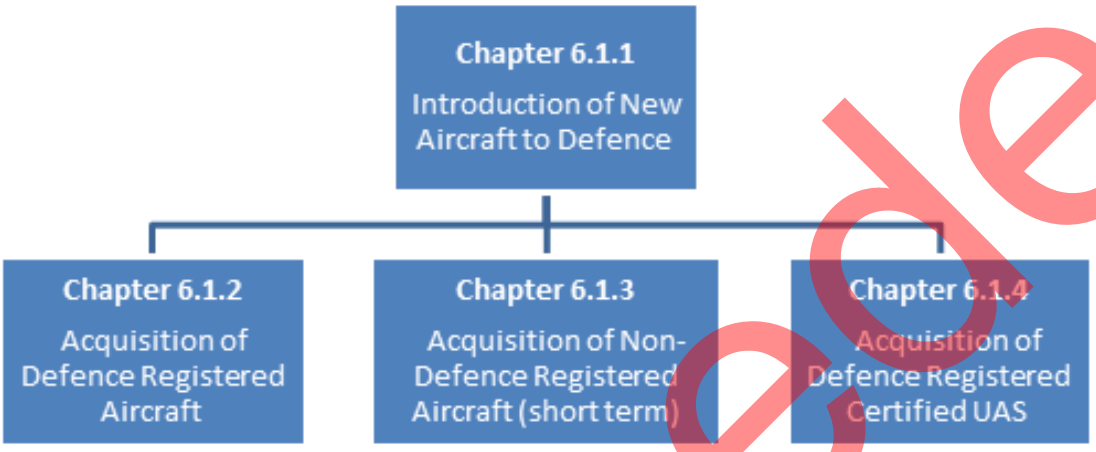

Figure 1: Chapter 6.1 structure

6.1.1.9 This chapter will also provide content that is common to the next four chapters, to avoid duplication.

Aircraft Registration

6.1.1.10 All Defence aircraft, apart from some non-certified UAS, must be included on the Register of a military or civil aviation authority. DASR separates these registrations into two categories; Defence registered aircraft and non-Defence registered aircraft. The latter are almost universally regulated by CASA. While other registrations are occasionally employed, they are always transitory arrangements[1].

6.1.1.11 A Defence registered aircraft is subject to Defence Aviation Safety Regulations (DASR) and DASA safety assurance oversight. An Australian civil registered aircraft, on the other hand, is subject to Civil Aviation Safety Regulations (CASR) and CASA safety assurance oversight as well as some limited DASA oversight.

6.1.1.12 When Defence is procuring an aircraft type that is also used under the civil regulatory framework, an important decision by the Capability Manager, required early in the acquisition process, is to determine whether the Defence aircraft will be Defence registered or civil[2] registered. This registration can have an enduring effect on Defence aviation capability, as summarised below:

1. **Defence registration.** Defence registration ensures the aircraft is within the exclusive jurisdiction of the DASR, which make specific allowance for:

   i. uniquely military roles, including weapons carriage and deployment, low flying, aerial delivery, clandestine flying, formation flying, transporting

Superseded

hazardous materials and dangerous goods etc — types of operations that may be heavily restricted or unsupportable under civil regulatory requirements

ii. flexibility in the approach to achieving compliance with the DASR

iii. the application of risk management where DASR compliance cannot be shown, provided a credible and defensible level of aviation safety performance is achieved

iv. Commanders to deviate from requirements (2) and (3) above in the event of compelling operational imperatives or emergencies.

DASA is experienced in regulating for the unique military operational context. Consequently, DASA is well-placed to advise Commanders on military aviation safety issues and to provide tailored independent safety assurance of military organisations and products.

2. **Civil registration.** Civil registration can initially be attractive to Capability Managers and acquisition organisations due to the simplicity of contractual and ongoing management, and potential faster introduction of the aircraft into service. However civil registration should only be considered for short term arrangements, or where an aircraft will not be considered a continuous 'State' aircraft. Complicating factors include that:

i. it can bind Defence to civil aviation safety regulations for design, maintenance and operation, and these regulations have not been customised to the unique military aviation context

ii. there may be a lack of risk-managed operational flexibility, which is the hallmark of Defence's aviation safety regulations

iii. it can bind Defence to the potential inflexibilities of the civil regulator

iv. there may be adverse diplomatic and security implications of Defence operating a non-Defence registered aircraft overseas.

6.1.1.13 Where a Capability Manager is considering civil registration for a temporary Defence aircraft, DASA should be engaged at the earliest practicable opportunity for consultation. Annex A presents a list of issues that should be explored during this engagement, to assist the Capability Manager in making an informed decision on Defence registration versus civil registration.

6.1.1.14 Annex B presents guidance on the structure and administration of the Defence Register.

Aviation Safety Responsibilities

6.1.1.15 DASP Manual Volume 1 states that aviation safety is a command responsibility, so commanders and managers are accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

6.1.1.16 The responsibility for ensuring (ie making sure) a new Defence aircraft is safe for flight falls directly on the Defence acquisition organisations and the relevant in-service support organisations. This includes, amongst other things, ensuring:

1. the aircraft design is safe for flight in the intended role and operating environment (ie aircraft design and certification)

Superseded

2. the physical aircraft standard of construction meets that design (ie aircraft production)

3. arrangements are in place to ensure the design remains safe (ie continued airworthiness)

4. arrangements are in place to ensure the aircraft remains in a condition for safe operation (ie continuing airworthiness)

5. arrangements are in place to design future changes and repairs (ie aircraft design)

6. operators are able to safely operate the aircraft (ie flight operations).

6.1.1.17 The role of DASA, on the other hand, is to gain assurance that the above elements have been executed effectively.

Aviation safety authorisations

6.1.1.18 When assured of safety, the relevant military or civil aviation safety authority (whether DASA or CASA) may issue a range of authorisations, often in the form of certificates, permits, approvals or licenses. For Defence registered aircraft, the list of authorisations is expansive, potentially comprising up to 12 different types of organisational, product and personnel authorisations. For civil registered aircraft, CASA will issue the civil equivalents to some or many of these 12 authorisations. Chapters 6.1.2 to 6.1.5 explore the Aviation Safety authorisations that may be issued by DASA and CASA for each acquisition category.

6.1.1.19 While DASA does not issue authorisations for civil registered aircraft, DASA may require that the aircraft are included within the scope of the Military Air Operator (MAO), issue a relevant Operations Specification (OpSpec) and conduct limited safety assurance oversight.

6.1.1.20 **Planning and coordination.** Aviation Safety authorisations issued by DASA or CASA are a major milestone in the aircraft acquisition process. Establishing the contracts, systems and people to merit each authorisation is usually complex, with considerable potential to waste time and resources. Effective engagement with the appropriate Aviation Safety authority (DASA for Defence registered aircraft, and both CASA and DASA for civil registered aircraft) is therefore in the best interests of all parties.

6.1.1.21 Engagement should ideally commence as soon as the Defence acquisition organisation has a reasonable view on the candidate aircraft, the need for Defence-unique design changes, and the probable operating and support constructs[3]. Engagement should be well advanced before Defence publishes any tender documents (eg Requests for Tender, Foreign Military Sales requests, etc) that may later affect an authorisation.

6.1.1.22. For civil registered aircraft, CASA will provide guidance on how to achieve the civil authorisations that will be required. DASA will do likewise for the new OpSpec, if one is to be published. This development of this DASA authorisation is far from a trivial endeavour. Not only does it cover the flying management of the MAO and other operational systems for the new aircraft, it also assesses whether the entire aviation safety construct (inclusive of all CASA authorisations) is likely to support safe Defence aviation.

6.1.1.23 For Defence registered aircraft, DASA will provide guidance on how to achieve the required DASA authorisations. Some additional guidance is available through DASA-sponsored courses and website resources.

Superseded

6.1.1.24 Chapters 6.1.2 to 6.1.4 provide tailored guidance on how engage with the relevant Aviation Safety authorities, since this varies widely between civil and Defence registered aircraft, and crewed and uncrewed aircraft.

6.1.1.25 **Documented agreements.** DASRs do not mandate any formal plans or agreements for achieving DASA authorisations. However, it is a practice that DASA highly recommends, given the substantial complexities in establishing the organisations and systems to manage Aviation Safety, and therefore the potential impacts (both positive and negative) on cost and schedule - and ultimately Defence capability.

6.1.1.26 For both Defence and civil registered aircraft, DASA advocates the production of an Aviation Safety Acquisition Management Plan (ASAMP). The ASAMP is an iterative agreement between applicants and DASA on the path to achieving DASA authorisations, and supports commanders and managers in accounting for parallel lines of effort and cross-regulation dependencies. It describes, amongst other things, the overarching acquisition strategy in the context of Aviation Safety and brings together the planned outcomes of the operational, technical, logistical and safety management activities.

6.1.1.27 The ASAMP should be drafted after the acquisition strategy solidifies, nominally following government acquisition approval, but before RFTs (or equivalent) are released. While ASAMPs have previously been drafted before initial contact with DASA has been made, this is rarely an efficient approach. The ideal time to draft the ASAMP is soon after the initial meeting with DASA, given that meeting will influence much of the ASAMP content. The ASAMP would normally be updated after contracts and agreements are signed, since this is the stage where the scope of most authorisations should be clear.

6.1.1.28 Chapters 6.1.2 to 6.1.5 provide guidance on the production of ASAMPs, tailored to the particular acquisition arrangement. ASAMP content varies widely between civil and Defence registered aircraft, with the latter including plans for achieving up to 12 different DASA authorisations. While the differences between crewed and uncrewed aircraft ASAMPs are less significant, the latter will focus on the unique challenges of separating the crew from the aircraft and the additional transitional authorisations that may be available for certified UAS.

Common Concepts

6.1.1.29 The next four chapters are dedicated to the four acquisition arrangements listed at Paragraph 6.1.1.6. To avoid duplication in those chapters, the remainder of this chapter will introduce several concepts that are likely to be common to each acquisition arrangement.

Recognition

6.1.1.30 Aviation Safety authority may acknowledge that products, services and data received from another Aviation Safety authority and the respective system they oversight are compatible within their own Aviation Safety framework. This concept, known as ‘recognition’, is extensively employed for new Defence aircraft acquisitions. Regardless of whether a new aircraft is Defence registered or not, recognition will almost certainly be applied for aircraft design and production. For non-Defence registered aircraft, recognition will also contribute to Defence’s confidence in aircraft maintenance and operation. DASP Manual Volume 3 Chapter 6.5, Recognition of Other Aviation Safety Authorities, provides further guidance on the application of recognition.

6.1.1.31 Where recognition is being considered for a certified UAS, DASA advice should be sought. Certified UAS are not yet commonplace, so the competence and capability of international Aviation Safety authorities in regulating and oversighting certified UAS is still evolving.

Superseded

Statement of Operating Intent and Usage (SOIU)

6.1.1.32 DASRs require all Defence registered aircraft and certified UAS (and certain other UAS when directed by the Authority) to have a Statement of Operating Intent (SOIU) that has been approved by the relevant Environmental Commander and DASA. The SOIU describes the approved roles, operating envelope, usage spectrum and operating environment for a particular aircraft type.

6.1.1.33 Development of an SOIU is not mandatory for a non-Defence registered aircraft, but may assist MAOs with establishing the operational context of their intended operations, to assist with identification of any additional safety controls required to provide an equivalent level of safety to that of Defence registered aircraft.

6.1.1.34 Annex C presents further information and development guidance for SOIUs.

Independent Review of Aviation Safety

6.1.1.35 DASP Manual Volume 3 Chapter 6, Independent Review of Aviation Safety, provides information on the scope and role of Airworthiness Boards (AwBs) within the framework of capability acquisition.

6.1.1.36 Historically, AwBs were identified as a 'gate' for issuance of some DASA authorisations. The contemporary role of the AwB in the acquisition process is to complement the role of the regulator in addressing parts of the 'system of systems' that are not adequately covered through regulatory oversight activity. DASA identifies that this increases flexibility and reduces the impost on the regulated community.

6.1.1.37 Chapters 6.1.2 to 6.1.4 provide guidance on the documentation package provided to Introduction into Service (IIS) AwBs for each acquisition type. The documentation will commonly consist of:

1. the extant submissions for the relevant DASA authorisations
2. an updated ASAMP which reflects the status of the acquisition program, details and plans for outstanding activities, and impact statements and associated risk management for outstanding activities
3. checklists and other artefacts.

6.1.1.38 An AwB is commonly convened prior to the first operation of a Defence registered aircraft, due to the often complex nature of organisational, risk management and other elements. Notwithstanding the aforementioned, there is no regulatory impediment to commencing limited operations, commensurate with risk, prior to the conduct and reporting of an IIS AwB. Progressive AwBs may be convened as the organisations and operational capabilities evolve.

6.1.1.39 An IIS AwB may be less common for non-Defence registered aircraft given that Defence aircraft that are continuous 'State' aircraft should be Defence registered. When determining whether an AwB is required, the Defence AA may take into account the complexity of support arrangements, whether Defence's operations are closely aligned to civil norms, and other similar factors.

6.1.2 Acquisition of (Crewed) Defence Registered Aircraft

Introduction

6.1.2.1 Aviation safety is a command and management responsibility. Commanders and senior managers are accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

6.1.2.2 Provided the aircraft and its support and operating arrangements meet the relevant Defence Aviation Safety Regulation (DASR) requirements, DASA may issue a range of 'authorisations', in the form of certificates, permits, approvals or licenses. These authorisations provide confidence to both the Capability Manager and the Australian Government that the aircraft is capable of safe flight.

6.1.2.3 While the respective DASRs define the required safety outcomes for these DASA authorisations, history has shown that additional guidance is needed if safety risks are to be efficiently and effectively eliminated or otherwise minimised so far as is reasonably practicable.

Purpose

6.1.2.4 This chapter guides Defence's aircraft acquisition organisations, relevant in-service organisations and Defence industry partners through the aviation safety requirements and recommended practices during the acquisition (whether through purchase, lease or other arrangement) of crewed aircraft that will be Defence registered.

Regulatory outcomes from the acquisition process

6.1.2.5 For a new Defence registered aircraft to operate, Command must ensure it is safe for flight. Command achieves this by ensuring the aircraft are designed, constructed, maintained and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation. In turn, if suitably assured of safety, DASA may issue a range of authorisations. Depending on the acquisition and support arrangements, this can extend to 12 different types of organisational, product and personnel authorisations, as follows:

1. organisational authorisations:
    i. Military Air Operator (MAO)
    ii. Military Design Organisation (MDO)
    iii. Military Production Organisation (MPO)
    iv. Approved Maintenance Organisation (AMO)
    v. Continuing Airworthiness Management Organisation (CAMO)
    vi. Maintenance Training Organisation (MTO)
    vii. Military Type Certificate Holder (MTCH) (currently an implicit authorisation)
2. product authorisations:

Superseded

i. Military Type Certificate (MTC) and associated Type Certificate Data Sheet (TCDS)

ii. Military Permit to Fly (MPTF)

iii. Aircraft Management Programme (AMP)

iv. Military Certificate of Airworthiness (CoA)

Note: *In addition, it may include a range of niche authorisations, for example a product conformity agreement, master minimum equipment list, and so on.*

3. personnel authorisations:

i. Military Aircraft Maintenance Licence (MAML)

Note: *DASA directly authorises certain management personnel within approved organisations. However, those authorisations are considered to be part of the organisational approval process in this chapter, so they are not separately listed here.*

6.1.2.6 Figure 1 summarises the range of DASA authorisations that are usually relevant to a new aircraft acquisition, grouped according to their relevance to aircraft design, construction, maintenance or operation. The subsequent paragraphs separately explore each group.

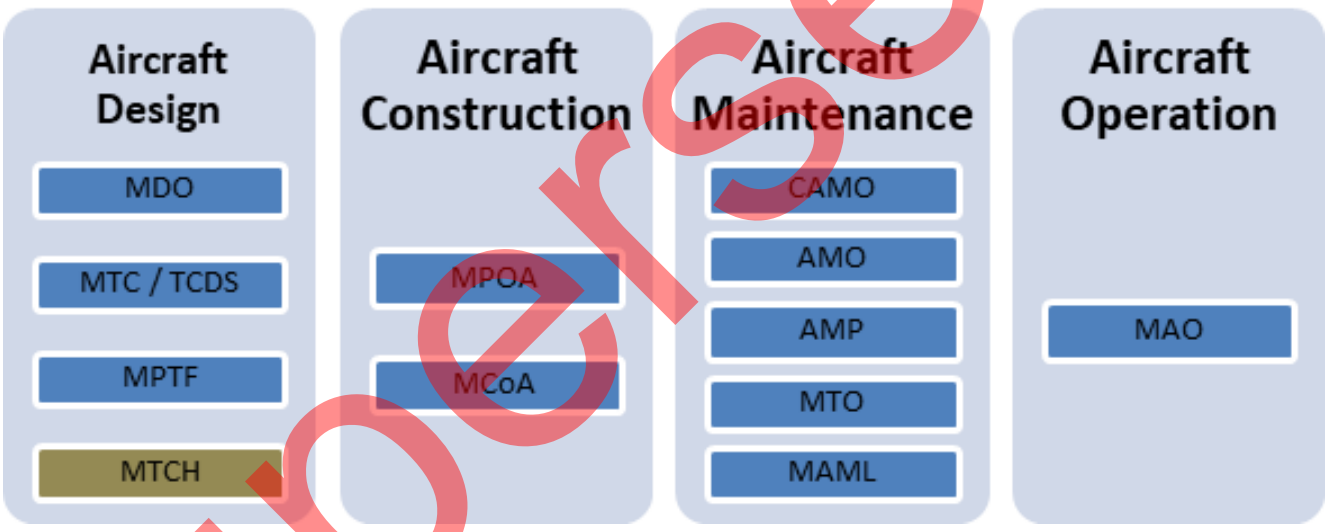

Figure 1: DASA authorisations relevant to Defence aircraft acquisitions[4]

Aircraft design (and certification)

6.1.2.7 New Defence crewed aircraft will normally be civil or military 'off-the-shelf' aircraft that are subsequently modified to meet Defence's capability requirements. Ensuring the final aircraft design is safe for flight in Defence's intended Configuration, Role and Environment (CRE) is a critical step in the acquisition process. Four separate DASA authorisations are relevant to this process, design, construction, maintenance or operation.

6.1.2.8 **Military Design Organisation (for initial aircraft design).** An organisation that has been approved by DASA to provide aircraft design services for a new Defence aircraft is termed a Military Design Organisation (MDO). These MDOs may be a military or industry organisation, and may be located in Australia or overseas. MDOs are often required for the design of new Defence aircraft,

Superseded

although as explored in the next four paragraphs, this requirement can be reduced, or even eliminated, in some circumstances.

6.1.2.9 **Military Type Certificate.** The Defence type certification process is central to confirming that the aircraft design is safe for Defence's intended Configuration, Role and Configuration (CRE) for the aircraft. At its core is the Type Certification Basis (TCB), which is a DASA-agreed set of airworthiness design requirements, including an airworthiness code and other standards, and tailoring to both as required.

6.1.2.10 At its extreme, type certification requires a DASA-approved MDO to create an aircraft design that complies with the TCB, and to produce evidence that demonstrates this compliance. In turn, DASA examines the evidence on a non-exhaustive basis, and if assured of safety, issues a Military Type Certificate (MTC)[5] and associated TCDS.

6.1.2.11 There is, however, a shortcut to the above approach that is employed for most Defence aircraft acquisitions. When Defence is procuring off-the-shelf aircraft or equipment, the Applicant[6] may seek relief from the need to develop new compliance demonstration evidence, to the extent an extant certification by a recognised National or Military Aviation Authority (NAA/MAA) is relevant to Defence's CRE. This is known as 'recognition of prior certification'. In rare circumstances, DASA can certify an entire new aircraft based solely on the prior certification of another NAA/MAA.

6.1.2.12 More commonly, however, Defence aircraft acquisitions employ a combination of the above two processes. That is, recognition of prior certification is used to cover the design of the off-the-shelf aircraft, and a DASA-approved MDO designs the Defence-unique modifications and produces the requisite compliance demonstration evidence. Sometimes another NAA/MAA may agree to certify some or all of the Defence-unique modifications, which may reduce or even remove the need for a DASA-approved MDO.

6.1.2.13 **Military Type Certificate Holder.** The MTC for a new Defence aircraft is issued by DASA to the Military Type Certificate Holder (MTCH), who takes on responsibility for ensuring the 'continued airworthiness' of the design[7]. This role is normally assigned to the relevant Defence SPO, who will implement standing arrangements with other Defence organisations, industry partners, and perhaps other militaries, to support the function. Amongst other things, the MTCH organisation is responsible for implementing systems for collecting, investigating and analysing aircraft occurrences which may affect its airworthiness, and holding (or providing access to) aircraft design information.

6.1.2.14 Note that DASA does not currently issue an explicit organisational approval for MTCHs, although this may change. Instead, the proposed MTCH arrangement is evaluated by DASA as part of its deliberations on whether to issue a MTC.

6.1.2.15 **Military Permit to Fly.** It is possible for DASA to issue a MTC for a new aircraft type immediately upon its addition to the Defence Register. More likely, however, there will be a period where the aircraft is not yet ready for a MTC because, for example:

1. the aircraft design is still under development
2. compliance demonstration evidence is still being created or compiled
3. Defence's MTC will leverage off the certification of another NAA/MAA, which is yet to be finalised

Superseded

6.1.2.16 DASA can issue a Military Permit to Fly (MPTF) to a MAO[8] in advance of the MTC if satisfied the aircraft design substantially complies with its agreed TCB, the configuration of the subject aircraft is clearly defined, the aircraft is capable of safe flight under defined conditions and for specified purposes, and any elevated risk has been justifiably retained. However, since the MPTF will usually impose (often significant) risk controls that limit the operation of the aircraft, extended operations under an MPTF are not common.

6.1.2.17 **Military Design Organisations (for in-service support).** Finally, throughout an aircraft's operational life, design changes are inevitable to remedy design defects, address obsolescence issues, design repairs, implement capability enhancements, and so on. These design changes will often be the purview of one or more DASA-approved MDOs, which are typically (but not essentially) the same as the MDOs that support the MTCH function.

6.1.2.18 Ultimately, both the MTCH and Continuing Airworthiness Management Organisation (CAMO – see below) must be able to demonstrate that sufficient design support arrangements are in place to maintain the safety of the aircraft[9], before a new aircraft is operated on the Defence Register. Depending on the aircraft acquisition contract, this design support function might initially be provided by the aircraft Original Equipment Manufacturer (OEM); if so, the in-service MDOs might not be needed immediately.

6.1.2.19 **Summary.** Summarised, the four DASA design-related authorisations that are usually relevant to aircraft acquisitions are presented in Figure 2. The MTCH is depicted in a different colour, to show that DASA does not (yet) directly issue an MTCH approval.

Figure 2: DASA authorisations related to aircraft design

6.1.2.20 DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MDOs, MTCs, MPTFs and MTCHs.

Aircraft production (or construction)

6.1.2.21 A MTC focuses on the safety of an aircraft's design. It does not consider the subsequent manufacture and assembly of the design, which is the purview of aircraft production (or

Superseded

'construction' in historic Defence parlance). The two DASA authorisations relevant to new aircraft production are Military Production Organisations and Military Certificates of Airworthiness.

6.1.2.22 **Military Production Organisation.** A Military Production Organisation (MPO) is a DASA-approved organisation that can manufacture and assemble parts, appliances, aircraft, engines or propellers to approved design data[10]. In the context of a Defence aircraft acquisition, MPOs can manufacture and assemble both the baseline aircraft (often called the 'green' aircraft) and the Defence-unique modifications to the green aircraft. They may be the same organisation, or there may be multiple different MPOs.

6.1.2.23 More commonly for new aircraft, however, Defence leverages the oversight provided by a DASA-recognised NAA/MAA of certain production organisations. This can reduce, or even eliminate, the need for DASA-approved MPOs.

6.1.2.24 **Military Certificate of Airworthiness.** As noted previously, a MTC is issued for an aircraft type. A separate DASA authorisation needs to subsequently be issued for each aircraft tail, namely the Military Certificate of Airworthiness (MCoA)[11], once DASA is satisfied the produced aircraft conforms to the design covered by the MTC. Central to DASA issuance of a MCoA is evidence that each product, part or appliance conforms to the approved design data and is in condition for safe operation.

6.1.2.25 A MCoA cannot be issued prior to the MTC. Where a new Defence aircraft is to be flown under a MPTF prior to the issue of a MTC, the MPTF effectively provides the function of the MCoA. As part of the process for seeking a MPTF, an applicant will need to demonstrate that the produced aircraft does indeed conform to the currently approved design data.

6.1.2.26 **Summary.** Summarised, the two DASA production-related authorisations that are usually relevant to new aircraft acquisitions are presented in Figure 3.

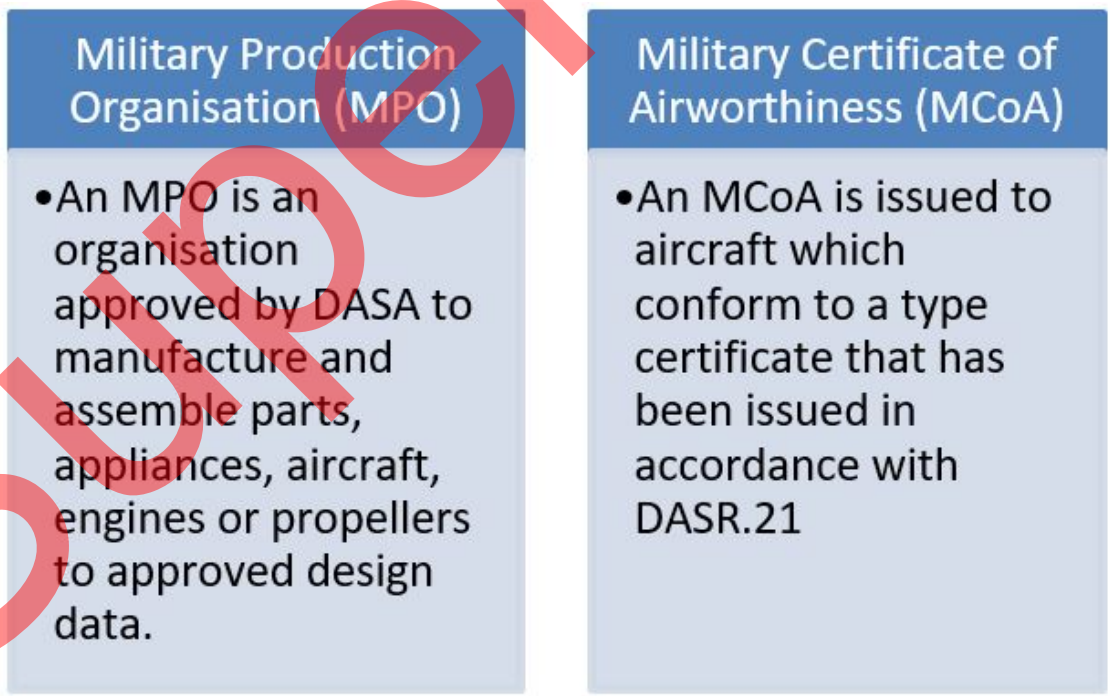

Figure 3: DASA authorisations related to production

6.1.2.27 DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MPOs and MCoAs.

Superseded

Aircraft maintenance (continuing airworthiness)

6.1.2.28 While Defence has long used the colloquial term of 'aircraft maintenance' to cover airworthiness activities beyond aircraft design and production, the DASRs purposely use the more expansive term of 'continuing airworthiness'. Aircraft maintenance is any one or combination of overhaul, repair, inspection, replacement, modification or defect/fault rectification of an aircraft or component. Continuing airworthiness encompasses this, plus maintenance management, maintenance training and maintenance licensing. For completeness, this section will use the term 'continuing airworthiness'.

6.1.2.29 Robust continuing airworthiness arrangements must be in place prior to the operation of a new Defence aircraft. Once assured of the sufficiency of these arrangements, DASA may issue three relevant organisational approvals, namely Continuing Airworthiness Management Organisations, Approved Maintenance Organisations and Maintenance Training Organisations. DASA may also approve Aircraft Maintenance Programmes and issue Military Aircraft Maintenance Licences to eligible personnel.

6.1.2.30 **Continuing Airworthiness Management Organisation.** Continuing Airworthiness covers all processes that ensure an aircraft continues to comply with initial airworthiness requirements and supports the ongoing validity of the aircraft's MCoA. The Continuing Airworthiness Management Organisation (CAMO), while not directly responsible for actual aircraft maintenance, is responsible for engaging organisations to conduct design and maintenance services. The CAMO will:

1. engage MDO(s) for design services as required
2. engage the MTCH for any matters that impact the aircraft's type design and type certification under MTC or an individual aircraft's CoA]
3. task AMOs to maintain products (aircraft, engines and propellers), parts and appliances and
4. provide governance and oversight to organisations performing DASR M functions on its behalf.

6.1.2.31 In most cases, the acquisition of a new aircraft type will not result in the creation of a new CAMO; rather, the scope of an extant CAMO will be expanded to include the new aircraft type. The presence of a suitable CAMO is integral to DASA's approval of a new MAO, or adding an additional aircraft to an extant MAO's scope.

6.1.2.32 **Aircraft Maintenance Organisations.** DASR provides two avenues for the maintenance of an aircraft and its components. The first is a DASA-approved Approved Maintenance Organisation (AMO), and the second is 'another maintenance organisation accepted by DASA'. A combination of both is usually employed for Defence aircraft.

6.1.2.33 An AMO is an organisation approved by DASA to conduct aircraft maintenance activities. This includes all actions required for restoring and maintaining an item in a serviceable condition including servicing, repair, modification, overhaul, inspection and determination of condition to maintain aircraft safety and airworthiness. AMOs may be a military or Defence Industry organisation, may be located in Australia or overseas, and may encompass one or multiple aircraft types. New Defence aircraft may be supported by one or several AMOs.

6.1.2.34 DASR Part M makes provision for maintenance services to be consumed from other maintenance organisations that are accepted by DASA. While the regulation infers that DASA explicitly accepts each of these maintenance organisations, this is not normally the case. Rather,

Superseded

DASA will automatically accept a maintenance organisation provided it is oversighted by a NAA/MAA that is 'recognised' as competent by DASA, and provided the CAMO ensures the conditions and caveats on the relevant 'recognition certificate' are met. Recognition certificates for each NAA/MAA recognised by DASA are available on DASA's website.

6.1.2.35 Prior to operation of a new Defence aircraft, the CAMO must demonstrate that arrangements are in place to maintain the aircraft in an airworthy condition. In limited circumstances, DASA may agree to the temporary absence of some maintenance arrangements, but only where this does not affect the near-term support of the aircraft.

6.1.2.36 **Aircraft Maintenance Programme.** An Aircraft Maintenance Programme (AMP) describes the scheduled maintenance tasks, their frequency of completion, the associated maintenance procedures, and so on, necessary to preserve the airworthiness of the aircraft. For aircraft acquisition projects, an initial AMP must be approved by DASA prior to the conduct of any maintenance activities. Maintenance activities can in some cases pre-date flying operations on the Defence Register, since they include aircraft preservation and other maintenance tasks required to prepare the aircraft for operation.

6.1.2.37 **Military Aircraft Maintenance Licenses.** AMOs require some personnel to hold particular categories of Military Aircraft Maintenance Licences (MAMLs). Furthermore, in order to be entitled to exercise certification privileges on a specific aircraft type, the holder of a MAML requires their licence to be endorsed with the relevant aircraft type ratings. As part of the AMO approval process for a new aircraft, the AMO will need to demonstrate that its personnel hold sufficient and applicable MAMLs.

6.1.2.38 **Maintenance Training Organisation.** A Maintenance Training Organisation (MTO) conducts training and examinations for maintenance personnel as specified in DASR 66. While a new MTO would rarely be required for a new Defence aircraft, an extant MTO would need to demonstrate its competence to conduct the type/task training and assessments for the new aircraft.

6.1.2.39 **Summary.** Summarised, the five DASA authorisations related to continuing airworthiness (of which maintenance is a component) of Defence aircraft acquisitions are presented in Figure 4.

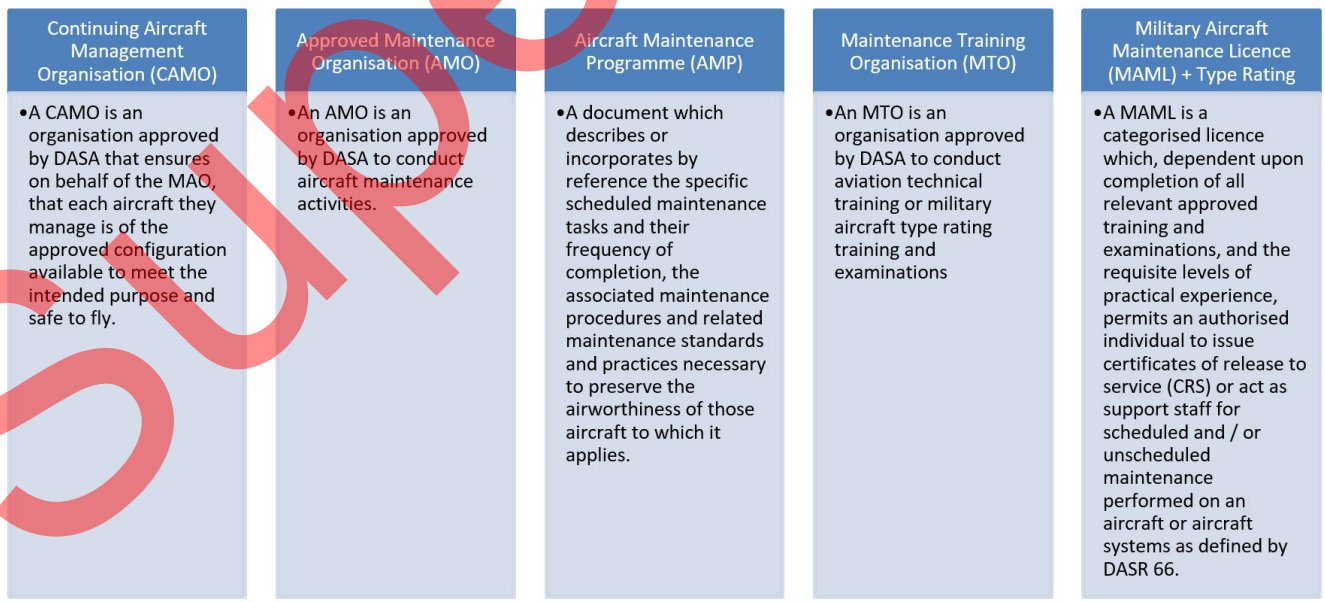

Figure 4: DASA continuing airworthiness-related authorisations

Superseded

6.1.2.40 DASPMAN Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into CAMOs, AMOs, AMPs, MTOs and MAMLs.

Aircraft operation

6.1.2.41 A Military Air Operator Certificate (MAOC) is the principal authorisation granted by DASA to conduct military air activities. Each aircraft type operated by the MAO is authorised by a separate DASA-issued Operations Specification (OpSpec) annex. The OpSpec annex details, amongst other things, key positions of the MAO, operating provisions, roles and tasks, specific approvals, and any limitations or conditions imposed by DASA.

6.1.2.42 The relevant OpSpec annex is required before first flight of the aircraft by the MAO[12]. DASA will issue the OpSpec annex once assured that the necessary Fundamental Inputs to Capability (FIC) elements, as well as quality and safety management systems, are in place to support intended operations.

6.1.2.43 Preparing a MAO to take on a new Defence aircraft can be a substantial undertaking. Amongst other things, for the new aircraft type the MAO will need to:

1. define the operating intent and usage for the aircraft through an approved Statement of Operating Intent and Usage (SOIU)
2. ensure arrangements are in place for maintaining the airworthiness of the aircraft through a CAMO and AMOs
3. implement the multitude of systems needed to manage Operations personnel and Air operations
4. produce/accept Orders, Instructions and Publications (OIP)[13]
5. establish an Aviation Safety Management System (ASMS).

6.1.2.44 Implementing these requirements, even for an existing MAO, is likely to require considerable planning and effort. Consequently, DASA recognises that a graduated capability growth plan for operational authorisations may be required. The Aviation Safety Acquisition Management Plan (ASAMP - see Chapter 6.1.1 and later in this chapter) is a suitable repository for reflecting the status of the acquisition program, including details of work completed, re-programing of remaining activities and risk management for the incomplete tasks.

6.1.2.45 **Summary.** Summarised, the singe DASA flight operations-related authorisation relevant to aircraft acquisitions is presented in Figure 5.

Superseded

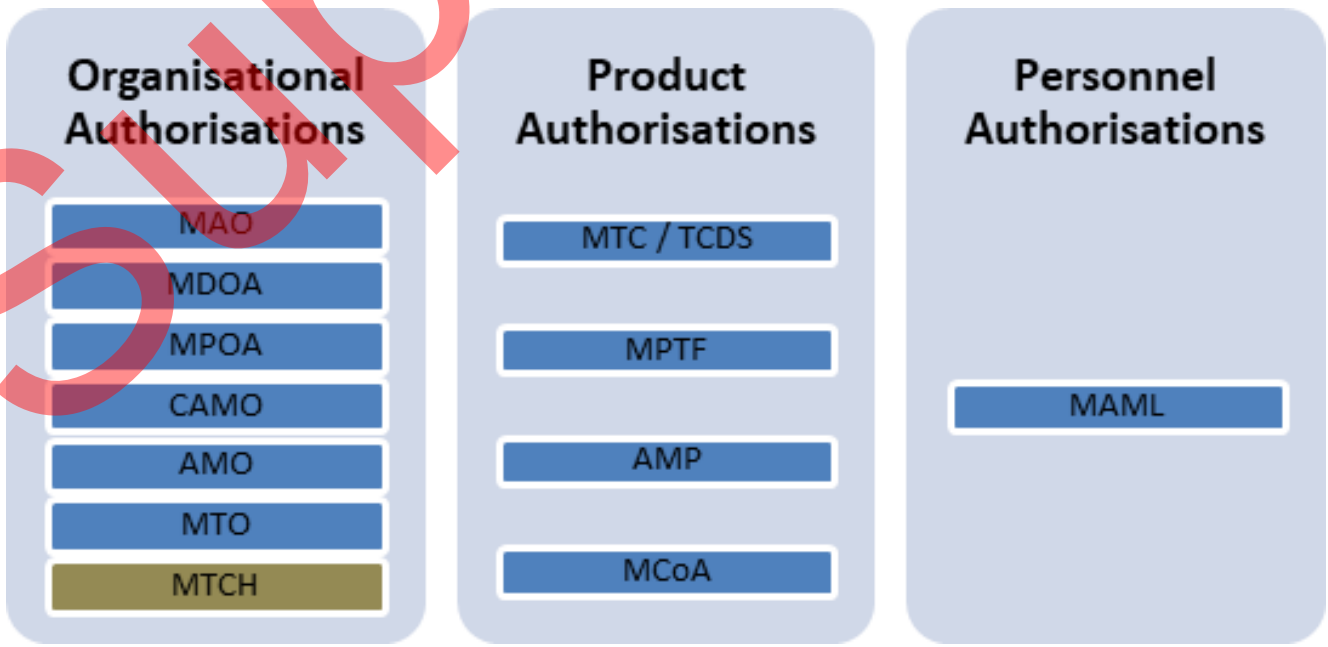
Figure 5: DASA authorisations related to aircraft operations

6.1.2.46 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MAOs.

Summary

6.1.2.47 This section has presented an overview of the DASA authorisations that may be relevant to new aircraft design, construction, maintenance and operation. Depending on the acquisition arrangements and the aircraft role, some authorisations might not be required.

6.1.2.48 The diagram at the start of this section (Figure 1) summarised all of the possible DASA authorisations according to whether they were relevant to new aircraft design, construction, maintenance or operation. However, another way of grouping them is according to whether they are organisational, product or personnel authorisations, as shown in Figure 6.



Superseded

Figure 6: DASA authorisations for new aircraft (grouped by category)

6.1.2.49 This grouping has the advantage that the eight organisational authorisations all use substantially the same processes for application and approval, and the three product authorisations have strong synergies. Consequently, for simplicity, this grouping will be used in the next section.

Processes, Plans and DASA Interaction

6.1.2.50 The previous section presented an overview of the DASA authorisations that may be relevant to new aircraft acquisitions. While the respective DASRs define the required safety outcomes for these DASA authorisations, history has shown that achieving the authorisations can be a complex and protracted journey. This section guides the reader though the process of achieving these DASA authorisations.

6.1.2.51 Figure 7 shows how the various DASA authorisations usually fit onto a project timeline. The vertical stripes present four significant milestones for introducing a new aircraft to Defence, the items above the dashed line show DASP-related project and Command activities, and the items below the line show the DASA authorisations. A time scale has purposely not been included, because this can vary enormously between aircraft acquisitions.

Superseded

Figure 7: Common project timeline for DASA authorisations

6.1.2.52 The elements below the dashed line can broadly be grouped into five activities, as shown in Figure 8. With the exception of Activity 1, the remaining activities are rarely sequential; more often than not Activities 2 and 3 are executed concurrently, and several activities may be cyclic.

Superseded

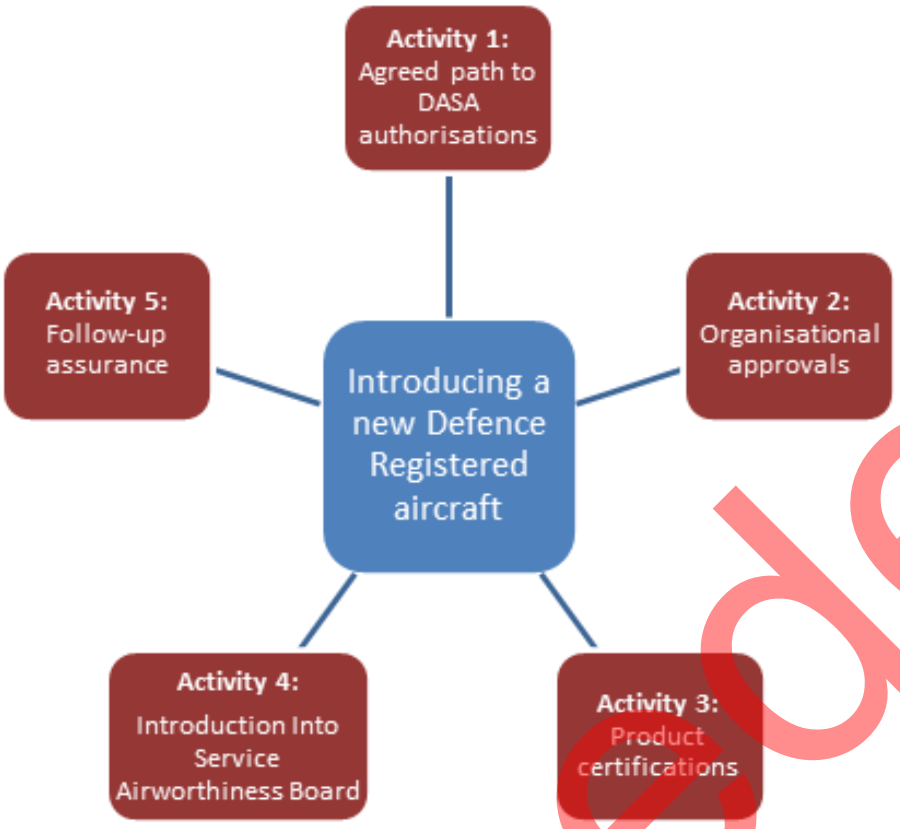


Figure 8: Activities in introducing a new Defence aircraft

6.1.2.53 Each of these five activities from Figure 8 is explored below.

Activity 1: Agreed path to authorisations

6.1.2.54 A major milestone in the aircraft acquisition process is the achievement of a range of DASA authorisations. However, establishing the contracts, systems and people to merit each authorisation is usually complex, with considerable potential to waste time and resources. Effective engagement with DASA is therefore in the best interests of all parties.

6.1.2.55 **Initial engagement.** Engagement should ideally commence as soon as Defence's acquisition organisation has a reasonable view on the candidate aircraft, the need for Defence-unique design changes, and the probable operating and support constructs[14]. Engagement should be well-advanced before Defence issues any tender documents (eg Requests for Tender, Foreign Military Sales Letter of Requests, etc) that may later affect an authorisation.

6.1.2.56 The initial engagement should involve DASA specialists, the Defence acquisition organisation, and capability manager representatives. If known, the Defence and industry organisations that will support the aircraft could also participate. Key outcomes will be:

1. a shared understanding of the project scope and schedule, candidate aircraft and the likely scope of Defence-unique design changes

Superseded

2. initial views on which of the seven DASA organisational approvals are likely to be needed and, for those that may not be needed, agree on the alternative means of achieving the same safety outcomes

3. initial views on how the aircraft might achieve an MTC, including how current or future certifications by DASA-recognised national or military airworthiness authorities (NAA/ MAAs) might contribute

4. initial views on whether an MPTF might be required to allow for test and other flying prior to the issue of an MTC

5. DASA should provide a management overview of each likely DASA authorisation, including: key milestones, common approval timeframes, recommended DASA collaboration, availability of training and other guidance material, and so on.

6.1.2.57 Annex A presents an expanded version of the above list, which can be used as a set of talking points for this initial engagement. Depending on the acquisition strategy, some of the details may initially be sparse. If so, further engagement should be scheduled for when the information is likely to become available, but still before releasing RFTs or equivalent documents.

6.1.2.58 **Documented agreement.** As noted in Chapter 6.1.1, DASRs do not mandate a plan or agreement for achieving DASA authorisations. It is, however, a practice that DASA highly recommends, given the substantial complexities in establishing the organisations and systems to manage aviation safety, and therefore the potential impacts (both positive and negative) on cost and schedule - and ultimately Defence capability.

6.1.2.59 DASA advocates the production of an Aviation Safety Acquisition Management Plan (ASAMP). The ASAMP is an iterative agreement between Applicants and DASA on the path to achieving DASA authorisations, and supports commanders and managers in accounting for parallel lines of effort and cross-regulation dependencies.

6.1.2.60 Annex B presents the suggested content and management arrangements for an ASAMP. Summarised, it suggests the main body of the ASAMP should describe the overarching aviation safety acquisition strategy and bring together the planned outcomes of the operational, technical, logistical and safety management activities. It should also describe the management of flight operations during acquisition, particularly if operations are to commence under an MPTF.

6.1.2.61 Annex B also suggests the ASAMP should include a series of annexes, with individual annexes dedicated to each DASA authorisation. Each annex could be sponsored by the relevant Applicant for the DASA authorisation, and could form an agreement between DASA and the Applicant on the path to the particular authorisation. For simple acquisitions, the annexes might directly present the information[15]. For more complex acquisitions, particularly where there are a range of Applicants for the various DASA authorisations, the annexes might merely contain a link to a planning document that is drafted and managed by the respective Applicant. Either way, the annexes should be 'modular', whereby each annex is configuration managed and approved separately to the main body of the ASAMP.

Superseded

6.1.2.62 The ASAMP should be drafted after the acquisition strategy solidifies (usually post Government approval), but before RFTs (or equivalent) are released. The ideal time to draft the ASAMP is usually soon after the initial engagement with DASA, and in fact that engagement will influence much of the ASAMP content. The ASAMP would normally be updated after contracts and agreements are signed, since the path to most DASA authorisations should be clear.

6.1.2.63 Once contracts and agreements are signed, the main body of the ASAMP need only be updated when there is a marked change in the acquisition strategy or high-level schedule for the project. The annexes, on the other hand, will probably be updated more frequently, particularly in the earlier stages of the project as knowledge and plans evolve.

6.1.2.64 **Ongoing engagement.** DASA's experience is that three forms of engagement should be maintained throughout the project lifecycle, as follows:

1. Periodic major stakeholder engagements, expanding on the initial engagement suggested previously in this section. This should occur throughout the acquisition project lifecycle, usually when significant milestones are approaching

2. Frequent coordination and status updates between senior project management staff (commonly the CASG Project Engineering Manager, the CM Transition Team lead, etc), and DASA's operational and technical leads for the acquisition

3. Engagement as required between each of the Applicants for a DASA authorisation and the respective DASA specialist.

6.1.2.65 **DASA assistance with contract reviews.** There is no DASR requirement for DASA to be engaged in seeking offers (eg RFT or equivalent), selecting the successful tenderer, negotiating the contract, and signing the contract. However, where a contract element may one day affect a DASA authorisation, prudent DASA involvement can reduce project cost and schedule risk. Areas where DASA can contribute include:

1. Prior to RFT (or equivalent) issue:

    i. confirming the RFT requirements for organisational approvals are appropriate for aircraft acquisition and/or in-service support

    ii. confirming the RFT airworthiness design requirements (including airworthiness codes and other standards), and proposed approach to aircraft certification, present a suitable pathway to MTC

    iii. confirming the RFT aircraft production arrangements present a suitable pathway to issue of MCoA

    iv. confirming aircraft registration pathways, particularly for significant modifications to a green aircraft by a third party

Superseded

v. providing expert input to specialist aircraft design technology requirements, such as aircraft structural integrity (ASI) design and in-service management systems.

2. For RFT assessment:

i. If any of the above RFT items seek preliminary plans for DASA organisational approvals or product certifications, then DASA can participate in the assessment of those plans

ii. otherwise, while the Defence acquisition organisation will conduct the tender evaluation, DASA staff are available for on-call advice and assistance as required[16]

3. For contract negotiation: DASA staff would rarely be directly involved in contract negotiations, but are available for on-call advice and assistance as required.

4. Final contract review: DASA does not review the mature contract prior to signature, but is available for advice and assistance as required.

6.1.2.66 **Delegations.** During the project lifecycle, organisations may elect to delegate their Command responsibilities, for example the appointment of the senior operator within the project transition team to make operational decisions in relation to the project. Once notified of the delegation, DASA will treat the decisions and approvals of the delegate as if the accountable manager had issued them.

6.1.2.67 Later in the project lifecycle, usually just before MTC issue, a 'Platform DoSA' will need to be appointed by DASA. The Platform DoSA role is normally delegated to the incumbent Defence CENGR of the platform MTCH organisation, and is responsible for assurance of MTCH actions with respect to reportable occurrences, issue of MCoAs, approval of flight conditions and issue of Airworthiness Directives. DASP Manual Volume 3 Chapter 4.3, Delegates of the Safety Authority, provides additional information.

Activity 2: Organisational approvals

6.1.2.68 Professional aircraft design, construction, maintenance and operation organisations are cornerstone to aviation safety. Implementing the required organisations for a new aircraft, and obtaining DASA approval of each organisation, is usually a significant activity for both the Applicants and DASA. This section explores the planning, establishment and assessment of new DASA-approved organisations.

6.1.2.69 **Planning.** As noted in Activity 1, the ASAMP should include a planning annex for each organisational approval. The ASAMP should plan for the organisational approvals to be achieved well prior to their need date, which are likely to be as follows:

Superseded

1. MAO: DASA authorisation is required prior to the first operation of the aircraft by the MAO[17]. This authorisation is reflected in DASA's issue of an OpSpec annex for the new aircraft

2. MDO:

   i. (for initial aircraft design): Required prior to design changes to the green aircraft, if those changes are not to be certified by a recognised NAA/MAA

   ii. (for in-service support): Required prior to first flight on the Defence Register, unless DASA has agreed to an alternative interim support arrangement

3. MTCH: Implementation of suitable MTCH arrangements are a prerequisite for issue of an MTC. However, depending on the acquisition arrangement, some of these functions may need to be in place earlier to support the initial MPTF

4. MPO: Required prior to any aircraft production activity, unless an alternative production approval path has been agreed by DASA

5. CAMO: Required prior to first flight of the aircraft on the Defence Register

6. AMO: Required prior to first flight of the aircraft on the Defence Register[19], unless an alternative interim maintenance arrangement has been agreed by DASA. AMOs will need MAMLs in sufficient numbers to meet AMO needs, relevant to the scope of operations and numbers of aircraft

7. MTO: Agreed in consultation with DASA.

6.1.2.70 Note that while DASA agreement to the above authorisation plans is not a regulatory requirement, it is encouraged by DASA. As Figure 9 shows, the time needed to implement a new organisation and then achieve a DASA organisational approval can be substantial, so careful management is needed to minimise Defence's schedule risk.

Superseded

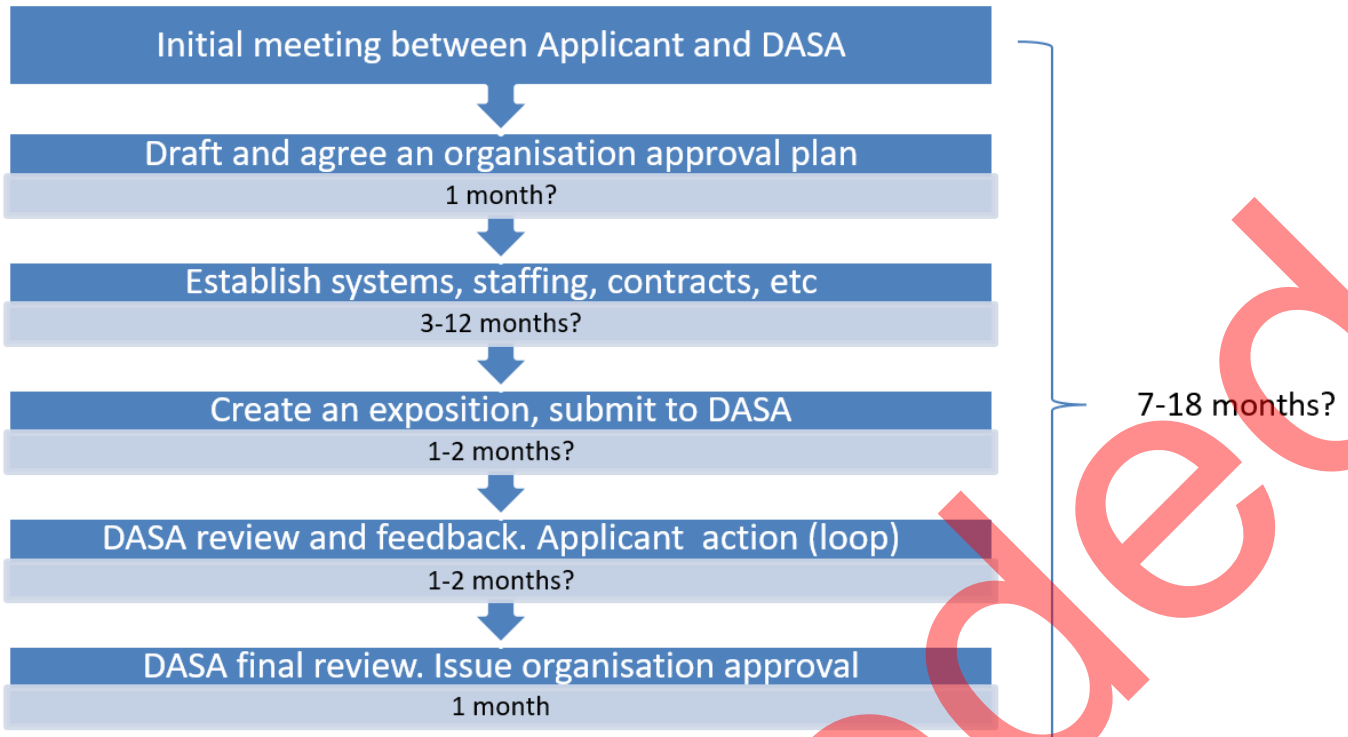

Figure 9: Timeline for DASA organisational approvals

6.1.2.71 **Establishing organisations.** DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, presents a description of each DASA organisational approval, including the key artefact(s) needed to show regulatory compliance - for example, the MDO's design organisation handbook, the AMO's Maintenance Organisation Exposition (MOE), the MAO's Operations Compliance Statement (OCS), and so on. Each of these artefacts will help guide the Applicant's efforts to establish an organisation that professionally supports Defence aviation safety, as will the Acceptable Means of Compliance (AMC) and Guidance Material (GM) accompanying the relevant DASRs. DASA-sponsored education courses and DASA website material also offer useful information.

6.1.2.72 However, Applicants must bear in mind that such guidance may be incomplete, or not entirely relevant to the local context. Consequently, DASA cannot overstate the importance of the Applicant's role in refining the organisation beyond DASR (and DASA) requirements. This might include, for example:

1. learning from other Defence organisations
2. learning from comparable civil organisations[20]
3. exploring the (often extensive) guidance material released by other NAA/MAAs[21]
4. consulting with staff and others with relevant domain expertise.

6.1.2.73 A robust and evolving Aviation Safety Management System (ASMS) is pivotal to establishing an organisation that optimises its contribution to Defence aviation safety. An ASMS utilises a systematic

Superseded

approach to managing aviation safety, including organisational structures, accountabilities, policies and procedures. An effective ASMS continuously improves an organisation's safety performance through pro-actively collecting and analysing safety data to predict, prevent and treat aviation hazards and risks. DASP Manual Volume 3 Chapter 6.2, Safety Management, provides further guidance.

6.1.2.74 **DASA assessment.** The annexes in Chapter 5.3 provide insight into DASA's approach to assessing, and ultimately approving, a new or expanded organisational approval. Most approvals follow a similar process, namely:

1. the Applicant drafts an 'Exposition' or similar document, as key evidence that their organisation has implemented the systems and processes needed to comply with the relevant DASRs

2. the applicant submits the relevant DASR Form to seek an organisational approval

3. DASA conducts an assessment of the Exposition and the documents it references, often as a desktop activity for new organisations; on occasion DASA may do an on-site assessment

4. if needed, the applicant remedies any deficiencies that preclude DASA's approval of the organisation

5. DASA issues an organisational approval, perhaps initially limited in scope

6. once the aircraft is operating and the organisation has the opportunity to exercise its approval, DASA will conduct a deeper assessment, usually including an on-site visit, placing particular emphasis on the effectiveness of the ASMS and system monitoring.

6.1.2.75 Figure 10 summarises the path through to DASA approval for the seven organisations common to new aircraft acquisitions.

Superseded

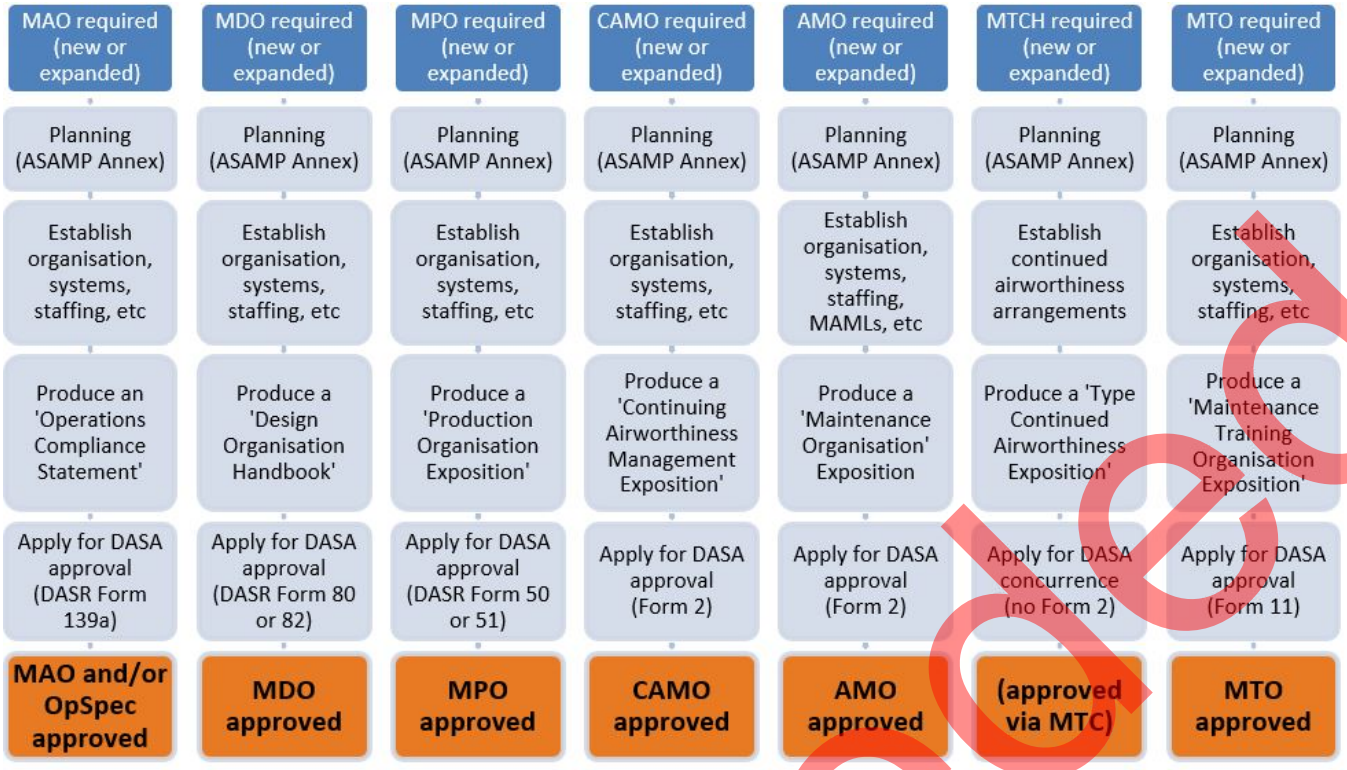

Figure 10: Path to DASA organisational approvals

Activity 3: Product authorisations

6.1.2.76 The four common product authorisations for new aircraft are the MTC, MCoA, MPTF and AMP. While an MPTF will often be issued prior to an MTC and MCoA, preparatory work on the other two will usually precede and support the issue of the MPTF. Hence, this section will consider the MPTF last.

6.1.2.77 Before exploring the four product authorisations, some brief discussion on safety risk management is warranted. Risk management is almost always a contributor to MTC and MPTF authorisations, so all stakeholders need to be conversant with Defence's 7-step risk management approach, as explained in the DASA Advisory Circular 003/2018, Risk Management in the DASP. Furthermore, DASA's experience is that this risk management is most effective when all parties robustly consult, cooperate and coordinate with each other. Critically, this must occur across organisational boundaries, and across specialisations (most notably between operators and engineers).

6.1.2.78 **MTC.** Achieving an MTC for a new aircraft is a significant milestone for an aircraft acquisition project, and one that commonly takes substantial planning and effort. While the path to an MTC is explored in DASP Manual Volume 3 Chapter 7.2, Certification, for the benefit of readers not needing that depth of information, a brief description of the process is included here.

Superseded

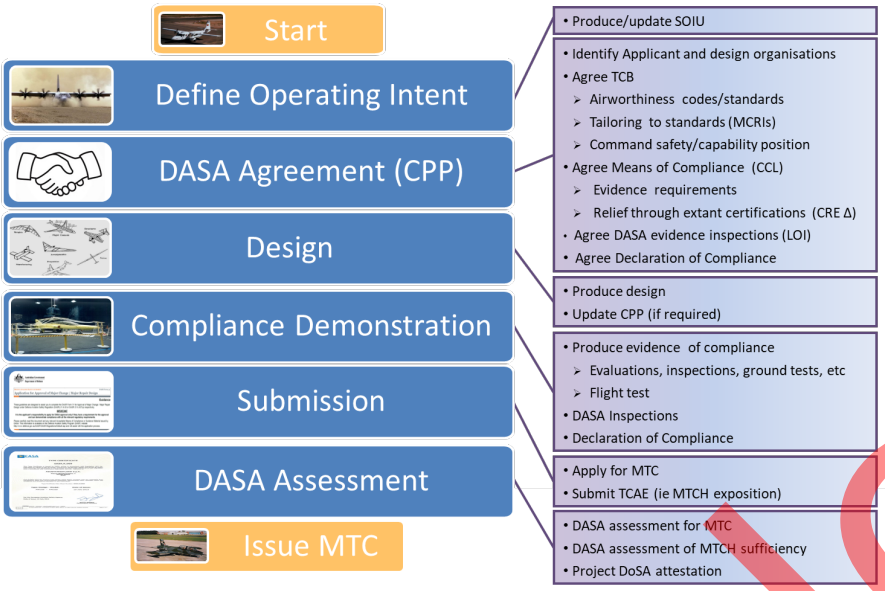

Figure 11: Path to issue of an MTC

6.1.2.79 An overview of the type certification process, culminating in an MTC, is shown in Figure 11. The first step, defining the operating intent for the aircraft, is pivotal to designers producing a design that is safe for Defence's intended Configuration, Role and Environment (CRE). A poorly-developed operating intent, or one developed late in the design lifecycle, can (and previously has) resulted in:

1. additional cost to re-design elements of the aircraft
2. operational limitations to eliminate the elevated risk, or
3. management and retention of elevated risk, often for the life of the aircraft.

6.1.2.80 The second step shows the Applicant and DASA agreeing on a Certification Program Plan (CPP). While a CPP is not explicitly required by DASR, it is inconceivable that Defence would pursue a certification program without an agreed CPP, since it imposes obligations on both the Applicant and DASA. Critically, the CPP:

1. agrees on the Type Certification Basis (TCB) for the new aircraft, which comprises the airworthiness requirements (inclusive of tailoring) that the design must meet
2. agrees on the evidence that will be produced by the design organisation(s) to demonstrate the design complies with the TCB
3. agrees on the application of 'recognition of prior acceptance', where existing product certifications by DASA-recognised NAA/MAAs will contribute to the certification of Defence's new aircraft [22]
4. defines the extent of DASA's inspections of compliance demonstration evidence.

Superseded

6.1.2.81 The tailoring of the TCB, mentioned in the first sub-paragraph above, is accomplished using one of five types of Military Certification Review Item (MCRI)[23]. Four of these MCRIs either maintain or improve the safety of the aircraft design, while the fifth, the 'Exception MCRI', can approve a reduction in the safety of the aircraft design. This reduction is only justifiable where requiring compliance with a TCB requirement would adversely affect Defence capability. While DASA ultimately approves the Exception MCRI, it is based heavily on Command's confirmation that a capability imperative exists, and that the risks due to the TCB non-compliance have been eliminated or otherwise minimised SFARP. The document used to communicate and record these Command risk decisions is normally the Airworthiness Issue Paper (AwIP). Guidance for AwIPs is provided at annex C.

6.1.2.82 The third step in the certification process is where the design organisation produces the design. For new Defence-unique designs, this often requires a DASA-approved MDO unless the design will be certified by a DASA-recognised NAA/MAA, as explained earlier in this chapter. The MDO must be in place before the design effort commences.

6.1.2.83 The fourth step, Compliance Demonstration, is where the MDO produces evidence that their design meets the DASA-agreed TCB. This step may require DASA approval of an MPTF to enable flight testing if the aircraft is already on the Defence Register. The MPTF is explored later in this section.

6.1.2.84 The fifth and six steps wrap up the certification process, and are largely self-explanatory. It is worth noting that while an Airworthiness Board (AwB) is not a prerequisite for DASA issue of an MTC, if the Defence Aviation Authority (Defence AA) elects to convene an AwB near to the MTC issue date, then DASA may wait until after that event to issue the MTC. AwBs are explored later in this chapter.

6.1.2.85 **MCoA.** As noted previously, an MCoA cannot be issued prior to the MTC. However, it is normal practice for the Defence acquisition organisation to be prepared in advance, so DASA[24] can issue MCoAs for the delivered fleet directly following the issue of the MTC. DASPMAN Volume 3 Chapter 5.3 presents the conditions and processes for MCoA issue.

6.1.2.86 **MPTF.** Once a new aircraft type has been added to the Defence Register, but prior to issue of the MTC, MAOs may need to operate the aircraft. For example, the flight test MAO may need to conduct flight tests to generate compliance demonstration evidence, and to contribute to operational test and evaluation (OT&E). The operational MAO may need to maintain crew currency, evolve OIP, conduct OT&E, and so on.

6.1.2.87 DASA can issue an MPTF if the aircraft design has been shown to substantially comply with its TCB, the configuration of the aircraft is clearly defined, the aircraft is capable of safe flight under defined conditions, and any elevated risk has been justifiably retained. An MPTF is effectively reliant on both the MTC and the MCoA processes being well-advanced.

6.1.2.88 The initial MPTF will usually constrain the MAO's operation of the aircraft. After all, the type certification program is still incomplete so there will be areas of the design that are known to be deficient or where uncertainty still remains, and hence the MPTF will impose commensurate risk controls. DASPMAN Volume 3 Chapter 7.5, Flight Conditions and MPTFs, explores MPTFs and their associated flight conditions, including risk management, the application process, periods of validity, and so on. The MAO will often self-impose additional constraints on flight operations, and will ease these constraints as the systems and personnel skills mature.

Superseded

6.1.2.89 **AMP.** CASG's Reliability and Aircraft Maintenance Program (RAMP) team, which is collocated with DASA's Melbourne office, provides Defence's centre of expertise for AMPs, and advises DASA on whether an AMP should be approved[25]. Both DASA and the RAMP team should be engaged early in the acquisition phase for guidance on AMP requirements.

Activity 4: Convene an Airworthiness Board

6.1.2.90 As discussed in Chapter 6.1.1, the Defence AA would normally require that an AwB be convened prior to operation of a new aircraft on the Defence Register[26]. The Introduction into Service AwB, normally held immediately prior to the commencement of flight operations, complement regulatory activities conducted by the DASA and build on the confidence of DASA authorisations. This AwB is underpinned by progressive check-ins by the board members with both DASA and the regulated community, focussing on:

1. understanding the status of DASA assurance of relevant products and organisations
2. safety assurance of the collective enterprise (CM, CASG, Industry) introducing the new platform;
3. potential organisational culture hazards; and
4. transition safety risks associated with the introduction of the capability through to reaching initial operational capability milestones.

6.1.2.91 The artefacts submitted by Applicants to the AwB would predominantly consist of already produced project documentation and attestations that collectively summarise the readiness to commence Flight Operations:

1. Airworthiness Plans, Artefacts, Approvals and Authorisations
2. FIC Status and Capability Realisation
3. Integrated Airworthiness System Assessment
4. MAO Risk Management and OIP

6.1.2.92 The Defence AA would normally require progressive AwBs during the initial operating period for a new aircraft, most likely aligned with key Operational Capability milestones. Hence the AwB can explore whether the operational and support systems are maturing commensurately. Periodicity might be influenced by the severity of organisational and/or product deficiencies noted during DASA assurance activities and/or a previous AwB.

6.1.2.93 Annex D presents additional guidance on the submissions, requirements and conduct of an AwB for a new aircraft type.

Superseded

Activity 5: Follow-up DASA assessments

6.1.2.94 The organisational and product authorisation requirements presented in this chapter are seldom wholly implemented when the Applicants apply for the relevant DASA authorisations. Provided DASA is satisfied the safety risks due to the deficiencies can be robustly managed, this may not preclude DASA from issuing the authorisation, as explored in the following paragraphs.

6.1.2.95 **Organisational approvals.** When DASA initially issues an organisational approval, the processes and people may not yet have been exercised for the new aircraft type. For example, an MDO may not have produced designs, the MAO may not have exercised its ASMS, organisational deficiencies may have been identified by DASA, and so on. Equally, the organisation may self-identify temporary deficiencies in their own processes and people.

6.1.2.96 These issues may not preclude DASA from issuing the organisational approval if satisfied the organisation has the ability to safely operate and support the aircraft. DASA may elect to moderate this risk through, amongst other things:

1. placing limitations on operations, initially via the initial MPTF and later via the OpSpec
2. initially constraining the 'privileges' that are available to organisations under some regulations
3. re-visiting the organisation soon after their systems and processes have been exercised.

6.1.2.97 Over time, once DASA is assured the deficiencies or lack of experience have been addressed, the constraints may be eased. The Defence AA may convene AwBs to provide additional confidence.

6.1.2.98 **Product authorisations.** As a matter of pragmatism, a MTC can be issued before compliance with the TCB has been entirely demonstrated. As a result, the MTC may include temporary limitations, or the TCB may include temporary Exception MCRIs (with supporting AwIPs documenting essential risk management), pending resolution of the outstanding design issues. Once evidence of TCB compliance is provided to DASA's satisfaction, the limitations or other risk management measures can be progressively removed.

Project completion

6.1.2.99 Even after the above five activities have been substantially completed, residual issues may still be outstanding. Provided these issues are sufficiently few in number and complexity[27], they have been professionally transitioned to the running system, and any associated risks are being managed in the relevant ASMS, DASA will in due course consider the acquisition project to be closed.

6.1.2.100 The residual issues will be monitored by DASA through normal compliance assurance activities.

Niche Applications

Superseded

6.1.2.101 So far, this chapter has focused on new aircraft types being acquired by Defence. This final section will explore three niche applications of the information presented in this chapter, namely fleet additions, acquisition of used aircraft, and Major design changes to in-service aircraft.

Fleet addition aircraft

6.1.2.102 When additional aircraft are to be added to an extant Defence fleet, the guidance presented earlier in this chapter is still mostly relevant, although it can be applied in a substantially abbreviated form. An assessment of each of the five activities from the previous section is presented below.

6.1.2.103 **Activity 1: Agreement on DASA authorisations.** The information presented in the previous section is entirely relevant. That is, the acquisition organisation should engage with DASA before contracts and other agreements are signed, and an agreed path to DASA approvals should be documented in an ASAMP. The ASAMP will be much abbreviated compared to the acquisition of a new aircraft type, and some of the ASAMP annexes will not be required.

6.1.2.104 **Activity 2: Organisational approvals.** Each of the organisational approvals will likely be in place, so this activity is limited to ensuring those organisations can manage the additional workload and (where applicable) the configuration differences of the new aircraft.

6.1.2.105 **Activity 3: Product certifications.** If the new aircraft are precisely the same configuration as the extant fleet, they can simply be listed on the MTC and individual MCoAs then issued for each new aircraft. More likely, however, there will be configuration differences. While other avenues may be acceptable, most often the new aircraft are added to the MTC mirroring the configuration of the extant fleet, and the configuration deltas for the new aircraft are processed as design changes (Major and Minor) to the common type design. If there will be a delay in completing this activity, an MPTF can be used to cover the configuration differences of the additional aircraft.

6.1.2.106 If there are substantial configuration differences to the extant fleet, perhaps even with changes to the TCB, the new aircraft might need to undergo a targeted type certification program that focuses on the configuration deltas. DASA's approval may be reflected as a separate model number on the MTC, or the deltas might be encompassed in a Military Supplemental Type Certificate (MSTC).

6.1.2.107 **Activity 4:** AwB. AwB independent review of additional aircraft would normally be considered as part of the next scheduled sustainment AwB. In exceptional circumstances, a separate AwB may be convened if the acquisition of additional aircraft requires appreciable changes to extant FIC arrangements.

6.1.2.108 **Activity 5:** Follow-up DASA assessments. The information on product deficiencies presented in the previous section is equally relevant to fleet addition aircraft. The information on organisational deficiencies, on the other hand, is unlikely to be applicable; rather, the next routine compliance assurance activity would check how the organisation is coping with the extra workload.

Used aircraft

Superseded

6.1.2.109 Where Defence elects to acquire used aircraft, the guidance presented earlier in this chapter is entirely relevant. However, there are additional actions that will need to be undertaken for Activity 3: Product Certification, namely the provision of additional documentation and the completion of additional inspections to support the issue of an MCoA.

6.1.2.110 **Documentation.** DASR 21.A.174 presents a list of the additional documentation needed for a used aircraft, namely:

1. (if the aircraft originates from a foreign military applying an EMAR based regulations): a Military Airworthiness Review Certificate;

2. (if the aircraft originates from a civil state of registry that is recognised by DASA): an export certificate of airworthiness from the recognised CAA;

3. (if the aircraft originates from elsewhere):

    i. a statement by the Authority of the State where the aircraft is, or was, registered, reflecting the airworthiness status of the aircraft on its register at time of transfer

    ii. a weight and balance report with a loading schedule

    iii. the flight manual and any other manuals required by the Authority of the State of registry

    iv. historical records to establish the production, modification, and maintenance standard of the aircraft, including all limitations associated with a restricted certificate of airworthiness

    v. a recommendation for the issuance of a certificate of airworthiness or restricted certificate of airworthiness and a Military Airworthiness Review Certificate following an airworthiness review in accordance with DASR M.

6.1.2.111 **Inspections.** Used aircraft require a more stringent inspection than new build aircraft, and must be performed by an appropriately qualified, independent and experienced organisation. The inspecting organisation is to conduct a comprehensive review of the aircraft design, maintenance and operational documentation, verified by a physical inspection of the airframe structure, engines and other systems.

6.1.2.112 The inspecting organisation is to provide inspection reports detailing the airworthiness inspection result. As a minimum, reports should include the following:

1. details of the aircraft inspected, including registration number, manufacturer, serial number, model designation, and Certificate of Airworthiness number

2. last known inspected configuration of the aircraft

Superseded

3. a summary of the usage and maintenance history of the aircraft, engines and propellers, including current maintenance, weight and balance, and lifed component status

4. details of any major structural and life-limited component changes made to items such as wings and tailplane, and a summary of the individual histories of such components, unless new when fitted

5. details of any accidents or incidents in which the aircraft has been involved

6. details of any major repairs or modifications performed on the aircraft, engines and propellers and verification that they have been properly approved and incorporated

7. details of any applicable aircraft-general, type-specific, engine or equipment airworthiness directives or service bulletins and verification that the aircraft complies

8. a condition assessment of flight safety critical components and fatigue-sensitive structure

9. recommendations for the resolution of any airworthiness deficiencies or concerns arising as a result of the airworthiness inspection

10. flight manuals and any other manuals.

6.1.2.113 Should Defence be contemplating the acquisition of used aircraft, DASA should be contacted early in the decision process. DAVENG staff in particular will provide the acquisition project with useful guidance.

Major design changes

6.1.2.114 This chapter has so far focused on aircraft acquisitions. However, the content can be extensively applied to particularly complex Major design changes to in-service aircraft. A Major design change is one that has an appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product .

6.1.2.115 Defence currently conducts around 70 Major design changes to its fleet each year. Most of these design changes have little if any significant impact on the aircraft operator or support organisations. Occasionally, however, Defence undertakes a Major design change whose effects pervade the DASP.

6.1.2.116 An example might be an extensive mid-life cockpit upgrade, which will not only challenge the design organisation, it can extensively affect MAO OIP, require simulator upgrades, change the aircrew training curriculum, allow new Performance Based Navigation approvals, require additional maintenance equipment and training, require new production organisations, require parallel operations of two different aircraft configurations for extended periods, and so on. An extensive flight test program to explore human factors and other certification issues might also be required.

Superseded

6.1.2.117 Making such pervasive changes to the aircraft and supporting systems can be a complex undertaking that requires coordination and often robust risk management across multiple organisational boundaries. While it perhaps does not have the complexities of introducing a new aircraft into service, it is far from straightforward and can introduce elevated safety risks if not executed well. In such circumstances, increased independent assurance from DASA is likely to benefit aviation safety.

6.1.2.118 Where DASA, in consultation with the MAO and CASG, identifies a Major design change that warrants this expanded DASA independent assurance, DASA will treat the project similarly to an aircraft acquisition. This may include, for example, increased scrutiny of organisational approvals, a closer assessment of how the new configuration is introduced into service (including, if necessary, imposing temporary operating constraints), greater assurance of risk management decisions, and so on. The Defence AA may require an AwB to be convened to provide an independent review of how well the new configuration has been integrated into Defence.

6.1.2.119 For these Major design changes, the guidance in the previous section is applicable almost in its entirety. Notably, an ASAMP should be raised, albeit some elements will self-evidently either be of limited scope or not applicable. An SOIU update may be required, organisational approvals may need to be expanded, and so on. The only element that is unchanged is the type certification process, since DASA certification oversight is always implemented commensurate with risk, and this is unaffected by the additional DASA scrutiny outlined in this section.

Annexes:

1. Project Initiation Meeting
2. ASAMP Guidance
3. Airworthiness Issue Papers
4. Airworthiness Board Guidance

6.1.3 Acquisition of Non-Defence-Registered Aircraft

Introduction

6.1.3.1 Civil registration of a Defence aircraft may be attractive to Capability Managers (CMs) and acquisition organisations. It may provide contractual and ongoing management simplicity, and sometimes lower costs and result in a faster introduction into service.

6.1.3.2 Regardless of the registration arrangement, Command retains the responsibility for ensuring the safety of aircraft occupants, other aircraft, people, and facilities on the ground. However, in the case of non-Defence-Registered (NDR) aircraft, DASA has a comparatively lesser role in guiding and assisting Command in meeting these obligations.

Purpose

Superseded

6.1.3.3 This chapter guides Defence's aircraft acquisition organisations and Military Air Operators through the aviation safety requirements and recommended practices during the acquisition of an NDR aircraft, but only to the extent, that DASA is involved in the process.

CONTENT UNDER REVIEW

Circa 2023, DASA is currently conducting a major review of the DASA approach and regulations for non-Defence Registered (NDR) aircraft. The review will assess, amongst other things, the legal implications of a State aircraft being regulated by a civil regulator, the need (if any) for DASR regulations to supplement the civil regulations, the role of DASA (if any) in aviation safety assurance, and so on.

Once the review is completed, DASR.NDR and this DASPMAN chapter will be updated. In the meantime, Defence organisations considering the acquisition of a NDR aircraft should contact DASA for advice.

Superseded

Annex A - Project Initiation Meeting

(a) This annex is intended to guide an initial project meeting between the Defence acquisition organisation, the capability manager and DASA specialists. On the DASA side, participants should include the Directors and/or their senior representatives from DIA, DAVNOPS, DCA and DAVENG.

Note: *Some of this information may already have been provided to DASA, if a meeting to explore Defence versus civil registration of the aircraft was convened, as discussed in Chapter 6.1.1*

(b) The following outline could be used as the basis for a meeting agenda.

Project Overview

(c) The acquisition lead should provide an introductory overview of:

1. the project aim and scope
2. the acquisition approach, including proposed contracts and agreements
3. the candidate aircraft type(s)
4. the likely scope of Defence-unique design changes
5. the broad schedule for contract signature(s), design, delivery, addition to the Defence Register, initial operation, etc
6. an overview of the Defence acquisition team (eg project office, capability sponsor, transition team, industry partners, etc)
7. any other information that will help participants understand the next items.

Aircraft operation

(d) The capability manager should ensure all participants have a broad understanding of likely arrangements for aircraft operations, including:

1. Who is the MAO(s)?
2. What is the scope of operations envisaged under the initial operational approval?
3. What is the status of the SOIU?
4. For existing MAOs, provide insight into the likely effort needed to adapt extant FMS, OIP, QMS, SMS, etc
5. What new operations facilities and buildings will be needed?
6. What are the MAO's broad plans for initially operating the aircraft, and then growing the capability over time?

Superseded

(e) The ensuing discussion should ensure that participants have sufficient context and information to draft and approve the MAO-related elements of the ASAMP.

Aircraft design, construction and maintenance

(f) The acquisition lead should ensure all participants have a broad understanding of likely arrangements for aircraft design, construction and maintenance. The information may be shallow at this stage; detail can be explored in subsequent sub-meetings with the relevant specialists.

(g) **Aircraft Design (and certification).** Based on whether the aircraft will be a continuous "State' aircraft, a decision regarding the type of aircraft registration can be made. Where Defence Registration of the acquired aircraft is being considered by the acquisition SPO and MAO, establish a shared broad understanding of the likely arrangements for initial design of the aircraft, and then in-service support of the design.

1. For the green aircraft (ie the unmodified common aircraft off the production line):
   i. To what extent has the green aircraft been certified by a DASA-recognised CAA/MAA? When?
2. For the Defence-unique modifications:
   i. Who will design the modifications?
   ii. Will another CAA/MAA certify the modifications (whether partially or fully) for Defence? From this, broadly understand the residual certification work that will fall on Defence.
   iii. Will DASA need to approve an MDO for the design? If so, who will be the applicant?
   iv. What does the project office expect their role will be in the type certification process?
   v. What is the broad schedule for certification?
3. Initial operations on the Defence Register (under MPTF):

Superseded

i. What scope of flight test may be needed?

ii. What scope of operations does the MAO intend to initially conduct under the MPTF?

iii. What is the broad schedule?

4. Military Type Certificate Holder (MTCH):

i. Which SPO will lead the MTCH function?

ii. Who will comprise the MTCH organisation

iii. What support from other organisations (eg other militaries) is there likely to be?

5. For in-service design functions (eg designing future modifications and repairs), which MDO approval will be required?

(h) **Aircraft production (construction)**. Establish a shared broad understanding of the likely arrangements for production of both the green aircraft and Defence-unique design changes

1. For the green aircraft:

i. Who will produce the aircraft?

ii. To what extent will a DASA's recognised CAA/MAA oversight the production of each Defence tail?

2. For the Defence-unique modifications:

i. Who will incorporate the Defence-unique modifications onto the aircraft?

ii. To what extent will a DASA's recognised CAA/MAA oversight the production of each Defence tail?

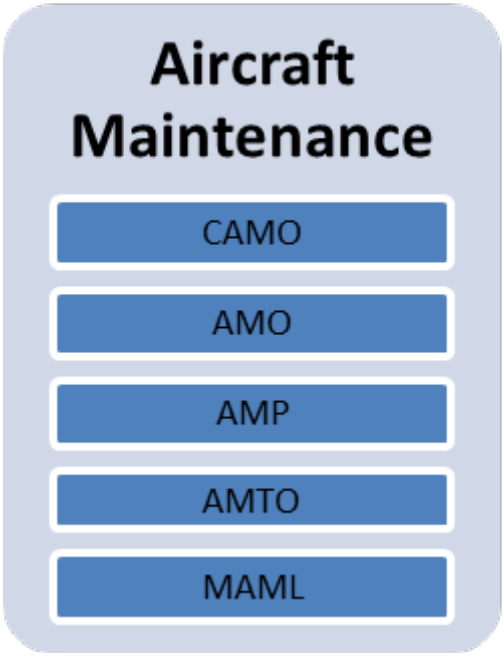
iii. Will DASA need to approve a MPO?

iv. Where Defence-unique modifications are made to used green aircraft, how will continuing airworthiness obligations be met?

3. What is the proposed broad approach to achieving Military Certificates of Airworthiness?

(i) **Aircraft maintenance**. Gain a shared broad understanding of the likely arrangements for aircraft maintenance:

Superseded



1. CAMO:
   i. Who will lead the CAMO function?
   ii. What organisations are likely to support the CAMO function?
2. AMOs:
   i. What Defence AMOs are proposed, and what is their likely scope?
   ii. What Industry AMOs are proposed, and what is their likely scope?
   iii. What works will be needed to create suitable facilities, and when is this scheduled?
   iv. What is the broad schedule for establishing the AMOs?
   v. What MAMLs are likely to be needed for each?
3. AMP:
   i. Will aircraft preservation activities be required after the aircraft is added to the Defence Register but before first flight operations?
   ii. What is the broad schedule for approval of the AMP?
   iii. Has the CASG Reliability and Aircraft Maintenance Program (RAMP) team been consulted, for assistance with contractual and other requirements?
4. AMTO:
   i. Who will be the AMTO?
   ii. What is the broad schedule for AMTO approval?
5. MAML:
   i. What is the broad schedule for attainment of MAMLs or new Military Aircraft Type Ratings?

Superseded

(j) The ensuing discussion, perhaps supplemented by specialist sub-group discussion (see below), should ensure that participants have sufficient context and information to draft and approve the ASAMP elements related to design, construction and maintenance.

DASA Assurance

(k) DASA should provide insight into how independent assurance will be conducted, and the common coordination arrangements:

1. identify the lead DASA POC (usually a DIA member)
2. identify a lead from each Directorate, and offer their direct assistance
3. agree on future interaction (timeline, participation in WGs, future liaison, etc)
4. introduce the role of the ASAMP, and agree on DASA's role in contributing to the draft
5. identify relevant DASA training courses and guidance material
6. provide insight into the likely need for AwBs, including timings and submission requirements.

Specialist sub-groups

(l) All of the above discussions should be held in the initial forum, to ensure all participants have a shared understanding of the broad project aims and arrangements. Either the same day, or on a later occasion, specialist sub-groups should convene to explore the issues relevant to them issues in more detail. This step has significant potential to reduce wasted effort by all parties, and will form the basis for the relevant ASAMP annexes (refer annex B).

Superseded

Annex B - ASAMP Guidance

Introduction

(a) The Defence Aviation Safety Regulations (DASR) establish a series of interrelated requirements that must be satisfied for the issue of DASA authorisations necessary to support Introduction into Service (IIS) and the commencement of flight operations of a new or modified aircraft. A representation of the interconnectivity of DASA authorisations for Defence registered aircraft acquisitions is in Appendix A. Coordinated development of the supporting data and artefacts required under the DASR for each DASA authorisation will minimise the potential to introduce capability risks of not having DASA authorisations in place to support the **intended** scope of operations prior to IIS. DASA recommends developing a programmatic plan (known as an Aviation Safety Acquisition Management Plan (ASAMP)) to coordinate the development of supporting data and artefacts required to achieve the interrelated DASA authorisations under the DASR.

Purpose

(b) This chapter describes the process of planning and the execution required to develop an ASAMP.

DASR Requirements

Identification of regulations

(c) This annex traverses multiple DASR to provide clear direction as to how the Capability Manager (CM) / Military Air Operators (MAO) and System Program Offices (SPO) may plan and document their strategy for achieving aviation safety requirements during acquisition[1]. The following DASR are applicable to this annex:

1. DASR ARO, NDR and UAS
2. DASR 21
3. DASR M
4. DASR 145
5. DASR 66
6. DASR 147
7. DASR SMS

Guidance

(d) Within the Defence Aviation Safety Framework (DASF), a MAO must obtain the required DASA authorisations prior to commencing aircraft flying operations using Defence registered, Non-Defence registered or Uncrewed Aircraft Systems. These DASA authorisations cover both:

Superseded

1. product, such as:

    i. MTC/TCDS

    ii. major change to type design

    iii. Military Certificates of Airworthiness

    iv. registration of aircraft

2. people and process, for instance:

    i. organisational approvals such as:

        – MAO

        – CAMO

        – MDO

Aircraft Maintenance Programme

maintenance licenses / type ratings and permits.

(e) Read narrowly, the DASR associated with each of these authorisations are self-contained and provide the detail required to achieve each authorisation as a standalone activity. However, experience in implementing these regulations has demonstrated that insufficient coordination of these authorisations poses a substantial risk to program goals and may cause risks to aviation safety. The design of the ASAMP framework supports development of a coherent strategy to achieve the required safety authorisations.

Why an ASAMP?

(f) The ASAMP design addresses conditions unique to the DASF and does not exist in comparable aviation safety frameworks. Specifically, Introduction-Into Service (IIS) activities under the DASF usually include multiple parallel lines of effort across Initial Airworthiness, Continuing Airworthiness and Flight Operations domains. These lines of effort cross organisational boundaries, such as the MAO, Capability Acquisition and Sustainment Group, industry, foreign militaries and CAAs/MAAs. Additionally, the integrated nature of the regulations means that considerations in one domain— such as shortfalls against airworthiness requirements identified during type certification— may require implementation of measures in the flying management system under the flight operations regulations. The MAO's development of a coordinated approach to aviation safety across Initial Airworthiness, Continuing Airworthiness and Flight Operations will assist in establishing that risks to safety have been eliminated or otherwise minimised so far as is reasonably practicable. The ASAMP supports commanders and managers to account for this cross-regulation dependency and fulfilment of safety obligations.

(g) DASA advice should be sought where there is uncertainty as to the need for an ASAMP.

Aviation Safety Acquisition Management Plan

(h) The ASAMP documents a strategy for achieving the required DASA authorisations required for IIS. These DASA authorisations include organisational authorisations, product authorisations

Superseded

and personnel authorisations. A supporting schedule should detail the requisite DASA authorisations, identify the responsible organisations, provide indicative submission dates, identify anticipated DASA involvement and specify required DASA response dates.

(i) The intended audience for the ASAMP is the CM/MAO, SPO, CAMO, DASA and Flight Test staff involved in the acquisition program. The ASAMP should contain sufficient detail to contextualise the contributions of each of these work areas[2].

(j) The CM/MAO and SPO should consider raising an ASAMP in the following circumstances:

1. when introducing a new aircraft type into Defence service
2. when incorporating substantial design changes that are complex, and require coordination of numerous, diverse activities to achieve the required DASA authorisations
3. when introducing a Certified or Specific Type A category Uncrewed Aviation System (UAS) into Defence service.

(k) The ASAMP should describe the overarching aviation safety acquisition strategy and bring together the planned outcomes of the operational, technical, logistic and safety management activities. The ASAMP needs to describe arrangements that will support IIS and all aviation safety activities required to realise the scope of operations described in the SOIU.

(l) The ASAMP should describe the management of flight operations during acquisition. Specifically, if flight operations are to commence prior to achieving all aviation safety authorisations (e.g. commencing flying before receiving MTC) the ASAMP must provide a detailed description of the process to be employed for identifying and managing aviation safety hazards during this period.

Acceptable approach to compliance

(m) Before the first flight under the DASF, commanders must ensure suitable arrangements for Initial Airworthiness, Continuing Airworthiness and Flight Operations are established. Therefore, it is incumbent on commanders to establish an aviation safety program that is capable of demonstrating compliance to all relevant aspects of the DASR for their specific context.

(n) **Determine applicable DASA authorisations.** The DASR are a suite of requirements that accommodate all forms of military aviation. Because of this necessary breadth, not all DASR will be applicable to every program. Therefore, it is necessary for the CM/MAO to determine which DASA authorisations are applicable to their program. A number of factors, including the method of procurement, method of registration, existing certifications with other airworthiness authorities, logistics support concepts, anticipated tasks and roles will influence this decision.

(o) **Planning.** The CM/MAO should plan how to achieve the required DASA authorisations. When government approves a new capability or major change, the IIS date (the date by which all DASA authorisations to conduct flight operations must be in place) is set. Hence, the CM/MAO should schedule (in the program plan—called out in the ASAMP) the DASA authorisations necessary to conduct flight operations in time to meet the IIS date. To identify the work breakdown structure to schedule the enabling activities for the necessary DASA authorisations, a CM/MAO should identify the task dependencies nested in the DASR and

Superseded

work backwards from the IIS date to determine the required sequence and schedule of activities.

(p) At this stage of development, it is not necessary for the CM/MAO to have detailed plans regarding exactly how to achieve each DASA authorisation. However, if the CM/MAO seeks relief from demonstrating compliance to DASR by utilising CAA/MAA recognition or another flexibility provision, then the CM/MAO should engage DASA to discuss the suitability of the proposed approach.

(q) **Workshops.** During the acquisition phase, there may be multiple ways for projects to achieve aviation safety requirements—with differing timelines, risks and resource or capability costs. When SPO and CM/MAO are evaluating the different options, DASA staff may be able support evaluation workshops. Early engagement with DASA is key to obtaining assistance. DASA staff can advise how the DASR will apply to the different options; and inform how a prospective applicant should structure their submissions to DASA.

(r) **Stakeholder endorsement.** The SPO should obtain stakeholder endorsement before approving an ASAMP. Senior executives from the organisations responsible for achieving tasks listed within the ASAMP should endorse the ASAMP. To ensure ACAUST may verify compliance within the OPAW framework required, the Project Manager must submit an ASAMP to ACAUST for endorsement. If the aircraft Type has been listed on a MAOC OPSPEC, the relevant FEG CDR must also endorse the ASAMP prior to ACAUST review. DG DASA endorsement is required. Prior to DASA endorsing the ASAMP, staff from each of the DASA Directorates (Initial Airworthiness, Continuing Airworthiness, Aviation Operations and Aviation Engineering) will confirm that the tasks outlined in the ASAMP are sufficient to achieve IIS. DASA staff will also identify caveats to the DG DASA's endorsement of the ASAMP. Detailed review at the endorsement stage minimises the likelihood of identifying additional aviation safety requirements during the latter stages of the acquisition process, and minimises attendant impacts on schedule and cost.

ASAMP content guidance

(s) The ASAMP is a flexible document that CM/MAO/SPO should modify to meet the needs of their project. However, the following topics are applicable to all new or modified aircraft types. The following paragraphs provide guidance regarding the content of an ASAMP.

(t) **Structure.** The ASAMP provides the high-level plan for achieving DASA Authorisations necessary for IIS. SPO's and CM/MAO's may find it beneficial however to also include lower-level, detailed planning information regarding how each specific DASA Authorisation will be achieved, the required tasks, assigned responsible organisations for accomplishment and task coordination and schedule. To minimise amendment and approval overhead, the low-level planning for individual DASA authorisations should be included as annexes to the ASAMP, with separate configuration control and Approval/Endorsement fields. Figure 1 below represents the structure of the ASAMP.

Superseded

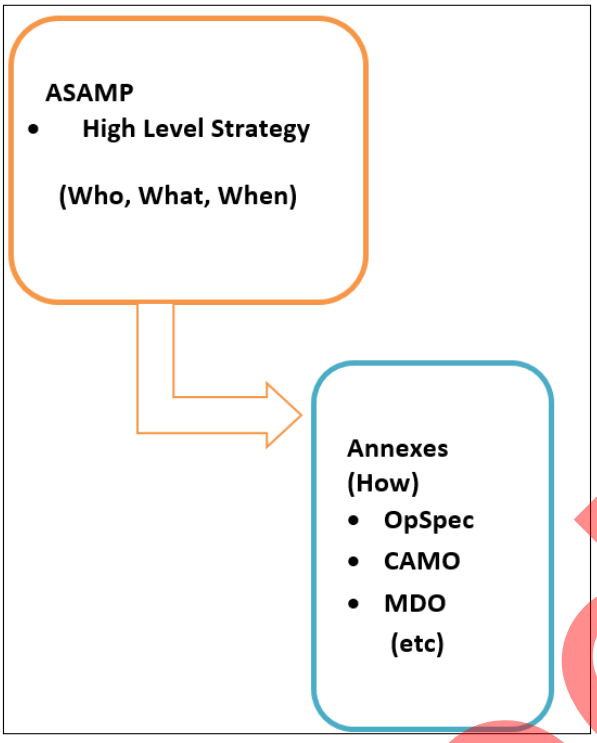


Figure 1: ASAMP Structure

(u) **Coordination and scheduling.** General programmatic and scheduling information, including a:

1. general description of the acquisition activity including key activities and a general description of the capability outcome and method of acquisition

2. high level acquisition schedule which details key capability milestones (eg delivery of aircraft, first flight, initial materiel release, full operating capability).

(v) Projects may choose to introduce new aircraft by starting with a minimum viable capability; and then progressively adding new roles, as support arrangements mature. If adopting this approach, projects should incorporate a basic description of the capability milestones into the ASAMP.

(w) **Registration of aircraft.** This section should detail the planning for the registration of new aircraft or additions to existing fleets. DASPMAN Chapter 6.1.1 annex B provides further guidance.

(x) **Initial and Continued Airworthiness aspects.** This section of the ASAMP should detail the planning for both product and organisation authorisations. Where the aircraft is to have an MTC, many of the certification details will be contained in the CPP. Therefore, the objective of this section is not to reiterate what is in the CPP[2]. Instead, this section is to focus on how artefacts developed in the Initial Airworthiness domain relate to the overall aviation safety program and how other DASA authorisations may affect Initial Airworthiness aspects. This section should include:

1. an overview of the key features of the certification strategy[3], such as:

   i. use of recognition of prior acceptance

   ii. indigenous development of compliance demonstration evidence

Superseded

iii. flight testing of Defence registered aircraft either in Australia or under another CAA/MAA.

2. identification of the certification products such as MTC or major changes to type. This should include general details of sequencing when multiple changes are required to achieve the scope of tasks described in the SOIU

3. a description of where to employ an MPTF to conduct flying without a, or with an invalid, Military Certificate of Airworthiness (MCoA)

4. identification of applicable MCoA requirements and a description of who will address these requirements and when

5. if the initial certification is less than the complete scope of the SOIU, an identification of the anticipated limitations at first flight (ie what the aircraft will be capable of at first flight) and the plan for achieving the full scope of the SOIU

6. identification of updates to organisational approvals and authorisations required to apply for type certificate or deliver in-service support (eg IAW DASR 21 SUBPART J and MTCH)

7. **Engine and aircraft structural integrity program content.** This section should identify Aircraft and Engine Structural Integrity Management Plan (ie ASIMP and ESIMP) requirements and scheduling; and which organisation(s) is/are responsible for their development.

(y) **Continuing Airworthiness aspects.** This section should describe the Continuing Airworthiness DASA authorisations required to operate the capability after IIS and beyond, including the required tasks, resources, scheduling; and organisation(s) responsible for developing the applications. Detailed planning with respect to how the authorisations will be achieved may be described in the ASAMP or further developed in the ASAMP CAMO annex, including:

1. identification of new organisational approvals and authorisations required (IAW DASR M, 145, 147) or variation to such

2. systems for granting personnel authorisations and licences (IAW DASR 66).

(z) **Flight Operations aspects.** This section should describe the DASA authorisations required to satisfy flight operations requirements for IIS and beyond. This section does not need to detail exactly how the CM/MAO will develop each element. However, it should include:

1. **Organisational authorisations.** This may also include variation of existing organisation authorisations of the OpSpec.

2. **Flying Management System.** This section should describe how the MAO will develop or modify the flying management system in compliance with DASR ORO.10.

3. **MAO OIP.** Usually, aircraft specific OIP will accompany the delivery or modification of aircraft. OIP includes the Aircraft Flight Manual (AFM) and Minimum Equipment List (MEL), as well as MAO developed OIP such as Checklists, Flying Orders, SFI, SI (OPS), STANMAN. OIP requiring DASA authorisations are the AFM, AMP, MMEL and MEL.

4. **Specific Approvals.** Some types of operations require Specific Approval from DASA (e.g. PBN, RVSM, use of EVIS). Where the SOIU includes these types of operations, the ASAMP should present a plan showing who is responsible for developing the application to DASA and when this activity is scheduled. CM/MAO/SPO liaison with

Superseded

DASA to establish timelines is important to ensure that the necessary authorisations are in place prior to first operational use relating to the Specific Approval.

5. **Specific limitations.** Acquisition projects may introduce a new aircraft with a narrower scope of operations than that described in the SOIU. In these cases, the ASAMP should acknowledge any Specific Limitations to the SOIU scope at IIS. This will support development of the initial OpSpec annex.

6. **Aircrew training and categorisation schemes.** This section should describe the plan for the initial aircrew cadre as well as any arrangements for the mature training system.

7. **Flight Simulation Training Device.** If a CM/MAO is acquiring a Flight Simulation Training Device, this section should describe basic details (number, type, location, operator) and key schedule milestones.

(aa) **Establishing Safety Management Systems.** Acquisition or major change projects require a number of stakeholders to establish safety programs associated with Initial Airworthiness, Continuing Airworthiness and flight operations, such as:

1. system safety programs

2. hazardous materials programs

3. flight operations risk management plans.

(ab) The ASAMP should outline the interfaces and information sharing arrangements between the relevant stakeholders' Safety Management Systems (SMS) to address the management of risk, and transfer of retained risks, into the existing MAO's SMS through acquisition and into sustainment.

DASA authorisation low-level planning

(ac) CM/MAO's are encouraged to document the low-level planning for achieving each DASA authorisation in annexes to the ASAMP. These low-level planning annexes should identify the key tasks, their indicative schedule and key stakeholders for each task that the CM/MAO needs to accomplish in order to gain the required DASA authorisation. Lastly, if the CM/MAO is proposing novel organisational structures or Alternative Means Of Compliance to achieve a particular DASA authorisation, then the relevant ASAMP annex should describe these arrangements in sufficient detail for DASA to evaluate their potential effectiveness.

(ad) **Coordination and scheduling.** The specific tasks required by the DASRs to achieve each DASA Authorisation often do not occur in isolation with other aviation safety activities (e.g. type certification, operational test and evaluation, initial training). Therefore, developers of the ASAMP should anticipate some tasks being stand alone, and others being dependent on outcomes from other streams of work during acquisition. The Integrated Product Manager (or similar role) should incorporate tasks and time to complete associated with DASA authorisation development into the overall acquisition program.

(ae) For this reason, some ASAMPs may break DASA authorisation compliance into a number of discrete work packages that can be incorporated into the aircraft acquisition or modification programs Work Break-down Structure (WBS) and schedule into tools like Open Plan Professional. This detailed planning should be documented within the relevant ASAMP annex for each DASA authorisation, and provide sufficient scheduling information such that the

Superseded

applicant, CM/MAO and DASA can identify when applications, plans, artefacts will be submitted to DASA for approval; and when the applicant anticipates a return.

(af) Annex content. The content of each ASAMP annex is scalable to the project. Table 1 provides suggested content with a supporting DASPMAN reference.

Table 1: Annex content

DASA Authorisation	Reference	Comment
MAOC & OpSpec	Vol 3 Chap 5.3 annex A Vol 3 chap 6.1.1 annex C (SOIU) Vol 2 DASR ORO.10 (FMS) Vol 2 DASR AO.GEN.05 (MAO OIP) DASA Advisory Circular 01/2022 and DASR SPA (Specific Approvals) Vol 3 Chap 5.3 annex A (OCS and OpSpec Variation)	The ASAMP annex for MAOC and OpSpec should detail the responsibilities and schedule for the development of the following artefacts supporting the MAOC OpSpec. OpSpec Variation: The ASAMP annex should outline the tasks and responsibilities for development of the DASA Form 139a, and reflect the dependency on SOIU and OCS development tasks. DASA recommends that MAO plan to submit the DASA Form 139a and associated OCS no less than six weeks prior to IIS. SOIU: The SOIU Configuration, Role and Environment (CRE) described should match Command intent. The SOIU should developed to provide sufficient detail to support both type certification and identification of the DASA authorisations required to support the intended scope of operations at IIS. OCS: DASA recommends that MAOs identify the traceability between DASR requirements and the amended MAO OIP/FMS as early in the acquisition/ modification program as possible so that MAOs can incorporate DASR requirements into the MAO's FMS/ OIP development cycle and OCS revision ahead of IIS. FMS: Where adding a new or modified platform, the MAO must demonstrate the suitability of the existing FMS elements in supporting the intended scope of operations set out in the SOIU. The determination of DASR FLTOPS regulation applicability will assist in scoping the required amendments to the FMS, including identifying key stakeholders, resources and inter-relationships between each FMS element impacted by the IIS of the new or modified aircraft.

Superseded

		OIP: Introduction or modification of platforms invariably requires new or modified OIP, including aircraft operational publications and MAO OIP such as Standing Instructions/Flying Orders/Special Flying Instructions, etc. The ASAMP annex should outline the responsibilities (developer, sponsor) and schedule for each OIP amendment or development. Specific Approvals: Some aircraft operations require specific endorsements annotated in the MAOC OpSpec. These include Performance Based Navigation (PBN), Required Vertical Separation Minima (RVSM) and use of night vision imaging systems (NVIS). The ASAMP annex should outline the tasks and schedule for the development of supporting artefacts required under DASR.SPA and DASA AC 01/2022 for each Specific Approvals. Training: The ASAMP annex for MAOC and OpSpec DASA authorisation should establish the tasks associated with aircrew training development and delivery, including LMP development, courseware development, training delivery and aircrew qualification. Where applicable, the tasks associated with FSTD qualification and permit issue should be included.
CAMO	Vol 3 Chap 5.3 annex H	The ASAMP annex for CAMO DASA authorisations should outline the intended schedule and responsible parties for development of the DASR M approval application package and Aircraft Maintenance Programme (AMP), including any desired engagement workshops with DASA Directorate of Continuing Airworthiness.
MDO	Vol 3 Chap 5.3 annex E	The ASAMP annex for MDO DASA authorisations should outline the responsibilities, resourcing and scheduling for the development of the Military Design Organisation Handbook.
MPO	Vol 3 Chap 5.3 annex F	The ASAMP annex for MPO DASA authorisations should outline the responsibilities, resourcing and scheduling for the development of the Military Production Organisation Exposition (POE).
AMO	Vol 3 Chap 5.3 annex G	The ASAMP annex for AMO DASA authorisations should outline the responsibilities, resourcing and

Superseded

		scheduling for the development of the Maintenance Organisation Exposition (MOE).
MTO	Vol 3 Chap 5.3 annex I	The ASAMP annex for MTO should outline the responsibilities, resourcing and scheduling for the development of the Maintenance Training Organisation Exposition (MTOE).
MTCHO	Vol 3 Chap 5.3 annex J	The ASAMP annex for MTCHO should outline the responsibilities, resourcing and scheduling for the development of the Type Continued Airworthiness Exposition (TCAE).
Defence Registration and Military Certificate of Airworthiness (MCoA)	Vol 3 Chap 6.1.1 annex B Vol 3 Chap 5.3 annex O	The ASAMP annex for MCoA DASA authorisations should outline the responsibilities, resourcing and scheduling for establishing aircraft registration and the development of the MCoA (where applicable) application through DASA Form 25a.
Military Aircraft Maintenance Licences (MAML)	Vol 3 Chap 5.3 annex W	The ASAMP annex for MAML DASA authorisations should outline the responsibilities, resourcing and scheduling for the establishment of a Military Aircraft Type Rating, and the DASA Form 19/19a for the required number of maintenance staff necessary to support IIS of the new aviation capability.

(ag) **ASAMP updates or variation.** The acquisition environment is dynamic and projects often need to change the acquisition strategy and plans in response to external events. Therefore, it is likely that the Integrated Program Management Plan will diverge from the agreed ASAMP over time. Applicants should periodically update the ASAMP so it remains relevant. Specifically, applicants should update the ASAMP if the project significantly changes the structure or scope of aviation safety authorisations. For example, if the initial ASAMP involved obtaining an MTC before IIS, and a delay occurs such that initial operations will actually commence under a MPTF, then then an ASAMP update is appropriate.

(ah) DASA recommends the CM/MAO provide an updated ASAMP as part of the application for initial (or variation to an) OpSpec for a new (or modified) capability. This updated ASAMP should reflect the status of the acquisition program, including details of work completed and re-programing of remaining activities. The ASAMP should provide an impact statement and reference out to risk management where tasks associated with initial-flight under DASR are incomplete.

Endorsement and approval

(ai) **ASAMP.** The IIS of a new aircraft system will involve a number of organisations to achieve the operational, technical, logistic and safety management outcomes articulated in the ASAMP. Accordingly, the SPO should identify the relevant stakeholder organisations, and seek their

Superseded

endorsement prior to approving the ASAMP. At minimum, stakeholders should include CM representative, MAO-AM, SPO Director, DG-DASA, and Environmental Commander. Additional stakeholder signatories identified by the SPO should be a minimum of O6/equivalent or above.

(aj) Each endorsement will assess the supportability from a stakeholder organisation resource and scheduling perspective of the overarching aviation safety acquisition strategy articulated by the ASAMP, as well as its suitability for achieving the desired IIS outcomes. Following ASAMP endorsement by all relevant stakeholders, approval of the ASAMP should be sought from the relevant one-star/equivalent CASG Branch representative (e.g. DG ASR for MC-55).

(ak) **ASAMP annexes.** As detailed in Para 20, where a MAO/SPO has elected to include low-level planning annexes for each DASA authorisation, the MAO/SPO should identify relevant DASA authorisation stakeholders (including within DASA) for ASAMP annex endorsement and MAO approval. DASA recommends that stakeholders be a minimum of O5/equivalent or above, DASA stakeholders will typically be the Director of the relevant DASA Directorate responsible for issuing the specific DASA authorisation. Stakeholder endorsement should consider the supportability and suitability of the work breakdown structure and associated responsibilities and resources supporting achievement of the relevant DASA authorisation.

(al) DASA endorsement of individual ASAMP Annexes will consider the suitability of the proposed low-level plans for achieving the specific DASA Authorisation, and alignment with the higher-level ASAMP. It will also assess the supportability from a DASA directorate resource and scheduling perspective of the DASA task elements within each ASAMP annex.

(am) Should a stakeholder review identify a misalignment with the higher-level ASAMP, the ASAMP annex should not be endorsed until the ASAMP is amended to restore alignment.

Superseded

Annex C - Airworthiness Issue Papers

(a) Airworthiness Issue Papers (AwIPs) are primarily used to manage and communicate risks associated with complex airworthiness issues. This annex outlines the role of AwIPs and describes how they are drafted and processed.

Role of an AwIP

(b) The AwIP provides a structured format for documenting the application of Defence's seven-step safety risk management process in accordance with the 7-step risk management process (refer DASA AC 003/2018). Other forms providing similar functionality include the AE628 Risk Decision Brief and various aircraft-bespoke forms.

(c) An AwIP provides a template for thoroughly documenting the risk, the actions undertaken to eliminate or otherwise minimise the risk so far as reasonably practicable (SFARP) and the assessment supporting the final decision-to-proceed. The structured format facilitates improved communication between all stakeholders involved in managing a risk to airworthiness. Unlike other risk decision forms, an AwIP enables DASA to provide an independent position on the credibility and defensibility of the risk management process, prior to the final decision-to-proceed.

(d) AwIPs **must** be used for managing risks associated with complex airworthiness issues, given they require a high level of visibility and sustained focus. This include issues that link to airworthiness.

(e) That is, AwIPs are used to address complex aviation safety issues resulting from design shortfalls identified as part of a certification activity (ie MTC/MRTC/MSTC issue or major change approval), or where role and environment differences result in a safety issue with the design. In these situations the AwIP will be used to underpin the approval of a Military Certification Review Item (MCRI).

(f) AwIPs **must not** be used for issues that do not have a link to airworthiness or are outside the scope of aviation safety. Examples include issues related to ground safety, logistics and hazardous materials in an aircraft's design.

(g) **Complexity.** An issue is complex if it exhibits several of the following characteristics: [1]

1. Defining the problem or problems creating the issue may be difficult with different stakeholders perceiving the issue in varied ways, leading to uncertainty about what the issue is and how it should be resolved.
2. The risks associated with the issue interact with each other in complicated, dependent ways that are not necessarily well understood.
3. The issue has diverse stakeholders spread across both technical, operational and other domains.
4. The issue will require iterative risk management and thus iterative discussions amongst these diverse stakeholders.
5. The issue has long-term implications and consequences that extend far beyond the immediate context, both in time and scope.

Superseded

6. The issue cannot be easily resolved with 'quick fix' solutions to meet timelines based on capability imperatives. Such solutions may lead to unintended and undesirable consequences.

7. The information required to resolve the issue is uncertain or incomplete.

8. The issue involves new and novel technologies that may not be well understood.

Raising AwIP

(h) Where the AwIP is raised to document type certification-related risks, usually the applicant for the airworthiness instrument (Military Type Certificate Holder (MTCH), Project Engineering Manager (PEM) or 21J design organisation) will raise the AwIP in consultation with relevant operational staff. The person raising the AwIP should decide, in consultation with DASA, whether an issue is 'complex'.

AwIP status

(i) An AwIP has two statuses, namely 'Open' and 'Closed'. In the 'Open' status the issue remains under investigation and review (ie whilst investigation of potential controls, assessment of whether identified controls are reasonably practicable, and exploring sources of reasonable knowledge remain ongoing).

(j) In the 'Closed' status, either the investigation is complete, with the risks eliminated or otherwise minimised SFARP and the risk remaining is retained; or the investigations and implementation of all reasonably practicable controls are not complete, but progressed to the stage where the issue is no longer 'complex'. Remaining investigations and controls must be captured and tracked in the relevant safety management system. In both situations appropriate through-life controls are in place and being managed within the relevant safety management system.

Processing an AwIP

(k) **Section 1 – Evaluation and Risk Management.** Section 1 of the AwIP presents a combined technical and operational evaluation of the risk, in accordance with the seven-step risk management process, to demonstrate that the risk/s has been eliminated or otherwise minimised so far as reasonably practicable. The DASA AwIP template, available on the DASA website, provides guidance to assist the drafter completing each of the seven steps.

(l) **Section 2 – Authority Position.** Once Section 1 is finalised, the applicant should submit the AwIP to the Authority (via the DASA Type Certification mailbox) for its position on the relevant risks[2]. DASA will assess whether the documented seven steps provide a credible and defensible basis for Command risk decisions. The possible scenarios, together with the likely DASA positions, are as follows:

1. The risk management is credible, defensible and well argued in Section 1. DASA will provide a supporting DASA position without the need to expand on the argument.

Superseded

2. The risk management is credible, defensible but inadequately argued in Section 1. DASA will provide a supporting DASA position that clarifies the Section 1 argument, drawing out the key matters to be considered in Section 3.

3. The risk management is not credible and defensible. DASA will return the AwIP for re-work of Section 1.

4. In rare circumstances, if the requested rework cannot be completed due to time pressures or an impasse, DASA would document a dissenting position to Command, highlighting the areas of concern, which Command can consider in developing its position.

(m) To avoid the need for re-work or a dissenting Authority position, the Section 1 drafter should provide a draft of Section 1 to DASA prior to its formal completion.

(n) **Section 3 – Command position.** Once the Authority position has been provided, the applicant/drafter will staff the AwIP to Command for a Command Position. The Command position should confirm that the risk has been eliminated or otherwise minimised SFARP, and that Command has made a decision-to-proceed.

(o) **Section 4 – Authority disposition.** DASA will complete Section 4 as follows:

1. DASA will decide whether the AwIP will remain 'Open' or is now 'Closed', providing any closure requirements and any comments relevant to this disposition.

2. DASA may close an AwIP even though a risk still exists. Where the AwIP assesses that specific controls will become reasonably practicable in the future (eg a modification is being implemented but will take 24 months to incorporate across the fleet) the AwIP may be closed if DASA considers that Command could effectively manage and track the implementation of risk controls through an alternate system such as the platform hazard log.

3. DASA may leave an AwIP 'Open' where investigation into potential controls continues, until all controls have either been assessed as not reasonably practicable or reasonably practicable controls have been implemented. DASA may also decide to leave an AwIP 'Open' when doing so would materially contribute to safety by keeping sustained focus on the issue.

4. DASA will document its assurance that the Command position in Section 3 of this AwIP is congruent with the evaluation in Section 1, as possibly modified by Section 2. The term 'congruent' means that the Command position aligns consistently and logically with the evidence and reasoning provided in Sections 1 and 2 [3]

Continuous Monitoring and Review

(p) All risks evaluated in an AwIP must be subject to continuous monitoring and review, in the same way as all other aviation safety risks, regardless of whether the AwIP is 'Open' or 'Closed'. Both Command, and the MTCH where applicable, should ensure that risks continue to be eliminated or otherwise minimised so far as reasonably practicable. Monitoring should identify any changes in the relevant risks (consequence, likelihood or both) and changes to the risk controls in place. Reviews conducted at a specified time, such as annually, may not be sufficient for continuous monitoring and review. Therefore, risks associated with AwIPs should

Superseded

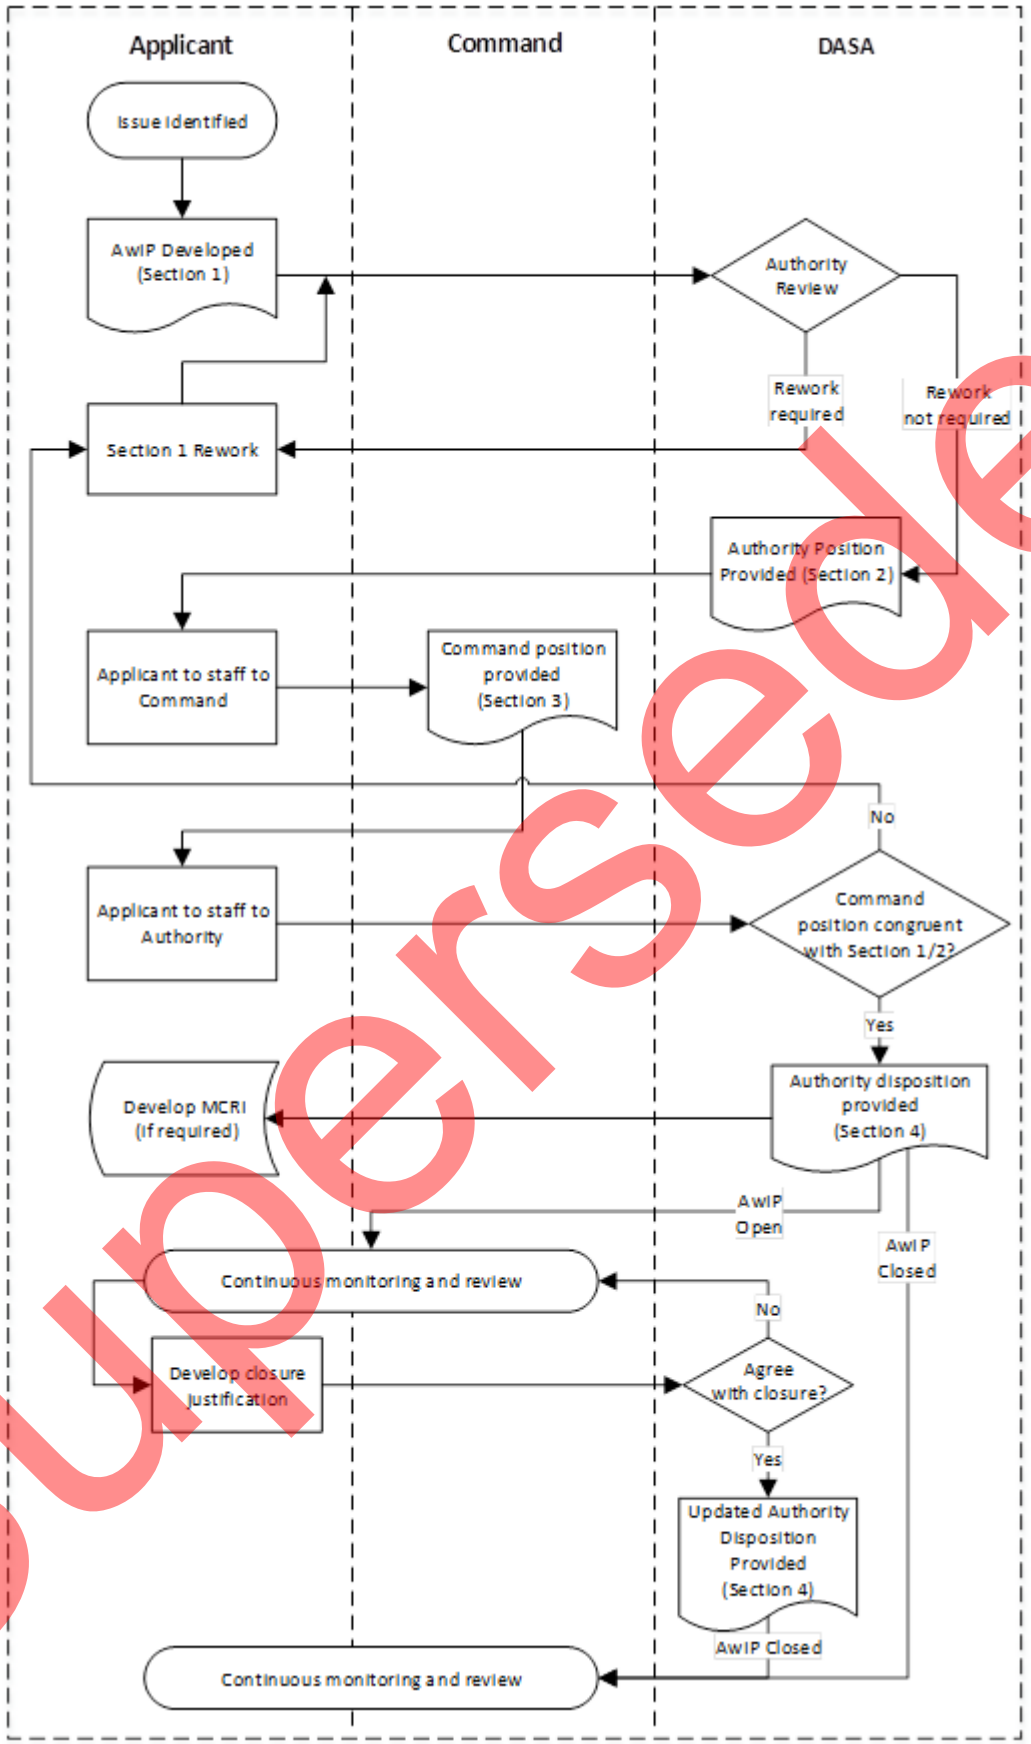
be integrated into standard safety management system practices to ensure appropriate management.

Version control

(q) Given the need for continuous monitoring and review, an 'Open' AwIP may move through several versions. Any changes to Section 1 should be resubmitted to the Authority for completion of a new Section 2 and later sections. Care must be taken to ensure rigorous version control.

Superseded

The AwIP Process



Superseded

AwIP management

(r) Command is responsible for managing AwIPs. That is, Command should:

1. maintain visibility of an AwIP's status and track its progress towards closure
2. ensure the seven-step risk management process in Section 1 is vigorously progressed
3. ensure that after completion of each Section, the AwIP is expeditiously forwarded to the organisation responsible for the following Section
4. ensure that reviews and AwIP updates occur as required
5. proactively maintain communications amongst relevant stakeholders
6. store the AwIP in an appropriate Objective folder
7. ensure that any alternative methods of risk management, such as platform hazard logs, are correctly established
8. (in-conjunction with the MTCHO) propose an AwIP should move to a different status providing suitable evidence to substantiate the proposal

AwIP assurance

(s) DASA does not actively monitor the progress that Command makes on specific 'Open' AwIPs. DASA's safety assurance role is limited to whether risks documented in the AwIP are being professionally managed. DASA may, during routine oversight, assure risks and controls are correctly captured within the relevant safety management system and that controls have been implemented and are subject to continual monitoring and review.

Additional Information

(t) Additional information and templates for AwIPs can be found:

1. in the AwIP template accessible from the DASA website -= DASA Templates page.
2. Additional guidance related to TCB tailoring is contained in Chapter 7.2 and associated annexes.
3. in the seven-step risk management framework detailed in AC 03/2018 Risk Management in the Defence Aviation Safety Program
4. DASA Point of Contact: DIA-DASA Type Certification Section dasa.typecert@defence.gov.au

Frequently Asked Questions

(u) How does one choose between an AwIP or other risk management form?

For non-complex aviation safety issues, another RDB form (such as the AE628) may be used instead of an AwIP provided the other form documents the seven-step risk management process. In choosing an alternative form to document an airworthiness issue the person raising the AwIP must be confident that DASA's concurrence with the risk management outcome is a 'given'. Given the 'decision to proceed' on these alternatives is not informed by a

Superseded

documented DASA position, the person raising the AwIP may be taking on some schedule risk when using alternative RDBs late in the process for gaining a certification.

(v) Are there any specific timings for when AwIPs should be raised?

No. DASA does not provide any specific timings on AwIPs, but they should be raised as soon as the need for an AwIP becomes evident. Processing times for AwIPs can be lengthy given multiple stakeholders. DASA's turnaround times for processing AwIPs are advised after their formal submission to the Authority.

(w) Do all TCB-related AwIPs result in Exception MCRIs?

No. TCB-related AwIPs should be used primarily to underpin Exception MCRIs but may occasionally be required for other types of MCRIs requiring risk decisions, for example some Special Condition MCRIs where risk decisions determine the certification requirement/ standard, or Equivalent Safety Finding MCRIs relying on implementation of operational controls. DASP Manual Volume 3 Chapter 7.2 Annex A provides more information.

(x) Is an AwIP always required to address a TCB non-compliance?

No. Equivalent risk management documentation may be used for some TCB non-compliances, depending on the context and complexity. See DASP Manual Volume 3 Chapter 7.2 Annex A for more information.

(y) Is a separate AwIP required for every risk?

No. A single AwIP can combine multiple risks provided they are closely related and their individual risk management remains clearly documented. An AwIP may be separated into sections covering risk or annexes used to provide individual evaluation of each risk.

(z) Can a MCRI be approved prior to closing the AwIP?

Yes. A MCRI may result in a level of risk above that represented by compliance with the Authority-prescribed design requirements and standards (ie Exception MCRIs and some Special Condition MCRIs). The MCRI can be approved against an 'Open' AwIP, provided Command has decided, in Section 3, to proceed with the elevated risk.

(aa) Can instruments be issued while an AwIP remains 'Open'?

Yes. Various instruments, such as a Military Type Certificate or Military Permit to Fly, can be issued while an AwIP remains 'Open'.

(ab) What is the preferred AwIP writing style?

Drafters should write AwIPs using clear, easy to understand, unambiguous, simple and concise language. The AwIP should avoid unnecessary verbiage and be precise enough to leave no uncertainty in the mind of the reader. Reference to other documents should not prevent readers from understanding the issues and their analysis.

(ac) Can a 'Closed' AwIP be reopened?

In rare circumstances, stakeholders may become aware of new information that puts in doubt the rationale for closing the AwIP. In such circumstances the AwIP may be reopened or a new AwIP raised.

(ad) Do AwIPs have a time limit for processing?

Superseded

No. AwIPs might stipulate requirements for closure and an associated timeframe but in some cases, they can remain open for years. For example, a long-term project may be established to investigate potential design solutions to resolve the risk. 'Open' AwIPs should be reviewed and updated regularly to ensure that the risk remains eliminated or otherwise minimised so far as reasonably practicable.

(ae) Who can access AwIPs?

Since AwIPs document the management of airworthiness or flight operations issues, DASA compliance assurance staff may periodically access AwIPs as part of their ongoing assurance. AwBs may also access AwIPs as part of their 'independent assurance function'. AwIPs are stored within the DASA's Objective folder relevant to the issue. A central Objective AwIP folder, using the alias functionality, collocates all AwIPs for ease of access.

(af) A risk control identified in an AwIP has been mandated by a DASA Airworthiness Directive (AD)—can the AwIP be closed if all other risk controls are implemented?

Yes. Provided all other AwIP risk controls are implemented, the AwIP could be closed. Even if the actions in the AD have yet to be implemented, the actions are mandatory and have been approved by DASA. Therefore, it is highly unlikely that DASA would wish to provide further assurance via the AwIP process for the specific risk control that is the subject of the AD.

(ag) What factors need to be considered for closure of older AwIPs?

Older AwIPs, especially those which pre-date the introduction of the DASR, will be in a different format to the four-section structure described above, and the risk assessment may not align with the contemporary 7-step risk management process. Nonetheless, it should still be clear which risk controls were assessed as reasonably practicable to inform the risk retention and decision-to-proceed.

Older format AwIPs will typically have a 'Proposed IP Closure Criteria' section, which may contain actions aside from implementation of risk controls. When justifying closure of older AwIPs, applicants should describe how the intent of all such actions has been met.

Applicants are also reminded of their Work Health and Safety (WHS) obligations when revisiting older AwIPs, especially obligations regarding continuous monitoring and review (ie consideration of changes in the hazard and risk context, and new possible controls).

Superseded

Annex D - Airworthiness Board Guidance

This content is under development. DASA is using a current aircraft acquisition to evolve the AwB focus, processes and data requirements, and this will lead to better guidance to the community on the submission requirements for AwBs for new aircraft. In the interim, interested parties should contact DASA directly for AwB submission requirements

6.1.3. Acquisition of Non-Defence-Registered Aircraft

6.1 Introduction of New Defence Aircraft Capabilities

6.1.1 Introduction

Background

6.1.1.1 Defence periodically adds aircraft to its inventory to meet a capability need. The aircraft may be purchased or leased, crewed or uncrewed, Defence or civil registered. An essential prerequisite for Defence operation of a new aircraft, regardless of the acquisition arrangement, is for Defence to confirm that it is safe for flight. This encompasses the safety of aircraft occupants, other airspace users, and overflown people and facilities.

6.1.1.2 The acquisition process for a new aircraft begins during the capability development phase of the life cycle, where operational requirements are defined and potential solutions investigated. The Aviation Safety management process commences concurrently with the acquisition process, and remains inextricably linked. Decisions made early in the acquisition process can have an enduring effect on Aviation Safety.

6.1.1.3 For a Defence aircraft to be safe for flight, the aircraft to be appropriately designed, constructed, maintained and operated, as explained in DASP Manual Volume 3 Chapter 3, The Defence Aviation Safety Program. It is the responsibility of aircraft acquisition organisations in Defence, relevant in-service organisations and Defence industry partners, to ensure a Defence aircraft is safe for flight, both from the initial design and throughout its Defence lifecycle. In turn, the relevant Aviation Safety authorities need to gain assurance that the aircraft is safe for flight. If suitably assured, the Aviation Safety authorities can issue a range of 'authorisations', usually in the form of certificates, permits, approvals or licenses.

Purpose

6.1.1.4 This series of chapters aims to guide Defence aircraft acquisition organisations, relevant in-service organisations and Defence industry partners through the aviation safety requirements and recommended practices during the aircraft acquisition process.

6.1.1.5 This first chapter provides a general introduction to acquiring new Defence aircraft, including registration requirements, Aviation Safety responsibilities, engagement with Aviation Safety authorities and other common concepts.

Applicability

6.1.1.6 This chapter is applicable to the acquisition (whether through purchase, lease or other arrangement) of the following Defence aircraft:

1. Defence registered crewed aircraft
2. Non-Defence registered crewed aircraft (short term)
3. Defence registered certified uncrewed aircraft systems (UAS)

Superseded

6.1.1.7 While the concepts in this chapter are also broadly applicable to Open and Specific category (ie non-certified) UAS, the regulatory approaches for these UAS are substantially different to certified aircraft, so DASP Manual Volume 3 Chapter 10, Uncrewed Aircraft Systems, separately covers their acquisition.

Structure

6.1.1.8 This chapter will provide context for the next four chapters, which will individually cover the three different arrangements for Defence aircraft acquisitions listed in paragraph 6, and as shown in Figure 1.

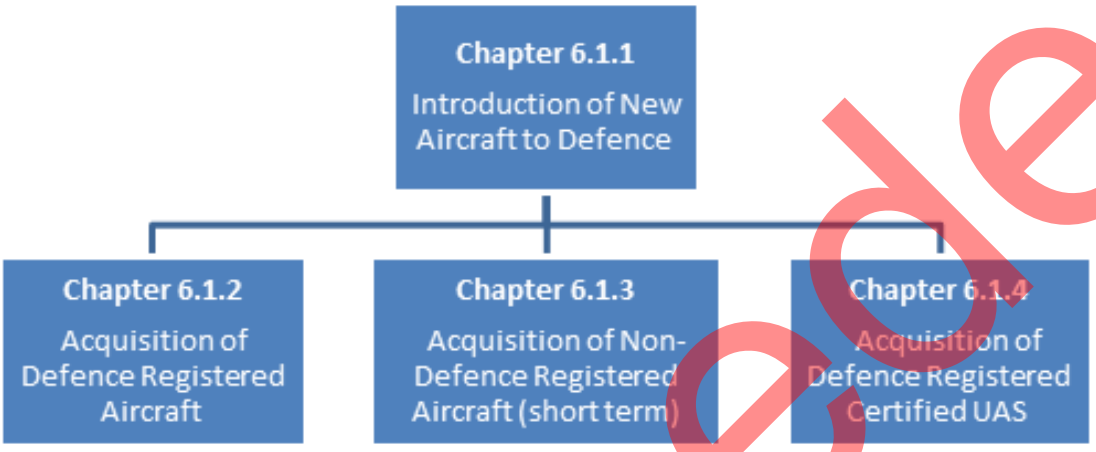

Figure 1: Chapter 6.1 structure

6.1.1.9 This chapter will also provide content that is common to the next four chapters, to avoid duplication.

Aircraft Registration

6.1.1.10 All Defence aircraft, apart from some non-certified UAS, must be included on the Register of a military or civil aviation authority. DASR separates these registrations into two categories; Defence registered aircraft and non-Defence registered aircraft. The latter are almost universally regulated by CASA. While other registrations are occasionally employed, they are always transitory arrangements[1].

6.1.1.11 A Defence registered aircraft is subject to Defence Aviation Safety Regulations (DASR) and DASA safety assurance oversight. An Australian civil registered aircraft, on the other hand, is subject to Civil Aviation Safety Regulations (CASR) and CASA safety assurance oversight as well as some limited DASA oversight.

6.1.1.12 When Defence is procuring an aircraft type that is also used under the civil regulatory framework, an important decision by the Capability Manager, required early in the acquisition process, is to determine whether the Defence aircraft will be Defence registered or civil[2] registered. This registration can have an enduring effect on Defence aviation capability, as summarised below:

1. **Defence registration.** Defence registration ensures the aircraft is within the exclusive jurisdiction of the DASR, which make specific allowance for:

   i. uniquely military roles, including weapons carriage and deployment, low flying, aerial delivery, clandestine flying, formation flying, transporting

Superseded

hazardous materials and dangerous goods etc — types of operations that may be heavily restricted or unsupportable under civil regulatory requirements

ii. flexibility in the approach to achieving compliance with the DASR

iii. the application of risk management where DASR compliance cannot be shown, provided a credible and defensible level of aviation safety performance is achieved

iv. Commanders to deviate from requirements (2) and (3) above in the event of compelling operational imperatives or emergencies.

DASA is experienced in regulating for the unique military operational context. Consequently, DASA is well-placed to advise Commanders on military aviation safety issues and to provide tailored independent safety assurance of military organisations and products.

2. **Civil registration.** Civil registration can initially be attractive to Capability Managers and acquisition organisations due to the simplicity of contractual and ongoing management, and potential faster introduction of the aircraft into service. However civil registration should only be considered for short term arrangements, or where an aircraft will not be considered a continuous 'State' aircraft. Complicating factors include that:

i. it can bind Defence to civil aviation safety regulations for design, maintenance and operation, and these regulations have not been customised to the unique military aviation context

ii. there may be a lack of risk-managed operational flexibility, which is the hallmark of Defence's aviation safety regulations

iii. it can bind Defence to the potential inflexibilities of the civil regulator

iv. there may be adverse diplomatic and security implications of Defence operating a non-Defence registered aircraft overseas.

6.1.1.13 Where a Capability Manager is considering civil registration for a temporary Defence aircraft, DASA should be engaged at the earliest practicable opportunity for consultation. Annex A presents a list of issues that should be explored during this engagement, to assist the Capability Manager in making an informed decision on Defence registration versus civil registration.

6.1.1.14 Annex B presents guidance on the structure and administration of the Defence Register.

Aviation Safety Responsibilities

6.1.1.15 DASP Manual Volume 1 states that aviation safety is a command responsibility, so commanders and managers are accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

6.1.1.16 The responsibility for ensuring (ie making sure) a new Defence aircraft is safe for flight falls directly on the Defence acquisition organisations and the relevant in-service support organisations. This includes, amongst other things, ensuring:

1. the aircraft design is safe for flight in the intended role and operating environment (ie aircraft design and certification)

Superseded

2. the physical aircraft standard of construction meets that design (ie aircraft production)

3. arrangements are in place to ensure the design remains safe (ie continued airworthiness)

4. arrangements are in place to ensure the aircraft remains in a condition for safe operation (ie continuing airworthiness)

5. arrangements are in place to design future changes and repairs (ie aircraft design)

6. operators are able to safely operate the aircraft (ie flight operations).

6.1.1.17 The role of DASA, on the other hand, is to gain assurance that the above elements have been executed effectively.

Aviation safety authorisations

6.1.1.18 When assured of safety, the relevant military or civil aviation safety authority (whether DASA or CASA) may issue a range of authorisations, often in the form of certificates, permits, approvals or licenses. For Defence registered aircraft, the list of authorisations is expansive, potentially comprising up to 12 different types of organisational, product and personnel authorisations. For civil registered aircraft, CASA will issue the civil equivalents to some or many of these 12 authorisations. Chapters 6.1.2 to 6.1.5 explore the Aviation Safety authorisations that may be issued by DASA and CASA for each acquisition category.

6.1.1.19 While DASA does not issue authorisations for civil registered aircraft, DASA may require that the aircraft are included within the scope of the Military Air Operator (MAO), issue a relevant Operations Specification (OpSpec) and conduct limited safety assurance oversight.

6.1.1.20 **Planning and coordination.** Aviation Safety authorisations issued by DASA or CASA are a major milestone in the aircraft acquisition process. Establishing the contracts, systems and people to merit each authorisation is usually complex, with considerable potential to waste time and resources. Effective engagement with the appropriate Aviation Safety authority (DASA for Defence registered aircraft, and both CASA and DASA for civil registered aircraft) is therefore in the best interests of all parties.

6.1.1.21 Engagement should ideally commence as soon as the Defence acquisition organisation has a reasonable view on the candidate aircraft, the need for Defence-unique design changes, and the probable operating and support constructs[3]. Engagement should be well advanced before Defence publishes any tender documents (eg Requests for Tender, Foreign Military Sales requests, etc) that may later affect an authorisation.

6.1.1.22. For civil registered aircraft, CASA will provide guidance on how to achieve the civil authorisations that will be required. DASA will do likewise for the new OpSpec, if one is to be published. This development of this DASA authorisation is far from a trivial endeavour. Not only does it cover the flying management of the MAO and other operational systems for the new aircraft, it also assesses whether the entire aviation safety construct (inclusive of all CASA authorisations) is likely to support safe Defence aviation.

6.1.1.23 For Defence registered aircraft, DASA will provide guidance on how to achieve the required DASA authorisations. Some additional guidance is available through DASA-sponsored courses and website resources.

Superseded

6.1.1.24 Chapters 6.1.2 to 6.1.4 provide tailored guidance on how engage with the relevant Aviation Safety authorities, since this varies widely between civil and Defence registered aircraft, and crewed and uncrewed aircraft.

6.1.1.25 **Documented agreements.** DASRs do not mandate any formal plans or agreements for achieving DASA authorisations. However, it is a practice that DASA highly recommends, given the substantial complexities in establishing the organisations and systems to manage Aviation Safety, and therefore the potential impacts (both positive and negative) on cost and schedule - and ultimately Defence capability.

6.1.1.26 For both Defence and civil registered aircraft, DASA advocates the production of an Aviation Safety Acquisition Management Plan (ASAMP). The ASAMP is an iterative agreement between applicants and DASA on the path to achieving DASA authorisations, and supports commanders and managers in accounting for parallel lines of effort and cross-regulation dependencies. It describes, amongst other things, the overarching acquisition strategy in the context of Aviation Safety and brings together the planned outcomes of the operational, technical, logistical and safety management activities.

6.1.1.27 The ASAMP should be drafted after the acquisition strategy solidifies, nominally following government acquisition approval, but before RFTs (or equivalent) are released. While ASAMPs have previously been drafted before initial contact with DASA has been made, this is rarely an efficient approach. The ideal time to draft the ASAMP is soon after the initial meeting with DASA, given that meeting will influence much of the ASAMP content. The ASAMP would normally be updated after contracts and agreements are signed, since this is the stage where the scope of most authorisations should be clear.

6.1.1.28 Chapters 6.1.2 to 6.1.5 provide guidance on the production of ASAMPs, tailored to the particular acquisition arrangement. ASAMP content varies widely between civil and Defence registered aircraft, with the latter including plans for achieving up to 12 different DASA authorisations. While the differences between crewed and uncrewed aircraft ASAMPs are less significant, the latter will focus on the unique challenges of separating the crew from the aircraft and the additional transitional authorisations that may be available for certified UAS.

Common Concepts

6.1.1.29 The next four chapters are dedicated to the four acquisition arrangements listed at Paragraph 6.1.1.6. To avoid duplication in those chapters, the remainder of this chapter will introduce several concepts that are likely to be common to each acquisition arrangement.

Recognition

6.1.1.30 Aviation Safety authority may acknowledge that products, services and data received from another Aviation Safety authority and the respective system they oversight are compatible within their own Aviation Safety framework. This concept, known as ‘recognition’, is extensively employed for new Defence aircraft acquisitions. Regardless of whether a new aircraft is Defence registered or not, recognition will almost certainly be applied for aircraft design and production. For non-Defence registered aircraft, recognition will also contribute to Defence’s confidence in aircraft maintenance and operation. DASP Manual Volume 3 Chapter 6.5, Recognition of Other Aviation Safety Authorities, provides further guidance on the application of recognition.

6.1.1.31 Where recognition is being considered for a certified UAS, DASA advice should be sought. Certified UAS are not yet commonplace, so the competence and capability of international Aviation Safety authorities in regulating and oversighting certified UAS is still evolving.

Superseded

Statement of Operating Intent and Usage (SOIU)

6.1.1.32 DASRs require all Defence registered aircraft and certified UAS (and certain other UAS when directed by the Authority) to have a Statement of Operating Intent (SOIU) that has been approved by the relevant Environmental Commander and DASA. The SOIU describes the approved roles, operating envelope, usage spectrum and operating environment for a particular aircraft type.

6.1.1.33 Development of an SOIU is not mandatory for a non-Defence registered aircraft, but may assist MAOs with establishing the operational context of their intended operations, to assist with identification of any additional safety controls required to provide an equivalent level of safety to that of Defence registered aircraft.

6.1.1.34 Annex C presents further information and development guidance for SOIUs.

Independent Review of Aviation Safety

6.1.1.35 DASP Manual Volume 3 Chapter 6, Independent Review of Aviation Safety, provides information on the scope and role of Airworthiness Boards (AwBs) within the framework of capability acquisition.

6.1.1.36 Historically, AwBs were identified as a 'gate' for issuance of some DASA authorisations. The contemporary role of the AwB in the acquisition process is to complement the role of the regulator in addressing parts of the 'system of systems' that are not adequately covered through regulatory oversight activity. DASA identifies that this increases flexibility and reduces the impost on the regulated community.

6.1.1.37 Chapters 6.1.2 to 6.1.4 provide guidance on the documentation package provided to Introduction into Service (IIS) AwBs for each acquisition type. The documentation will commonly consist of:

1. the extant submissions for the relevant DASA authorisations
2. an updated ASAMP which reflects the status of the acquisition program, details and plans for outstanding activities, and impact statements and associated risk management for outstanding activities
3. checklists and other artefacts.

6.1.1.38 An AwB is commonly convened prior to the first operation of a Defence registered aircraft, due to the often complex nature of organisational, risk management and other elements. Notwithstanding the aforementioned, there is no regulatory impediment to commencing limited operations, commensurate with risk, prior to the conduct and reporting of an IIS AwB. Progressive AwBs may be convened as the organisations and operational capabilities evolve.

6.1.1.39 An IIS AwB may be less common for non-Defence registered aircraft given that Defence aircraft that are continuous 'State' aircraft should be Defence registered. When determining whether an AwB is required, the Defence AA may take into account the complexity of support arrangements, whether Defence's operations are closely aligned to civil norms, and other similar factors.

6.1.2 Acquisition of (Crewed) Defence Registered Aircraft

Introduction

6.1.2.1 Aviation safety is a command and management responsibility. Commanders and senior managers are accountable for ensuring aviation systems under their command or control are designed, constructed, maintained, and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation.

6.1.2.2 Provided the aircraft and its support and operating arrangements meet the relevant Defence Aviation Safety Regulation (DASR) requirements, DASA may issue a range of 'authorisations', in the form of certificates, permits, approvals or licenses. These authorisations provide confidence to both the Capability Manager and the Australian Government that the aircraft is capable of safe flight.

6.1.2.3 While the respective DASRs define the required safety outcomes for these DASA authorisations, history has shown that additional guidance is needed if safety risks are to be efficiently and effectively eliminated or otherwise minimised so far as is reasonably practicable.

Purpose

6.1.2.4 This chapter guides Defence's aircraft acquisition organisations, relevant in-service organisations and Defence industry partners through the aviation safety requirements and recommended practices during the acquisition (whether through purchase, lease or other arrangement) of crewed aircraft that will be Defence registered.

Regulatory outcomes from the acquisition process

6.1.2.5 For a new Defence registered aircraft to operate, Command must ensure it is safe for flight. Command achieves this by ensuring the aircraft are designed, constructed, maintained and operated to approved standards and limitations by competent and authorised personnel acting as members of an approved organisation. In turn, if suitably assured of safety, DASA may issue a range of authorisations. Depending on the acquisition and support arrangements, this can extend to 12 different types of organisational, product and personnel authorisations, as follows:

1. organisational authorisations:
    i. Military Air Operator (MAO)
    ii. Military Design Organisation (MDO)
    iii. Military Production Organisation (MPO)
    iv. Approved Maintenance Organisation (AMO)
    v. Continuing Airworthiness Management Organisation (CAMO)
    vi. Maintenance Training Organisation (MTO)
    vii. Military Type Certificate Holder (MTCH) (currently an implicit authorisation)
2. product authorisations:

Superseded

i. Military Type Certificate (MTC) and associated Type Certificate Data Sheet (TCDS)

ii. Military Permit to Fly (MPTF)

iii. Aircraft Management Programme (AMP)

iv. Military Certificate of Airworthiness (CoA)

Note: *In addition, it may include a range of niche authorisations, for example a product conformity agreement, master minimum equipment list, and so on.*

3. personnel authorisations:

i. Military Aircraft Maintenance Licence (MAML)

Note: *DASA directly authorises certain management personnel within approved organisations. However, those authorisations are considered to be part of the organisational approval process in this chapter, so they are not separately listed here.*

6.1.2.6 Figure 1 summarises the range of DASA authorisations that are usually relevant to a new aircraft acquisition, grouped according to their relevance to aircraft design, construction, maintenance or operation. The subsequent paragraphs separately explore each group.

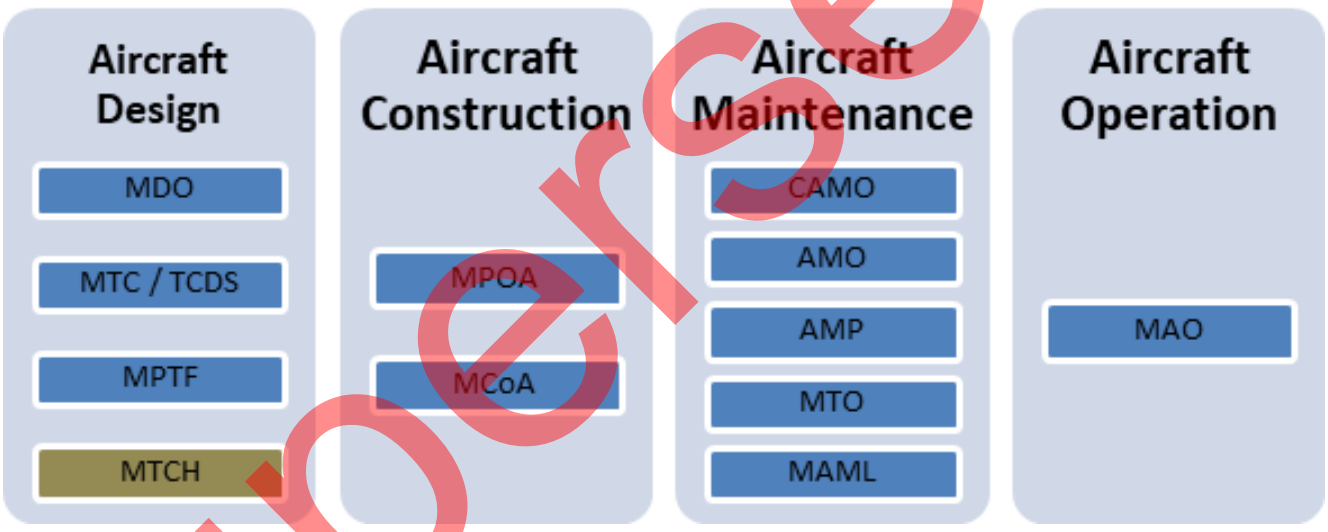

Figure 1: DASA authorisations relevant to Defence aircraft acquisitions[4]

Aircraft design (and certification)

6.1.2.7 New Defence crewed aircraft will normally be civil or military 'off-the-shelf' aircraft that are subsequently modified to meet Defence's capability requirements. Ensuring the final aircraft design is safe for flight in Defence's intended Configuration, Role and Environment (CRE) is a critical step in the acquisition process. Four separate DASA authorisations are relevant to this process, design, construction, maintenance or operation.

6.1.2.8 **Military Design Organisation (for initial aircraft design).** An organisation that has been approved by DASA to provide aircraft design services for a new Defence aircraft is termed a Military Design Organisation (MDO). These MDOs may be a military or industry organisation, and may be located in Australia or overseas. MDOs are often required for the design of new Defence aircraft,

Superseded

although as explored in the next four paragraphs, this requirement can be reduced, or even eliminated, in some circumstances.

6.1.2.9 **Military Type Certificate.** The Defence type certification process is central to confirming that the aircraft design is safe for Defence's intended Configuration, Role and Configuration (CRE) for the aircraft. At its core is the Type Certification Basis (TCB), which is a DASA-agreed set of airworthiness design requirements, including an airworthiness code and other standards, and tailoring to both as required.

6.1.2.10 At its extreme, type certification requires a DASA-approved MDO to create an aircraft design that complies with the TCB, and to produce evidence that demonstrates this compliance. In turn, DASA examines the evidence on a non-exhaustive basis, and if assured of safety, issues a Military Type Certificate (MTC)[5] and associated TCDS.

6.1.2.11 There is, however, a shortcut to the above approach that is employed for most Defence aircraft acquisitions. When Defence is procuring off-the-shelf aircraft or equipment, the Applicant[6] may seek relief from the need to develop new compliance demonstration evidence, to the extent an extant certification by a recognised National or Military Aviation Authority (NAA/MAA) is relevant to Defence's CRE. This is known as 'recognition of prior certification'. In rare circumstances, DASA can certify an entire new aircraft based solely on the prior certification of another NAA/MAA.

6.1.2.12 More commonly, however, Defence aircraft acquisitions employ a combination of the above two processes. That is, recognition of prior certification is used to cover the design of the off-the-shelf aircraft, and a DASA-approved MDO designs the Defence-unique modifications and produces the requisite compliance demonstration evidence. Sometimes another NAA/MAA may agree to certify some or all of the Defence-unique modifications, which may reduce or even remove the need for a DASA-approved MDO.

6.1.2.13 **Military Type Certificate Holder.** The MTC for a new Defence aircraft is issued by DASA to the Military Type Certificate Holder (MTCH), who takes on responsibility for ensuring the 'continued airworthiness' of the design[7]. This role is normally assigned to the relevant Defence SPO, who will implement standing arrangements with other Defence organisations, industry partners, and perhaps other militaries, to support the function. Amongst other things, the MTCH organisation is responsible for implementing systems for collecting, investigating and analysing aircraft occurrences which may affect its airworthiness, and holding (or providing access to) aircraft design information.

6.1.2.14 Note that DASA does not currently issue an explicit organisational approval for MTCHs, although this may change. Instead, the proposed MTCH arrangement is evaluated by DASA as part of its deliberations on whether to issue a MTC.

6.1.2.15 **Military Permit to Fly.** It is possible for DASA to issue a MTC for a new aircraft type immediately upon its addition to the Defence Register. More likely, however, there will be a period where the aircraft is not yet ready for a MTC because, for example:

1. the aircraft design is still under development
2. compliance demonstration evidence is still being created or compiled
3. Defence's MTC will leverage off the certification of another NAA/MAA, which is yet to be finalised

Superseded

6.1.2.16 DASA can issue a Military Permit to Fly (MPTF) to a MAO[8] in advance of the MTC if satisfied the aircraft design substantially complies with its agreed TCB, the configuration of the subject aircraft is clearly defined, the aircraft is capable of safe flight under defined conditions and for specified purposes, and any elevated risk has been justifiably retained. However, since the MPTF will usually impose (often significant) risk controls that limit the operation of the aircraft, extended operations under an MPTF are not common.

6.1.2.17 **Military Design Organisations (for in-service support).** Finally, throughout an aircraft's operational life, design changes are inevitable to remedy design defects, address obsolescence issues, design repairs, implement capability enhancements, and so on. These design changes will often be the purview of one or more DASA-approved MDOs, which are typically (but not essentially) the same as the MDOs that support the MTCH function.

6.1.2.18 Ultimately, both the MTCH and Continuing Airworthiness Management Organisation (CAMO – see below) must be able to demonstrate that sufficient design support arrangements are in place to maintain the safety of the aircraft[9], before a new aircraft is operated on the Defence Register. Depending on the aircraft acquisition contract, this design support function might initially be provided by the aircraft Original Equipment Manufacturer (OEM); if so, the in-service MDOs might not be needed immediately.

6.1.2.19 **Summary.** Summarised, the four DASA design-related authorisations that are usually relevant to aircraft acquisitions are presented in Figure 2. The MTCH is depicted in a different colour, to show that DASA does not (yet) directly issue an MTCH approval.

Figure 2: DASA authorisations related to aircraft design

6.1.2.20 DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MDOs, MTCs, MPTFs and MTCHs.

Aircraft production (or construction)

6.1.2.21 A MTC focuses on the safety of an aircraft's design. It does not consider the subsequent manufacture and assembly of the design, which is the purview of aircraft production (or

Superseded

'construction' in historic Defence parlance). The two DASA authorisations relevant to new aircraft production are Military Production Organisations and Military Certificates of Airworthiness.

6.1.2.22 **Military Production Organisation.** A Military Production Organisation (MPO) is a DASA-approved organisation that can manufacture and assemble parts, appliances, aircraft, engines or propellers to approved design data[10]. In the context of a Defence aircraft acquisition, MPOs can manufacture and assemble both the baseline aircraft (often called the 'green' aircraft) and the Defence-unique modifications to the green aircraft. They may be the same organisation, or there may be multiple different MPOs.

6.1.2.23 More commonly for new aircraft, however, Defence leverages the oversight provided by a DASA-recognised NAA/MAA of certain production organisations. This can reduce, or even eliminate, the need for DASA-approved MPOs.

6.1.2.24 **Military Certificate of Airworthiness.** As noted previously, a MTC is issued for an aircraft type. A separate DASA authorisation needs to subsequently be issued for each aircraft tail, namely the Military Certificate of Airworthiness (MCoA)[11], once DASA is satisfied the produced aircraft conforms to the design covered by the MTC. Central to DASA issuance of a MCoA is evidence that each product, part or appliance conforms to the approved design data and is in condition for safe operation.

6.1.2.25 A MCoA cannot be issued prior to the MTC. Where a new Defence aircraft is to be flown under a MPTF prior to the issue of a MTC, the MPTF effectively provides the function of the MCoA. As part of the process for seeking a MPTF, an applicant will need to demonstrate that the produced aircraft does indeed conform to the currently approved design data.

6.1.2.26 **Summary.** Summarised, the two DASA production-related authorisations that are usually relevant to new aircraft acquisitions are presented in Figure 3.

Figure 3: DASA authorisations related to production

6.1.2.27 DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MPOs and MCoAs.

Superseded

Aircraft maintenance (continuing airworthiness)

6.1.2.28 While Defence has long used the colloquial term of 'aircraft maintenance' to cover airworthiness activities beyond aircraft design and production, the DASRs purposely use the more expansive term of 'continuing airworthiness'. Aircraft maintenance is any one or combination of overhaul, repair, inspection, replacement, modification or defect/fault rectification of an aircraft or component. Continuing airworthiness encompasses this, plus maintenance management, maintenance training and maintenance licensing. For completeness, this section will use the term 'continuing airworthiness'.

6.1.2.29 Robust continuing airworthiness arrangements must be in place prior to the operation of a new Defence aircraft. Once assured of the sufficiency of these arrangements, DASA may issue three relevant organisational approvals, namely Continuing Airworthiness Management Organisations, Approved Maintenance Organisations and Maintenance Training Organisations. DASA may also approve Aircraft Maintenance Programmes and issue Military Aircraft Maintenance Licences to eligible personnel.

6.1.2.30 **Continuing Airworthiness Management Organisation.** Continuing Airworthiness covers all processes that ensure an aircraft continues to comply with initial airworthiness requirements and supports the ongoing validity of the aircraft's MCoA. The Continuing Airworthiness Management Organisation (CAMO), while not directly responsible for actual aircraft maintenance, is responsible for engaging organisations to conduct design and maintenance services. The CAMO will:

1. engage MDO(s) for design services as required
2. engage the MTCH for any matters that impact the aircraft's type design and type certification under MTC or an individual aircraft's CoA]
3. task AMOs to maintain products (aircraft, engines and propellers), parts and appliances and
4. provide governance and oversight to organisations performing DASR M functions on its behalf.

6.1.2.31 In most cases, the acquisition of a new aircraft type will not result in the creation of a new CAMO; rather, the scope of an extant CAMO will be expanded to include the new aircraft type. The presence of a suitable CAMO is integral to DASA's approval of a new MAO, or adding an additional aircraft to an extant MAO's scope.

6.1.2.32 **Aircraft Maintenance Organisations.** DASR provides two avenues for the maintenance of an aircraft and its components. The first is a DASA-approved Approved Maintenance Organisation (AMO), and the second is 'another maintenance organisation accepted by DASA'. A combination of both is usually employed for Defence aircraft.

6.1.2.33 An AMO is an organisation approved by DASA to conduct aircraft maintenance activities. This includes all actions required for restoring and maintaining an item in a serviceable condition including servicing, repair, modification, overhaul, inspection and determination of condition to maintain aircraft safety and airworthiness. AMOs may be a military or Defence Industry organisation, may be located in Australia or overseas, and may encompass one or multiple aircraft types. New Defence aircraft may be supported by one or several AMOs.

6.1.2.34 DASR Part M makes provision for maintenance services to be consumed from other maintenance organisations that are accepted by DASA. While the regulation infers that DASA explicitly accepts each of these maintenance organisations, this is not normally the case. Rather,

Superseded

DASA will automatically accept a maintenance organisation provided it is oversighted by a NAA/MAA that is 'recognised' as competent by DASA, and provided the CAMO ensures the conditions and caveats on the relevant 'recognition certificate' are met. Recognition certificates for each NAA/MAA recognised by DASA are available on DASA's website.

6.1.2.35 Prior to operation of a new Defence aircraft, the CAMO must demonstrate that arrangements are in place to maintain the aircraft in an airworthy condition. In limited circumstances, DASA may agree to the temporary absence of some maintenance arrangements, but only where this does not affect the near-term support of the aircraft.

6.1.2.36 **Aircraft Maintenance Programme.** An Aircraft Maintenance Programme (AMP) describes the scheduled maintenance tasks, their frequency of completion, the associated maintenance procedures, and so on, necessary to preserve the airworthiness of the aircraft. For aircraft acquisition projects, an initial AMP must be approved by DASA prior to the conduct of any maintenance activities. Maintenance activities can in some cases pre-date flying operations on the Defence Register, since they include aircraft preservation and other maintenance tasks required to prepare the aircraft for operation.

6.1.2.37 **Military Aircraft Maintenance Licenses.** AMOs require some personnel to hold particular categories of Military Aircraft Maintenance Licences (MAMLs). Furthermore, in order to be entitled to exercise certification privileges on a specific aircraft type, the holder of a MAML requires their licence to be endorsed with the relevant aircraft type ratings. As part of the AMO approval process for a new aircraft, the AMO will need to demonstrate that its personnel hold sufficient and applicable MAMLs.

6.1.2.38 **Maintenance Training Organisation.** A Maintenance Training Organisation (MTO) conducts training and examinations for maintenance personnel as specified in DASR 66. While a new MTO would rarely be required for a new Defence aircraft, an extant MTO would need to demonstrate its competence to conduct the type/task training and assessments for the new aircraft.

6.1.2.39 **Summary.** Summarised, the five DASA authorisations related to continuing airworthiness (of which maintenance is a component) of Defence aircraft acquisitions are presented in Figure 4.

Continuing Aircraft Management Organisation (CAMO)	Approved Maintenance Organisation (AMO)	Aircraft Maintenance Programme (AMP)	Maintenance Training Organisation (MTO)	Military Aircraft Maintenance Licence (MAML) + Type Rating
•A CAMO is an organisation approved by DASA that ensures on behalf of the MAO, that each aircraft they manage is of the approved configuration available to meet the intended purpose and safe to fly.	•An AMO is an organisation approved by DASA to conduct aircraft maintenance activities.	•A document which describes or incorporates by reference the specific scheduled maintenance tasks and their frequency of completion, the associated maintenance procedures and related maintenance standards and practices necessary to preserve the airworthiness of those aircraft to which it applies.	•An MTO is an organisation approved by DASA to conduct aviation technical training or military aircraft type rating training and examinations	•A MAML is a categorised licence which, dependent upon completion of all relevant approved training and examinations, and the requisite levels of practical experience, permits an authorised individual to issue certificates of release to service (CRS) or act as support staff for scheduled and / or unscheduled maintenance performed on an aircraft or aircraft systems as defined by DASR 66.

Figure 4: DASA continuing airworthiness-related authorisations

Superseded

6.1.2.40 DASPMAN Volume 3 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into CAMOs, AMOs, AMPs, MTOs and MAMLs.

Aircraft operation

6.1.2.41 A Military Air Operator Certificate (MAOC) is the principal authorisation granted by DASA to conduct military air activities. Each aircraft type operated by the MAO is authorised by a separate DASA-issued Operations Specification (OpSpec) annex. The OpSpec annex details, amongst other things, key positions of the MAO, operating provisions, roles and tasks, specific approvals, and any limitations or conditions imposed by DASA.

6.1.2.42 The relevant OpSpec annex is required before first flight of the aircraft by the MAO[12]. DASA will issue the OpSpec annex once assured that the necessary Fundamental Inputs to Capability (FIC) elements, as well as quality and safety management systems, are in place to support intended operations.

6.1.2.43 Preparing a MAO to take on a new Defence aircraft can be a substantial undertaking. Amongst other things, for the new aircraft type the MAO will need to:

1. define the operating intent and usage for the aircraft through an approved Statement of Operating Intent and Usage (SOIU)
2. ensure arrangements are in place for maintaining the airworthiness of the aircraft through a CAMO and AMOs
3. implement the multitude of systems needed to manage Operations personnel and Air operations
4. produce/accept Orders, Instructions and Publications (OIP)[13]
5. establish an Aviation Safety Management System (ASMS).

6.1.2.44 Implementing these requirements, even for an existing MAO, is likely to require considerable planning and effort. Consequently, DASA recognises that a graduated capability growth plan for operational authorisations may be required. The Aviation Safety Acquisition Management Plan (ASAMP - see Chapter 6.1.1 and later in this chapter) is a suitable repository for reflecting the status of the acquisition program, including details of work completed, re-programing of remaining activities and risk management for the incomplete tasks.

6.1.2.45 **Summary.** Summarised, the singe DASA flight operations-related authorisation relevant to aircraft acquisitions is presented in Figure 5.

Superseded

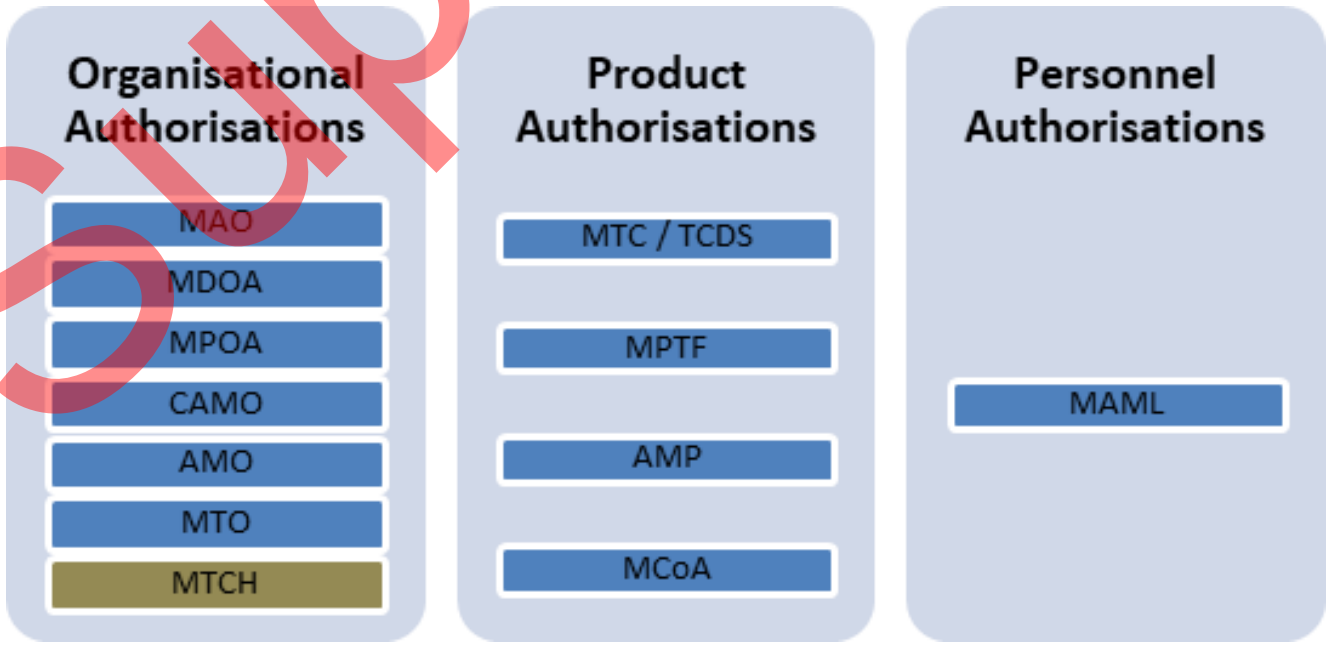
Figure 5: DASA authorisations related to aircraft operations

6.1.2.46 Chapter 5.3, Aviation Safety Authorisations, provides additional insight into MAOs.

Summary

6.1.2.47 This section has presented an overview of the DASA authorisations that may be relevant to new aircraft design, construction, maintenance and operation. Depending on the acquisition arrangements and the aircraft role, some authorisations might not be required.

6.1.2.48 The diagram at the start of this section (Figure 1) summarised all of the possible DASA authorisations according to whether they were relevant to new aircraft design, construction, maintenance or operation. However, another way of grouping them is according to whether they are organisational, product or personnel authorisations, as shown in Figure 6.



Superseded

Figure 6: DASA authorisations for new aircraft (grouped by category)

6.1.2.49 This grouping has the advantage that the eight organisational authorisations all use substantially the same processes for application and approval, and the three product authorisations have strong synergies. Consequently, for simplicity, this grouping will be used in the next section.

Processes, Plans and DASA Interaction

6.1.2.50 The previous section presented an overview of the DASA authorisations that may be relevant to new aircraft acquisitions. While the respective DASRs define the required safety outcomes for these DASA authorisations, history has shown that achieving the authorisations can be a complex and protracted journey. This section guides the reader though the process of achieving these DASA authorisations.

6.1.2.51 Figure 7 shows how the various DASA authorisations usually fit onto a project timeline. The vertical stripes present four significant milestones for introducing a new aircraft to Defence, the items above the dashed line show DASP-related project and Command activities, and the items below the line show the DASA authorisations. A time scale has purposely not been included, because this can vary enormously between aircraft acquisitions.

Superseded

Figure 7: Common project timeline for DASA authorisations

6.1.2.52 The elements below the dashed line can broadly be grouped into five activities, as shown in Figure 8. With the exception of Activity 1, the remaining activities are rarely sequential; more often than not Activities 2 and 3 are executed concurrently, and several activities may be cyclic.

Superseded

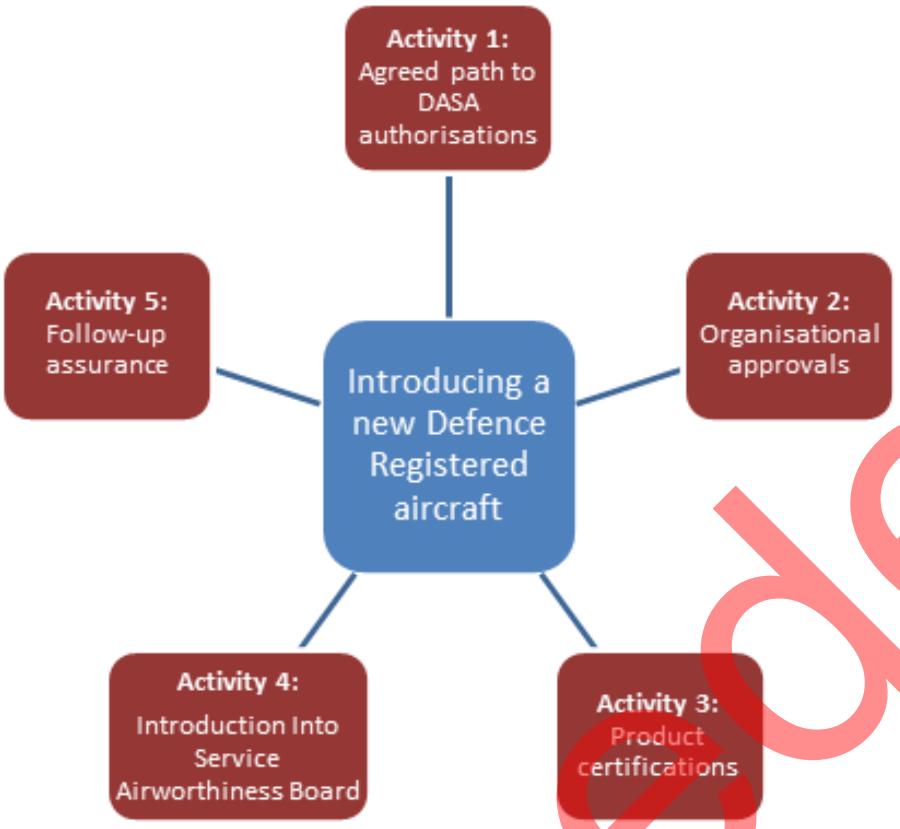


Figure 8: Activities in introducing a new Defence aircraft

6.1.2.53 Each of these five activities from Figure 8 is explored below.

Activity 1: Agreed path to authorisations

6.1.2.54 A major milestone in the aircraft acquisition process is the achievement of a range of DASA authorisations. However, establishing the contracts, systems and people to merit each authorisation is usually complex, with considerable potential to waste time and resources. Effective engagement with DASA is therefore in the best interests of all parties.

6.1.2.55 **Initial engagement.** Engagement should ideally commence as soon as Defence's acquisition organisation has a reasonable view on the candidate aircraft, the need for Defence-unique design changes, and the probable operating and support constructs[14]. Engagement should be well-advanced before Defence issues any tender documents (eg Requests for Tender, Foreign Military Sales Letter of Requests, etc) that may later affect an authorisation.

6.1.2.56 The initial engagement should involve DASA specialists, the Defence acquisition organisation, and capability manager representatives. If known, the Defence and industry organisations that will support the aircraft could also participate. Key outcomes will be:

1. a shared understanding of the project scope and schedule, candidate aircraft and the likely scope of Defence-unique design changes

Superseded

2. initial views on which of the seven DASA organisational approvals are likely to be needed and, for those that may not be needed, agree on the alternative means of achieving the same safety outcomes

3. initial views on how the aircraft might achieve an MTC, including how current or future certifications by DASA-recognised national or military airworthiness authorities (NAA/ MAAs) might contribute

4. initial views on whether an MPTF might be required to allow for test and other flying prior to the issue of an MTC

5. DASA should provide a management overview of each likely DASA authorisation, including: key milestones, common approval timeframes, recommended DASA collaboration, availability of training and other guidance material, and so on.

6.1.2.57 Annex A presents an expanded version of the above list, which can be used as a set of talking points for this initial engagement. Depending on the acquisition strategy, some of the details may initially be sparse. If so, further engagement should be scheduled for when the information is likely to become available, but still before releasing RFTs or equivalent documents.

6.1.2.58 **Documented agreement.** As noted in Chapter 6.1.1, DASRs do not mandate a plan or agreement for achieving DASA authorisations. It is, however, a practice that DASA highly recommends, given the substantial complexities in establishing the organisations and systems to manage aviation safety, and therefore the potential impacts (both positive and negative) on cost and schedule - and ultimately Defence capability.

6.1.2.59 DASA advocates the production of an Aviation Safety Acquisition Management Plan (ASAMP). The ASAMP is an iterative agreement between Applicants and DASA on the path to achieving DASA authorisations, and supports commanders and managers in accounting for parallel lines of effort and cross-regulation dependencies.

6.1.2.60 Annex B presents the suggested content and management arrangements for an ASAMP. Summarised, it suggests the main body of the ASAMP should describe the overarching aviation safety acquisition strategy and bring together the planned outcomes of the operational, technical, logistical and safety management activities. It should also describe the management of flight operations during acquisition, particularly if operations are to commence under an MPTF.

6.1.2.61 Annex B also suggests the ASAMP should include a series of annexes, with individual annexes dedicated to each DASA authorisation. Each annex could be sponsored by the relevant Applicant for the DASA authorisation, and could form an agreement between DASA and the Applicant on the path to the particular authorisation. For simple acquisitions, the annexes might directly present the information[15]. For more complex acquisitions, particularly where there are a range of Applicants for the various DASA authorisations, the annexes might merely contain a link to a planning document that is drafted and managed by the respective Applicant. Either way, the annexes should be 'modular', whereby each annex is configuration managed and approved separately to the main body of the ASAMP.

Superseded

6.1.2.62 The ASAMP should be drafted after the acquisition strategy solidifies (usually post Government approval), but before RFTs (or equivalent) are released. The ideal time to draft the ASAMP is usually soon after the initial engagement with DASA, and in fact that engagement will influence much of the ASAMP content. The ASAMP would normally be updated after contracts and agreements are signed, since the path to most DASA authorisations should be clear.

6.1.2.63 Once contracts and agreements are signed, the main body of the ASAMP need only be updated when there is a marked change in the acquisition strategy or high-level schedule for the project. The annexes, on the other hand, will probably be updated more frequently, particularly in the earlier stages of the project as knowledge and plans evolve.

6.1.2.64 **Ongoing engagement.** DASA's experience is that three forms of engagement should be maintained throughout the project lifecycle, as follows:

1. Periodic major stakeholder engagements, expanding on the initial engagement suggested previously in this section. This should occur throughout the acquisition project lifecycle, usually when significant milestones are approaching

2. Frequent coordination and status updates between senior project management staff (commonly the CASG Project Engineering Manager, the CM Transition Team lead, etc), and DASA's operational and technical leads for the acquisition

3. Engagement as required between each of the Applicants for a DASA authorisation and the respective DASA specialist.

6.1.2.65 **DASA assistance with contract reviews.** There is no DASR requirement for DASA to be engaged in seeking offers (eg RFT or equivalent), selecting the successful tenderer, negotiating the contract, and signing the contract. However, where a contract element may one day affect a DASA authorisation, prudent DASA involvement can reduce project cost and schedule risk. Areas where DASA can contribute include:

1. Prior to RFT (or equivalent) issue:

    i. confirming the RFT requirements for organisational approvals are appropriate for aircraft acquisition and/or in-service support

    ii. confirming the RFT airworthiness design requirements (including airworthiness codes and other standards), and proposed approach to aircraft certification, present a suitable pathway to MTC

    iii. confirming the RFT aircraft production arrangements present a suitable pathway to issue of MCoA

    iv. confirming aircraft registration pathways, particularly for significant modifications to a green aircraft by a third party

Superseded

v. providing expert input to specialist aircraft design technology requirements, such as aircraft structural integrity (ASI) design and in-service management systems.

2. For RFT assessment:

i. If any of the above RFT items seek preliminary plans for DASA organisational approvals or product certifications, then DASA can participate in the assessment of those plans

ii. otherwise, while the Defence acquisition organisation will conduct the tender evaluation, DASA staff are available for on-call advice and assistance as required[16]

3. For contract negotiation: DASA staff would rarely be directly involved in contract negotiations, but are available for on-call advice and assistance as required.

4. Final contract review: DASA does not review the mature contract prior to signature, but is available for advice and assistance as required.

6.1.2.66 **Delegations.** During the project lifecycle, organisations may elect to delegate their Command responsibilities, for example the appointment of the senior operator within the project transition team to make operational decisions in relation to the project. Once notified of the delegation, DASA will treat the decisions and approvals of the delegate as if the accountable manager had issued them.

6.1.2.67 Later in the project lifecycle, usually just before MTC issue, a 'Platform DoSA' will need to be appointed by DASA. The Platform DoSA role is normally delegated to the incumbent Defence CENGR of the platform MTCH organisation, and is responsible for assurance of MTCH actions with respect to reportable occurrences, issue of MCoAs, approval of flight conditions and issue of Airworthiness Directives. DASP Manual Volume 3 Chapter 4.3, Delegates of the Safety Authority, provides additional information.

Activity 2: Organisational approvals

6.1.2.68 Professional aircraft design, construction, maintenance and operation organisations are cornerstone to aviation safety. Implementing the required organisations for a new aircraft, and obtaining DASA approval of each organisation, is usually a significant activity for both the Applicants and DASA. This section explores the planning, establishment and assessment of new DASA-approved organisations.

6.1.2.69 **Planning.** As noted in Activity 1, the ASAMP should include a planning annex for each organisational approval. The ASAMP should plan for the organisational approvals to be achieved well prior to their need date, which are likely to be as follows:

Superseded

1. MAO: DASA authorisation is required prior to the first operation of the aircraft by the MAO[17]. This authorisation is reflected in DASA's issue of an OpSpec annex for the new aircraft

2. MDO:

   i. (for initial aircraft design): Required prior to design changes to the green aircraft, if those changes are not to be certified by a recognised NAA/MAA

   ii. (for in-service support): Required prior to first flight on the Defence Register, unless DASA has agreed to an alternative interim support arrangement

3. MTCH: Implementation of suitable MTCH arrangements are a prerequisite for issue of an MTC. However, depending on the acquisition arrangement, some of these functions may need to be in place earlier to support the initial MPTF

4. MPO: Required prior to any aircraft production activity, unless an alternative production approval path has been agreed by DASA

5. CAMO: Required prior to first flight of the aircraft on the Defence Register

6. AMO: Required prior to first flight of the aircraft on the Defence Register[19], unless an alternative interim maintenance arrangement has been agreed by DASA. AMOs will need MAMLs in sufficient numbers to meet AMO needs, relevant to the scope of operations and numbers of aircraft

7. MTO: Agreed in consultation with DASA.

6.1.2.70 Note that while DASA agreement to the above authorisation plans is not a regulatory requirement, it is encouraged by DASA. As Figure 9 shows, the time needed to implement a new organisation and then achieve a DASA organisational approval can be substantial, so careful management is needed to minimise Defence's schedule risk.

Superseded

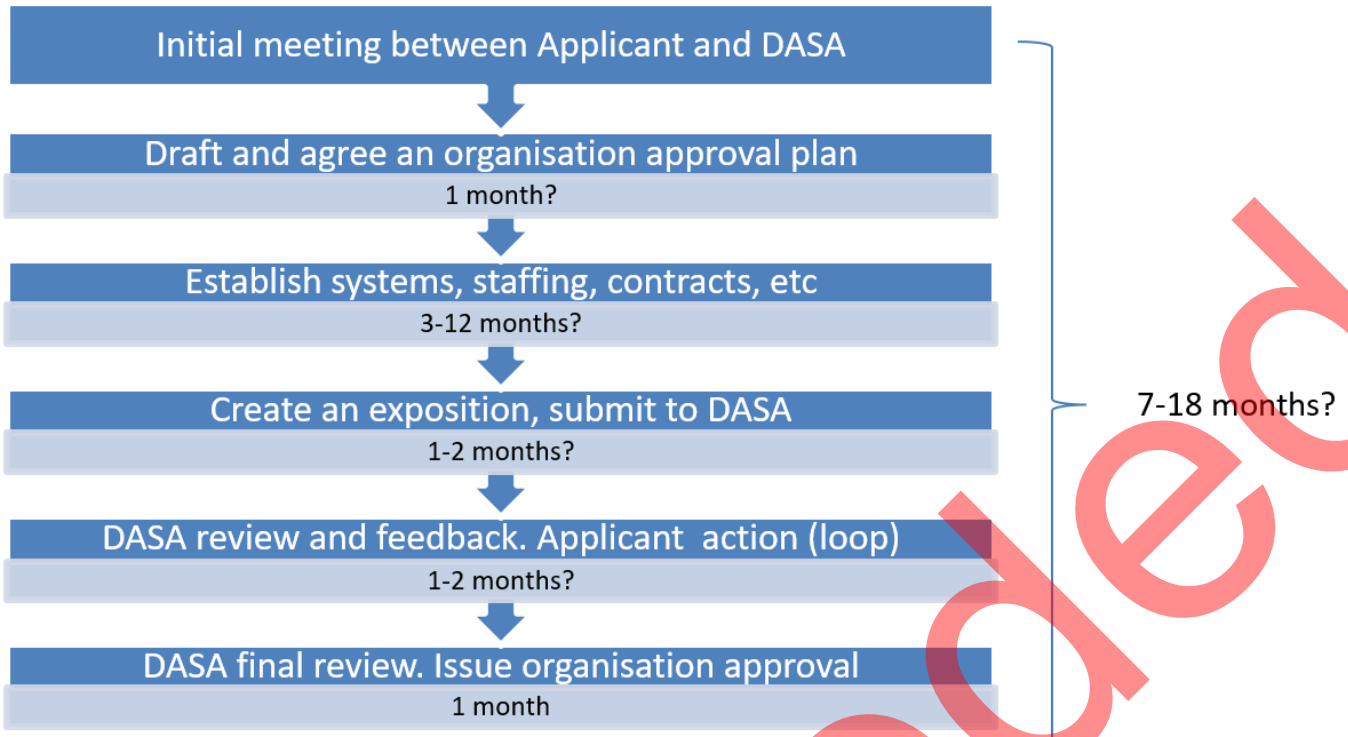

Figure 9: Timeline for DASA organisational approvals

6.1.2.71 **Establishing organisations.** DASP Manual Volume 3 Chapter 5.3, Aviation Safety Authorisations, presents a description of each DASA organisational approval, including the key artefact(s) needed to show regulatory compliance - for example, the MDO's design organisation handbook, the AMO's Maintenance Organisation Exposition (MOE), the MAO's Operations Compliance Statement (OCS), and so on. Each of these artefacts will help guide the Applicant's efforts to establish an organisation that professionally supports Defence aviation safety, as will the Acceptable Means of Compliance (AMC) and Guidance Material (GM) accompanying the relevant DASRs. DASA-sponsored education courses and DASA website material also offer useful information.

6.1.2.72 However, Applicants must bear in mind that such guidance may be incomplete, or not entirely relevant to the local context. Consequently, DASA cannot overstate the importance of the Applicant's role in refining the organisation beyond DASR (and DASA) requirements. This might include, for example:

1. learning from other Defence organisations
2. learning from comparable civil organisations[20]
3. exploring the (often extensive) guidance material released by other NAA/MAAs[21]
4. consulting with staff and others with relevant domain expertise.

6.1.2.73 A robust and evolving Aviation Safety Management System (ASMS) is pivotal to establishing an organisation that optimises its contribution to Defence aviation safety. An ASMS utilises a systematic

Superseded

approach to managing aviation safety, including organisational structures, accountabilities, policies and procedures. An effective ASMS continuously improves an organisation's safety performance through pro-actively collecting and analysing safety data to predict, prevent and treat aviation hazards and risks. DASP Manual Volume 3 Chapter 6.2, Safety Management, provides further guidance.

6.1.2.74 **DASA assessment.** The annexes in Chapter 5.3 provide insight into DASA's approach to assessing, and ultimately approving, a new or expanded organisational approval. Most approvals follow a similar process, namely:

1. the Applicant drafts an 'Exposition' or similar document, as key evidence that their organisation has implemented the systems and processes needed to comply with the relevant DASRs

2. the applicant submits the relevant DASR Form to seek an organisational approval

3. DASA conducts an assessment of the Exposition and the documents it references, often as a desktop activity for new organisations; on occasion DASA may do an on-site assessment

4. if needed, the applicant remedies any deficiencies that preclude DASA's approval of the organisation

5. DASA issues an organisational approval, perhaps initially limited in scope

6. once the aircraft is operating and the organisation has the opportunity to exercise its approval, DASA will conduct a deeper assessment, usually including an on-site visit, placing particular emphasis on the effectiveness of the ASMS and system monitoring.

6.1.2.75 Figure 10 summarises the path through to DASA approval for the seven organisations common to new aircraft acquisitions.

Superseded

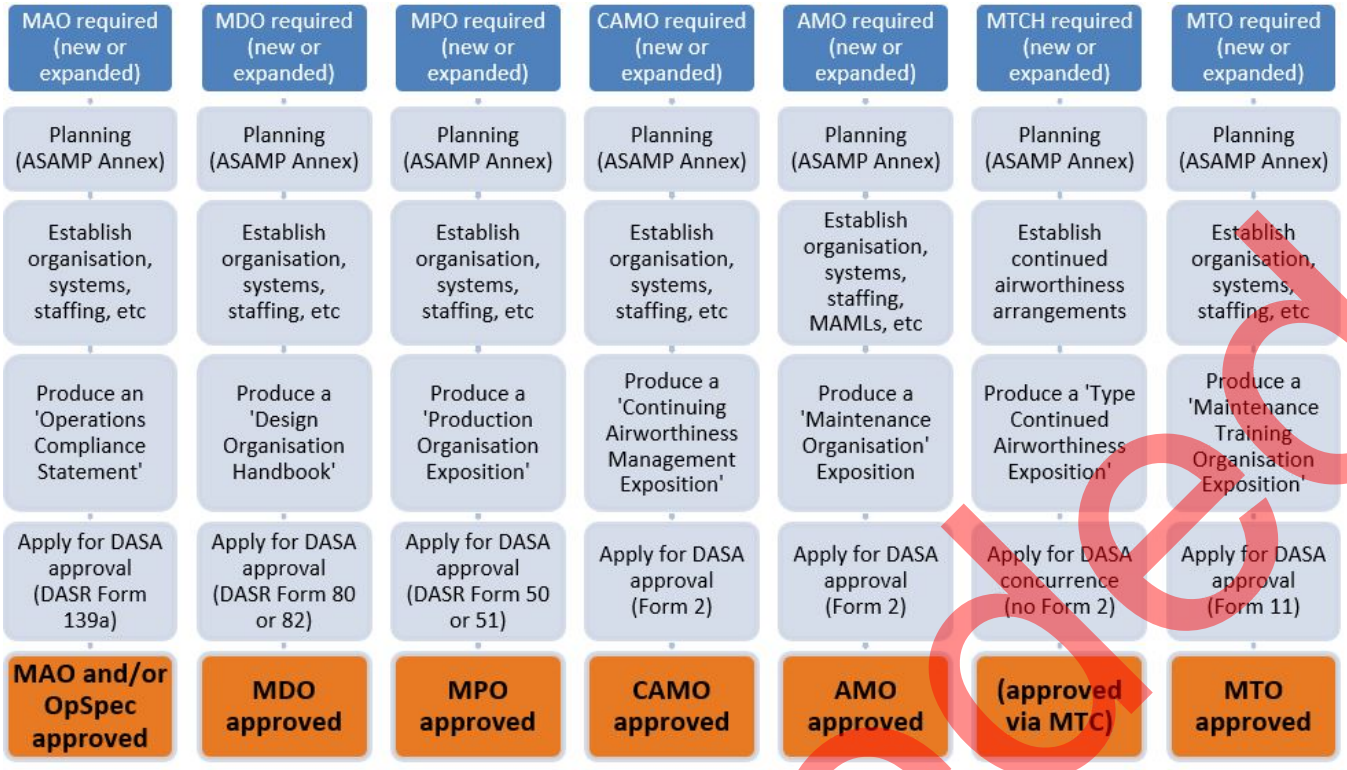

Figure 10: Path to DASA organisational approvals

Activity 3: Product authorisations

6.1.2.76 The four common product authorisations for new aircraft are the MTC, MCoA, MPTF and AMP. While an MPTF will often be issued prior to an MTC and MCoA, preparatory work on the other two will usually precede and support the issue of the MPTF. Hence, this section will consider the MPTF last.

6.1.2.77 Before exploring the four product authorisations, some brief discussion on safety risk management is warranted. Risk management is almost always a contributor to MTC and MPTF authorisations, so all stakeholders need to be conversant with Defence's 7-step risk management approach, as explained in the DASA Advisory Circular 003/2018, Risk Management in the DASP. Furthermore, DASA's experience is that this risk management is most effective when all parties robustly consult, cooperate and coordinate with each other. Critically, this must occur across organisational boundaries, and across specialisations (most notably between operators and engineers).

6.1.2.78 **MTC.** Achieving an MTC for a new aircraft is a significant milestone for an aircraft acquisition project, and one that commonly takes substantial planning and effort. While the path to an MTC is explored in DASP Manual Volume 3 Chapter 7.2, Certification, for the benefit of readers not needing that depth of information, a brief description of the process is included here.

Superseded

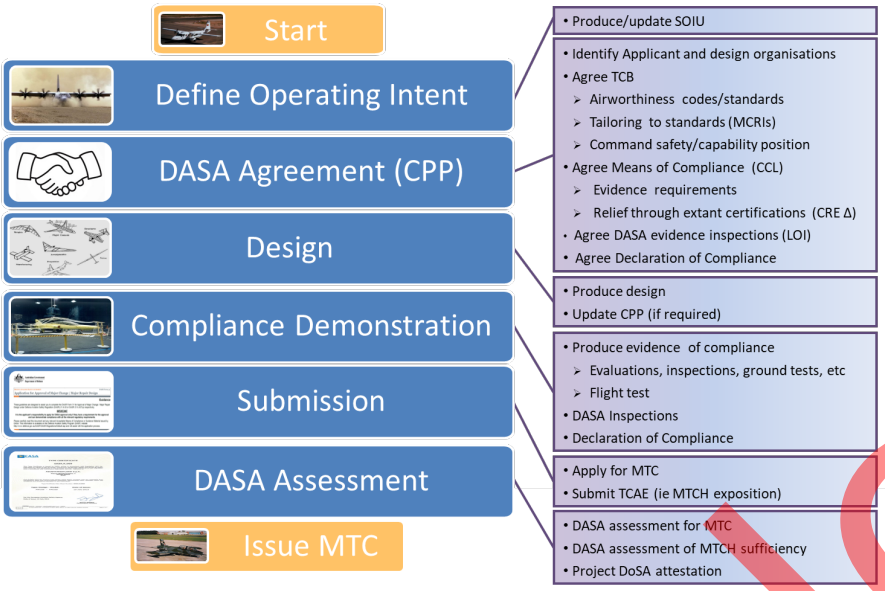

Figure 11: Path to issue of an MTC

6.1.2.79 An overview of the type certification process, culminating in an MTC, is shown in Figure 11. The first step, defining the operating intent for the aircraft, is pivotal to designers producing a design that is safe for Defence's intended Configuration, Role and Environment (CRE). A poorly-developed operating intent, or one developed late in the design lifecycle, can (and previously has) resulted in:

1. additional cost to re-design elements of the aircraft
2. operational limitations to eliminate the elevated risk, or
3. management and retention of elevated risk, often for the life of the aircraft.

6.1.2.80 The second step shows the Applicant and DASA agreeing on a Certification Program Plan (CPP). While a CPP is not explicitly required by DASR, it is inconceivable that Defence would pursue a certification program without an agreed CPP, since it imposes obligations on both the Applicant and DASA. Critically, the CPP:

1. agrees on the Type Certification Basis (TCB) for the new aircraft, which comprises the airworthiness requirements (inclusive of tailoring) that the design must meet
2. agrees on the evidence that will be produced by the design organisation(s) to demonstrate the design complies with the TCB
3. agrees on the application of 'recognition of prior acceptance', where existing product certifications by DASA-recognised NAA/MAAs will contribute to the certification of Defence's new aircraft [22]
4. defines the extent of DASA's inspections of compliance demonstration evidence.

Superseded

6.1.2.81 The tailoring of the TCB, mentioned in the first sub-paragraph above, is accomplished using one of five types of Military Certification Review Item (MCRI)[23]. Four of these MCRIs either maintain or improve the safety of the aircraft design, while the fifth, the 'Exception MCRI', can approve a reduction in the safety of the aircraft design. This reduction is only justifiable where requiring compliance with a TCB requirement would adversely affect Defence capability. While DASA ultimately approves the Exception MCRI, it is based heavily on Command's confirmation that a capability imperative exists, and that the risks due to the TCB non-compliance have been eliminated or otherwise minimised SFARP. The document used to communicate and record these Command risk decisions is normally the Airworthiness Issue Paper (AwIP). Guidance for AwIPs is provided at annex C.

6.1.2.82 The third step in the certification process is where the design organisation produces the design. For new Defence-unique designs, this often requires a DASA-approved MDO unless the design will be certified by a DASA-recognised NAA/MAA, as explained earlier in this chapter. The MDO must be in place before the design effort commences.

6.1.2.83 The fourth step, Compliance Demonstration, is where the MDO produces evidence that their design meets the DASA-agreed TCB. This step may require DASA approval of an MPTF to enable flight testing if the aircraft is already on the Defence Register. The MPTF is explored later in this section.

6.1.2.84 The fifth and six steps wrap up the certification process, and are largely self-explanatory. It is worth noting that while an Airworthiness Board (AwB) is not a prerequisite for DASA issue of an MTC, if the Defence Aviation Authority (Defence AA) elects to convene an AwB near to the MTC issue date, then DASA may wait until after that event to issue the MTC. AwBs are explored later in this chapter.

6.1.2.85 **MCoA.** As noted previously, an MCoA cannot be issued prior to the MTC. However, it is normal practice for the Defence acquisition organisation to be prepared in advance, so DASA[24] can issue MCoAs for the delivered fleet directly following the issue of the MTC. DASPMAN Volume 3 Chapter 5.3 presents the conditions and processes for MCoA issue.

6.1.2.86 **MPTF.** Once a new aircraft type has been added to the Defence Register, but prior to issue of the MTC, MAOs may need to operate the aircraft. For example, the flight test MAO may need to conduct flight tests to generate compliance demonstration evidence, and to contribute to operational test and evaluation (OT&E). The operational MAO may need to maintain crew currency, evolve OIP, conduct OT&E, and so on.

6.1.2.87 DASA can issue an MPTF if the aircraft design has been shown to substantially comply with its TCB, the configuration of the aircraft is clearly defined, the aircraft is capable of safe flight under defined conditions, and any elevated risk has been justifiably retained. An MPTF is effectively reliant on both the MTC and the MCoA processes being well-advanced.

6.1.2.88 The initial MPTF will usually constrain the MAO's operation of the aircraft. After all, the type certification program is still incomplete so there will be areas of the design that are known to be deficient or where uncertainty still remains, and hence the MPTF will impose commensurate risk controls. DASPMAN Volume 3 Chapter 7.5, Flight Conditions and MPTFs, explores MPTFs and their associated flight conditions, including risk management, the application process, periods of validity, and so on. The MAO will often self-impose additional constraints on flight operations, and will ease these constraints as the systems and personnel skills mature.

Superseded

6.1.2.89 **AMP.** CASG's Reliability and Aircraft Maintenance Program (RAMP) team, which is collocated with DASA's Melbourne office, provides Defence's centre of expertise for AMPs, and advises DASA on whether an AMP should be approved[25]. Both DASA and the RAMP team should be engaged early in the acquisition phase for guidance on AMP requirements.

Activity 4: Convene an Airworthiness Board

6.1.2.90 As discussed in Chapter 6.1.1, the Defence AA would normally require that an AwB be convened prior to operation of a new aircraft on the Defence Register[26]. The Introduction into Service AwB, normally held immediately prior to the commencement of flight operations, complement regulatory activities conducted by the DASA and build on the confidence of DASA authorisations. This AwB is underpinned by progressive check-ins by the board members with both DASA and the regulated community, focussing on:

1. understanding the status of DASA assurance of relevant products and organisations
2. safety assurance of the collective enterprise (CM, CASG, Industry) introducing the new platform;
3. potential organisational culture hazards; and
4. transition safety risks associated with the introduction of the capability through to reaching initial operational capability milestones.

6.1.2.91 The artefacts submitted by Applicants to the AwB would predominantly consist of already produced project documentation and attestations that collectively summarise the readiness to commence Flight Operations:

1. Airworthiness Plans, Artefacts, Approvals and Authorisations
2. FIC Status and Capability Realisation
3. Integrated Airworthiness System Assessment
4. MAO Risk Management and OIP

6.1.2.92 The Defence AA would normally require progressive AwBs during the initial operating period for a new aircraft, most likely aligned with key Operational Capability milestones. Hence the AwB can explore whether the operational and support systems are maturing commensurately. Periodicity might be influenced by the severity of organisational and/or product deficiencies noted during DASA assurance activities and/or a previous AwB.

6.1.2.93 Annex D presents additional guidance on the submissions, requirements and conduct of an AwB for a new aircraft type.

Superseded

Activity 5: Follow-up DASA assessments

6.1.2.94 The organisational and product authorisation requirements presented in this chapter are seldom wholly implemented when the Applicants apply for the relevant DASA authorisations. Provided DASA is satisfied the safety risks due to the deficiencies can be robustly managed, this may not preclude DASA from issuing the authorisation, as explored in the following paragraphs.

6.1.2.95 **Organisational approvals.** When DASA initially issues an organisational approval, the processes and people may not yet have been exercised for the new aircraft type. For example, an MDO may not have produced designs, the MAO may not have exercised its ASMS, organisational deficiencies may have been identified by DASA, and so on. Equally, the organisation may self-identify temporary deficiencies in their own processes and people.

6.1.2.96 These issues may not preclude DASA from issuing the organisational approval if satisfied the organisation has the ability to safely operate and support the aircraft. DASA may elect to moderate this risk through, amongst other things:

1. placing limitations on operations, initially via the initial MPTF and later via the OpSpec
2. initially constraining the 'privileges' that are available to organisations under some regulations
3. re-visiting the organisation soon after their systems and processes have been exercised.

6.1.2.97 Over time, once DASA is assured the deficiencies or lack of experience have been addressed, the constraints may be eased. The Defence AA may convene AwBs to provide additional confidence.

6.1.2.98 **Product authorisations.** As a matter of pragmatism, a MTC can be issued before compliance with the TCB has been entirely demonstrated. As a result, the MTC may include temporary limitations, or the TCB may include temporary Exception MCRIs (with supporting AwIPs documenting essential risk management), pending resolution of the outstanding design issues. Once evidence of TCB compliance is provided to DASA's satisfaction, the limitations or other risk management measures can be progressively removed.

Project completion

6.1.2.99 Even after the above five activities have been substantially completed, residual issues may still be outstanding. Provided these issues are sufficiently few in number and complexity[27], they have been professionally transitioned to the running system, and any associated risks are being managed in the relevant ASMS, DASA will in due course consider the acquisition project to be closed.

6.1.2.100 The residual issues will be monitored by DASA through normal compliance assurance activities.

Niche Applications

Superseded

6.1.2.101 So far, this chapter has focused on new aircraft types being acquired by Defence. This final section will explore three niche applications of the information presented in this chapter, namely fleet additions, acquisition of used aircraft, and Major design changes to in-service aircraft.

Fleet addition aircraft

6.1.2.102 When additional aircraft are to be added to an extant Defence fleet, the guidance presented earlier in this chapter is still mostly relevant, although it can be applied in a substantially abbreviated form. An assessment of each of the five activities from the previous section is presented below.

6.1.2.103 **Activity 1: Agreement on DASA authorisations.** The information presented in the previous section is entirely relevant. That is, the acquisition organisation should engage with DASA before contracts and other agreements are signed, and an agreed path to DASA approvals should be documented in an ASAMP. The ASAMP will be much abbreviated compared to the acquisition of a new aircraft type, and some of the ASAMP annexes will not be required.

6.1.2.104 **Activity 2: Organisational approvals.** Each of the organisational approvals will likely be in place, so this activity is limited to ensuring those organisations can manage the additional workload and (where applicable) the configuration differences of the new aircraft.

6.1.2.105 **Activity 3: Product certifications.** If the new aircraft are precisely the same configuration as the extant fleet, they can simply be listed on the MTC and individual MCoAs then issued for each new aircraft. More likely, however, there will be configuration differences. While other avenues may be acceptable, most often the new aircraft are added to the MTC mirroring the configuration of the extant fleet, and the configuration deltas for the new aircraft are processed as design changes (Major and Minor) to the common type design. If there will be a delay in completing this activity, an MPTF can be used to cover the configuration differences of the additional aircraft.

6.1.2.106 If there are substantial configuration differences to the extant fleet, perhaps even with changes to the TCB, the new aircraft might need to undergo a targeted type certification program that focuses on the configuration deltas. DASA's approval may be reflected as a separate model number on the MTC, or the deltas might be encompassed in a Military Supplemental Type Certificate (MSTC).

6.1.2.107 **Activity 4:** AwB. AwB independent review of additional aircraft would normally be considered as part of the next scheduled sustainment AwB. In exceptional circumstances, a separate AwB may be convened if the acquisition of additional aircraft requires appreciable changes to extant FIC arrangements.

6.1.2.108 **Activity 5:** Follow-up DASA assessments. The information on product deficiencies presented in the previous section is equally relevant to fleet addition aircraft. The information on organisational deficiencies, on the other hand, is unlikely to be applicable; rather, the next routine compliance assurance activity would check how the organisation is coping with the extra workload.

Used aircraft

Superseded

6.1.2.109 Where Defence elects to acquire used aircraft, the guidance presented earlier in this chapter is entirely relevant. However, there are additional actions that will need to be undertaken for Activity 3: Product Certification, namely the provision of additional documentation and the completion of additional inspections to support the issue of an MCoA.

6.1.2.110 **Documentation.** DASR 21.A.174 presents a list of the additional documentation needed for a used aircraft, namely:

1. (if the aircraft originates from a foreign military applying an EMAR based regulations): a Military Airworthiness Review Certificate;

2. (if the aircraft originates from a civil state of registry that is recognised by DASA): an export certificate of airworthiness from the recognised CAA;

3. (if the aircraft originates from elsewhere):

    i. a statement by the Authority of the State where the aircraft is, or was, registered, reflecting the airworthiness status of the aircraft on its register at time of transfer

    ii. a weight and balance report with a loading schedule

    iii. the flight manual and any other manuals required by the Authority of the State of registry

    iv. historical records to establish the production, modification, and maintenance standard of the aircraft, including all limitations associated with a restricted certificate of airworthiness

    v. a recommendation for the issuance of a certificate of airworthiness or restricted certificate of airworthiness and a Military Airworthiness Review Certificate following an airworthiness review in accordance with DASR M.

6.1.2.111 **Inspections.** Used aircraft require a more stringent inspection than new build aircraft, and must be performed by an appropriately qualified, independent and experienced organisation. The inspecting organisation is to conduct a comprehensive review of the aircraft design, maintenance and operational documentation, verified by a physical inspection of the airframe structure, engines and other systems.

6.1.2.112 The inspecting organisation is to provide inspection reports detailing the airworthiness inspection result. As a minimum, reports should include the following:

1. details of the aircraft inspected, including registration number, manufacturer, serial number, model designation, and Certificate of Airworthiness number

2. last known inspected configuration of the aircraft

Superseded

3. a summary of the usage and maintenance history of the aircraft, engines and propellers, including current maintenance, weight and balance, and lifed component status

4. details of any major structural and life-limited component changes made to items such as wings and tailplane, and a summary of the individual histories of such components, unless new when fitted

5. details of any accidents or incidents in which the aircraft has been involved

6. details of any major repairs or modifications performed on the aircraft, engines and propellers and verification that they have been properly approved and incorporated

7. details of any applicable aircraft-general, type-specific, engine or equipment airworthiness directives or service bulletins and verification that the aircraft complies

8. a condition assessment of flight safety critical components and fatigue-sensitive structure

9. recommendations for the resolution of any airworthiness deficiencies or concerns arising as a result of the airworthiness inspection

10. flight manuals and any other manuals.

6.1.2.113 Should Defence be contemplating the acquisition of used aircraft, DASA should be contacted early in the decision process. DAVENG staff in particular will provide the acquisition project with useful guidance.

Major design changes

6.1.2.114 This chapter has so far focused on aircraft acquisitions. However, the content can be extensively applied to particularly complex Major design changes to in-service aircraft. A Major design change is one that has an appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product .

6.1.2.115 Defence currently conducts around 70 Major design changes to its fleet each year. Most of these design changes have little if any significant impact on the aircraft operator or support organisations. Occasionally, however, Defence undertakes a Major design change whose effects pervade the DASP.

6.1.2.116 An example might be an extensive mid-life cockpit upgrade, which will not only challenge the design organisation, it can extensively affect MAO OIP, require simulator upgrades, change the aircrew training curriculum, allow new Performance Based Navigation approvals, require additional maintenance equipment and training, require new production organisations, require parallel operations of two different aircraft configurations for extended periods, and so on. An extensive flight test program to explore human factors and other certification issues might also be required.

Superseded

6.1.2.117 Making such pervasive changes to the aircraft and supporting systems can be a complex undertaking that requires coordination and often robust risk management across multiple organisational boundaries. While it perhaps does not have the complexities of introducing a new aircraft into service, it is far from straightforward and can introduce elevated safety risks if not executed well. In such circumstances, increased independent assurance from DASA is likely to benefit aviation safety.

6.1.2.118 Where DASA, in consultation with the MAO and CASG, identifies a Major design change that warrants this expanded DASA independent assurance, DASA will treat the project similarly to an aircraft acquisition. This may include, for example, increased scrutiny of organisational approvals, a closer assessment of how the new configuration is introduced into service (including, if necessary, imposing temporary operating constraints), greater assurance of risk management decisions, and so on. The Defence AA may require an AwB to be convened to provide an independent review of how well the new configuration has been integrated into Defence.

6.1.2.119 For these Major design changes, the guidance in the previous section is applicable almost in its entirety. Notably, an ASAMP should be raised, albeit some elements will self-evidently either be of limited scope or not applicable. An SOIU update may be required, organisational approvals may need to be expanded, and so on. The only element that is unchanged is the type certification process, since DASA certification oversight is always implemented commensurate with risk, and this is unaffected by the additional DASA scrutiny outlined in this section.

Annexes:

1. Project Initiation Meeting
2. ASAMP Guidance
3. Airworthiness Issue Papers
4. Airworthiness Board Guidance

6.1.3 Acquisition of Non-Defence-Registered Aircraft

Introduction

6.1.3.1 Civil registration of a Defence aircraft may be attractive to Capability Managers (CMs) and acquisition organisations. It may provide contractual and ongoing management simplicity, and sometimes lower costs and result in a faster introduction into service.

6.1.3.2 Regardless of the registration arrangement, Command retains the responsibility for ensuring the safety of aircraft occupants, other aircraft, people, and facilities on the ground. However, in the case of non-Defence-Registered (NDR) aircraft, DASA has a comparatively lesser role in guiding and assisting Command in meeting these obligations.

Purpose

Superseded

6.1.3.3 This chapter guides Defence's aircraft acquisition organisations and Military Air Operators through the aviation safety requirements and recommended practices during the acquisition of an NDR aircraft, but only to the extent, that DASA is involved in the process.

CONTENT UNDER REVIEW

Circa 2023, DASA is currently conducting a major review of the DASA approach and regulations for non-Defence Registered (NDR) aircraft. The review will assess, amongst other things, the legal implications of a State aircraft being regulated by a civil regulator, the need (if any) for DASR regulations to supplement the civil regulations, the role of DASA (if any) in aviation safety assurance, and so on.

Once the review is completed, DASR.NDR and this DASPMAN chapter will be updated. In the meantime, Defence organisations considering the acquisition of a NDR aircraft should contact DASA for advice.

6.5. Recognition of other Aviation Safety Authorities

6.5.1 Introduction

6.5.1.1 To promote flexibility and efficiency in the DASP, DASA recognises other aviation authorities and the independent safety assurance they apply to the platforms, organisations and people within their remit. The concept of recognition in aviation safety has its origins in the Chicago Convention and is applied by CAAs and MAAs worldwide.

6.5.1.2 Recognition is a formal acknowledgement by DASA that another aviation authority applies a credible and defensible aviation safety framework. Recognition is established through recognition certificates issued by DG DASA and available on the DASA recognition web page.

6.5.1.3 The interoperability and capability needs of the Defence aviation community are what drives DASA's recognition program and provisions. DASA applies a 'top-down' approach to recognition, involving the analysis of an authority, its aviation safety policy or regulations and corresponding oversight.

6.5.1.4 Recognition assessments do not consider specific aircraft platforms, operating organisations or service providers. A key responsibility of the Defence aviation community is therefore to ensure the suitability of specific arrangements that leverage recognition provisions.

6.5.1.5 The remainder of this section describes the core concepts underpinning aviation authority recognition in the DASP and provides an overview of practical applications.

6.5.2 Understanding Recognition

Benefits

6.5.2.1 Recognition promotes interoperability between the DASP and other aviation safety frameworks through increased flexibility and efficiency.

6.5.2.2 **Flexibility.** Recognition effectively extends DASA's safety assurance across the people, processes and products that are subject to the recognised authority's safety oversight. This expands the opportunities available to the Defence aviation community to interoperate with partner forces, or to exchange products and services across regulatory boundaries, while remaining compliant with the requirements of the DASP.

6.5.2.3 **Efficiency.** Recognition enables Defence to avoid the repetition of credible independent safety assurance that's already applied by a recognised authority. This enables Defence to focus resources on areas of greater need; eg elements that are unique to the Australian context.

Recognition tiers

6.5.2.4 DASA uses three 'tiers' to clearly identify the scope of recognition and the applicable responsibilities. DASA is responsible for establishing Tier 1 and Tier 2 recognition, while Tier 3 is a Defence aviation community ensure responsibility carried out as a means to comply with applicable DASR. Table 1 below provides a summary.

Superseded

6.5.2.5 **Tier 1 – Competent authority.** An authority recognised by DASA at Tier 1 has been assessed to be appropriately empowered and resourced to credibly carry out its mandate. Tier 1 recognition is established through the issuance of a recognition certificate. Tier 1 recognition considers the recognised authority's competence within the context of its respective nation or military service and does not enable the exchange of products and services between aviation safety frameworks. Tier 1 recognition may support safety risk management decisions by Defence aviation commanders and managers regarding matters such as:

1. the carriage of Defence personnel aboard non-Defence aircraft
2. Defence participation in exercises involving foreign military aircraft.

6.5.2.6 **Tier 2 – Interoperability provisions.** Once Tier 1 recognition is in place, DASA may recognise an authority at Tier 2 to enable specific interoperability provisions between the DASP and the recognised authority's aviation safety framework. Tier 2 recognition is established through annexes to individual recognition certificates. The interoperability provisions established through Tier 2 recognition are aligned to the following areas:

1. flight operations
2. design and certification of aircraft
3. maintenance of aircraft and components
4. production of aircraft and components.

6.5.2.7 Tier 2 recognition provisions are underpinned by a detailed assessment of the recognised authority's aviation safety policy (including regulations) and the independent assurance processes the authority applies within specific areas of interest. Where the assessment identifies any differences between the DASP and the recognised framework that may impact aviation safety, these are treated through scope limitations, conditions and caveats applicable to the Tier 2 recognition as identified in certificate annexes.

6.5.2.8 **Tier 3 – Ensuring suitability.** Tier 3 recognition is an ensure activity carried out by the Defence aviation community. At Tier 3, regulated entities leverage the recognition provisions established by DASA at Tiers 1 and 2 in order to achieve compliance with applicable DASR. The section below titled 'Leveraging recognition' provides further detail.

Table 1 Recognition tiers

	Responsibility of …	**Established through …**
Tier 1 – Competent authority	DASA (*assure*)	Recognition certificate
Tier 2 – Interoperability provisions	DASA (*assure*)	Annexes to recognition certificate
Tier 3 – Ensuring suitability	Regulated community (*ensure*)	Compliance with applicable DASR and relevant recognition certificate annex

Recognition certificates

Superseded

6.5.2.9 Where DASA's assessment of an authority supports Tier 1 recognition, a certificate is issued to formally establish the outcomes of the assessment. Each certificate states the name of the recognised authority, the scope of recognition and the applicable terms.

6.5.2.10 Tier 2 recognition provisions are identified within annexes to recognition certificates. Each annex specifies:

1. **Scope**. The scope defines the personnel, process and product integrity controls that are acceptable within the DASP, for example, specific types of organisation approvals or airworthiness authorisations.
2. **Conditions.** The conditions may place specific limitations on the scope. For example, where the recognised authority applies more than one regulation set, DASA may only accept products or services that are subject to one specific regulation set.
3. **Caveats.** The caveats define the minimum checks to be carried out, and measures to be put in place where appropriate, to ensure the suitability of recognition arrangements from an Aviation Safety perspective.
4. **Notes.** Notes provide contextual information to assist, advise and inform organisations seeking to leverage recognition.

Establishing recognition

6.5.2.11 To establish recognition of other MAAs, DASA applies a process based closely on European Defence Agency and Five Eyes standards[1]. Central to this are the candidate authority's responses, and supporting evidence, against approximately 200 questions based on ICAO Standards and Recommended Practices.

6.5.2.12 To recognise CAAs, DASA leverages results from the ICAO Universal Safety Oversight Audit Programme and assesses relevant legislation and regulations.

Limitations

6.5.2.13 **Scope limited to Aviation Safety.** Recognition is not applicable to areas that are outside DASA's remit, or outside the typical remit of an aviation authority. For example, the design, production and maintenance of explosive ordnance, to the extent that these do not concern Aviation Safety, are outside the scope of DASA's recognition framework.

6.5.2.14 **Responsibility to ensure suitability.** Recognition provides flexible means by which the Defence aviation community can achieve compliance with applicable DASR. In all cases, this places a responsibility on regulated entities to ensure the suitability of their specific arrangements that leverage recognition provisions. Put another way, recognition does not provide 'carte-blanche' permission to interoperate with other aviation frameworks in a way that's contrary to the requirements of applicable policy or legislation, eg the DASR or the WHS Act.

6.5.2.15 One of the reasons for this limitation is that DASA recognition assessments do not assess the suitability of individual aviation platforms, operating organisations or service providers. This is a Tier 3 recognition activity carried out by the Defence aviation community. Further, Recognition provisions are only applicable where the relevant people, processes or products are subject to the safety oversight of a recognised aviation authority.

Leveraging recognition

Superseded

6.5.2.16 Recognition provides a flexible and efficient means by which regulated entities can achieve compliance with applicable DASR. The applicability of recognition in a particular area may be identified within regulation text, Acceptable Means of Compliance and/or Guidance Material. Readers should then refer to the relevant CAA or MAA recognition certificate, where available, for specific Tier 2 provisions.

6.5.2.17 The Tier 2 recognition provisions within annexes to recognition certificates should regarded in the same way as DASR AMC in the sense that they provide an acceptable means to comply with the DASR. Similarly, regulated entities seeking to leverage recognition must be able to show, to DASA's satisfaction, how the relevant Tier 3 responsibilities are being fulfilled. In most cases, this will involve an application to DASA to issue an authorisation or amend an existing authorisation. As with AMC, a regulated entity may seek a variation to applicable requirements; this variation may be considered by DASA as an Alternative Means of Compliance (AltMoC). See Section 5.2 *Aviation safety policy* for further information about the concept of AltMoC.

Flight operations

6.5.2.18 Recognition underpins the responsibilities of Military Air Operators and Sponsors in relation to the operation of Non-Defence Registered Aircraft by Defence organisations[2] and Defence personnel[3]. Recognition also supports safety risk management decisions made by Sponsors of foreign military air operations in Australia[4].

Initial and Continued Airworthiness

6.5.2.19 **Type-certification and 'major' modifications.** See Section 7.2 Product Certification.

6.5.2.20 **Airworthiness Directives.** Other authorities' Airworthiness Directives (ADs) are not automatically applicable to Defence aircraft. Instead, it is up to each MTC holder to ensure that relevant ADs or equivalent are monitored as part of its system for collection, investigation and analysis of data related to failures, malfunctions and defects[5].

6.5.2.21 **Certificates of Airworthiness.** Recognition certificates may enable an applicant for a DASA Certificate of Airworthiness to use evidence originating from a recognised authority[6]. The types of evidence, the organisations suitable to provide it and the associated terms are described in the 'aircraft production' annex of recognition certificates.

6.5.2.22 **Military Permits to Fly.** Recognition certificates may enable an applicant for an MPTF to use relevant documents acceptable through recognition to support the application[7]. As the reasons for requiring an MPTF vary significantly, the recognition annexes generally do not identify which particular documents are acceptable.

Continuing Airworthiness

6.5.2.23 **Alternate Artefacts**. The DASR and recognition certificate annexes identify several airworthiness authorisations and artefacts by name, eg US Navy Flight Clearance for aircraft or EASA Form 1 for components. In the event that the named authorisation or artefact is not able to be provided to Defence, DASA may agree to the acceptance of an Alternate Artefact via a DASR Form 155. Additional detail on the acceptance of Alternate Artefacts for components may be found in Section 8.2.3.

Superseded

6.5.2.24 **Repairs and 'minor' modifications**. A CAMO may consume data for repairs and 'minor' modifications when the data is produced by an organisation acceptable through recognition[8]. For further information, see:

1. Section 8.2.1 Continuing Airworthiness Management

    i. AMC and GM to DASR M.A.304(d) Data for modifications and repairs.

6.5.2.25 **Maintenance of aircraft and components**. A CAMO may have maintenance of aircraft and components carried out by an organisation acceptable to DASA through recognition[9]. See the following references for further information:

1. Section 8.2.1 Continuing Airworthiness Management
2. AMC to DASR M.A.201(g) Responsibilities
3. DASR M.A.801 Aircraft certificate of release to service (AUS)
4. DASR M.A.802 Component certificate of release to service (AUS).

Superseded

6.6.1 Introduction

Purpose

6.6.1.1 Aircraft Structural Integrity Program (ASIP) and Propulsion System Integrity Program (PSIP) activities occur throughout the complete aircraft life-cycle from requirements definition, design, verification / certification and in-service sustainment. Furthermore, an effective ASIP and PSIP aims to maximise holistic outcomes for Defence Capability, including safety, cost-of-ownership and availability outcomes. Notwithstanding these broader objectives, the purpose of Section 6.6 is limited to:

1. Describing how airworthiness-related aspects of ASIPs and PSIPs interface with the DASP.
2. Describing how an effective ASIP and PSIP assists the regulated community to meet their respective DASR obligations.
3. Providing additional guidance on elements of ASIPs and PSIPs that impact airworthiness.

Audience

6.6.1.2 Section 6.6 is relevant to:

1. Military Type Certificate Holder (MTCH) organisations
2. Continuing Airworthiness Management Organisations (CAMOs)
3. DASR 145 maintenance organisations
4. organisations involved in ASIP or PSIP activities for ADF aircraft (including CASG business units and contractor organisations).

What are Integrity Programs?

6.6.1.3 'Integrity' is defined as the level of safety, performance, durability, reliability, operability and supportability of the various air vehicle systems.

6.6.1.4 There are many threats that can compromise integrity of aircraft, including:

1. inadequate design or certification
2. material or manufacturing discrepancies
3. maintenance deficiencies or maintenance-induced damage
4. environmental degradation
5. operational usage or environment differing from design assumptions
6. procedural or management shortfalls.

Superseded

6.6.1.5 Integrity programs[1] comprise a series of time-phased tasks that occur through development, acquisition and sustainment to counter and manage these threats. The goal of integrity programs is to ensure that the desired level of integrity is maintained throughout the life of an aircraft or system to maximise capability outcomes (ie safety, cost effectiveness and mission readiness).

6.6.1.6 Whilst the goal of integrity programs focuses on overall capability, maintaining integrity of the aircraft structure and propulsion system is an essential airworthiness principle[2]. Integrity program outputs include the Airworthiness Limitations (AwL) and Instructions for Continuing Airworthiness (ICA) necessary to ensure that integrity does not reduce below the required level throughout the service life of the aircraft. As shown in Figure 1, these outputs encompass:

1. prevention (eg periodic application of corrosion-inhibiting compounds)
2. inspection (eg detection of normal or abnormal degradation)
3. repair / modification / replacement (eg restoring integrity through rectification of damage that exceeds a specified level, modification or retirement of components at specified life limits).

6.6.1.7 Not depicted in Figure 1 is the ongoing monitoring and periodic assessment components of integrity programs, which provide the feedback loop to ensure that the ICA and AwL remain valid in light of actual operational experience.

Figure 1: Maintaining Integrity In-Service

Defence ASIP and PSIP Policy

6.6.1.8 Separate to DASP requirements, it is Defence Policy (Engineering and Maintenance Manual (EMM) Section 7.29-7.38) that every Defence-registered aircraft type must have an effective and efficient Aircraft Structural Integrity Program (ASIP) and Propulsion System Integrity Program (PSIP).

6.6.1.9 Note that historically, Defence has implemented Engine Structural Integrity (ESI) programs that focus on the high energy, non-containable structural components within gas turbine engines. In contrast, the PSIP scope includes all propulsion system components, including engine, engine accessories and propeller. Some platforms still follow the ESI philosophy, in instances where there was minimal benefit to be gained from transitioning.

6.6.1.10 The principal objective of this policy is to support capability outcomes; including safety, capability delivery and assurance, and cost-effectiveness. On behalf of Capability Managers, Capability Acquisition and Sustainment Group (CASG) is responsible for ensuring effective and efficient programs are implemented and executed, and will appoint organisations as ASIP and PSIP managers to assist in discharging this responsibility. Typically, CASG will appoint the contractor or

Superseded

organisation providing aircraft / propulsion system through-life support as the ASIP and PSIP manager, but in some cases these responsibilities may be retained by CASG.

6.6.1.11 Compared to the civil sector, military operations and the Defence context typically dictate the need for more proactive and complex integrity programs. This is due to the propensity for higher operational usage variability and Configuration, Role and Environment (CRE) deviating from design assumptions, plus Defence's desire to more closely specify and control the useful service life and maintain independence of military action. MIL-STD-1530D (ASIP) and MIL-STD-3024 (PSIP) provide exemplar frameworks for meeting the Defence Policy objectives and requirements.

6.6.1.12 Note that for brevity, the collective abbreviations SIP for the ASIP and PSIP, and SIMP for the ASI and PSI Management Plans (ie the document that describes the program) are used hereon in.

Using Section 6.6

6.6.1.13 Acknowledging the broader Defence Policy mandate and objectives outlined above, the purpose of Section 6.6 is to describe how the SIP interface with the DASP and provide guidance to assist the regulated community to meet their respective DASR obligations.

6.6.1.14 Regulations and obligations related to integrity programs are distributed throughout DASR and guidance material. Effective SIPs will therefore contribute to supporting compliance against a number of DASR 21 and DASR M requirements. This Section expands upon relevant regulation, Acceptable Means of Compliance (AMC) and Guidance Material (GM).

6.6.1.15 DASA's scope of interest with respect to SIPs is how these programs contribute to airworthiness of the aircraft structure and propulsion system; in particular, how airworthiness is established (initial airworthiness) and then maintained in-service (continued and continuing airworthiness).

6.6.1.16 Section 6.6 is intended to be used by:

1. Military Type Certificate Holders (MTCHs) and Continuing Airworthiness Management Organisations (CAMOs) to understand how the SIPs for their platform should or can support their respective DASR obligations
2. DASR 145 maintenance organisations to understand how their activities support SIPs
3. CASG and industry (particularly SIP managers) to understand how SIPs interface with DASR and the associated responsibilities and requirements.

6.6.1.17 Whilst Section 6.6 describes how an effective SIP can simultaneously support MTCH and CAMO obligations, this should not be construed as suggesting that SIP execution should be fragmented within or between organisations (eg government MTCH versus CAMO, or between teams within a contracted support provider).

6.6.1.18 This Section is applicable to all aircraft operating under a Military Type Certificate (MTC), including certified category Unmanned Aircraft Systems (UAS). In accordance with DASR UAS.30(b)3, Specific Type A UAS must comply with DASR initial and continuing airworthiness regulations as directed by DASA. As outlined in the Initial and Continuing Airworthiness Requirements for Specific Category UAS Factsheet, normal practice is for the UAS operating permit applicant to propose a suitable extent of compliance for DASA approval. UAS operating permit applicants should consider tailoring and adapting the concepts outlined in this Section, based on each specific application, as part of developing their broader proposal for initial and continuing airworthiness requirements.

Superseded

6.6.1.19 The remainder of this Section is structured as follows:

1. Section 6.6.2: SIP considerations with respect to initial airworthiness
2. Section 6.6.3: SIP considerations with respect to continued airworthiness
3. Section 6.6.4: SIP considerations with respect to continuing airworthiness
4. Section 6.6.5: guidance on SIMPs under DASR
5. Section 6.6.6: consolidated list of the main SIP-related DASR responsibilities
6. Annex A and Annex B: additional guidance specific to structures and propulsion systems respectively.

6.6.2 Integrity Programs and Initial Airworthiness

Type Certification Basis

6.6.2.1 The TCB is an agreed set of airworthiness requirements that a product must be compliant with in order to be issued a Military Type Certificate (MTC). The TCB will normally include a primary certification code and any supplementation required for the Defence context and Configuration, Role and Environment (CRE) (refer DASR 21.A.17A). The Defence Aviation Safety Design Requirements Manual (DASDRM) lists the primary certification codes recognised by DASA and prescribes the supplementary design requirements that must be applied as special conditions (refer DASR 21.A.16B) to account for the Defence context and CRE.

6.6.2.2 The primary certification codes recognised by DASA provide a sound basis for the safe design of structures and propulsion systems for Defence aircraft. Subject to tailoring for the Defence CRE, these codes all are sufficient to ensure that an adequate level of integrity is established during design and certification.

6.6.2.3 However, recognised codes may require supplementation related to in service SIP monitoring and assessment, and tracking life accrual. The DASDRM Section 3 Chapters 12 and 13 provide these supplementary airworthiness design requirements and further information on type certification for structures and propulsion systems respectively. Note that these requirements are general in nature, and a deliberate assessment should be conducted based on the aircraft type, underlying airworthiness code and intended Defence CRE to determine the specific TCB wording and / or standards. Applicants are recommended to engage with DASA early in the TCB development process.

6.6.2.4 Section 7.2 also provides general information on the development of the certification basis for MTC, Military Supplemental Type Certificate (MSTC) or major change to MTC applications.

Compliance Demonstration and CRE Assessment

6.6.2.5 Along with the primary certification code and standards used, the suitability of design analysis and verification for the Defence CRE contributes significantly to the level of integrity, and therefore safety, achieved throughout the service life.

6.6.2.6 Defence rarely has direct input into the original design requirements for new aircraft, and often receives changes to a MTC and repair designs that are not exclusively designed for Defence. Unless a design has explicitly accounted for the Defence CRE, then a CRE Assessment (CREA) is

Superseded

required to ensure the design is safe for the intended Defence use. This is an essential step in leveraging prior Civil / Military Aviation Authority (CAA / MAA) certification for the purpose of obtaining a MTC or MSTC / major change approval (refer to DASR 21.A.20 and Section 7.2 for further information).

6.6.2.7 CREAs involve assessing whether the intended Defence CRE is compatible with the as designed CRE. For aircraft structures and propulsion systems, the CREA should examine the configuration and role related usage, loads and environment such as operating weights, altitudes, speeds; and repeated manoeuvre, dynamic, gust and thermal environments. Basic comparisons of aircraft role(s), mission mix or flight profiles (as articulated in the in the Statement of Operating Intent and Usage (SOIU)) will usually not provide adequate fidelity to identify meaningful CRE differences for structures and propulsion systems, and will therefore be insufficient in isolation. Fatigue degradation in particular can be highly sensitive to small changes in usage, loads and environment.

6.6.2.8 CREAs for structures and propulsion systems therefore usually require detailed and quantitative analysis. The SOIU should be considered a starting point for understanding the intended CRE, and an attempt should be made to better-quantify anticipated usage, loads and environment to the extent necessary, with greater fidelity than the basic information in the SOIU (eg using data from similar aircraft types). The aim should be to undertake a quantitative comparison between the as-designed and intended CRE that, for example, allows conclusions to be made regarding relative severity and impact on AwLs.

6.6.2.9 The CREA is the responsibility of the applicant for a MTC or MSTC / major change when leveraging prior certification. However, applicants should ensure that the analysis, which supports the structures or propulsion system CREA, is developed by a suitably-experienced organisation with access to the requisite data. This will likely require support from the aircraft / engine Original Equipment Manufacturer (OEM), a design organisation with sufficient technical capability and access to relevant data, and / or the expertise available within the SIP.

6.6.2.10 **Inconclusive CREAs.** CREAs for structures and propulsion systems sometimes cannot conclude with sufficient confidence whether the intended Defence CRE is compatible with the as-designed CRE. This often occurs during initial acquisition due to an inability to describe the intended Defence CRE with adequate fidelity. In this situation, follow-on activities should be conducted in service to obtain and assess further data, and should be managed through the SIP. Further assessment may only be possible once the ADF operational concept is fully defined and / or once a sufficient quantity of in-service data is available. In this situation a decision will need to be made as to whether:

1. there is a suitable basis to establish compliance for the TCB requirements affected by the inconclusive CREA outcome, or if they need to remain non compliant until follow-on activities are conducted
2. mitigating actions (eg additional lifing factors) are required to eliminate or otherwise minimise any associated risks so far as is reasonably practicable
3. there is any residual elevated risk that needs to be retained by the appropriate risk management authority.

6.6.2.11 These decisions will require experienced professional judgement and will generally be based on the level of uncertainty with the CREA and a qualitative risk assessment. Applicants are recommended to engage with DASA early when there is a lack of data or uncertainty with CREAs.

Military Type Certificate

Superseded

6.6.2.12 As per DASR 21.A.41 the MTC includes:

1. the type design (DASR 21.A.31), encompassing:
    i. the drawings and specifications, and a listing of those drawings and specifications, necessary to define the configuration and the design features of the product shown to comply with the TCB
    ii. information on materials, processes and methods of manufacture and assembly necessary to ensure the conformity of the product
    iii. an approved airworthiness limitations section of the ICA (as defined by the applicable airworthiness codes)
2. operating limitations
3. the Type Certificate Data Sheet (TCDS)
4. the TCB.

6.6.2.13 Under the DASR definition, the MTC does not include:

1. ICA (aside from those requirements identified as AwLs)[3]
2. off-board systems and processes, with the exception of any data which is defined as part of the AwLs (refer Section 6.6.2.24.d.(ii)), such as the SIP systems for ongoing monitoring and periodic assessment
3. organisational expositions and SIMPs.

6.6.2.14 As described at Section 6.6.2.3, the TCB requirements should encompass the DASDRM design requirements related to key SIP[4] elements. Whilst compliance must be established for these TCB requirements in order to obtain a MTC, these SIP elements do not subsequently form part of the type design and MTC[5] (with the exception of any data defined as AwLs, as discussed at Section 6.6.4.5). Nevertheless, the SIP manager, on behalf of the MTCH, should ensure that all relevant SIP elements continue to comply with the relevant TCB requirements, and that alterations to the SIP systems / processes are managed with appropriate rigour, including documentation in the DASA endorsed SIMP.

Critical Parts

6.6.2.15 **Identification of Critical Parts.** It is vital that Defence understands which parts of the aircraft structure and propulsion system are essential for safe flight and therefore could have a significant impact on safety if they were to fail or not perform their intended function. This is important for effective execution of the SIP and assisting regulated entities in discharging their respective obligations. Note that structural or propulsion system critical parts are not limited to those identified as being susceptible to fatigue failure, but include all parts irrespective of their potential failure mode(s) or 'critical characteristic'. It is the consequence following failure or inability to perform the intended function that is the key factor.

6.6.2.16 The primary consideration for defining what constitutes a structural or propulsion system critical part should be the certification basis for the aircraft and propulsion system. However, noting that not all airworthiness codes are equivalent, and some are not explicit on definition of critical parts, general definitions for structural and propulsion system critical parts are provided in DASR AMC

Superseded

21.A.41. Also refer to Annex A and Annex B to this Section for further information on structural critical parts and propulsion system critical parts respectively.

6.6.2.17 Structural and propulsion system critical parts should normally be defined by the responsible OEM / design organisation and it is important to understand the criteria used for this process. The applicant should ensure the definition used by the OEM / design organisation is consistent with the TCB and / or the general definitions provided in DASR AMC 21.A.41. Otherwise, a dedicated activity may be required to identify critical parts using an acceptable definition; in this instance, applicants are encouraged to engage with DASA early.

6.6.2.18 Note that some definitions for 'propulsion system' include drive system. However, as per the definitions used by DASA, drive system structural critical parts should be managed under the ASIP. More generally, the OEM responsible for a given part is the best indicator of which SIP is most appropriate (ie engine or propeller OEM = PSIP and airframe OEM = ASIP). Note also that there is nothing preventing structural and propulsion critical parts being managed under an integrated program.

6.6.2.19 The applicant for a MTC or MSTC / major change should identify a list of critical parts, consistent with the TCB and the intended Defence CRE, and submit this to DASA as part of the application (refer DASR AMC 21.A.41 and AMC1 21.A.97). The definition and listing of critical parts should be included, either directly or by reference, in the SIMP. If the list of structural or propulsion system critical parts is provided as part of a broader 'safety-critical' item list for the aircraft type, then the parent aircraft system for each item should be identified.

6.6.2.20 **Maintaining Critical Parts List.** The MTCH should maintain and update the list of critical parts for the MTC based on design changes (including introduction of alternate part numbers), repairs, new / revised analysis or in service experience. Design changes and new repair designs should identify any new critical parts using the same criteria as initially used to obtain the MTC. The MTCH should also identify new critical parts as required through undertaking their continued airworthiness obligations under DASR 21.A.3A and DASR 21.A.44(c) (eg occurrences or new / revised analysis may indicate that original assumptions regarding a part's function or potential failure mode(s) are incorrect).

6.6.2.21 **Use of Critical Parts List.** The regulated community can use the definition and published[6] list of critical parts to assist in discharging some of their respective obligations. This includes, but is not limited to, assisting with:

1. understanding how the broader SIP contributes to maintaining airworthiness under DASR
2. identification of AwLs by applicants for a MTC or MSTC / major change
3. ongoing management of AwLs by MTCHs (eg identifying if a new maintenance requirement should be treated as an AwL)
4. design and classification of modifications and repairs by design organisations
5. identification of critical maintenance task candidates for the purpose of determining error capture methods (DASR AMC M.A.302(d)(3))
6. decisions regarding deferred defects or 'endanger flight safety' assessments by CAMOs or DASR 145 maintenance organisations (DASR M.A.801(h) and DASR 145.A.50(a))

Superseded

7. identification of reportable occurrences by all regulated entities.

Airworthiness Limitations

6.6.2.22 **AwL Definition.** AwLs are established through the certification process as being essential for preventing and / or detecting failures that may lead to an unsafe condition. AwLs may apply to many systems including the aircraft structure, propulsion system, fuel system and wiring. For aircraft structures and propulsion systems, AwLs will be associated with critical parts. A common misconception is that structural and propulsion system AwLs are only fatigue-related. AwLs are established to prevent any potential unsafe condition developing, which for structures and propulsion systems can relate to any threat including, but not limited to: fatigue, environmental degradation (eg corrosion, hot-corrosion, deterioration of organic compounds, etc), disbonding, mechanical wear, creep, flutter or other aeroelastic instability, vibration / aeroacoustics and accidental / discrete-source damage.

6.6.2.23 Note that the term Certification Maintenance Requirement (CMR) has a specific meaning under civil airworthiness codes for transport-category aircraft (refer Section 7.2.5.3). Applicants should therefore consider whether it is appropriate to use this term for aircraft structure and propulsion system mandatory maintenance actions, especially for civil-derivative aircraft types.

6.6.2.24 For aircraft structures and propulsion systems, AwLs are considered to encompass (refer DASR AMC 21.A.41):

1. mandatory modification, retirement or replacement intervals
2. mandatory inspection requirements: including inspection interval(s) and the inspection method
3. mandatory post-flight inspections and maintenance actions associated with any use of either the rated 30 second or 2 minute one-engine-inoperative power (for rotorcraft engines with such power ratings)
4. the definition of the interval under a. and b. above includes:
   i. the interval metric[7]
   ii. any algorithm, equation, factor(s) or other engineering data which must be used to calculate life accrual against the interval.

6.6.2.25 The inspection method under Section 6.6.2.24.b is considered to include the inspection technique[8], reference standards and any other inspection procedure parameters, which impact the detectable flaw size or probability of detection.

6.6.2.26 Tracking life accrual[9] against AwL intervals for structural or propulsion system critical parts often involves algorithms, damage equations, conversion factors or other similar data. Under the definition above, any data that is inextricably linked with calculation of life accrual is considered mandatory and therefore should be treated and managed as part of the AwL. Some examples include:

1. algorithms and look-up data which convert parametric or strain time-history data into per-flight damage increments
2. flight hour conversion factors for lifing parameters which are difficult to monitor flight-by-flight

Superseded

3. engine rotational speed ‘gates’ used to define full or partial cycles

4. time-in-temperature matrices to track creep or thermal fatigue life accrual for engine hot-section parts

5. fill-in data or factors used to account for missing data.

6.6.2.27 AwLs for aircraft structure can include mandatory actions for specific structural locations or parts (eg modification, replacement or inspection) and an overall safety-based life limit for the aircraft. The overall safety-based life limit is often referred to as the Limit of Validity for civil certified aircraft.

6.6.2.28 **Identification of AwL.** Structural and propulsion system AwLs should normally be defined by the responsible OEM / design organisation. The applicant for a MTC or MSTC / major change should ensure that (refer DASR AMC 21.A.41, DASR AMC1 21.A.97):

1. structural and propulsion system AwLs have been identified and are segregated and clearly distinguishable from other ICA

2. structural and propulsion system AwLs are consistent with the TCB and the intended Defence CRE

3. the relevant data is collated and submitted to DASA as part of the application.

6.6.2.29 Once approved by DASA, the definition and list of AwLs should be included, either directly or by reference, in the TCDS and SIMP.

6.6.2.30 Structural and propulsion system AwLs can often be highly sensitive to small changes in usage, loads and environment, and therefore a detailed and quantitative CREA is typically required (refer Section 6.6.2.8). Note that this includes all aspects of the AwL, including the algorithms, equations, factors or other data to calculate life accrual, as these too can be impacted by differences in CRE. For example, damage look-up data, factors in damage equations or fill-in data may be based on mission profile severity, which will vary between different operators.

6.6.2.31 Depending on the underlying airworthiness code, AwL terminology may differ, and mandatory requirements may not be explicitly segregated within the ICA provided by the OEM. In these cases, the applicant should define a list of structural and propulsion system AwLs consistent with the definition of Section 6.6.2.24. A well-defined list of critical parts will assist with this activity. Ensuring that AwLs are clearly identified as such, and segregated from the remainder of the ICA, assists the regulated community to fully discharge their respective obligations and ensures mandatory requirements are not altered or deferred without appropriate rigour and assurance.

6.6.2.32 **Ongoing Validity of AwLs.** Ensuring AwLs remain compliant with the TCB and appropriate for the Defence CRE is a MTCH continued airworthiness obligation. AwLs should be updated or introduced as required based on design changes, repairs, new / revised analysis or in service experience.

6.6.2.33 **New or updated structural and propulsion system AwLs.** Any change to a MTC or repair design that introduces or alters an AwL (increase or decrease) should be classified as a major change / repair (per DASR GM 21.A.91 and DASR GM 21.A.435). Any alteration of the parameters or data that are encompassed by the definition at Section 6.6.2.24 is also considered a change to the AwL.

6.6.2.34 It is important to ensure that any change or repair that impacts AwLs has explicitly accounted for the Defence CRE (as outlined in Sections 6.6.2.5-6.6.2.9).

Superseded

6.6.2.35 Changes / repairs that introduce or alter inspection-based AwLs for structures and propulsion systems require special attention as there is an inextricable link between the inspection interval(s) and method (refer Section 6.6.2.25). Design organisations should ensure that suitably-qualified and competent personnel oversee these changes / repairs and that suitable standards are used which govern the parameters that define the inspection method.

6.6.2.36 Allowing aircraft to exceed an AwL should not be approved as a change or repair unless compliance with the TCB can be demonstrated. Exceeding an AwL invariably involves an elevated level of risk (beyond that inherent in the TCB) and should only be considered where there is a compelling imperative to continue operations. Where compliance with the TCB cannot be shown, a change or repair approval is not an appropriate instrument. In this case, a Military Permit to Fly should be considered.

6.6.3 Integrity Programs and Continued Airworthiness

Investigation of Occurrences

6.6.3.1 **Overview.** Collection, investigation and analysis of failures, malfunctions, defects or other occurrences which cause or might cause adverse effects on airworthiness (collectively referred to as 'occurrences' hereafter) by DASR 21 approval holder(s) is an essential continued airworthiness activity and enables risks and hazards associated with the type design to be identified and addressed (DASR 21.A.3A(a)).

6.6.3.2 Any occurrence that is deemed to have resulted in, or may result in, an unsafe condition must also be reported to DASA and other organisations required by the implementing regulations. Another organisation may have already deemed an occurrence as reportable to DASA, or the occurrence may be deemed reportable by the relevant DASR 21 approval holder in accordance with DASR 21.A.3A(b).

6.6.3.3 Refer to DASR AMC 21.A.3B(b) for further detail on the definition of an unsafe condition and DASR GM 21.A.3B(b) for guidance on determining when an unsafe condition exists. DASR AMC GR.40 also provides examples of reportable occurrences. DASR AMC GR.40 Section II (Technical) and Section III (Aircraft Maintenance and Repair) are most applicable to structures and propulsion systems. Note that the DASR AMC GR.40 examples should not be used by design organisations like a 'checklist' for determining when a report has to be made to DASA. After receipt of reports from the primary sources of information, the design organisation will normally perform some kind of analysis to determine whether an occurrence has resulted or may result in an unsafe condition (refer guidance at DASR GM 21.A.3B(b)) and if a report to DASA should be made.

6.6.3.4 When a reportable occurrence results from a manufacturing or design deficiency, then the DASR 21 approval holder must also report to DASA the results of its investigation and any action it is taking, or proposes to take, to correct the deficiency (DASR 21.A.3A(c)(1)). Furthermore, when an Airworthiness Directive is required to correct an unsafe condition the DASR 21 approval holder must submit the proposed corrective action and / or required inspections (including the necessary details) to DASA for approval (DASR 21.A.3B(c)(1)). Further discussion on occurrence reporting and determination of unsafe conditions is beyond the scope of this Section.

6.6.3.5 **Structures and Propulsion Systems Guidance.** Investigation and analysis of occurrences for aircraft structure and propulsion systems often requires specific skills due to the complex nature of these systems and their associated failure modes, and the specialised design methods and tools typically employed. The MTCH should ensure that all structural and propulsion system occurrences

Superseded

are investigated and analysed using the expertise available within the SIP and / or the responsible design organisation (if separate).

6.6.3.6 There have been many cases throughout aviation history where catastrophic structural or propulsion system failures were preceded by little or no warning in terms of prior defects or failures. Therefore, whilst trending is important (refer Section 6.6.3.8), each individual structural and propulsion system occurrence should be promptly collected, investigated and analysed.

6.6.3.7 Investigation and analysis should compare the actual occurrence with the assumptions made during design and type certification, and determine if the MTC (including AwL and operating limitations) or ICA need to be amended.

6.6.3.8 The MTCH should also ensure that all relevant occurrences and data are captured by the SIP for ongoing monitoring and periodic assessment (refer Sections 6.6.3.11-6.6.3.26). This ensures that the SIP identifies any risks and hazards associated with the type design that are only evident through longer-term aggregation and trending of occurrences.

6.6.3.9 **Retention of Components.** Thorough and detailed examination (ie forensic techniques) is often crucial to understand the root-cause for failures in structural or propulsion system parts and prevent further failures occurring. Processes should therefore be established that allows retired, damaged or defective components to be examined as and when required.

6.6.3.10 The MTCH, and / or the responsible design organisation, should determine when an unserviceable or unsalvageable component (refer DASR 145.A.42) needs to be subject to further examination as part of an investigation. Furthermore, the MTCH or relevant design/repair approval holder should advise the CAMO and in turn, DASR 145 organisation as to when the decision has been made that such components are no longer required for investigation. Note that where an unserviceable or unsalvageable component is the subject of an occurrence report, the DASR 145 organisation should retain the component until the investigation has determined that the component is not required to be retained for further examination (refer DASR 145.A.42).

Ongoing Monitoring and Periodic Assessments

6.6.3.11 **Overview.** OEMs make many assumptions during design regarding factors such as operational usage, loads and environment; material performance; and manufacturing and assembly processes in order to demonstrate compliance with the TCB and develop operating limitations and AwLs.

6.6.3.12 In-service experience and additional testing or analysis may show that certain assumptions are no longer valid. Furthermore, the OEM's assumptions cannot always specifically account for the usage and environment of every operator. This is especially the case for military aircraft as role(s), tactics and environment can vary significantly between operators and evolve over time. Operations for many ADF aircraft have historically been shown to be different and, in some cases, significantly more severe than the OEM design assumptions.

6.6.3.13 It is essential to identify, and act upon as required, any instances where the design assumptions are no longer valid throughout the service life. The MTCH is responsible for ensuring the continued integrity of the aircraft structure and propulsion system through ongoing monitoring and periodic assessment (DASR 21.A.44(c)). The purpose of these two facets include:

1. ongoing monitoring of service experience in order to collect the data required for, and to determine the periodicity of, assessments

Superseded

2. periodic assessment to ensure that the assumptions made during design and certification that could affect the integrity of structural and propulsion system critical parts remain valid for the Defence CRE.

6.6.3.14 Assumptions may be identified as no longer valid for the entire global fleet, a subset of the global fleet, or just the Defence CRE. The scope of the MTCH obligation under DASR 21.A.44(c) is ensuring that the Defence type design and MTC remains compliant with the TCB. A particular focus is ensuring the operating limitations and AwLs established during certification remain valid for the Defence CRE.

6.6.3.15 The MTCH is accountable for defining the system and processes for ongoing monitoring and periodic assessment in accordance with DASR 21.A.44(c) and the TCB requirements derived from the DASDRM. For new acquisitions, the CASG Project Office will typically be responsible for ensuring the necessary systems and processes are in place and fit-for-purpose prior to obtaining a MTC.

6.6.3.16 In practice, execution of the DASR 21.A.44(c) obligation should be fulfilled through the broader SIP for each aircraft type. The SIP manager should ensure that the SIP systems and processes for monitoring and assessment continue to meet the requirements of DASR 21.A.44(c) and the TCB.

6.6.3.17 **Ongoing Monitoring.** Ongoing monitoring involves collecting relevant service experience data, and evaluating the data to identify significant events, exceedances of baseline assumptions, trends or anomalies that require more detailed assessment. These activities should occur continuously throughout the service life and result in the following outputs:

1. trigger and / or determine the frequency at which more detailed periodic assessments should be performed
2. identify any events, exceedances of baselines, trends or anomalies that require further investigation as part of the periodic assessments
3. collate and store all relevant service experience data required for periodic assessments, and future trending and analysis purposes.

6.6.3.18 Relevant service experience data collected and evaluated through ongoing monitoring should include, but is not limited to:

1. operational usage
2. failures, malfunctions, defects and other occurrences, and other unserviceabilities
3. maintenance findings, results of inspections and repair information
4. condition and health monitoring data
5. detailed inspection or testing of aircraft / parts with service history.

6.6.3.19 The usage data required for ongoing monitoring and periodic assessment is often extensive and complex. Integrity of structural and propulsion system critical parts for a given aircraft type can be impacted by a variety of usage and environmental factors, so collection of a large number of usage parameters is often required to compare to all the relevant design assumptions. Furthermore, the quantity of data required may vary from a statistically-representative sample through to data for all operations.

Superseded

6.6.3.20 The MTCH should define the data required for the purposes of DASR 21.A.44(c) and establish the necessary arrangements with the operating and maintenance organisations to collect this data through the SIP. The SIMP should outline the specific responsibilities for each aircraft type.

6.6.3.21 Where available, and relevant to the ADF CRE, service experience from other operators should also be considered.

6.6.3.22 **Periodic Assessment.** Periodic assessments involves detailed analysis to test whether the assumptions made during design and certification that could affect the integrity of structural and propulsion system critical parts remain valid based on the intended and actual Defence CRE.

6.6.3.23 Periodic assessments should identify whether there is a need to update the MTC (including AwLs and operating limitations), ICA or monitoring provisions (eg tracking life accrual or health monitoring) in order to ensure continued compliance with the TCB. These subsequent updates are separate to the periodic assessment process and should be conducted in accordance with the relevant DASR.

6.6.3.24 Periodic assessments should also identify when there is a need to update the systems or processes for ongoing monitoring to ensure the necessary data is being collected.

6.6.3.25 Access to a minimum level of type design data and suitable expertise is necessary to undertake the analysis required. This should be considered by the MTCH when identifying organisations to undertake periodic assessment.

6.6.3.26 Refer to Annex A and Annex B for more detailed guidance regarding ongoing monitoring and periodic assessment for structures and propulsion systems.

6.6.4 Integrity Programs and Continuing Airworthiness

Tracking Status of Service Life-Limited Components

6.6.4.1 **Tracking against Structural and Propulsion System AwLs.** The operating organisation is accountable for recording the status of service life-limited components; ie tracking life accrual against AwLs (DASR M.A.305(d)(4)). 'Service life-limited' parts under DASR refers to parts that as a condition of their type-certificate, may not exceed a specified operating time, calendar time, number of operating cycles, or any other approved life consumption unit. These mandatory actions are referred to as AwLs throughout this Section.

6.6.4.2 Variation in actual aircraft usage and configuration can have a significant impact on when AwL actions (such as component replacements or inspections) need to be performed. The system for tracking life accrual should ensure that individual aircraft or components (as relevant) do not exceed AwL intervals. For aircraft structures and propulsion systems, this often requires capturing and analysing a variety of usage parameters in addition to measuring accrual of AwL interval metrics such as flight hours, flight / engine cycles or landings to ensure the underlying basis of the AwL interval is not exceeded. Many AwL intervals are promulgated in 'simple' metrics such as flight hours or flight / engine cycles, however, actual damage / life accrual for the failure mechanism in question is usually more complex and varies based upon a range of operational factors. Therefore, additional usage parameters must often be captured and analysed to ensure individual aircraft or components are not exceeding the underlying basis of the AwL. For structural and propulsion system AwLs, the SIP for each aircraft type should support this obligation through calculation of the relevant lifing metrics and / or data analysis.

Superseded

6.6.4.3 **System Requirements.** The philosophy and complexity of the system[10] required for tracking life accrual may vary significantly based on the certification basis, the aircraft / propulsion system type and role, and the nature of each individual AwL. Furthermore, tracking the status of structural and propulsion system life-limited critical parts for military aircraft is typically more complex than that required for civil aircraft. Additional guidance and examples for structures and propulsion systems are provided in Annex A and Annex B respectively.

6.6.4.4 The DASDRM structures and propulsion system chapters each include an essential airworthiness design requirement on tracking life accrual against critical part AwLs. The MTCH should provide the technical requirements for the system, including the usage parameters that need to be captured, with these requirements ideally being based on OEM data or advice.

6.6.4.5 As outlined in Section 6.6.2.24.d.(ii), any algorithm, equation, factor or other engineering data which must be used to calculate life accrual is considered part of the AwL and therefore MTC. However, the broader system for tracking life accrual that is built around this data is generally not considered part of the MTC.

6.6.4.6 Tracking life accrual usually requires a complete usage history for each individual aircraft / component. Therefore, relevant data from all ground and flight operations should be captured (including pre-delivery usage if feasible) and the system should conservatively account for missing data. As identified at Section 6.6.2.26, fill-in data / factors used to account for missing data is typically considered part of the AwL. Significant quantities of missing data can impact the accuracy of life accrual, and therefore targets for valid data capture should be established and monitored[11].

6.6.4.7 Depending upon the type of AwL, tracking life accrual could include both tracking total life and tracking life since last maintenance action (eg for repeat inspection intervals).

6.6.4.8 When critical parts can be transferred between aircraft or engines then the system should have the ability to track life accrual at the component level.

6.6.4.9 Life accrual for structural and propulsion system critical parts can be sensitive to small variations in usage or configuration. Therefore, the system for tracking life accrual should be subject to initial validation. Validation should test the entire system (on-board and off-board elements) in an end-to-end fashion; ie from raw / input data through to the AwL lifing metric outputs. Validation should ensure that the system produces reliable, repeatable and suitably conservative outputs so that AwL intervals are not exceeded in-service.

6.6.4.10 Even validated systems can result in incorrect outputs if subject to bad input data. Therefore, the system should include means to identify and account for missing or erroneous input data, and include quality checks of processed data.

6.6.4.11 The period between a ground / flight operation and updated life accrual data being available will vary between platforms. In some cases near real-time update of life accrual data will be available following operations, whilst other cases will involve more lag (eg when processes require engineer-in-the-loop or complex data processing to produce life accrual outputs). Therefore, the system for tracking life accrual should take into account reporting lag to ensure that AwLs are not exceeded.

6.6.4.12 **Relationship between Continuing and Continued Airworthiness Obligations.** The operating organisation is accountable for ensuring that individual aircraft / components do not exceed the underlying basis of AwL intervals. This is a continuing airworthiness obligation as it relates to the aircraft complying with the airworthiness requirements in force and being in a condition for

Superseded

safe operation. Whilst the operating organisation is accountable, the SIP for each aircraft type should support this obligation through calculation of the relevant lifing metrics and / or data analysis when this level of complexity is required.

6.6.4.13 There is also an obvious relationship with the MTCH *continued* airworthiness obligation to ensure that AwLs remain valid for the Defence CRE. The interaction between the *continuing* versus *continued* airworthiness processes to ensure individual aircraft / components do not exceed the underlying basis of AwL intervals will vary between platforms and SIP philosophies. For some platforms, if SIP analysis indicates that individual aircraft may exceed the underlying basis of an AwL, then the MTCH may revise the AwL (for all aircraft) so that it fully encompasses all outliers in terms of life accrual rates. For other platforms, the CAMO may routinely adjust scheduled maintenance (ie maintenance events which correspond to when AwL actions are undertaken) based on individual aircraft life accrual rates and SIP outputs, to ensure no aircraft / components exceed the underlying basis of the AwL interval.

6.6.4.14 For structures and propulsion systems, there will often be significant overlap in terms of the usage parameters and data analysis required to fulfil both continuing and continued airworthiness functions. Therefore, a single SIP system[12] can simultaneously be supporting both continuing and continued airworthiness responsibilities. Where this is the case, those executing the SIP must remain cognisant of the separate DASR responsibilities the single system is supporting.

6.6.4.15 **Used Critical Parts.** Acquisition of critical parts with prior (non-ADF) usage poses particular challenges for tracking life accrual against AwLs. Used critical parts can enter the ADF system in a number of ways, including acquisition of used aircraft or engines, purchase of used spares, or participation in a global parts-pooling arrangement. Even though the headline life-consumption metric will be provided for used components, the ability to understand the actual life accrual against the underlying basis of the AwL interval generally requires more detailed usage data.

6.6.4.16 Along with any relevant previous configuration and maintenance records, the CAMO should endeavour to obtain detailed usage parameters that enables the severity of non-ADF usage to be sufficiently understood. The CASG Project Office should undertake this on behalf of the CAMO for acquisition of used aircraft/engines. The CAMO may not necessarily need to hold this data if the organisation managing the system has access to the non-ADF usage data (eg global sustainment provider). If such data cannot be obtained, then the CAMO should seek advice from the MTCH and expertise available within the SIP to ensure appropriately-conservative assumptions regarding life accrual for non-ADF usage are implemented.

Aircraft Maintenance Programme

6.6.4.17 This section describes how an effective SIP can support the development and ongoing validity of relevant Aircraft Maintenance Programme (AMP) elements. Due to the broader Defence SIP Policy mandate, SIPs will often overlap with CAMO Reliability Programme (RP) obligations for the aircraft structure and propulsion system (ie SIP data and assessments can be leveraged to ensure relevant AMP elements remain effective). Therefore, CAMOs should be aware of the existing SIP scope and functions for each aircraft type, and may leverage the SIP to reduce the need for separate RP processes where appropriate. The AMP should identify where and how SIP supports the CAMO RP requirement (DASR M.A.302(f)) for the aircraft structure and propulsion system[13].

6.6.4.18 **AMP Compliance with Mandatory Requirements.** The AMP must establish compliance with mandatory requirements (ie AwLs) and identify these as such to prevent inadvertent variation[14]. The SIP, through the SIMP and TCDS, will provide the definition of structural / propulsion system AwLs, listing of AwLs as required, and reference to authoritative source for AwLs. This should assist

Superseded

the CAMO in identifying mandatory requirements (including changes thereto) and their authoritative source in the AMP.

6.6.4.19 Note that AwLs are developed as part of the certification process and should not be extended or altered by the CAMO. Whilst there may be instances where the RP identifies the need to update AwLs, this is more often initiated through MTCH continued airworthiness obligations (refer Section 6.6.3), and in all cases should be developed and approved as a major change to the MTC.

6.6.4.20 **Basis of AMP Tasks and Intervals.** The AMP should be established based on anticipated ADF utilisation of the aircraft[15]. When developing an AMP, the SIP can provide data and assessments that will assist the CAMO in ensuring that structural and propulsion system AMP tasks and intervals reflect anticipated ADF utilisation.

6.6.4.21 Furthermore, whilst the AMP tasks and intervals will normally be based upon the OEM's recommended maintenance programme[16], the CAMO may need or desire to introduce additional or alternative instructions. For aircraft structures and propulsion systems, the SIP expertise, data and assessments can provide the supporting information for alternative and / or additional tasks and intervals proposed by the CAMO (DASR AMC M.A.302(d)).

6.6.4.22 **Periodic Review and Amendment of the AMP.** The AMP must be subject to periodic review to ensure it remains valid in light of operating experience[17], instructions issued by DASA and any new and / or modified maintenance instructions promulgated by the MTCH or other design approval holder (DASR M.A.302(g)). For aircraft structures and propulsion systems, the SIP expertise, data and assessments can support the periodic review and amendment of relevant AMP elements.

6.6.4.23 Some RP approaches used for other aircraft systems may not be appropriate for structures and propulsion systems. For example, systems approaches for establishing alert levels / performance standards, use of mean-time-between-failure style metrics, and statistical analysis techniques will usually not lead to meaningful or effective outcomes for structural and propulsion system integrity. Therefore, leveraging the SIP expertise, data and assessments to support periodic review and amendment of relevant AMP elements can lead to more effective and robust outcomes and avoid duplication of effort.

6.6.4.24 To support periodic review and amendment of relevant AMP elements, the SIP should assess all relevant service experience and compare this to the assumptions that underpin the AMP intervals and tasks to ensure they remain valid. Relevant service experience data should include, but is not limited to:

1. operational usage
2. occurrences and other unserviceabilities
3. maintenance findings, results of inspections, and repair information
4. condition and health monitoring data.

6.6.4.25 Where available, and relevant to the ADF CRE, service experience from other operators should also be considered.

6.6.4.26 Note that despite the separate obligations, there is a degree of commonality between the monitoring and assessments to support ongoing validity of relevant AMP elements and those required under DASR 21.A.44(c) (see Section 6.6.3). Whereas the objective of DASR 21.A.44(c) is to ensure the MTC remains compliant with the TCB, the objective of DASR M.A.302(g) is to ensure the maintenance tasks and intervals implemented through the AMP remain valid for the individual

Superseded

operator. Nevertheless, similar expertise, data and assessment methods are required in both cases. Therefore, the SIP systems and processes (as overseen by the SIP manager) should be able to support both sets of obligations within the scope of the aircraft structure and propulsion system. The CAMO should ensure that the SIP is cognisant of their DASR M.A.302 requirements.

6.6.4.27 **Condition and Health Monitoring.** SIP condition monitoring and health monitoring elements can also support the DASR RP requirement for certain aircraft systems or components and in turn contribute to ensuring the ongoing effectiveness of the AMP. Condition / health monitoring elements can be comprised of many different techniques that will vary between the system or component(s) being monitored. Examples for structures and propulsion systems may include:

1. scheduled inspection of general component condition (including through non-destructive and remote visual inspections techniques),
2. vibration monitoring
3. monitoring of parameters such as oil / fluid / gas temperatures and pressures
4. performance monitoring
5. wear debris analysis
6. oil condition monitoring
7. embedded sensors to detect structural failures or redistribution of loads.

6.6.4.28 Condition / health monitoring requirements may be promulgated through ICA, in which case the CAMO would be expected to incorporate these requirements in the AMP, or they may be implemented as an additional measure to support reliability, availability and maintainability goals.

6.6.4.29 Note that condition / health monitoring for the purposes described in this section should not be conflated with Structural Condition Monitoring (SCM) under the MTCH DASR 21.A.44(c) obligation (refer to Annex A for further information on SCM). These two concepts serve separate purposes, but are related in that data from condition / health monitoring techniques may be a subset of the source data for SCM.

Recording Operational Usage

6.6.4.30 In addition to basic aircraft record keeping and tracking life accrual, the collection of operational usage data is required to support the MTCH obligation to undertake ongoing monitoring and periodic assessment (DASR 21.A.44(c), refer Section 6.6.3).

6.6.4.31 The nature of the usage data required will vary significantly between aircraft and propulsion system types and roles. The MTCH should define the data required for supporting the DASR 21.A.44(c) obligation, including any technical requirements for the system to collect the data. These requirements should ideally be based on OEM data or advice.

6.6.4.32 The operating organisation is responsible for ensuring that the required usage data is collected through the continuing airworthiness record system (DASR M.A.305(c)).

6.6.5 Structural / System Integrity Management Plan (SIMP)

Purpose of SIMPs under DASR

Superseded

6.6.5.1 SIMPs are a key document that assists the regulated community in the following two main ways:

1. SIMPs provide a consolidated reference for key structural and propulsion system information such as the relevant airworthiness design requirements and standards, certification outcomes and the definition and source for critical parts and AwLs.

2. SIMPs document how the SIP contributes to supporting a number of MTCH and CAMO DASR obligations. From this perspective, SIMPs should be considered subordinate to the Type Continued Airworthiness Exposition (TCAE), Continuing Airworthiness Management Exposition (CAME) and AMP document. The relevant sections of the TCAE, CAME and AMP should refer down to SIMPs and the relevant sections of the SIMPs should refer to the regulation(s) the content is supporting.

6.6.5.2 SIMPs are therefore considered AMC under DASR.

SIMP Content, Structure and Management

6.6.5.3 Given the purpose of SIMPs under DASR outlined above, DASA's policy is that it will endorse all SIMPs. However, SIMPs serve a broader purpose under Defence Policy[18], therefore, not all content will be directly relevant to the DASP.

6.6.5.4 The SIMP content that requires DASA endorsement is listed in Table 1. For ease of review and management, DASA recommends that this content be contained in a dedicated section of the SIMP. All other SIMP content should be managed by the SIP manager in coordination with CASG.

6.6.5.5 DASA expects that SIMPs will be maintained by the SIP manager, and that the MTCH and CAMO will have reviewed the content listed in Table 1 that is relevant to them prior to SIMPs being submitted for DASA endorsement. Best practice is to ensure the sections of the SIMP that are relevant to either the MTCH or CAMO are clearly identified.

6.6.5.6 An indicative SIMP amendment process is shown below in Figure 2. Note that since SIMPs serves a broader purpose under Defence Policy, DASA endorsement should not be viewed as the final step, and SIMP approval should be provided by a suitable Defence representative (notionally a senior Defence engineer within the CASG System Program Office).

Table 1: SIMP Content Requiring DASA Endorsement

Content	DASR Reference	Section 6.6 Reference
A list of the key structural / propulsion system airworthiness design standards, Defence-unique airworthiness requirements (ie derived from DASDRM) and reference to the TCB	21.A.16A 21.A.16B 21.A.17A	6.6.2.1 - 6.6.2.3
The basis of sovereign type certification for the structure / propulsion system, including: • type certification approach (eg how prior recognition was leveraged)	21.A.20	6.6.2.5 - 6.6.2.11

Superseded

• reference to structures / propulsion system CREAs and sovereign compliance demonstration evidence • reference to certification outcomes such as relevant Military Certification Review Items and Airworthiness Issue Papers • description of any outstanding structures/propulsion system certification issues and the proposed resolution pathway		
Definition of structural / propulsion system critical parts Either a list of, or reference to, the authoritative source for critical parts	21.A.41	6.6.2.15 - 6.6.2.19
Definition of structural / propulsion system AwLs, and details of what algorithms, damage equations, conversion factors or other data are encompassed within the AwL definition Reference to the authoritative source for structural / propulsion system AwLs Listing of structural / propulsion system AwLs (as required)	21.A.41	6.6.2.22 - 6.6.2.31
Description of organisations involved, and the typical process followed, for investigation of structural / propulsion system failures, malfunctions, defects and other occurrences Description of the process that allows retired, damaged or defective components to be subject to detailed examination as and when required	21.A.3A(a)	6.6.3.1 - 6.6.3.10
Details of the systems and processes for ongoing monitoring and periodic structural / propulsion system integrity assessment, including: • organisational responsibilities • input data requirements and how this data is collected and validated • periodic assessment frequency and / or trigger(s) • periodic assessment methodology • expected outputs • outcomes of, and reference to, completed assessments	21.A.44(c)	6.6.3.11 - 6.6.3.26
Details of the system and processes for tracking structural / propulsion system life-limited components, including organisational responsibilities	M.A.305(d)(4)	6.6.4.1 - 6.6.4.16

Superseded

Description of if and how the SIP supports the development and ongoing validity of relevant structural / propulsion system elements of the AMP	M.A.302	6.6.4.17 - 6.6.4.29
Process for managing amendments to the SIMP, including frequency and triggers for amendments	N/A	N/A
Any other information requested by DASA specific to the aircraft type	N/A	N/A

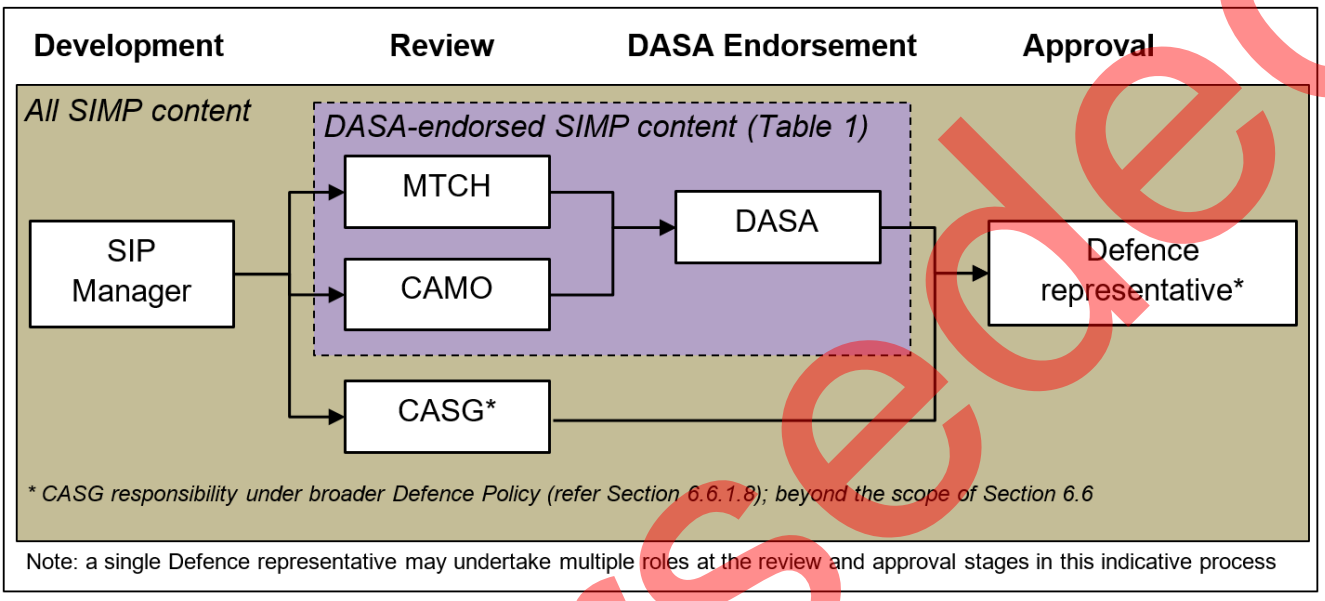

Figure 2: Indicative SIMP Amendment Process

ASIMP Volume 2 / Force Structural Maintenance Plan (FSMP)

6.6.5.7 Discussion on SIMPs until this point has been in reference to the ASIMP Volume 1 and PSIMP.

6.6.5.8 Some aircraft types also use an ASIMP Volume 2 / FSMP. These vary in scope, but typically consolidate information such as structural classifications and / or listing of critical parts, and details (including reference to substantiating and supporting data) of locations identified through analysis, test or service experience that require modification, inspection or repair. DASA supports use of an ASIMP Volume 2 / FSMP as they are a valuable document for ASIP stakeholders, however, DASA does not have any expectation that they should be maintained for every aircraft type.

6.6.5.9 In the capacity outlined above, an ASIMP Volume 2 / FSMP should simply be a consolidated reference of previously-approved design data, and therefore does not require DASA endorsement or approval.

6.6.5.10 The only exception may be where the ASIMP Volume 1 identifies the ASIMP Volume 2 / FSMP as the authoritative source for structural AwLs. This may be the case for some legacy platforms where the ASIMP Volume 2 was historically used to approve and publish AwLs (ie there is no other authoritative 'source' document(s) to refer to). In this case, the ASIMP Volume 2 / FSMP should clearly distinguish AwLs from other structural maintenance requirements. Furthermore, moving forward they should not be used as the vehicle to approve new or updated AwLs, rather they should reference the separately approved design data. In this capacity the ASIMP Volume 2 / FSMP should be treated like other manuals issued by the MTCH (DASR 21.A.57). As noted under DASR AMC 21.A.57,

Superseded

approval and issuing the manual may be separate to approval of the technical content (ie approval of the AwLs).

6.6.6 SIP-Related DASR Responsibilities

6.6.6.1 The main SIP-related DASR responsibilities are consolidated by organisation in Table 2.

6.6.6.2 Whilst SIP-related DASR responsibilities are distributed across different organisations, DASA expects that each SIP will continue to be managed and led by a single organisation (ie SIP manager appointed by CASG). Organisational responsibilities are listed below so that each regulated entity understands what they are accountable for, and so SIP managers can understand how their SIP contribute to supporting various obligations under DASR.

Table 2: Consolidated SIP-Related DASR Responsibilities

DASR Responsibility	DASR Reference	Section Reference
Applicants for MTC and MSTC / Major Changes		
Develop and submit proposed TCB for DASA approval Ensure the structures / propulsion system airworthiness design requirements specified in the DASDRM are addressed in the TCB	21.A.16A 21.A.16B 21.A.17A	6.6.2.1 - 6.6.2.3
Compliance demonstration, including ensuring that CRE differences that impact structures / propulsion systems are identified and assessed when leveraging prior CAA / MAA certification	21.A.20	6.6.2.5 - 6.6.2.11
Define and identify structural / propulsion system critical parts and AwLs for the design, consistent with the TCB and the intended Defence CRE, and submit this data to DASA as part of the application	21.A.41	6.6.2.15 - 6.6.2.19 6.6.2.22 - 6.6.2.31
Military Type Certificate Holder		
Collection, investigation and analysis of failures, malfunctions, defects and other occurrences for structures and propulsion systems, including decisions regarding examination of retired, damaged or defective parts	21.A.3A(a)	6.6.3.1 - 6.6.3.10
Occurrence reporting for structures and propulsion systems	21.A.3A(b)	
Report to DASA the results of investigation and any action taken or proposed to correct manufacturing or	21.A.3A(c)	

Superseded

design deficiencies that have resulted in a reportable occurrence		
Submit the proposed corrective action and / or required inspections to DASA for approval when an Airworthiness Directive is required to correct an unsafe condition	21.A.3B(c)	
Establish and execute system and processes for ongoing monitoring & periodic assessment throughout service life	21.A.44(c)	6.6.3.11 - 6.6.3.26
Provide technical requirements to the operating organisation / CAMO regarding the systems for monitoring usage and tracking against structural and propulsion system AwLs	Supporting M.A.305(d)(4) and M.A.305(c)	6.6.4.4 6.6.4.31
Review relevant SIMP content and ensure it supports MTCH obligations Ensure the TCAE refers to the SIMP in relevant sections	Various	6.6.5
DASR M (Operating Organisation / CAMO)		
Tracking life accrual against structural and propulsion system AwLs	M.A.305(d)(4)	6.6.4.1 - 6.6.4.16
Ensure structures and propulsion system aspects of the AMP are subject to periodic review and continue to be valid in light of operating experience	M.A.302(g)	6.6.4.17 - 6.6.4.29
Collecting operational usage data as defined by the MTCH	M.A.305(c)	6.6.4.30 -6.6.4.32
Occurrence reporting for structures and propulsion systems	M.A.202	N/A
Review relevant SIMP content and ensure it supports DASR M obligations Ensure the CAME and AMP document refers to the SIMP in relevant sections	Various	6.6.5
DASR 145 (Maintenance Organisation)		
Support collection of service experience data required for ongoing monitoring and periodic assessment, and tracking life accrual against structural and propulsion system AwLs	Supporting 21.A.44(c) and M.A.305(d)(4)	6.6.3.20 6.6.4.1 - 6.6.4.11

Superseded

Retain unserviceable or unsalvageable components that are the subject of an occurrence report until the investigation has determined that the component is not required to be retained for further examination	145.A.42	6.6.3.9 - 6.6.3.10
Occurrence reporting for structures and propulsion systems	145.A.60	N/A

6.6.3. Integrity Programs under the DASP

6.6.1 Introduction

Purpose

6.6.1.1 Aircraft Structural Integrity Program (ASIP) and Propulsion System Integrity Program (PSIP) activities occur throughout the complete aircraft life-cycle from requirements definition, design, verification / certification and in-service sustainment. Furthermore, an effective ASIP and PSIP aims to maximise holistic outcomes for Defence Capability, including safety, cost-of-ownership and availability outcomes. Notwithstanding these broader objectives, the purpose of Section 6.6 is limited to:

1. Describing how airworthiness-related aspects of ASIPs and PSIPs interface with the DASP.
2. Describing how an effective ASIP and PSIP assists the regulated community to meet their respective DASR obligations.
3. Providing additional guidance on elements of ASIPs and PSIPs that impact airworthiness.

Audience

6.6.1.2 Section 6.6 is relevant to:

1. Military Type Certificate Holder (MTCH) organisations
2. Continuing Airworthiness Management Organisations (CAMOs)
3. DASR 145 maintenance organisations
4. organisations involved in ASIP or PSIP activities for ADF aircraft (including CASG business units and contractor organisations).

What are Integrity Programs?

6.6.1.3 'Integrity' is defined as the level of safety, performance, durability, reliability, operability and supportability of the various air vehicle systems.

6.6.1.4 There are many threats that can compromise integrity of aircraft, including:

1. inadequate design or certification
2. material or manufacturing discrepancies
3. maintenance deficiencies or maintenance-induced damage
4. environmental degradation
5. operational usage or environment differing from design assumptions
6. procedural or management shortfalls.

Superseded

6.6.1.5 Integrity programs[1] comprise a series of time-phased tasks that occur through development, acquisition and sustainment to counter and manage these threats. The goal of integrity programs is to ensure that the desired level of integrity is maintained throughout the life of an aircraft or system to maximise capability outcomes (ie safety, cost effectiveness and mission readiness).

6.6.1.6 Whilst the goal of integrity programs focuses on overall capability, maintaining integrity of the aircraft structure and propulsion system is an essential airworthiness principle[2]. Integrity program outputs include the Airworthiness Limitations (AwL) and Instructions for Continuing Airworthiness (ICA) necessary to ensure that integrity does not reduce below the required level throughout the service life of the aircraft. As shown in Figure 1, these outputs encompass:

1. prevention (eg periodic application of corrosion-inhibiting compounds)
2. inspection (eg detection of normal or abnormal degradation)
3. repair / modification / replacement (eg restoring integrity through rectification of damage that exceeds a specified level, modification or retirement of components at specified life limits).

6.6.1.7 Not depicted in Figure 1 is the ongoing monitoring and periodic assessment components of integrity programs, which provide the feedback loop to ensure that the ICA and AwL remain valid in light of actual operational experience.

Figure 1: Maintaining Integrity In-Service

Defence ASIP and PSIP Policy

6.6.1.8 Separate to DASP requirements, it is Defence Policy (Engineering and Maintenance Manual (EMM) Section 7.29-7.38) that every Defence-registered aircraft type must have an effective and efficient Aircraft Structural Integrity Program (ASIP) and Propulsion System Integrity Program (PSIP).

6.6.1.9 Note that historically, Defence has implemented Engine Structural Integrity (ESI) programs that focus on the high energy, non-containable structural components within gas turbine engines. In contrast, the PSIP scope includes all propulsion system components, including engine, engine accessories and propeller. Some platforms still follow the ESI philosophy, in instances where there was minimal benefit to be gained from transitioning.

6.6.1.10 The principal objective of this policy is to support capability outcomes; including safety, capability delivery and assurance, and cost-effectiveness. On behalf of Capability Managers, Capability Acquisition and Sustainment Group (CASG) is responsible for ensuring effective and efficient programs are implemented and executed, and will appoint organisations as ASIP and PSIP managers to assist in discharging this responsibility. Typically, CASG will appoint the contractor or

Superseded

organisation providing aircraft / propulsion system through-life support as the ASIP and PSIP manager, but in some cases these responsibilities may be retained by CASG.

6.6.1.11 Compared to the civil sector, military operations and the Defence context typically dictate the need for more proactive and complex integrity programs. This is due to the propensity for higher operational usage variability and Configuration, Role and Environment (CRE) deviating from design assumptions, plus Defence's desire to more closely specify and control the useful service life and maintain independence of military action. MIL-STD-1530D (ASIP) and MIL-STD-3024 (PSIP) provide exemplar frameworks for meeting the Defence Policy objectives and requirements.

6.6.1.12 Note that for brevity, the collective abbreviations SIP for the ASIP and PSIP, and SIMP for the ASI and PSI Management Plans (ie the document that describes the program) are used hereon in.

Using Section 6.6

6.6.1.13 Acknowledging the broader Defence Policy mandate and objectives outlined above, the purpose of Section 6.6 is to describe how the SIP interface with the DASP and provide guidance to assist the regulated community to meet their respective DASR obligations.

6.6.1.14 Regulations and obligations related to integrity programs are distributed throughout DASR and guidance material. Effective SIPs will therefore contribute to supporting compliance against a number of DASR 21 and DASR M requirements. This Section expands upon relevant regulation, Acceptable Means of Compliance (AMC) and Guidance Material (GM).

6.6.1.15 DASA's scope of interest with respect to SIPs is how these programs contribute to airworthiness of the aircraft structure and propulsion system; in particular, how airworthiness is established (initial airworthiness) and then maintained in-service (continued and continuing airworthiness).

6.6.1.16 Section 6.6 is intended to be used by:

1. Military Type Certificate Holders (MTCHs) and Continuing Airworthiness Management Organisations (CAMOs) to understand how the SIPs for their platform should or can support their respective DASR obligations
2. DASR 145 maintenance organisations to understand how their activities support SIPs
3. CASG and industry (particularly SIP managers) to understand how SIPs interface with DASR and the associated responsibilities and requirements.

6.6.1.17 Whilst Section 6.6 describes how an effective SIP can simultaneously support MTCH and CAMO obligations, this should not be construed as suggesting that SIP execution should be fragmented within or between organisations (eg government MTCH versus CAMO, or between teams within a contracted support provider).

6.6.1.18 This Section is applicable to all aircraft operating under a Military Type Certificate (MTC), including certified category Unmanned Aircraft Systems (UAS). In accordance with DASR UAS.30(b)3, Specific Type A UAS must comply with DASR initial and continuing airworthiness regulations as directed by DASA. As outlined in the Initial and Continuing Airworthiness Requirements for Specific Category UAS Factsheet, normal practice is for the UAS operating permit applicant to propose a suitable extent of compliance for DASA approval. UAS operating permit applicants should consider tailoring and adapting the concepts outlined in this Section, based on each specific application, as part of developing their broader proposal for initial and continuing airworthiness requirements.

Superseded

6.6.1.19 The remainder of this Section is structured as follows:

1. Section 6.6.2: SIP considerations with respect to initial airworthiness
2. Section 6.6.3: SIP considerations with respect to continued airworthiness
3. Section 6.6.4: SIP considerations with respect to continuing airworthiness
4. Section 6.6.5: guidance on SIMPs under DASR
5. Section 6.6.6: consolidated list of the main SIP-related DASR responsibilities
6. Annex A and Annex B: additional guidance specific to structures and propulsion systems respectively.

6.6.2 Integrity Programs and Initial Airworthiness

Type Certification Basis

6.6.2.1 The TCB is an agreed set of airworthiness requirements that a product must be compliant with in order to be issued a Military Type Certificate (MTC). The TCB will normally include a primary certification code and any supplementation required for the Defence context and Configuration, Role and Environment (CRE) (refer DASR 21.A.17A). The Defence Aviation Safety Design Requirements Manual (DASDRM) lists the primary certification codes recognised by DASA and prescribes the supplementary design requirements that must be applied as special conditions (refer DASR 21.A.16B) to account for the Defence context and CRE.

6.6.2.2 The primary certification codes recognised by DASA provide a sound basis for the safe design of structures and propulsion systems for Defence aircraft. Subject to tailoring for the Defence CRE, these codes all are sufficient to ensure that an adequate level of integrity is established during design and certification.

6.6.2.3 However, recognised codes may require supplementation related to in service SIP monitoring and assessment, and tracking life accrual. The DASDRM Section 3 Chapters 12 and 13 provide these supplementary airworthiness design requirements and further information on type certification for structures and propulsion systems respectively. Note that these requirements are general in nature, and a deliberate assessment should be conducted based on the aircraft type, underlying airworthiness code and intended Defence CRE to determine the specific TCB wording and / or standards. Applicants are recommended to engage with DASA early in the TCB development process.

6.6.2.4 Section 7.2 also provides general information on the development of the certification basis for MTC, Military Supplemental Type Certificate (MSTC) or major change to MTC applications.

Compliance Demonstration and CRE Assessment

6.6.2.5 Along with the primary certification code and standards used, the suitability of design analysis and verification for the Defence CRE contributes significantly to the level of integrity, and therefore safety, achieved throughout the service life.

6.6.2.6 Defence rarely has direct input into the original design requirements for new aircraft, and often receives changes to a MTC and repair designs that are not exclusively designed for Defence. Unless a design has explicitly accounted for the Defence CRE, then a CRE Assessment (CREA) is required to ensure the design is safe for the intended Defence use. This is an essential step in

Superseded

leveraging prior Civil / Military Aviation Authority (CAA / MAA) certification for the purpose of obtaining a MTC or MSTC / major change approval (refer to DASR 21.A.20 and Section 7.2 for further information).

6.6.2.7 CREAs involve assessing whether the intended Defence CRE is compatible with the as designed CRE. For aircraft structures and propulsion systems, the CREA should examine the configuration and role related usage, loads and environment such as operating weights, altitudes, speeds; and repeated manoeuvre, dynamic, gust and thermal environments. Basic comparisons of aircraft role(s), mission mix or flight profiles (as articulated in the in the Statement of Operating Intent and Usage (SOIU)) will usually not provide adequate fidelity to identify meaningful CRE differences for structures and propulsion systems, and will therefore be insufficient in isolation. Fatigue degradation in particular can be highly sensitive to small changes in usage, loads and environment.

6.6.2.8 CREAs for structures and propulsion systems therefore usually require detailed and quantitative analysis. The SOIU should be considered a starting point for understanding the intended CRE, and an attempt should be made to better-quantify anticipated usage, loads and environment to the extent necessary, with greater fidelity than the basic information in the SOIU (eg using data from similar aircraft types). The aim should be to undertake a quantitative comparison between the as-designed and intended CRE that, for example, allows conclusions to be made regarding relative severity and impact on AwLs.

6.6.2.9 The CREA is the responsibility of the applicant for a MTC or MSTC / major change when leveraging prior certification. However, applicants should ensure that the analysis, which supports the structures or propulsion system CREA, is developed by a suitably-experienced organisation with access to the requisite data. This will likely require support from the aircraft / engine Original Equipment Manufacturer (OEM), a design organisation with sufficient technical capability and access to relevant data, and / or the expertise available within the SIP.

6.6.2.10 **Inconclusive CREAs.** CREAs for structures and propulsion systems sometimes cannot conclude with sufficient confidence whether the intended Defence CRE is compatible with the as-designed CRE. This often occurs during initial acquisition due to an inability to describe the intended Defence CRE with adequate fidelity. In this situation, follow-on activities should be conducted in service to obtain and assess further data, and should be managed through the SIP. Further assessment may only be possible once the ADF operational concept is fully defined and / or once a sufficient quantity of in-service data is available. In this situation a decision will need to be made as to whether:

1. there is a suitable basis to establish compliance for the TCB requirements affected by the inconclusive CREA outcome, or if they need to remain non compliant until follow-on activities are conducted
2. mitigating actions (eg additional lifing factors) are required to eliminate or otherwise minimise any associated risks so far as is reasonably practicable
3. there is any residual elevated risk that needs to be retained by the appropriate risk management authority.

6.6.2.11 These decisions will require experienced professional judgement and will generally be based on the level of uncertainty with the CREA and a qualitative risk assessment. Applicants are recommended to engage with DASA early when there is a lack of data or uncertainty with CREAs.

Military Type Certificate

6.6.2.12 As per DASR 21.A.41 the MTC includes:

Superseded

1. the type design (DASR 21.A.31), encompassing:
    i. the drawings and specifications, and a listing of those drawings and specifications, necessary to define the configuration and the design features of the product shown to comply with the TCB
    ii. information on materials, processes and methods of manufacture and assembly necessary to ensure the conformity of the product
    iii. an approved airworthiness limitations section of the ICA (as defined by the applicable airworthiness codes)
2. operating limitations
3. the Type Certificate Data Sheet (TCDS)
4. the TCB.

6.6.2.13 Under the DASR definition, the MTC does not include:

1. ICA (aside from those requirements identified as AwLs)[3]
2. off-board systems and processes, with the exception of any data which is defined as part of the AwLs (refer Section 6.6.2.24.d.(ii)), such as the SIP systems for ongoing monitoring and periodic assessment
3. organisational expositions and SIMPs.

6.6.2.14 As described at Section 6.6.2.3, the TCB requirements should encompass the DASDRM design requirements related to key SIP[4] elements. Whilst compliance must be established for these TCB requirements in order to obtain a MTC, these SIP elements do not subsequently form part of the type design and MTC[5] (with the exception of any data defined as AwLs, as discussed at Section 6.6.4.5). Nevertheless, the SIP manager, on behalf of the MTCH, should ensure that all relevant SIP elements continue to comply with the relevant TCB requirements, and that alterations to the SIP systems / processes are managed with appropriate rigour, including documentation in the DASA endorsed SIMP.

Critical Parts

6.6.2.15 **Identification of Critical Parts.** It is vital that Defence understands which parts of the aircraft structure and propulsion system are essential for safe flight and therefore could have a significant impact on safety if they were to fail or not perform their intended function. This is important for effective execution of the SIP and assisting regulated entities in discharging their respective obligations. Note that structural or propulsion system critical parts are not limited to those identified as being susceptible to fatigue failure, but include all parts irrespective of their potential failure mode(s) or 'critical characteristic'. It is the consequence following failure or inability to perform the intended function that is the key factor.

6.6.2.16 The primary consideration for defining what constitutes a structural or propulsion system critical part should be the certification basis for the aircraft and propulsion system. However, noting that not all airworthiness codes are equivalent, and some are not explicit on definition of critical parts, general definitions for structural and propulsion system critical parts are provided in DASR AMC 21.A.41. Also refer to Annex A and Annex B to this Section for further information on structural critical parts and propulsion system critical parts respectively.

Superseded

6.6.2.17 Structural and propulsion system critical parts should normally be defined by the responsible OEM / design organisation and it is important to understand the criteria used for this process. The applicant should ensure the definition used by the OEM / design organisation is consistent with the TCB and / or the general definitions provided in DASR AMC 21.A.41. Otherwise, a dedicated activity may be required to identify critical parts using an acceptable definition; in this instance, applicants are encouraged to engage with DASA early.

6.6.2.18 Note that some definitions for 'propulsion system' include drive system. However, as per the definitions used by DASA, drive system structural critical parts should be managed under the ASIP. More generally, the OEM responsible for a given part is the best indicator of which SIP is most appropriate (ie engine or propeller OEM = PSIP and airframe OEM = ASIP). Note also that there is nothing preventing structural and propulsion critical parts being managed under an integrated program.

6.6.2.19 The applicant for a MTC or MSTC / major change should identify a list of critical parts, consistent with the TCB and the intended Defence CRE, and submit this to DASA as part of the application (refer DASR AMC 21.A.41 and AMC1 21.A.97). The definition and listing of critical parts should be included, either directly or by reference, in the SIMP. If the list of structural or propulsion system critical parts is provided as part of a broader 'safety-critical' item list for the aircraft type, then the parent aircraft system for each item should be identified.

6.6.2.20 **Maintaining Critical Parts List.** The MTCH should maintain and update the list of critical parts for the MTC based on design changes (including introduction of alternate part numbers), repairs, new / revised analysis or in service experience. Design changes and new repair designs should identify any new critical parts using the same criteria as initially used to obtain the MTC. The MTCH should also identify new critical parts as required through undertaking their continued airworthiness obligations under DASR 21.A.3A and DASR 21.A.44(c) (eg occurrences or new / revised analysis may indicate that original assumptions regarding a part's function or potential failure mode(s) are incorrect).

6.6.2.21 **Use of Critical Parts List.** The regulated community can use the definition and published[6] list of critical parts to assist in discharging some of their respective obligations. This includes, but is not limited to, assisting with:

1. understanding how the broader SIP contributes to maintaining airworthiness under DASR
2. identification of AwLs by applicants for a MTC or MSTC / major change
3. ongoing management of AwLs by MTCHs (eg identifying if a new maintenance requirement should be treated as an AwL)
4. design and classification of modifications and repairs by design organisations
5. identification of critical maintenance task candidates for the purpose of determining error capture methods (DASR AMC M.A.302(d)(3))
6. decisions regarding deferred defects or 'endanger flight safety' assessments by CAMOs or DASR 145 maintenance organisations (DASR M.A.801(h) and DASR 145.A.50(a))
7. identification of reportable occurrences by all regulated entities.

Airworthiness Limitations

Superseded

6.6.2.22 **AwL Definition.** AwLs are established through the certification process as being essential for preventing and / or detecting failures that may lead to an unsafe condition. AwLs may apply to many systems including the aircraft structure, propulsion system, fuel system and wiring. For aircraft structures and propulsion systems, AwLs will be associated with critical parts. A common misconception is that structural and propulsion system AwLs are only fatigue-related. AwLs are established to prevent any potential unsafe condition developing, which for structures and propulsion systems can relate to any threat including, but not limited to: fatigue, environmental degradation (eg corrosion, hot-corrosion, deterioration of organic compounds, etc), disbonding, mechanical wear, creep, flutter or other aeroelastic instability, vibration / aeroacoustics and accidental / discrete-source damage.

6.6.2.23 Note that the term Certification Maintenance Requirement (CMR) has a specific meaning under civil airworthiness codes for transport-category aircraft (refer Section 7.2.5.3). Applicants should therefore consider whether it is appropriate to use this term for aircraft structure and propulsion system mandatory maintenance actions, especially for civil-derivative aircraft types.

6.6.2.24 For aircraft structures and propulsion systems, AwLs are considered to encompass (refer DASR AMC 21.A.41):

1. mandatory modification, retirement or replacement intervals
2. mandatory inspection requirements: including inspection interval(s) and the inspection method
3. mandatory post-flight inspections and maintenance actions associated with any use of either the rated 30 second or 2 minute one-engine-inoperative power (for rotorcraft engines with such power ratings)
4. the definition of the interval under a. and b. above includes:
    i. the interval metric[7]
    ii. any algorithm, equation, factor(s) or other engineering data which must be used to calculate life accrual against the interval.

6.6.2.25 The inspection method under Section 6.6.2.24.b is considered to include the inspection technique[8], reference standards and any other inspection procedure parameters, which impact the detectable flaw size or probability of detection.

6.6.2.26 Tracking life accrual[9] against AwL intervals for structural or propulsion system critical parts often involves algorithms, damage equations, conversion factors or other similar data. Under the definition above, any data that is inextricably linked with calculation of life accrual is considered mandatory and therefore should be treated and managed as part of the AwL. Some examples include:

1. algorithms and look-up data which convert parametric or strain time-history data into per-flight damage increments
2. flight hour conversion factors for lifing parameters which are difficult to monitor flight-by-flight
3. engine rotational speed ‘gates’ used to define full or partial cycles
4. time-in-temperature matrices to track creep or thermal fatigue life accrual for engine hot-section parts

Superseded

5. fill-in data or factors used to account for missing data.

6.6.2.27 AwLs for aircraft structure can include mandatory actions for specific structural locations or parts (eg modification, replacement or inspection) and an overall safety-based life limit for the aircraft. The overall safety-based life limit is often referred to as the Limit of Validity for civil certified aircraft.

6.6.2.28 **Identification of AwL.** Structural and propulsion system AwLs should normally be defined by the responsible OEM / design organisation. The applicant for a MTC or MSTC / major change should ensure that (refer DASR AMC 21.A.41, DASR AMC1 21.A.97):

1. structural and propulsion system AwLs have been identified and are segregated and clearly distinguishable from other ICA

2. structural and propulsion system AwLs are consistent with the TCB and the intended Defence CRE

3. the relevant data is collated and submitted to DASA as part of the application.

6.6.2.29 Once approved by DASA, the definition and list of AwLs should be included, either directly or by reference, in the TCDS and SIMP.

6.6.2.30 Structural and propulsion system AwLs can often be highly sensitive to small changes in usage, loads and environment, and therefore a detailed and quantitative CREA is typically required (refer Section 6.6.2.8). Note that this includes all aspects of the AwL, including the algorithms, equations, factors or other data to calculate life accrual, as these too can be impacted by differences in CRE. For example, damage look-up data, factors in damage equations or fill-in data may be based on mission profile severity, which will vary between different operators.

6.6.2.31 Depending on the underlying airworthiness code, AwL terminology may differ, and mandatory requirements may not be explicitly segregated within the ICA provided by the OEM. In these cases, the applicant should define a list of structural and propulsion system AwLs consistent with the definition of Section 6.6.2.24. A well-defined list of critical parts will assist with this activity. Ensuring that AwLs are clearly identified as such, and segregated from the remainder of the ICA, assists the regulated community to fully discharge their respective obligations and ensures mandatory requirements are not altered or deferred without appropriate rigour and assurance.

6.6.2.32 **Ongoing Validity of AwLs.** Ensuring AwLs remain compliant with the TCB and appropriate for the Defence CRE is a MTCH continued airworthiness obligation. AwLs should be updated or introduced as required based on design changes, repairs, new / revised analysis or in service experience.

6.6.2.33 **New or updated structural and propulsion system AwLs.** Any change to a MTC or repair design that introduces or alters an AwL (increase or decrease) should be classified as a major change / repair (per DASR GM 21.A.91 and DASR GM 21.A.435). Any alteration of the parameters or data that are encompassed by the definition at Section 6.6.2.24 is also considered a change to the AwL.

6.6.2.34 It is important to ensure that any change or repair that impacts AwLs has explicitly accounted for the Defence CRE (as outlined in Sections 6.6.2.5-6.6.2.9).

6.6.2.35 Changes / repairs that introduce or alter inspection-based AwLs for structures and propulsion systems require special attention as there is an inextricable link between the inspection interval(s) and method (refer Section 6.6.2.25). Design organisations should ensure that suitably-

Superseded

qualified and competent personnel oversee these changes / repairs and that suitable standards are used which govern the parameters that define the inspection method.

6.6.2.36 Allowing aircraft to exceed an AwL should not be approved as a change or repair unless compliance with the TCB can be demonstrated. Exceeding an AwL invariably involves an elevated level of risk (beyond that inherent in the TCB) and should only be considered where there is a compelling imperative to continue operations. Where compliance with the TCB cannot be shown, a change or repair approval is not an appropriate instrument. In this case, a Military Permit to Fly should be considered.

6.6.3 Integrity Programs and Continued Airworthiness

Investigation of Occurrences

6.6.3.1 **Overview.** Collection, investigation and analysis of failures, malfunctions, defects or other occurrences which cause or might cause adverse effects on airworthiness (collectively referred to as 'occurrences' hereafter) by DASR 21 approval holder(s) is an essential continued airworthiness activity and enables risks and hazards associated with the type design to be identified and addressed (DASR 21.A.3A(a)).

6.6.3.2 Any occurrence that is deemed to have resulted in, or may result in, an unsafe condition must also be reported to DASA and other organisations required by the implementing regulations. Another organisation may have already deemed an occurrence as reportable to DASA, or the occurrence may be deemed reportable by the relevant DASR 21 approval holder in accordance with DASR 21.A.3A(b).

6.6.3.3 Refer to DASR AMC 21.A.3B(b) for further detail on the definition of an unsafe condition and DASR GM 21.A.3B(b) for guidance on determining when an unsafe condition exists. DASR AMC GR.40 also provides examples of reportable occurrences. DASR AMC GR.40 Section II (Technical) and Section III (Aircraft Maintenance and Repair) are most applicable to structures and propulsion systems. Note that the DASR AMC GR.40 examples should not be used by design organisations like a 'checklist' for determining when a report has to be made to DASA. After receipt of reports from the primary sources of information, the design organisation will normally perform some kind of analysis to determine whether an occurrence has resulted or may result in an unsafe condition (refer guidance at DASR GM 21.A.3B(b)) and if a report to DASA should be made.

6.6.3.4 When a reportable occurrence results from a manufacturing or design deficiency, then the DASR 21 approval holder must also report to DASA the results of its investigation and any action it is taking, or proposes to take, to correct the deficiency (DASR 21.A.3A(c)(1)). Furthermore, when an Airworthiness Directive is required to correct an unsafe condition the DASR 21 approval holder must submit the proposed corrective action and / or required inspections (including the necessary details) to DASA for approval (DASR 21.A.3B(c)(1)). Further discussion on occurrence reporting and determination of unsafe conditions is beyond the scope of this Section.

6.6.3.5 **Structures and Propulsion Systems Guidance.** Investigation and analysis of occurrences for aircraft structure and propulsion systems often requires specific skills due to the complex nature of these systems and their associated failure modes, and the specialised design methods and tools typically employed. The MTCH should ensure that all structural and propulsion system occurrences are investigated and analysed using the expertise available within the SIP and / or the responsible design organisation (if separate).

Superseded

6.6.3.6 There have been many cases throughout aviation history where catastrophic structural or propulsion system failures were preceded by little or no warning in terms of prior defects or failures. Therefore, whilst trending is important (refer Section 6.6.3.8), each individual structural and propulsion system occurrence should be promptly collected, investigated and analysed.

6.6.3.7 Investigation and analysis should compare the actual occurrence with the assumptions made during design and type certification, and determine if the MTC (including AwL and operating limitations) or ICA need to be amended.

6.6.3.8 The MTCH should also ensure that all relevant occurrences and data are captured by the SIP for ongoing monitoring and periodic assessment (refer Sections 6.6.3.11-6.6.3.26). This ensures that the SIP identifies any risks and hazards associated with the type design that are only evident through longer-term aggregation and trending of occurrences.

6.6.3.9 **Retention of Components.** Thorough and detailed examination (ie forensic techniques) is often crucial to understand the root-cause for failures in structural or propulsion system parts and prevent further failures occurring. Processes should therefore be established that allows retired, damaged or defective components to be examined as and when required.

6.6.3.10 The MTCH, and / or the responsible design organisation, should determine when an unserviceable or unsalvageable component (refer DASR 145.A.42) needs to be subject to further examination as part of an investigation. Furthermore, the MTCH or relevant design/repair approval holder should advise the CAMO and in turn, DASR 145 organisation as to when the decision has been made that such components are no longer required for investigation. Note that where an unserviceable or unsalvageable component is the subject of an occurrence report, the DASR 145 organisation should retain the component until the investigation has determined that the component is not required to be retained for further examination (refer DASR 145.A.42).

Ongoing Monitoring and Periodic Assessments

6.6.3.11 **Overview.** OEMs make many assumptions during design regarding factors such as operational usage, loads and environment; material performance; and manufacturing and assembly processes in order to demonstrate compliance with the TCB and develop operating limitations and AwLs.

6.6.3.12 In-service experience and additional testing or analysis may show that certain assumptions are no longer valid. Furthermore, the OEM's assumptions cannot always specifically account for the usage and environment of every operator. This is especially the case for military aircraft as role(s), tactics and environment can vary significantly between operators and evolve over time. Operations for many ADF aircraft have historically been shown to be different and, in some cases, significantly more severe than the OEM design assumptions.

6.6.3.13 It is essential to identify, and act upon as required, any instances where the design assumptions are no longer valid throughout the service life. The MTCH is responsible for ensuring the continued integrity of the aircraft structure and propulsion system through ongoing monitoring and periodic assessment (DASR 21.A.44(c)). The purpose of these two facets include:

1. ongoing monitoring of service experience in order to collect the data required for, and to determine the periodicity of, assessments

2. periodic assessment to ensure that the assumptions made during design and certification that could affect the integrity of structural and propulsion system critical parts remain valid for the Defence CRE.

Superseded

6.6.3.14 Assumptions may be identified as no longer valid for the entire global fleet, a subset of the global fleet, or just the Defence CRE. The scope of the MTCH obligation under DASR 21.A.44(c) is ensuring that the Defence type design and MTC remains compliant with the TCB. A particular focus is ensuring the operating limitations and AwLs established during certification remain valid for the Defence CRE.

6.6.3.15 The MTCH is accountable for defining the system and processes for ongoing monitoring and periodic assessment in accordance with DASR 21.A.44(c) and the TCB requirements derived from the DASDRM. For new acquisitions, the CASG Project Office will typically be responsible for ensuring the necessary systems and processes are in place and fit-for-purpose prior to obtaining a MTC.

6.6.3.16 In practice, execution of the DASR 21.A.44(c) obligation should be fulfilled through the broader SIP for each aircraft type. The SIP manager should ensure that the SIP systems and processes for monitoring and assessment continue to meet the requirements of DASR 21.A.44(c) and the TCB.

6.6.3.17 **Ongoing Monitoring.** Ongoing monitoring involves collecting relevant service experience data, and evaluating the data to identify significant events, exceedances of baseline assumptions, trends or anomalies that require more detailed assessment. These activities should occur continuously throughout the service life and result in the following outputs:

1. trigger and / or determine the frequency at which more detailed periodic assessments should be performed
2. identify any events, exceedances of baselines, trends or anomalies that require further investigation as part of the periodic assessments
3. collate and store all relevant service experience data required for periodic assessments, and future trending and analysis purposes.

6.6.3.18 Relevant service experience data collected and evaluated through ongoing monitoring should include, but is not limited to:

1. operational usage
2. failures, malfunctions, defects and other occurrences, and other unserviceabilities
3. maintenance findings, results of inspections and repair information
4. condition and health monitoring data
5. detailed inspection or testing of aircraft / parts with service history.

6.6.3.19 The usage data required for ongoing monitoring and periodic assessment is often extensive and complex. Integrity of structural and propulsion system critical parts for a given aircraft type can be impacted by a variety of usage and environmental factors, so collection of a large number of usage parameters is often required to compare to all the relevant design assumptions. Furthermore, the quantity of data required may vary from a statistically-representative sample through to data for all operations.

6.6.3.20 The MTCH should define the data required for the purposes of DASR 21.A.44(c) and establish the necessary arrangements with the operating and maintenance organisations to collect this data through the SIP. The SIMP should outline the specific responsibilities for each aircraft type.

6.6.3.21 Where available, and relevant to the ADF CRE, service experience from other operators should also be considered.

Superseded

6.6.3.22 **Periodic Assessment.** Periodic assessments involves detailed analysis to test whether the assumptions made during design and certification that could affect the integrity of structural and propulsion system critical parts remain valid based on the intended and actual Defence CRE.

6.6.3.23 Periodic assessments should identify whether there is a need to update the MTC (including AwLs and operating limitations), ICA or monitoring provisions (eg tracking life accrual or health monitoring) in order to ensure continued compliance with the TCB. These subsequent updates are separate to the periodic assessment process and should be conducted in accordance with the relevant DASR.

6.6.3.24 Periodic assessments should also identify when there is a need to update the systems or processes for ongoing monitoring to ensure the necessary data is being collected.

6.6.3.25 Access to a minimum level of type design data and suitable expertise is necessary to undertake the analysis required. This should be considered by the MTCH when identifying organisations to undertake periodic assessment.

6.6.3.26 Refer to Annex A and Annex B for more detailed guidance regarding ongoing monitoring and periodic assessment for structures and propulsion systems.

6.6.4 Integrity Programs and Continuing Airworthiness

Tracking Status of Service Life-Limited Components

6.6.4.1 **Tracking against Structural and Propulsion System AwLs.** The operating organisation is accountable for recording the status of service life-limited components; ie tracking life accrual against AwLs (DASR M.A.305(d)(4)). 'Service life-limited' parts under DASR refers to parts that as a condition of their type-certificate, may not exceed a specified operating time, calendar time, number of operating cycles, or any other approved life consumption unit. These mandatory actions are referred to as AwLs throughout this Section.

6.6.4.2 Variation in actual aircraft usage and configuration can have a significant impact on when AwL actions (such as component replacements or inspections) need to be performed. The system for tracking life accrual should ensure that individual aircraft or components (as relevant) do not exceed AwL intervals. For aircraft structures and propulsion systems, this often requires capturing and analysing a variety of usage parameters in addition to measuring accrual of AwL interval metrics such as flight hours, flight / engine cycles or landings to ensure the underlying basis of the AwL interval is not exceeded. Many AwL intervals are promulgated in 'simple' metrics such as flight hours or flight / engine cycles, however, actual damage / life accrual for the failure mechanism in question is usually more complex and varies based upon a range of operational factors. Therefore, additional usage parameters must often be captured and analysed to ensure individual aircraft or components are not exceeding the underlying basis of the AwL. For structural and propulsion system AwLs, the SIP for each aircraft type should support this obligation through calculation of the relevant lifing metrics and / or data analysis.

6.6.4.3 **System Requirements.** The philosophy and complexity of the system[10] required for tracking life accrual may vary significantly based on the certification basis, the aircraft / propulsion system type and role, and the nature of each individual AwL. Furthermore, tracking the status of structural and propulsion system life-limited critical parts for military aircraft is typically more complex than that required for civil aircraft. Additional guidance and examples for structures and propulsion systems are provided in Annex A and Annex B respectively.

Superseded

6.6.4.4 The DASDRM structures and propulsion system chapters each include an essential airworthiness design requirement on tracking life accrual against critical part AwLs. The MTCH should provide the technical requirements for the system, including the usage parameters that need to be captured, with these requirements ideally being based on OEM data or advice.

6.6.4.5 As outlined in Section 6.6.2.24.d.(ii), any algorithm, equation, factor or other engineering data which must be used to calculate life accrual is considered part of the AwL and therefore MTC. However, the broader system for tracking life accrual that is built around this data is generally not considered part of the MTC.

6.6.4.6 Tracking life accrual usually requires a complete usage history for each individual aircraft / component. Therefore, relevant data from all ground and flight operations should be captured (including pre-delivery usage if feasible) and the system should conservatively account for missing data. As identified at Section 6.6.2.26, fill-in data / factors used to account for missing data is typically considered part of the AwL. Significant quantities of missing data can impact the accuracy of life accrual, and therefore targets for valid data capture should be established and monitored[11].

6.6.4.7 Depending upon the type of AwL, tracking life accrual could include both tracking total life and tracking life since last maintenance action (eg for repeat inspection intervals).

6.6.4.8 When critical parts can be transferred between aircraft or engines then the system should have the ability to track life accrual at the component level.

6.6.4.9 Life accrual for structural and propulsion system critical parts can be sensitive to small variations in usage or configuration. Therefore, the system for tracking life accrual should be subject to initial validation. Validation should test the entire system (on-board and off-board elements) in an end-to-end fashion; ie from raw / input data through to the AwL lifing metric outputs. Validation should ensure that the system produces reliable, repeatable and suitably conservative outputs so that AwL intervals are not exceeded in-service.

6.6.4.10 Even validated systems can result in incorrect outputs if subject to bad input data. Therefore, the system should include means to identify and account for missing or erroneous input data, and include quality checks of processed data.

6.6.4.11 The period between a ground / flight operation and updated life accrual data being available will vary between platforms. In some cases near real-time update of life accrual data will be available following operations, whilst other cases will involve more lag (eg when processes require engineer-in-the-loop or complex data processing to produce life accrual outputs). Therefore, the system for tracking life accrual should take into account reporting lag to ensure that AwLs are not exceeded.

6.6.4.12 **Relationship between Continuing and Continued Airworthiness Obligations.** The operating organisation is accountable for ensuring that individual aircraft / components do not exceed the underlying basis of AwL intervals. This is a continuing airworthiness obligation as it relates to the aircraft complying with the airworthiness requirements in force and being in a condition for safe operation. Whilst the operating organisation is accountable, the SIP for each aircraft type should support this obligation through calculation of the relevant lifing metrics and / or data analysis when this level of complexity is required.

6.6.4.13 There is also an obvious relationship with the MTCH *continued* airworthiness obligation to ensure that AwLs remain valid for the Defence CRE. The interaction between the *continuing* versus *continued* airworthiness processes to ensure individual aircraft / components do not exceed the underlying basis of AwL intervals will vary between platforms and SIP philosophies. For some

Superseded

platforms, if SIP analysis indicates that individual aircraft may exceed the underlying basis of an AwL, then the MTCH may revise the AwL (for all aircraft) so that it fully encompasses all outliers in terms of life accrual rates. For other platforms, the CAMO may routinely adjust scheduled maintenance (ie maintenance events which correspond to when AwL actions are undertaken) based on individual aircraft life accrual rates and SIP outputs, to ensure no aircraft / components exceed the underlying basis of the AwL interval.

6.6.4.14 For structures and propulsion systems, there will often be significant overlap in terms of the usage parameters and data analysis required to fulfil both continuing and continued airworthiness functions. Therefore, a single SIP system[12] can simultaneously be supporting both continuing and continued airworthiness responsibilities. Where this is the case, those executing the SIP must remain cognisant of the separate DASR responsibilities the single system is supporting.

6.6.4.15 **Used Critical Parts.** Acquisition of critical parts with prior (non-ADF) usage poses particular challenges for tracking life accrual against AwLs. Used critical parts can enter the ADF system in a number of ways, including acquisition of used aircraft or engines, purchase of used spares, or participation in a global parts-pooling arrangement. Even though the headline life-consumption metric will be provided for used components, the ability to understand the actual life accrual against the underlying basis of the AwL interval generally requires more detailed usage data.

6.6.4.16 Along with any relevant previous configuration and maintenance records, the CAMO should endeavour to obtain detailed usage parameters that enables the severity of non-ADF usage to be sufficiently understood. The CASG Project Office should undertake this on behalf of the CAMO for acquisition of used aircraft/engines. The CAMO may not necessarily need to hold this data if the organisation managing the system has access to the non-ADF usage data (eg global sustainment provider). If such data cannot be obtained, then the CAMO should seek advice from the MTCH and expertise available within the SIP to ensure appropriately-conservative assumptions regarding life accrual for non-ADF usage are implemented.

Aircraft Maintenance Programme

6.6.4.17 This section describes how an effective SIP can support the development and ongoing validity of relevant Aircraft Maintenance Programme (AMP) elements. Due to the broader Defence SIP Policy mandate, SIPs will often overlap with CAMO Reliability Programme (RP) obligations for the aircraft structure and propulsion system (ie SIP data and assessments can be leveraged to ensure relevant AMP elements remain effective). Therefore, CAMOs should be aware of the existing SIP scope and functions for each aircraft type, and may leverage the SIP to reduce the need for separate RP processes where appropriate. The AMP should identify where and how SIP supports the CAMO RP requirement (DASR M.A.302(f)) for the aircraft structure and propulsion system[13].

6.6.4.18 **AMP Compliance with Mandatory Requirements.** The AMP must establish compliance with mandatory requirements (ie AwLs) and identify these as such to prevent inadvertent variation[14]. The SIP, through the SIMP and TCDS, will provide the definition of structural / propulsion system AwLs, listing of AwLs as required, and reference to authoritative source for AwLs. This should assist the CAMO in identifying mandatory requirements (including changes thereto) and their authoritative source in the AMP.

6.6.4.19 Note that AwLs are developed as part of the certification process and should not be extended or altered by the CAMO. Whilst there may be instances where the RP identifies the need to update AwLs, this is more often initiated through MTCH continued airworthiness obligations (refer Section 6.6.3), and in all cases should be developed and approved as a major change to the MTC.

Superseded

6.6.4.20 **Basis of AMP Tasks and Intervals.** The AMP should be established based on anticipated ADF utilisation of the aircraft[15]. When developing an AMP, the SIP can provide data and assessments that will assist the CAMO in ensuring that structural and propulsion system AMP tasks and intervals reflect anticipated ADF utilisation.

6.6.4.21 Furthermore, whilst the AMP tasks and intervals will normally be based upon the OEM's recommended maintenance programme[16], the CAMO may need or desire to introduce additional or alternative instructions. For aircraft structures and propulsion systems, the SIP expertise, data and assessments can provide the supporting information for alternative and / or additional tasks and intervals proposed by the CAMO (DASR AMC M.A.302(d)).

6.6.4.22 **Periodic Review and Amendment of the AMP.** The AMP must be subject to periodic review to ensure it remains valid in light of operating experience[17], instructions issued by DASA and any new and / or modified maintenance instructions promulgated by the MTCH or other design approval holder (DASR M.A.302(g)). For aircraft structures and propulsion systems, the SIP expertise, data and assessments can support the periodic review and amendment of relevant AMP elements.

6.6.4.23 Some RP approaches used for other aircraft systems may not be appropriate for structures and propulsion systems. For example, systems approaches for establishing alert levels / performance standards, use of mean-time-between-failure style metrics, and statistical analysis techniques will usually not lead to meaningful or effective outcomes for structural and propulsion system integrity. Therefore, leveraging the SIP expertise, data and assessments to support periodic review and amendment of relevant AMP elements can lead to more effective and robust outcomes and avoid duplication of effort.

6.6.4.24 To support periodic review and amendment of relevant AMP elements, the SIP should assess all relevant service experience and compare this to the assumptions that underpin the AMP intervals and tasks to ensure they remain valid. Relevant service experience data should include, but is not limited to:

1. operational usage
2. occurrences and other unserviceabilities
3. maintenance findings, results of inspections, and repair information
4. condition and health monitoring data.

6.6.4.25 Where available, and relevant to the ADF CRE, service experience from other operators should also be considered.

6.6.4.26 Note that despite the separate obligations, there is a degree of commonality between the monitoring and assessments to support ongoing validity of relevant AMP elements and those required under DASR 21.A.44(c) (see Section 6.6.3). Whereas the objective of DASR 21.A.44(c) is to ensure the MTC remains compliant with the TCB, the objective of DASR M.A.302(g) is to ensure the maintenance tasks and intervals implemented through the AMP remain valid for the individual operator. Nevertheless, similar expertise, data and assessment methods are required in both cases. Therefore, the SIP systems and processes (as overseen by the SIP manager) should be able to support both sets of obligations within the scope of the aircraft structure and propulsion system. The CAMO should ensure that the SIP is cognisant of their DASR M.A.302 requirements.

6.6.4.27 **Condition and Health Monitoring.** SIP condition monitoring and health monitoring elements can also support the DASR RP requirement for certain aircraft systems or components and

Superseded

in turn contribute to ensuring the ongoing effectiveness of the AMP. Condition / health monitoring elements can be comprised of many different techniques that will vary between the system or component(s) being monitored. Examples for structures and propulsion systems may include:

1. scheduled inspection of general component condition (including through non-destructive and remote visual inspections techniques),
2. vibration monitoring
3. monitoring of parameters such as oil / fluid / gas temperatures and pressures
4. performance monitoring
5. wear debris analysis
6. oil condition monitoring
7. embedded sensors to detect structural failures or redistribution of loads.

6.6.4.28 Condition / health monitoring requirements may be promulgated through ICA, in which case the CAMO would be expected to incorporate these requirements in the AMP, or they may be implemented as an additional measure to support reliability, availability and maintainability goals.

6.6.4.29 Note that condition / health monitoring for the purposes described in this section should not be conflated with Structural Condition Monitoring (SCM) under the MTCH DASR 21.A.44(c) obligation (refer to Annex A for further information on SCM). These two concepts serve separate purposes, but are related in that data from condition / health monitoring techniques may be a subset of the source data for SCM.

Recording Operational Usage

6.6.4.30 In addition to basic aircraft record keeping and tracking life accrual, the collection of operational usage data is required to support the MTCH obligation to undertake ongoing monitoring and periodic assessment (DASR 21.A.44(c), refer Section 6.6.3).

6.6.4.31 The nature of the usage data required will vary significantly between aircraft and propulsion system types and roles. The MTCH should define the data required for supporting the DASR 21.A.44(c) obligation, including any technical requirements for the system to collect the data. These requirements should ideally be based on OEM data or advice.

6.6.4.32 The operating organisation is responsible for ensuring that the required usage data is collected through the continuing airworthiness record system (DASR M.A.305(c)).

6.6.5 Structural / System Integrity Management Plan (SIMP)

Purpose of SIMPs under DASR

6.6.5.1 SIMPs are a key document that assists the regulated community in the following two main ways:

1. SIMPs provide a consolidated reference for key structural and propulsion system information such as the relevant airworthiness design requirements and standards, certification outcomes and the definition and source for critical parts and AwLs.

Superseded

2. SIMPs document how the SIP contributes to supporting a number of MTCH and CAMO DASR obligations. From this perspective, SIMPs should be considered subordinate to the Type Continued Airworthiness Exposition (TCAE), Continuing Airworthiness Management Exposition (CAME) and AMP document. The relevant sections of the TCAE, CAME and AMP should refer down to SIMPs and the relevant sections of the SIMPs should refer to the regulation(s) the content is supporting.

6.6.5.2 SIMPs are therefore considered AMC under DASR.

SIMP Content, Structure and Management

6.6.5.3 Given the purpose of SIMPs under DASR outlined above, DASA's policy is that it will endorse all SIMPs. However, SIMPs serve a broader purpose under Defence Policy[18], therefore, not all content will be directly relevant to the DASP.

6.6.5.4 The SIMP content that requires DASA endorsement is listed in Table 1. For ease of review and management, DASA recommends that this content be contained in a dedicated section of the SIMP. All other SIMP content should be managed by the SIP manager in coordination with CASG.

6.6.5.5 DASA expects that SIMPs will be maintained by the SIP manager, and that the MTCH and CAMO will have reviewed the content listed in Table 1 that is relevant to them prior to SIMPs being submitted for DASA endorsement. Best practice is to ensure the sections of the SIMP that are relevant to either the MTCH or CAMO are clearly identified.

6.6.5.6 An indicative SIMP amendment process is shown below in Figure 2. Note that since SIMPs serves a broader purpose under Defence Policy, DASA endorsement should not be viewed as the final step, and SIMP approval should be provided by a suitable Defence representative (notionally a senior Defence engineer within the CASG System Program Office).

Table 1: SIMP Content Requiring DASA Endorsement

Content	DASR Reference	Section 6.6 Reference
A list of the key structural / propulsion system airworthiness design standards, Defence-unique airworthiness requirements (ie derived from DASDRM) and reference to the TCB	21.A.16A 21.A.16B 21.A.17A	6.6.2.1 - 6.6.2.3
The basis of sovereign type certification for the structure / propulsion system, including: • type certification approach (eg how prior recognition was leveraged) • reference to structures / propulsion system CREAs and sovereign compliance demonstration evidence • reference to certification outcomes such as relevant Military Certification Review Items and Airworthiness Issue Papers	21.A.20	6.6.2.5 - 6.6.2.11

Superseded

• description of any outstanding structures/propulsion system certification issues and the proposed resolution pathway		
Definition of structural / propulsion system critical parts Either a list of, or reference to, the authoritative source for critical parts	21.A.41	6.6.2.15 - 6.6.2.19
Definition of structural / propulsion system AwLs, and details of what algorithms, damage equations, conversion factors or other data are encompassed within the AwL definition Reference to the authoritative source for structural / propulsion system AwLs Listing of structural / propulsion system AwLs (as required)	21.A.41	6.6.2.22 - 6.6.2.31
Description of organisations involved, and the typical process followed, for investigation of structural / propulsion system failures, malfunctions, defects and other occurrences Description of the process that allows retired, damaged or defective components to be subject to detailed examination as and when required	21.A.3A(a)	6.6.3.1 - 6.6.3.10
Details of the systems and processes for ongoing monitoring and periodic structural / propulsion system integrity assessment, including: • organisational responsibilities • input data requirements and how this data is collected and validated • periodic assessment frequency and / or trigger(s) • periodic assessment methodology • expected outputs • outcomes of, and reference to, completed assessments	21.A.44(c)	6.6.3.11 - 6.6.3.26
Details of the system and processes for tracking structural / propulsion system life-limited components, including organisational responsibilities	M.A.305(d)(4)	6.6.4.1 - 6.6.4.16
Description of if and how the SIP supports the development and ongoing validity of relevant structural / propulsion system elements of the AMP	M.A.302	6.6.4.17 - 6.6.4.29

Superseded

Process for managing amendments to the SIMP, including frequency and triggers for amendments	N/A	N/A
Any other information requested by DASA specific to the aircraft type	N/A	N/A

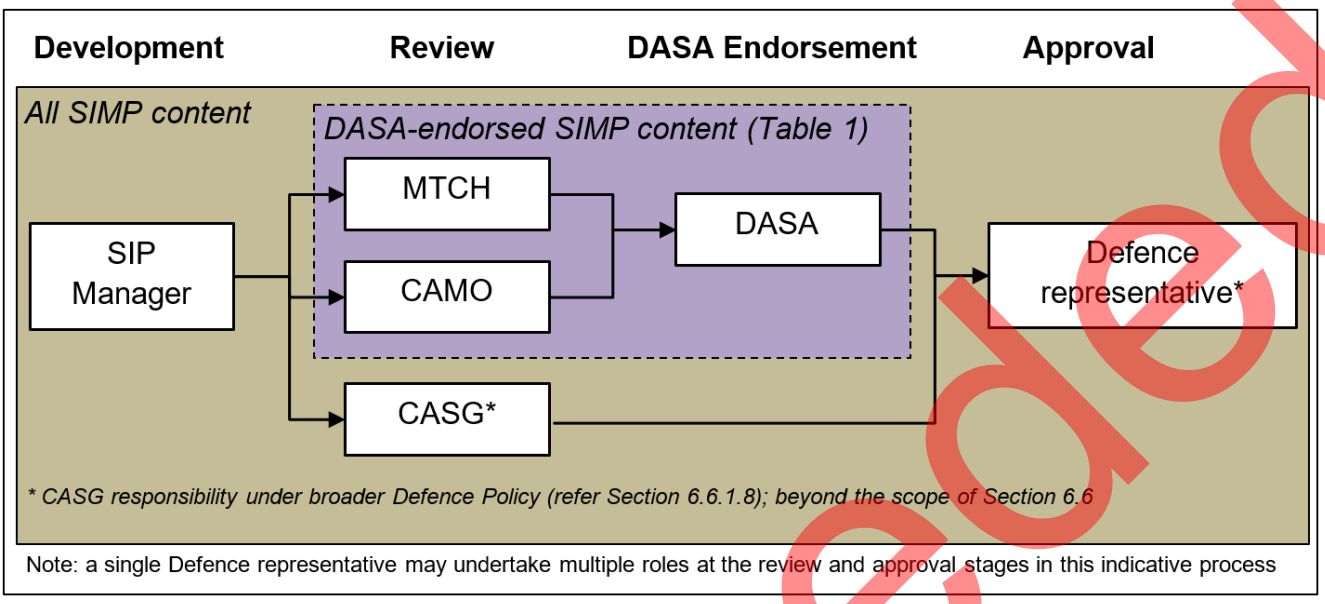

Figure 2: Indicative SIMP Amendment Process

ASIMP Volume 2 / Force Structural Maintenance Plan (FSMP)

6.6.5.7 Discussion on SIMPs until this point has been in reference to the ASIMP Volume 1 and PSIMP.

6.6.5.8 Some aircraft types also use an ASIMP Volume 2 / FSMP. These vary in scope, but typically consolidate information such as structural classifications and / or listing of critical parts, and details (including reference to substantiating and supporting data) of locations identified through analysis, test or service experience that require modification, inspection or repair. DASA supports use of an ASIMP Volume 2 / FSMP as they are a valuable document for ASIP stakeholders, however, DASA does not have any expectation that they should be maintained for every aircraft type.

6.6.5.9 In the capacity outlined above, an ASIMP Volume 2 / FSMP should simply be a consolidated reference of previously-approved design data, and therefore does not require DASA endorsement or approval.

6.6.5.10 The only exception may be where the ASIMP Volume 1 identifies the ASIMP Volume 2 / FSMP as the authoritative source for structural AwLs. This may be the case for some legacy platforms where the ASIMP Volume 2 was historically used to approve and publish AwLs (ie there is no other authoritative 'source' document(s) to refer to). In this case, the ASIMP Volume 2 / FSMP should clearly distinguish AwLs from other structural maintenance requirements. Furthermore, moving forward they should not be used as the vehicle to approve new or updated AwLs, rather they should reference the separately approved design data. In this capacity the ASIMP Volume 2 / FSMP should be treated like other manuals issued by the MTCH (DASR 21.A.57). As noted under DASR AMC 21.A.57, approval and issuing the manual may be separate to approval of the technical content (ie approval of the AwLs).

Superseded

6.6.6 SIP-Related DASR Responsibilities

6.6.6.1 The main SIP-related DASR responsibilities are consolidated by organisation in Table 2.

6.6.6.2 Whilst SIP-related DASR responsibilities are distributed across different organisations, DASA expects that each SIP will continue to be managed and led by a single organisation (ie SIP manager appointed by CASG). Organisational responsibilities are listed below so that each regulated entity understands what they are accountable for, and so SIP managers can understand how their SIP contribute to supporting various obligations under DASR.

Table 2: Consolidated SIP-Related DASR Responsibilities

DASR Responsibility	DASR Reference	Section Reference
Applicants for MTC and MSTC / Major Changes		
Develop and submit proposed TCB for DASA approval Ensure the structures / propulsion system airworthiness design requirements specified in the DASDRM are addressed in the TCB	21.A.16A 21.A.16B 21.A.17A	6.6.2.1 - 6.6.2.3
Compliance demonstration, including ensuring that CRE differences that impact structures / propulsion systems are identified and assessed when leveraging prior CAA / MAA certification	21.A.20	6.6.2.5 - 6.6.2.11
Define and identify structural / propulsion system critical parts and AwLs for the design, consistent with the TCB and the intended Defence CRE, and submit this data to DASA as part of the application	21.A.41	6.6.2.15 - 6.6.2.19 6.6.2.22 - 6.6.2.31
Military Type Certificate Holder		
Collection, investigation and analysis of failures, malfunctions, defects and other occurrences for structures and propulsion systems, including decisions regarding examination of retired, damaged or defective parts	21.A.3A(a)	6.6.3.1 - 6.6.3.10
Occurrence reporting for structures and propulsion systems	21.A.3A(b)	
Report to DASA the results of investigation and any action taken or proposed to correct manufacturing or design deficiencies that have resulted in a reportable occurrence	21.A.3A(c)	
Submit the proposed corrective action and / or required inspections to DASA for approval when an	21.A.3B(c)

6.7.1 Introduction

6.7.1.1 Defence Aviation Orders, Instructions and Publications (OIP) comprise those documents that provide direction, guidance and other information relevant to the generation, operation and sustainment of Defence aviation capabilities. Defence Aviation OIP should be distinguished from aviation-related Defence records that preserve the memory or knowledge of Defence aviation events, activities, decisions and personnel.

6.7.1.2 Whilst not all Defence Aviation OIP has an aviation safety impact, many documents have the potential to contribute to aviation safety hazards. Accordingly, the effective lifecycle management of Defence Aviation OIP can eliminate or minimise the risk associated with these hazards and thus significantly enhance the safe conduct of ADF aviation operations.

6.7.2 Defence Aviation OIP

6.7.2.1 Defence OIP comprises a broad set of documents that include Defence manuals, Service and Group-issued publications, handbooks and directives, and organisational standard operating procedures and instructions. Defence Aviation OIP comprises Defence OIP that is:

1. used during aviation materiel system design activities
2. continuing airworthiness OIP including aircraft maintenance and maintenance management OIP
3. other maintenance and maintenance management OIP for ground-based aviation-related materiel systems
4. Flight operations OIP used to operate aircraft (including flying orders and aircrew manuals)
5. used to operate ground-based aviation-related systems (such as air navigation systems and air battle management systems)
6. used to publish, support and explain aviation regulations
7. used in the logistics support of aviation materiel systems
8. used in support of aviation-related capability management
9. used in support of aviation-related information management.

6.7.2.2 Defence Aviation OIP may be produced entirely within Defence or derived from other documents; sometimes acquired from sources external to defence. In order to eliminate or minimise risk associated with aviation safety hazards, Defence Aviation OIP should undergo a process of drafting, review and amendment (Lifecycle Management Process) to ensure that the published OIP reflects the Defence Configuration, Role and Environment (CRE). Where appropriate, Defence

Superseded

Aviation OIP should also satisfy Defence standardisation requirements – e.g. standardised OIP format used for aircrew flight manuals.

What are OIP's aviation safety hazards?

6.7.2.3 Poor management of Defence Aviation OIP can create aviation safety hazards through the:

1. display of incorrect information leading to unsafe decisions or actions
2. display of correct and timely information but presented in a way that increases the likelihood that the information may be missed or misread, leading to unsafe decisions or actions
3. ongoing display of superseded information that creates inconsistencies and ambiguities.
4. failure to include information required to make good safety-related decisions and take appropriate safety-related actions
5. need for memory-based execution of safety-related decisions or actions when OIP is not available to the user when required.

6.7.2.4 Various forms of Defence Aviation OIP are used by personnel responsible for aviation-related design, operation, maintenance and continuing airworthiness management. OIP documents and communicates requirements, procedures and other information to those who need it to perform their duties. Aviation safety hazards in poorly managed OIP may directly contribute to the incorrect design, maintenance and operation of aircraft, aerodromes and air navigation services. The aim of effective OIP lifecycle management is to present accurate and complete information, presented in a manner that is unambiguous and easy to read in an operational environment.

6.7.3 Defence Aviation OIP Manual

6.7.3.1 The Defence Aviation OIP Management Manual (AVOIPMAN), provides policy, requirements and guidance with respect to the lifecycle management of Defence Aviation OIP. The AVOIPMAN is issued by Chief of Air Force, as a nominated policy owner within the Defence Administrative Policy Framework.

6.7.3.2 The requirements detailed in the AVOIPMAN should be followed by all personnel within the Defence Aviation Community including those in DASR-regulated organisations, in order to eliminate or minimise risk associated with aviation safety hazards. Whilst many of the AVOIPMAN requirements would markedly reduce the creation of aviation safety hazards, the intent of the manual is to ensure that OIP lifecycle management effectively contributes to the generation of aviation capabilities. In particular, the AVOIPMAN describes the characteristics of effective OIP lifecycle management and provides guidance on how to achieve these characteristics.

What is the relationship between the AVOIPMAN and DASR?

6.7.3.3 The AVOIPMAN requirements supplement, and are consistent with, the DASR applicable to OIP management. While most DASR focus solely on the accuracy and completeness of relevant aviation OIP, aviation OIP that cause or contribute to aviation hazards are the focus of DASR SMS. In addition to accuracy and completeness, DASR SMS also encompasses the usability / readability of aviation OIP that causes or contributes to aviation hazards.

Superseded

6.7.3.4 Under DASA's Present, Suitable, Operating and Effective (PSOE) assurance model (detailed in DASP Manual Volume 3 Section 5), the SMS of an organisation may be found to be not operating correctly if hazards related to aviation OIP are not recorded correctly. An organisation's SMS may be found to be ineffective if hazards related to aviation OIP are recorded, but related risk is not being eliminated or minimised So Far as Reasonably Practicable (SFARP). The AVOIPMAN will assist DASR approved organisations eliminate or minimise risk SFARP by providing a common set of OIP management expectations across defence groups – particularly in Capability Acquisition and Sustainment Group, who are often responsible for producing aviation OIP used by Navy, Army and Air Force.

6.7.3.5 The AVOIPMAN specifies two key management roles, namely the Issuing Authority and the OIP Sponsor. The Issuing Authority has prime responsibility for managing a specific OIP Type[1]. The OIP Sponsor has prime responsibility for managing a specific OIP document (content and format), within the requirements established by the Issuing Authority for the relevant OIP Type.

6.7.3.6 No DASR mentions or explicitly regulates OIP Issuing Authorities. The flight operations DASR mention and regulate the OIP Sponsor in ways that are consistent with the AVOIPMAN requirements. Initial and Continuing Airworthiness DASR do not mention or regulate the OIP Sponsor but do regulate other people and organisations in ways that support the Issuing Authority and OIP Sponsor. In particular, Initial and Continuing Airworthiness DASR place requirements on design organisations, maintenance organisations and Continuing Airworthiness Management Organisations with respect to OIP management. So collectively, the DASR contribute to effective OIP management of aviation safety elements of the broad AVOIPMAN requirements.

6.7.3.7 Conversely, the AVOIPMAN requirements support the discharge of DASR obligations. The AVOIPMAN make clear that the process to approve and release the content of new OIP, or amended OIP must include any relevant approvals mandated within Defence regulatory frameworks. For Defence Aviation OIP, the main regulatory framework is that provided within the DASP. Whilst the content of most OIP types are not subject to DASR approvals, such approvals apply to much OIP relevant to the design, maintenance and operation of aircraft, aerodromes and air navigation systems. Other regulatory frameworks also apply, such as the Explosive Safety Regulatory Framework and the requirements of the Defence Landworthiness Management System relevant to some ground-based systems and equipment within the aviation domain.

6.7.3.8 Both the AVOIPMAN and DASR provide requirements aimed at ensuring effective OIP lifecycle management. The assurance of Defence Aviation OIP may occur as part of the range of activities that include system and desktop reviews and formal onsite auditing.

6.7.4 Conclusion

6.7.4.1 The ineffective lifecycle management of Defence Aviation OIP creates aviation safety hazards that threaten the desired outcomes of the Defence Aviation Safety Program. Compliance with the DASR requirements relevant to OIP management markedly reduces the likelihood that the hazards will eventuate. Regulated organisations should also remain cognisant of the broader AVOIPMAN requirements to ensure safe, capability focused, outcomes.

Superseded

6.8.1 Data Integrity

Introduction

6.8.1.1 In the context of Defence aviation, data is defined in many ways. The Australian Defence Glossary states it is the raw material used to represent information or from which information can be derived. Capability Acquisition and Sustainment Group policy blurs the distinction between 'data' and 'information', defining 'technical data' as recorded information, regardless of the form or method of the recording, of a scientific or technical nature. DASR 145 explains that 'maintenance data' comprises requirements, procedures, operational directive or information and instructions and standards.

6.8.1.2 For the purposes of the DASP, data comprises all data and information used by aircraft design engineers, aircraft operators, aircraft maintainers, continuing airworthiness management staff, air navigation service providers, aerodrome operators, aviation logistics support staff and aviation training organisations. Data can either be acquired from sources external to Defence and used as-is, acquired externally and processed within Defence to create modified data, or created, collected and processed within Defence. Annex A provides a useful taxonomy of data used within the DASP.

Data as an aviation safety hazard

6.8.1.3 Data used in both aircraft and ground applications may create substantial aviation safety risks. Data that is insufficient, corrupt or erroneous may lead to users being presented with inaccurate information, the correct information not being available at the required time or people being presented with incomplete information. Accordingly, data represents an aviation safety hazard. The resultant aviation safety risks vary considerably in both their likelihoods and consequences. Some undetected data errors, such as incorrect throwaway lives, create direct safety consequences. Others, such as incorrect records of maintainer authorisations, may simply reduce safety margins. Further, the extent to which poor data can be subject to effective downstream risk controls, before adverse consequences are realised, also markedly varies. For some data types, ample opportunity exists to establish downstream risk controls. For other types, little can be credibly done to identify anything but the grossest errors. For example, the inaccurate calculation of a take-off or landing speed by aircrew provides no opportunity for the errors to be independently detected. In contrast, errors in published maintenance requirements provide the opportunity for errors to be independently detected by maintainers.

What is data intergity?

6.8.1.4 The term used to characterise the 'goodness' of data is data integrity. Although focused on aeronautical data, RTCA DO-200B Standards for Processing Aeronautical Data, provides the most comprehensive list of data integrity characteristics that are equally relevant to all data types. Annex B lists and defines these data characteristics. Ideally, all data used in Defence should exhibit values of these data characteristics tailored to the intended data use and the risks posed by their inadequate integrity. Nevertheless, setting exacting requirements for all data characteristics would come at a cost that may not be reasonably practicable for data types that do not generate higher aviation safety risks.

Superseded

What is the data chain?

6.8.1.5 Defence can both acquire and create data of poor integrity. Initially high integrity data can be processed and presented to users in ways that corrupt its integrity. To best understand how data may be corrupted, DO-200B discusses the data processing chain that conceptually applies to all the data categories detailed in Annex A. Any data chain comprises a mix of five types of functional links, namely Origination, Transmission, Preparation, Application Integration, and End-Use of data. A chain can be of varying length given a link type can occur more than once. Within any chain, the links are typically performed by different organisations.

6.8.1.6 DO-200B also describes how the Transmission, Preparation and Application Integration functional links can be further divided into the following six processing phases:

1. **Receive Phase.** The Receive Phase involves the reception of the original data from its source. The data originator may either be a Defence organisation or a source external to Defence.

2. **Assemble Phase.** The Assemble Phase involves the collection and collation of data from one or more data sources.

3. **Translate Phase.** The Translate Phase involves changing, where necessary, how information is to be displayed to the eventual consumer of the data.

4. **Select Phase.** The Select Phase involves selecting specific data elements from the collection of data produced by the assemble phase.

5. **Format Phase.** The Format Phase involves converting the selected data subset into a format that is acceptable to the next functional link in the chain.

6. **Distribute Phase.** The Distribute Phase involves the delivery of the formatted data set to its users. Examples of delivery media are magnetic or optical media, solid state devices, direct computer-to-computer links or wireless data communications.

How do DASR regulate data integrity?

6.8.1.7 The DASR do not provide a discrete section on the management of data to assure data integrity. Spread throughout the Initial Airworthiness, Continuing Airworthiness, Flight Operations, Air Navigation Service Providers and Aerodromes regulations are what could be termed 'entry control' requirements for people operating in the data chain, as well as the eventual end-users of the data. These regulations do not place requirements on the creation of data, but on those using the data. The requirements are often couched in different terms, with the intent that before data is used it is assessed to determine whether it is accurate, applicable, approved, current and credible.

6.8.1.8 DASR ANSP does not provide entry control requirements for the use of data. It requires that an Air Navigation Service Provider that provides an Aeronautical Information Service must provide documents that detail Aeronautical Information product development and Aeronautical Information delivery procedures. Such procedures would aim to develop and provide Aeronautical Information of adequate integrity. At this time, DASR does not require organisations processing aeronautical data to be DO-200B compliant, but in practice DASA has issued a DO-200B based Letter of Acceptance to AIS-AF for its major aeronautical data product.

Ensuring data integrity in practice

Superseded

6.8.1.9 Data integrity should be ensured in two scenarios. In the first scenario, pre-existing data is used to take a decision or perform an action. In the second scenario, data is created or processed for use by others. These scenarios will be discussed in turn.

6.8.1.10 When using pre-existing data, to take a decision or perform an action, one should:

1. understand, where practicable, the data quality requirements for each of the relevant data characteristics outlined in Annex B
2. only use data received from a reputable source such as from a currently accredited data supplier
3. only use current data
4. look for any indications that the data may have corrupted in transit from its source or supplier, either intentionally or unintentionally
5. confirm the data has the required resolution for its intended purpose
6. confirm the data is complete given its intended purpose
7. ensure the data format is unlikely to be misread or misinterpreted with, where applicable, clear units of measurement
8. rectify any identified problems with data integrity.

6.8.1.11 When creating or processing data for use by others, one should:

1. understand, where practicable, what data quality requirements are needed for each of the relevant data characteristics outlined in Annex B
2. ensure any created data is not corrupted during data processing activities
3. ensure the processed data has the required resolution for its intended purpose
4. ensure the processed data is complete given its intended purpose
5. ensure the processed data is generated in the required format, either human readable or digital
6. provide the processed data in a format that is unlikely to be misread or misinterpreted, with, where applicable clear units of measurement
7. ensure that any software tools used during any data processing stage are subject to the tool qualification process discussed below in paragraph 6.8.15.
8. rectify any identified problems with data integrity.

Required rigour

6.8.1.12 The rigour that should be applied in performing these activities depends on the proposed use of the data and its criticality. As criticality increases, the rigour applied in questioning the integrity of data by personnel processing and using the data should become increasingly robust. Of greatest concern should be data that once created and used downstream provides little opportunity for people to verify its integrity, apart from the potential for gross error checks.

Superseded

6.8.1.13 Accordingly, the effort that should be applied in asking and answering these questions needs to be commensurate with the risk that poor data integrity poses to aviation safety. These risks depend on a range of variables relevant to a specific data type used in a specific scenario. Nevertheless, one can characterise data as follows:

1. **Category 1.** Aviation data in which poor integrity creates credible higher aviation safety risks. Little or no opportunity exists for effective downstream risk treatments.
2. **Category 2.** Aviation data in which poor integrity creates credible higher aviation safety risks. Opportunity exists for effective downstream risk treatments.
3. **Category 3.** Aviation data in which poor integrity creates credible lower aviation safety risks. Little or no opportunity exists for effective downstream risk treatments.
4. **Category 4.** Aviation data in which poor integrity creates credible lower aviation safety risks. Opportunity exists for effective downstream risk treatments.

6.8.1.14 These categories require decreasing degrees of safety assurance with Category 1 deserving the most attention. Given that any data type may contain data that falls within multiple categories, Annex A also provides a subjective assessment of the most severe credible category for each listed data type.

Software Tool qualification

6.8.1.15 Within the data chain explained in paragraph 6.8.6, designers and operators use software tools to create and process data. Depending on their function, these tools may require qualification before use to ensure they do not generate low integrity data. A historic problem has been well-meaning Defence members either writing or buying software data-processing applications without appropriate integrity, or using extant tools, sometimes written by their predecessors, of uncertain integrity.

6.8.1.16 Qualification of a software tool is required when engineering or other processes are eliminated, reduced or automated by the use of a software tool without its output being verified. The purpose of the tool qualification is to ensure that the tool provides confidence at least equivalent to that of the processes eliminated, reduced or automated.

6.8.1.17 Annex C provides guidance on software tool qualification. Personnel creating or amending software tools should understand the defined process and be informed by the documented guidance.

Risk management

6.8.1.18 Where identified problems with data integrity cannot be effectively rectified, personnel should diligently apply the seven-step Safety Risk Management process described at AC 003/2018 Risk Management in the Defence Aviation Safety Program.

6.8.1.19 In applying the seven-step process to data hazards, organisations should consider:

1. their ability to engage with the supplier of the data to confirm its integrity before use
2. introducing gross error checks at various stages of the data processing
3. performing sensitivity analyses on the data to confirm the extent that inaccurate data would affect the decision or the performance of the action

Superseded

4. using, the range of verification and validation techniques detailed in DO-200B Appendix C, such as semantic consistency, digital error detection and sampling, to help minimise the risk

5. Attaining multiple sources of truly independent data.

6.8.2 Conclusion

6.8.2.1 Data plays an important role in aviation safety. Poor data will lead to aviation safety hazards and may not provide any or little opportunity to the user for risk treatment. Designer and operators use software tools to create and process data. When a software tool eliminates, reduces or automates an engineering process and its output is not verified, software tool qualification is required as per DO-200B. The seven-step Safety Risk Management process should be applied when the user identifies a problem with data integrity and cannot effectively rectify the problem. Effective data processing may reduce not only the likelihood but also the consequences that poor integrity data will generate towards aviation safety risks. The onus is on all personnel in the data chain, as well as the data's end-user, to question data integrity and eliminate or otherwise minimise risks So Far As is Reasonably Practicable (SFARP).

6.8.1 Data Integrity

Introduction

6.8.1.1 In the context of Defence aviation, data is defined in many ways. The Australian Defence Glossary states it is the raw material used to represent information or from which information can be derived. Capability Acquisition and Sustainment Group policy blurs the distinction between 'data' and 'information', defining 'technical data' as recorded information, regardless of the form or method of the recording, of a scientific or technical nature. DASR 145 explains that 'maintenance data' comprises requirements, procedures, operational directive or information and instructions and standards.

6.8.1.2 For the purposes of the DASP, data comprises all data and information used by aircraft design engineers, aircraft operators, aircraft maintainers, continuing airworthiness management staff, air navigation service providers, aerodrome operators, aviation logistics support staff and aviation training organisations. Data can either be acquired from sources external to Defence and used as-is, acquired externally and processed within Defence to create modified data, or created, collected and processed within Defence. Annex A provides a useful taxonomy of data used within the DASP.

Data as an aviation safety hazard

6.8.1.3 Data used in both aircraft and ground applications may create substantial aviation safety risks. Data that is insufficient, corrupt or erroneous may lead to users being presented with inaccurate information, the correct information not being available at the required time or people being presented with incomplete information. Accordingly, data represents an aviation safety hazard. The resultant aviation safety risks vary considerably in both their likelihoods and consequences. Some undetected data errors, such as incorrect throwaway lives, create direct safety consequences. Others, such as incorrect records of maintainer authorisations, may simply reduce safety margins. Further, the extent to which poor data can be subject to effective downstream risk controls, before adverse consequences are realised, also markedly varies. For some data types, ample opportunity exists to establish downstream risk controls. For other types, little can be credibly done to identify anything but the grossest errors. For example, the inaccurate calculation of a take-off or landing speed by aircrew provides no opportunity for the errors to be independently detected. In contrast, errors in published maintenance requirements provide the opportunity for errors to be independently detected by maintainers.

What is data intergity?

6.8.1.4 The term used to characterise the 'goodness' of data is data integrity. Although focused on aeronautical data, RTCA DO-200B Standards for Processing Aeronautical Data, provides the most comprehensive list of data integrity characteristics that are equally relevant to all data types. Annex B lists and defines these data characteristics. Ideally, all data used in Defence should exhibit values of these data characteristics tailored to the intended data use and the risks posed by their inadequate integrity. Nevertheless, setting exacting requirements for all data characteristics would come at a cost that may not be reasonably practicable for data types that do not generate higher aviation safety risks.

What is the data chain?

Superseded

6.8.1.5 Defence can both acquire and create data of poor integrity. Initially high integrity data can be processed and presented to users in ways that corrupt its integrity. To best understand how data may be corrupted, DO-200B discusses the data processing chain that conceptually applies to all the data categories detailed in Annex A. Any data chain comprises a mix of five types of functional links, namely Origination, Transmission, Preparation, Application Integration, and End-Use of data. A chain can be of varying length given a link type can occur more than once. Within any chain, the links are typically performed by different organisations.

6.8.1.6 DO-200B also describes how the Transmission, Preparation and Application Integration functional links can be further divided into the following six processing phases:

1. **Receive Phase.** The Receive Phase involves the reception of the original data from its source. The data originator may either be a Defence organisation or a source external to Defence.

2. **Assemble Phase.** The Assemble Phase involves the collection and collation of data from one or more data sources.

3. **Translate Phase.** The Translate Phase involves changing, where necessary, how information is to be displayed to the eventual consumer of the data.

4. **Select Phase.** The Select Phase involves selecting specific data elements from the collection of data produced by the assemble phase.

5. **Format Phase.** The Format Phase involves converting the selected data subset into a format that is acceptable to the next functional link in the chain.

6. **Distribute Phase.** The Distribute Phase involves the delivery of the formatted data set to its users. Examples of delivery media are magnetic or optical media, solid state devices, direct computer-to-computer links or wireless data communications.

How do DASR regulate data integrity?

6.8.1.7 The DASR do not provide a discrete section on the management of data to assure data integrity. Spread throughout the Initial Airworthiness, Continuing Airworthiness, Flight Operations, Air Navigation Service Providers and Aerodromes regulations are what could be termed 'entry control' requirements for people operating in the data chain, as well as the eventual end-users of the data. These regulations do not place requirements on the creation of data, but on those using the data. The requirements are often couched in different terms, with the intent that before data is used it is assessed to determine whether it is accurate, applicable, approved, current and credible.

6.8.1.8 DASR ANSP does not provide entry control requirements for the use of data. It requires that an Air Navigation Service Provider that provides an Aeronautical Information Service must provide documents that detail Aeronautical Information product development and Aeronautical Information delivery procedures. Such procedures would aim to develop and provide Aeronautical Information of adequate integrity. At this time, DASR does not require organisations processing aeronautical data to be DO-200B compliant, but in practice DASA has issued a DO-200B based Letter of Acceptance to AIS-AF for its major aeronautical data product.

Ensuring data integrity in practice

6.8.1.9 Data integrity should be ensured in two scenarios. In the first scenario, pre-existing data is used to take a decision or perform an action. In the second scenario, data is created or processed for use by others. These scenarios will be discussed in turn.

Superseded

6.8.1.10 When using pre-existing data, to take a decision or perform an action, one should:

1. understand, where practicable, the data quality requirements for each of the relevant data characteristics outlined in Annex B
2. only use data received from a reputable source such as from a currently accredited data supplier
3. only use current data
4. look for any indications that the data may have corrupted in transit from its source or supplier, either intentionally or unintentionally
5. confirm the data has the required resolution for its intended purpose
6. confirm the data is complete given its intended purpose
7. ensure the data format is unlikely to be misread or misinterpreted with, where applicable, clear units of measurement
8. rectify any identified problems with data integrity.

6.8.1.11 When creating or processing data for use by others, one should:

1. understand, where practicable, what data quality requirements are needed for each of the relevant data characteristics outlined in Annex B
2. ensure any created data is not corrupted during data processing activities
3. ensure the processed data has the required resolution for its intended purpose
4. ensure the processed data is complete given its intended purpose
5. ensure the processed data is generated in the required format, either human readable or digital
6. provide the processed data in a format that is unlikely to be misread or misinterpreted, with, where applicable clear units of measurement
7. ensure that any software tools used during any data processing stage are subject to the tool qualification process discussed below in paragraph 6.8.15.
8. rectify any identified problems with data integrity.

Required rigour

6.8.1.12 The rigour that should be applied in performing these activities depends on the proposed use of the data and its criticality. As criticality increases, the rigour applied in questioning the integrity of data by personnel processing and using the data should become increasingly robust. Of greatest concern should be data that once created and used downstream provides little opportunity for people to verify its integrity, apart from the potential for gross error checks.

6.8.1.13 Accordingly, the effort that should be applied in asking and answering these questions needs to be commensurate with the risk that poor data integrity poses to aviation safety. These risks depend on a range of variables relevant to a specific data type used in a specific scenario. Nevertheless, one can characterise data as follows:

Superseded

1. **Category 1.** Aviation data in which poor integrity creates credible higher aviation safety risks. Little or no opportunity exists for effective downstream risk treatments.

2. **Category 2.** Aviation data in which poor integrity creates credible higher aviation safety risks. Opportunity exists for effective downstream risk treatments.

3. **Category 3.** Aviation data in which poor integrity creates credible lower aviation safety risks. Little or no opportunity exists for effective downstream risk treatments.

4. **Category 4.** Aviation data in which poor integrity creates credible lower aviation safety risks. Opportunity exists for effective downstream risk treatments.

6.8.1.14 These categories require decreasing degrees of safety assurance with Category 1 deserving the most attention. Given that any data type may contain data that falls within multiple categories, Annex A also provides a subjective assessment of the most severe credible category for each listed data type.

Software Tool qualification

6.8.1.15 Within the data chain explained in paragraph 6.8.6, designers and operators use software tools to create and process data. Depending on their function, these tools may require qualification before use to ensure they do not generate low integrity data. A historic problem has been well-meaning Defence members either writing or buying software data-processing applications without appropriate integrity, or using extant tools, sometimes written by their predecessors, of uncertain integrity.

6.8.1.16 Qualification of a software tool is required when engineering or other processes are eliminated, reduced or automated by the use of a software tool without its output being verified. The purpose of the tool qualification is to ensure that the tool provides confidence at least equivalent to that of the processes eliminated, reduced or automated.

6.8.1.17 Annex C provides guidance on software tool qualification. Personnel creating or amending software tools should understand the defined process and be informed by the documented guidance.

Risk management

6.8.1.18 Where identified problems with data integrity cannot be effectively rectified, personnel should diligently apply the seven-step Safety Risk Management process described at AC 003/2018 Risk Management in the Defence Aviation Safety Program.

6.8.1.19 In applying the seven-step process to data hazards, organisations should consider:

1. their ability to engage with the supplier of the data to confirm its integrity before use

2. introducing gross error checks at various stages of the data processing

3. performing sensitivity analyses on the data to confirm the extent that inaccurate data would affect the decision or the performance of the action

4. using, the range of verification and validation techniques detailed in DO-200B Appendix C, such as semantic consistency, digital error detection and sampling, to help minimise the risk

5. Attaining multiple sources of truly independent data.

Superseded

6.8.2 Conclusion

6.8.2.1 Data plays an important role in aviation safety. Poor data will lead to aviation safety hazards and may not provide any or little opportunity to the user for risk treatment. Designer and operators use software tools to create and process data. When a software tool eliminates, reduces or automates an engineering process and its output is not verified, software tool qualification is required as per DO-200B. The seven-step Safety Risk Management process should be applied when the user identifies a problem with data integrity and cannot effectively rectify the problem. Effective data processing may reduce not only the likelihood but also the consequences that poor integrity data will generate towards aviation safety risks. The onus is on all personnel in the data chain, as well as the data's end-user, to question data integrity and eliminate or otherwise minimise risks So Far As is Reasonably Practicable (SFARP).

Annex A - Aviation Data

Aviation Data

The table below summarises the type of aviation data relevant to the DASP, categorised by their intended application. The category assessments are subjective, and intended as a starting point only. Before application, they need to be critically re-assessed, taking into account the local context.

Application	Data	Processed or displayed by	Most credible severe data category
Initial airworthiness	Data used to inform the design of, and changes to, aircraft configurations	Designer modelling/ calculation tools eg Electrical Loads Analysis	Category 2
	Data used to decide whether aircraft designs are compliant with type certification requirements		Category 1
	Data used to create or change instructions for continuing airworthiness	spreadsheets and databases	Category 2
	Data used to create or change aircraft operating limits		Category 2
	Data used to create or change aircraft flight manual technical procedures		Category 1
	Data used to inform and record engineer authorisations	Spreadsheets, Emerald	Category 4
	Data recording aircraft type design		Category 4

Superseded

	Data recording aircraft type certification basis outcomes	TCB management databases	Category 3
	Technical Standards and specifications used for design purposes	Specification/standards spreadsheets and databases	Category 2
	Hazard/risk data	Hazard Logs/Risk management spreadsheets and databases	Category 4
Continuing airworthiness	Data used to create or change aircraft maintenance procedures, intervals and limitations	Hardcopy and electronic management systems	Category 2
	Fleet planning data	Fleet planning applications	Category 4
	Data used to manage aircraft configurations	Computer aided maintenance management systems	Category 2
	Data used to inform and record maintainer licenses and approvals	Computer aided maintenance management systems, spreadsheets	Category 4
	Data used to provide 'Authority to fit'	ATF applications	Category 1
	Hazard/risk data	Hazard Logs/Risk management spreadsheets and databases	Category 3
Flight operations	Mission planning data	Mission planning applications	Category 1
	Data used to operate aircraft	Hardcopy, Electronic flight bags, document management systems	Category 1

Superseded

	Aircraft Take-Off and Landing Data (TOLD)	TOLD applications	Category 1
	Data used to calculate aircraft performance	Eg power settings, flight – limiting masses, distances, times and/or speeds	Category 1
	Weight and balance data	Weight and balance management applications	Category 1
	Data used to inform and record aircrew training, competence, currency, categorisation and experience	Aircrew categorisation/ experience management applications (eg PEX)	Category 4
	Hazard/risk data	ASOR data, hazard logs/risk management spreadsheets and databases	Category 3
	Flight data recorder/cockpit data recorder data	Data in FDR/CVR and extracted data	Category 4
Aerodromes	Data used to inform the design of, and changes to, aerodrome configurations	Designer modelling/ calculation tools	Category 3
	Data used to create or change aerodrome operating limitations		Category 2
	Data used to create or change aerodrome operating procedures		Category 2
	Data recording aerodrome certification outcomes	management databases	Category 4

Superseded

	Technical Standards and specifications used for design purposes	Specification/standards spreadsheets and databases	Category 4
	Hazard/risk data	Hazard Logs/Risk management spreadsheets and databases	Category 4
	Data used to create or change aerodrome maintenance procedures	Hardcopy and electronic management systems	Category 4
	Data used to manage aerodrome configurations	Computer aided maintenance management systems	Category 4
	Data used to inform and record aerodrome maintainer licenses and approvals	Computer aided maintenance management systems, spreadsheets	Category 4
	Hazard/risk data	Hazard Logs/Risk management spreadsheets and databases	Category 4
	Data used to inform and record aerodrome staff training, competence, currency, categorisation and experience	Categorisation/experience management applications	Category 4
ANSP	Data used to inform the design of, and changes to, ANS	Designer modelling/ calculation tools	Category 3
	Data used to create or change ANS operating limitations		Category 2

Superseded

	Data used to create or change ANS operating procedures		Category 2
	Technical Standards and specifications used for design purposes	Specification/standards spreadsheets and databases	Category 4
	Hazard/risk data	Hazard Logs/Risk management spreadsheets and databases	Category 4
	Data used to create or change ANS maintenance procedures	Hardcopy and electronic management systems	Category 4
	Data used to manage ANS configurations	Computer aided maintenance management systems	Category 4
	Data used to inform and record ANS maintainer licenses and approvals	Computer aided maintenance management systems, spreadsheets	Category 4
	Hazard/risk data	Hazard Logs/Risk management spreadsheets and databases	Category 4
	Data used to inform and record ANS staff training, competence, currency, categorisation and experience	Categorisation/experience management applications	Category 4
Safety assurance	Safety assurance data	DASA SIS	Category 4
Logistics	Logistics data		Category 4
Training	Training data		Category 4

Superseded

Accuracy

The degree of conformance between the estimated or measured value and its true value.

Assurance Level

The degree of confidence in the process to provide valid/uncorrupted data. This can be categorized into three levels: 1, 2, and 3; with 1 being the highest degree of confidence.

Completeness

The degree of confidence that all of the data needed to support the intended use is provided.

Data Quality

A degree or level of confidence that the data provided meets the requirements of the user. These requirements include levels of accuracy, resolution, assurance level, traceability, timeliness, completeness, and format.

Format (as a structure)

A structure of data elements, records and files arranged to meet standards, specifications or Data Quality Requirements.

Resolution

A number of units or digits to which a measured or calculated value is expressed and used. Resolution only applies to data derived from measured values.

Timeliness

The degree of confidence that the data is applicable to the period of its intended use.

Traceability

The ability of a system or data product to provide a record of the changes made to that product and thereby enables an audit trail to be followed from the end-user to the data originator.

Superseded

Tool Qualification as per DO-200B

(a) Software tools can be used to eliminate, reduce or automate data processing activities. Tool qualification is the process by which assurance is achieved that any tools employed will neither introduce errors into the data nor fail to detect an error.

Preferred ADF standards

(b) Section 2.4.5 of RTCA DO-200B Standards for Processing Aeronautical Data is the preferred starting point for software tool qualification, given it calls out other Defence-recognised standards when appropriate. Although DO-200B discusses only Aeronautical Data, its data-focused tool qualification process applies to all form of aviation-related data.

New and existing tools

(c) All new software tools intended for use should be subjected to the process in Section 2.4.5 of DO-200B. The modification of an existing tools, shall be reviewed to determine whether the tool is required to undergo qualification; where a decision is made that qualification is not required, justification for that shall be provided.

Is tool qualification needed?

(d) Section 2.4.5 begins by explaining how to determine whether a specific software tool requires qualification and, if so, how to determine the Tool Qualification Level. Figure 2-1 provides the flowchart detailing the series of questions that must be asked to determine the need for qualification, and if so, the type of qualification. Tools requiring qualification should be qualified as either an 'error detection tool' or as a 'data processing tool'.

Determining the tool qualification level

(e) When tool qualification is needed, section 2.4.5 explains how to determine the relevant Tool Qualification Level (TQL). The required TQL varies depending on whether the tool is 'error detecting' or 'data processing' as well its appropriate Data Process Assurance Level (DPAL). Appendix C to DO-200B explain how to determine the DPAL through a preliminary system safety assessment that considers credible failure modes and their associate consequences. The consequences of failure or partial performance of the process being replaced determine the DPAL required of the tool.

(f) The process for determining the DPAL is similar to that used to determine software Design Assurance Levels (DAL) within RTCA DO-178C Software Considerations in Airborne Systems and Equipment Certification. Indeed, Table C-1 in DO-200B Appendix C shows the relationship between DPALs and DALs.

(g) Having determined the DPAL, Table 2-1 of DO-200B is used to determine the required TQL. Note that tools with a DPAL3 do not require qualification given that the preliminary safety assessment has determined that the data on which the tool would be used has no safety effect.

Qualifying tools

Superseded

(h) For those tools to be qualified, DO-200B requires use of the process in RTCA DO-330 Software Tool Qualification Considerations. However, this latter standard cannot be used in isolation, with DO-200B Appendix D providing extensive guidance on how to adapt DO-33O for software tools used in the processing of Aeronautical Data. In particular Tables D-1 through D-10 in Appendix D should be applied given they modify Tables T-0 through T-10 in DO-330.

Pre-existing tools that have not been previously qualified

(i) Whether or not a pre-existing tool requires qualification as described in this section depends on its assessed DPAL. Accordingly, the relevant DPAL should be determined as described in paragraph 5.

(j) Tools with an assessed DPAL1 require qualification in accordance with the requirements of DO-330.

(k) Whether or not pre-existing unqualified tools with an assessed DPAL2 require qualification is a risk management judgement to be made by the organisations using the tools. The system safety assessment informing the DPAL2 classification provides the appropriate starting point. An argument may be defensibly made that qualification of DPAL2 tools is unnecessary if they have a history of successful use that provides confidence in their design. In forming a view about tool history, organisations should consider whether evidence exists that:

1. the tool's functional requirements have been defined and verified through, for example, a functional flow block diagram
2. configuration management has been applied throughout the tool lifecycle
3. the effects of configuration changes have been analysed to determine their effect on tool operation, particularly with respect to safety-related functions
4. the tool is stable and mature
5. problem reporting during tool's service history provides assurance that data is available and that in-service problems were reported and recorded, and are retrievable
6. whether the tool has been 'qualified' by any process different to that described in this section
7. the intended tool usage (considering intended CRE) is relevant to the tool service history.

(l) The decision whether to qualify the tool becomes more difficult if information is not available to answer some or all of these questions, or the answers do not increase confidence in the tool's integrity. Organisations need to make a defensible decision based on engagement with stakeholders whose personnel's safety is affected by the use of the tool. Importantly, the decision whether or not to qualify the tool should also consider the availability of other risk treatments that justify not qualifying the tool. Such treatments may reduce the likelihood that the continued use of an unqualified tool will adversely affect aviation safety or may reduce the safety consequences where risks are realised.

Engaging with DASA

(m) Where tool qualification occurs as part of an organisation seeking approval from DASA as a Data Services provider, DASA may seek explanation from the organisations on how the tools

Superseded

were qualified. What processes were involved in the tool qualification process? For all other circumstances, organisations are not required to engage DASA. Nevertheless, organisations may seek DASA advice, at any time, on tool qualification.

Superseded

6.9. Cybersecurity in Aviation*

6.9.1 Introduction

6.9.1.1 Hazards to Defence aircraft may include threats from Cyber security. Command retains the responsibility for ensuring the safety of aircraft occupants, other aircraft, people and facilities on the ground. As such, Cyber hazards to Aviation Safety must be eliminated or otherwise minimised So Far As Reasonably Practicable (SFARP).

6.9.2 Purpose

6.9.2.1 This chapter guides Defence's aircraft acquisition organisations and Military Air Operators (MAOs) through the aviation safety requirements and recommended practices for treating Cyber hazards to aviation safety.

Superseded

Superseded

6.10.1 Introduction

Purpose

6.10.1.1 The purpose of the Aircraft Crash Protection (CP) policy is to assure that all Defence type certificated crewed aircraft are operated in a manner which eliminates or otherwise minimises the CP risks to personnel So Far as is Reasonably Practicable (SFARP). This chapter provides guidance to help understand how CP risk is identified, and then managed within an SMS, with guidance to help contextualise and establish reasonable knowledge.

Background

6.10.1.2 The Authority has defined the Contemporary Crash Protection Design Requirements (CCPDR) as the most demanding of requirements between the FAR/CSs for civil CCPDR, and relevant military standards for CCPDR. Ideally, Defence aircraft and contracted aircraft which carry Defence personnel should meet CCPDR as prescribed within the Defence Aviation Safety Design Requirements Manual (DASDRM). However, it is not always feasible to select the most CCPDR compliant platform because acquisition/contracting decisions are based on a much wider range of considerations.

6.10.1.3 In the event that an aircraft is unable to meet the contemporary standards for crash protection, the identified deficiencies will likely be captured within an MCRI, and where applicable, an associated AwIP that details the risk management mitigations. This AwIP, and the system's risk register then provide the basis for review and monitoring of the associated risks as a result of a survivable crash occurring.

6.10.1.4 As required by the WHS Act 2011, and implemented through DASR SMS, the MAO must maintain a system to eliminate or otherwise minimise risk So Far As is Reasonably Practicable (SFARP) to personnel resulting from a survivable crash.

6.10.1.5 Historically, crash protection within the ADF has been regulated in the Authority Rules for Operations (through ARO.40), and before that in a Defence Aviation Authority Directive (DAAD 002/16). It was determined in 2023 that regulating CP through specific obligations on the MAO no longer provided value given the context differences between the contemporary aviation safety environment and that which existed when the CP policy was first published. This change in approach allows MAOs to make risk management decisions without the undue influence of artificial priorities inferred from the existence of specific CP regulations.

6.10.1.6 Large parts of the guidance contained within the regulation did however remain valuable, assisting for a common understanding of the elements of CP for assessment. The CP guidance has transferred here, to DASPMAN Volume 3, to capture the corporate knowledge whilst allowing for greater flexibility in the management of crash protection risk.

Superseded

6.10.2 Periodic review of risk assessments

6.10.2.1 Review of Crash Protection is treated like all other risks to health and safety, utilising a risk based approach. Aircraft which represent a high risk, or where the level of risk is not well understood, should be subject to more frequent monitoring and review. Conversely for aircraft which afford a high level of CP or in which there is a lower risk of a survivable crash occurring, less frequent assessment may be more appropriate.

6.10.2.2 The DASA prescribed CCPDR will continue to evolve over time as better standards and practices are identified, this may result in supplementation to an aircraft's certification basis. In-service management is essential to ensure that CP risks are continually assessed and treated by platform. When an aircraft type fully meets the CCPDR, the MTCH and MAO should ensure that CP risks are periodically re-evaluated in service as part of the regular review of control measures under as required under DASR SMS. Where an aircraft does not meet the CCPDR, it is important that the risk is managed under the current provisions in the DASR, being TCB tailoring and an Airworthiness issue paper and/or safety management system. Furthermore, aircraft Configuration, Role and Environment (CRE) can change due to a variety of factors, which may in turn result in a change of the CP risk (and other). Hence, risk treatments should be routinely reviewed to ensure their currency dependent on severity of risk.

6.10.3 Principles of Crashworthiness

6.10.3.1 To optimise occupant protection, a systems approach to CP is necessary, encompassing the following key initial airworthiness and flight operations CP principles. The key to an optimised CP system for a particular aircraft is balance between the principles such that any one factor is not significantly degraded.

Initial airworthiness CP principles

6.10.3.2 **Aircraft crash resistance.** The ability of the aircraft structure to provide a protective shell for occupants in the event of a survivable crash is a key factor for occupant survival. The structure and equipment should be designed to allow deformation in a controlled, predictable manner so that forces imposed upon the occupants will be tolerable while still maintaining a protective shell. This aspect also relates to the restraint of concentrated (or high) mass items, to prevent parts of the aircraft becoming projectiles within the cabin during a crash creating crushing or blunt trauma hazards (e.g. engines/transmission/blades coming through the roof, internally mounted items dislodging, etc.).

6.10.3.3 **Occupant retention.** Protection should be afforded to occupants by the aircraft's retention system, which comprises the seat, seat retention and occupant restraint system assembly. The retention system plays a major role for all aircraft types in preventing occupant contact injuries associated with body parts flailing into aircraft structures. For helicopters the retention system also plays a predominant role in energy absorption.

6.10.3.4 **Cargo and equipment retention.** Restraint systems should be designed to control cargo and ancillary equipment displacements that are hazardous to occupants during a survivable crash.

6.10.3.5 **Post-crash emergency escape provisions.** Occupants should retain the ability to rapidly evacuate the aircraft during non-crash ground emergencies, and after survivable crash conditions. The ability to escape is impacted by aircraft deformation, lighting, escape hatches, and so on.

Superseded

6.10.3.6 **Post-crash injury prevention.** The crash protection system should be designed to prevent post-crash environmental hazards that could seriously injure occupants. For hazards which cannot be prevented, the crash protection system should protect occupants from exposure to the hazards. Potential post-crash environmental hazards include fire, toxic fumes and submersion. This principle can be extended to include equipment that can improve post-crash survivability after the crash sequence. Such equipment includes first aid kits, survival kits and emergency locator transmitters.

Flight Operations CP considerations

6.10.3.7 **Cargo and equipment configuration.** Cargo (including role equipment) configuration in an aircraft can have significant implications on CP and post-crash egress. Consideration must be applied to the way in which this cargo is arranged (its orientation, presence of sharp edges etc.) and where that cargo is restrained in the aircraft. Specific examples include operating with life rafts in helicopter cabins or specialist medical equipment on Aeromedical Evacuation (AME) fixed wing aircraft. Refer to AMC and GM to DASR ACD.60(a) for further guidance.

6.10.3.8 **Secondary seating.** There are operational circumstances where Mission Essential Personnel (MEP) cannot be seated in crashworthy seats during flight and must utilise non-standard restraints and/or seating, eg Special Operations contingency loading. The CP risks for these circumstances should be routinely assessed and treated in accordance with DASR ORO.70.B – Non- standard aircraft restraint and seating.

6.10.3.9 **Carriage of personal equipment.** Equipment carried on the individual, eg ALSE, load carriage equipment, body armour, should be risk assessed and treated in the context of CP and DASR ORO.70 – Carriage of Personnel on Defence Aircraft. Routinely reassessing the CP risks associated with the carriage of personal equipment is especially pertinent as there are many different forms and versions of ADF combat ensemble.

6.10.3.10 **Egress procedures.** Risks to egress in post-crash circumstances should be considered and treated as part of CP risk assessments. This should include consideration of cockpit/cabin configurations which can block egress routes or cargo/equipment which could make egress hazardous in a post-crash situation.

6.10.4 Guidance and exceptions

6.10.4.1 Given the purpose of the CP requirements are to increase the safety of the personnel on board in the event of a survivable crash, there are some situations where compliance with the ADF CCPDR will not result in a measurable improvement in safety:

6.10.4.2 **Aircraft fitted with ejection seats.** The ability of an occupant to eject from an aircraft prior to a severe crash reduces the benefit which might be obtainable by improving the CP attributes of these aircraft. Previous CP assessments of ejection seat aircraft did not recommend reasonably practicable treatments to reduce the risks of survivable crashes to occupants, when there is the ability to eject from the aircraft in most crash scenarios (refer to DASDRM for further information). It is therefore highly likely, if not certain, that for any aircraft fitted with ejection seats there will be no reasonably practicable treatments for CP shortfalls and thus the risk is considered to be minimised SFARP.

6.10.4.3 **Ostensibly equivalent civil derivative aircraft.** Certain civil derivative Defence registered aircraft may be exempted from CCPDR supplementation, provided all the following condition are met:

Superseded

1. aircraft is compliant to all civil airworthiness requirements defined in its type certification basis;

2. no significant CRE divergence from the civil certified aircraft; and

3. which maintain alignment of CRE and continued operation of the aircraft in a manner ostensibly equivalent to its civil counterpart.

6.10.4.4 The determination of whether this principle applies should be supported by and articulated through the applicable aircraft's SOIU, and be re-evaluated in the case of any CRE changes.

Crashworthiness Limiting factors.

6.10.4.5 Where a particular aspect of crashworthiness is significantly degraded beyond that of other aspects, it is important that the overall level of crashworthiness is still accurately articulated. For example, any aircraft for which the initial impact will never be survivable is unlikely to benefit from best in class post-crash fire protection. In these cases where one aspect becomes a limiting factor for the aircraft, any other aspects that will not provide improvement cannot be considered to "increase" the crashworthiness. This aims to ensure that any limiting factors to the crashworthiness of the aircraft are adequately identified, and that any non-functional safety improvements do not decrease the CP risk. This should not reduce the importance or desire to improve aspects of crashworthiness that can be improved, only that the risks are required to be evaluated and articulated accurately where limiting factors are present, and design changes are not considered in isolation.

Other Considerations/mitigations

6.10.4.6 **Changes to aircraft CRE.** Proposed changes to the CRE of an aircraft have the potential to affect the CP attributes of an aircraft from both an airworthiness and flight operations perspective. For example, a modification that adds significant weight to a helicopter may change the crash impact attenuation properties of the undercarriage. A change in aircraft operating environment may alter the prevalent crash types for which the aircraft was designed. Changes to an aircraft's CRE must be carefully assessed to ensure the level of CP inherent in the original design and its operation are not compromised, and any impacts on extant CP attributes are evaluated to identify treatment options and confirm that associated risks are reduced SFARP.

6.10.4.7 **Planned Withdrawal Date.** Aircraft close to the Planned Withdrawal Date (PWD) are subject to the scope of this guidance. The risks associated with CP shortfalls of Defence aircraft close to PWD must be assessed to ensure the risks in the event of a survivable crash are minimised SFARP. However, due to the expected significantly lower operating hours in the remaining life of an aircraft close to the PWD, the likelihood of a survivable crash occurring is significantly reduced and therefore any benefits gained through treating shortfalls to CCPDR are likely to be significantly reduced. Consequently, treatments are less likely to be reasonably practicable, with the exception of those which are relatively low cost and can be implemented in a short timeframe. The above needs to be considered when involving conducting an assessment and retaining any residual risk, for an aircraft that has been identified for withdrawal from service.

6.10.4.8 **Limited Configuration Control.** Defence may pursue support arrangements involving Limited Configuration Control (LCC) to maintain configuration parity with other operators to minimise in-service support costs and avoid an 'orphan' or unique fleet. Regardless, aircraft with LCC are subject to the requirements of the DASDRM.

Superseded

6.10.5 Treating CP risk to personnel

6.10.5.1 The core working components of this guidance are aligned to SMS requirements, where risk is identified, analysed, evaluated, communicated and managed by the appropriate entity. The CP risk assessment process described here is conducted as part of DASR SMS. The SMS process can then be used to define the means to assess risk, identify treatments, assess the benefit of operational or technical treatments, make a judgement of whether risk has been minimised SFARP, and have the appropriate Risk Management Authority (RMA) retain any residual CP risk.

6.10.5.2 **Mission specific CP considerations.** 'Standing' risk assessments should be based on standard/routine aircraft CRE and any risks identified would be eliminated or otherwise minimised SFARP via additional controls, including amendments to Orders, Instructions, Procedures (OIP). Hence, it is assumed that any key risks will be identified and managed. Mission specific risks refers to risks that would arise from non-standard or operational contingency tasks where additional consideration should be given to any impacts on survivability in the event of a survivable crash. Assessment of mission specific risks is an ongoing process and captured under Core Risk Profiles (CRP), Mission Risk Profiles (MRP) or Risk Management Plans (RMP) through the Risk Management process. A balanced approach to treating risks is required, in order to achieve the mission. This may include assessing the benefits of exposing Defence personnel to any risks, for example, whether the need to carry passengers outweighs any risks associated with a contingency scenario, or the carriage of specific Dangerous Goods (DG).

6.10.6 CP Risk Management Guidance

6.10.6.1 Management of CP risk follows the Defence 7 step risk management process. Given the complexities with assessing CP risk, the below is guidance regarding an acceptable method of conducting that assessment.

6.10.6.2 CP risk assessments should involve a number of stakeholder agencies and organisations. A system must be in place to treat the outstanding risks identified through the risk assessment process. General guidance on Risk Management is contained within the DASR SMS, with the below guidance providing additional CP specific context and guidance. CP risk assessment and treatment processes should be informed by reference to both these sources. This guidance introduces common descriptors for consequence and likelihood, and a common safety risk matrix across the aviation safety and WHS domains. It also introduces likelihood definitions for system level and activity level contexts, which enables risk assessments to be translated across safety management systems. This process involves establishing the risk assessment context, conducting a CP evaluation, establishing the pre-treatment risk level, identifying and prioritising risk treatments, establishing the post-treatment risk level and communicating the outcomes to the appropriate authority to inform risk treatment decisions.

Establish the CP Context

6.10.6.3 The context of the risk analysis for CP is that the risks to occupants for design related shortfalls are only realised in the event of a 'survivable' crash. Although CP risks are usually related to aircraft designs which are not fully compliant to the CCPDR, risk treatments will eliminate or otherwise minimise the risk SFARP through either operational or design controls, e.g. cease or minimise flight over water if there is insufficient life rafts/life raft capacity in accordance with the

Superseded

CCPDR. Design related controls aim to improve aircraft crash performance by following principles contained in the Defence Aviation Safety Design Requirements Manual (DASDRM).

6.10.6.4 The CP evaluation is to be conducted by the relevant organisation for acquisition and in-service aircraft types. This is conducted in accordance with DASR Part 21 and the Authority prescribed CCPDR in the DASDRM. The result will be an overall level of CP provided to occupants in the event of a survivable crash, expressed in terms of the CP risk level definitions in Table 1.

6.10.6.5 Where there are shortfalls against the CP design requirements, the risks associated with those shortfalls need to be identified, analysed and evaluated to inform risk treatment decisions. The risks associated with CP shortfalls will be at their most extreme in a worst case survivable crash and it is these risks that should be considered in the risk assessment.

Table 1 – CP Shortfalls Definitions	
Level of CP Provided to	Description
Good	The level of CP provided to occupants largely meets the CCPDR.
Moderate	The level of CP provided to occupants exhibits some shortfalls against CCPDR. The envelope for 'potentially survivable crashes' is therefore reduced.
Poor	The level of CP provided to occupants exhibits significant shortfalls against CCPDR. The envelope for 'potentially survivable crashes' is therefore markedly reduced.

Table 1: CP risk level definitions

Pre-treatment Risk Assessment

6.10.6.6 The level of risk associated with CP shortfalls, based on the existing CP attributes of the design for the current ADF CRE must be established to inform risk treatment decisions. The risk context includes the aircraft CP design and operating context as defined in the Statement of Operating Intent and Usage (SOIU) and supporting operational instructions that may include roles, missions/profiles, operating environment, annual rate of effort and passenger carriage requirements. This risk analysis must be conducted collaboratively by the relevant MDOA/MTCH for airworthiness aspects and MAO representatives for operational aspects. The key activities to be completed include:

1. **Identification of the worst case survivable crash scenario within the ADF CRE.** This activity is largely subjective as it is based on the ADF operating context (roles, missions/profiles, etc.).

2. **Establishing Consequence.** The evaluation of the CP design against the CCPDR (Good, Moderate or Poor) is used to inform the pre-treatment consequence in the event of a survivable crash. The Guidance column in Table 2, together with informed judgement of the operating context by technical and operational representatives, should be used to establish the consequence level.

Superseded

Table 2 – Safety Consequence and CP Guidance Descriptors		
Consequence Label	**Safety Matrix Definition**	**Guidance in CP Context – in the event of a survivable crash**
(E) Catastrophic	• Multiple fatalities **OR** 10 or more injuries/illnesses categorised as **'Critical'**	CP Level of Poor – the envelope is significantly reduced. Where there are multiple occupants on-board (typically crew and passengers in vicinity of >10 occupants), it would be expected that there would be multiple fatalities and serious injuries
(D) Critical	• Single fatality and/or permanent disability **OR** 10 or more injuries/illnesses categorised as **'Major'**	CP Level of Poor – the envelope is significantly reduced. Where there are few occupants on-board (typically crew only), it would be expected that there would be at least one fatality and serious injury
(C) Major	• Serious injury or illness requiring immediate admission to hospital as an in-patient and/or permanent partial disability **OR** 10 or more injuries/illnesses categorised as **'Moderate'**	CP Level of Moderate – the envelope is reduced; however, there is a moderate amount of crash protection. Fatalities are not expected to occur, but could occur
(B) Moderate	• Injury or illness causing no permanent disability, which requires non-emergency medical attention by a registered health practitioner **OR** 10 or more injuries/illnesses categorised as **'Minor'**	CP Level of Good – shortfalls are not significant, so the envelope is only marginally reduced. Occupants are not likely to sustain serious injuries, but if occurring it is likely that the injuries are somewhere between serious and minor
(A) Minor	• Minor injury or illness that is treatable in the workplace (first aid) or by a registered health practitioner, with no follow up treatment required	CP Level of Good – while this is potentially a CP context consequence, it is only likely in the 'best case' survivable crashes and would therefore not normally be applicable

3. **Establishing Likelihood.** Likelihood for the CP risk analysis is the likelihood given for the probability of a survivable crash occurring on a per annum basis. This likelihood will be based on a combination of available data inputs including the worst case survivable crash scenario, accident rates (where available for the aircraft being assessed or similar aircraft types), fleet ROE, System Safety Program data (where available and appropriate for use in determining a crash rate) and ADF operating context as defined in the SOIU. Note that an indicative quantitative value for likelihood can be expressed in terms of the percentage likelihood of a survivable crash occurring on a per annum basis, based on the aircraft ROE and the predicted survivable crash rate. Refer to Table 3.

Superseded

Table 3 – Safety Likelihood and CP Guidance Descriptors			
Likelihood (p.a.) = Predicted Future Crash Rate (crashes/hour x Annual Rates of Effort (ROE) (hours/year) **Likelihood Label** (per year)	**Safety Matrix Definition for *System Context***	***Qualitative Guidance* on the likelihood of a survivable crash**	***Qualitative Guidance* on the likelihood of a survivable crash occurring during fleet operations on a per annum basis**
(5) Almost Certain	• Expected to occur several times a year or often during the system life cycle • Is known to occur frequently in similar systems being used in the same role and operating environment	• Aircraft with known poor safety records and significant safety deficiencies in the ADF CRE context • Aircraft that fly all their operations in the 'challenging environment'	Greater than 20% chance per annum
(4) Probable	• Expected to occur one or more times per year or several times in the system life cycle • Is known to have occurred, but is not certain to occur	• Aircraft that fly high risk flight profiles for most of their operations and/or experiencing high rates of effort are likely to fall under this definition of likelihood • Aircraft that fly the majority of their operations in the 'challenging environment'	Greater than 10% but less than 20% chance per annum
(3) Occasional	• Expected to occur less than once per year or infrequently during the system life cycle	• Aircraft that fly high risk profiles for a substantial part of their operational life	Greater than 5% but less than 10% chance per annum
(2) Improbable	• Not expected to occur, but possible to experience one or more events during the system life cycle	• Aircraft that usually fly low risk flight profiles in a 'benign environment', however sometimes fly high risk profiles as required	Greater than 3% but less than 5% chance per annum
(1) Rare	• Only expected to occur in rare or exceptional circumstances or no more than once during the system life cycle	• Aircraft that fly a majority of their operations in the 'benign environment' • Aircraft that almost always fly low risk profiles and operate similar to RPT aircraft	Less than 3% chance per annum

Superseded

4. **Establishing Likelihood -** Example. If the survivable crash rate for an aircraft type is determined as 8.5×10^{-6} survivable crashes per flight hour and the fleet annual ROE is 6500 hours, then the likelihood of a survivable crash occurring on a per annum basis is expressed as: Likelihood = $8.5 \times 10^{-6} \times 6500 = 0.055 = 5.5\%$. Based on the quantitative guidance, the likelihood is evaluated as OCCASIONAL (between 5% and 10%). The qualitative guidance, in conjunction with operational and technical staff judgements, should be used to validate the evaluation, especially when the calculated value is on the margins of likelihood levels, as per the above example calculation.

Further analysis of the aircraft type and its CRE may determine that the value calculated is not representative of the actual likelihood. Where appropriate justification is provided, the likelihood level should be adjusted to reflect the level judged to be more appropriate. For example, based on a qualitative analysis, IMPROBABLE may more accurately describe the likelihood for the example case.

5. **Guidance on determining relevant survivable crashes for CP risk analysis.** Many of the issues encountered with the results of risk analysis from implementation of the previous CP policies have been due to poor quantitative evaluation of the risks to occupants in the event of a survivable crash, based on a limited analysis of the survivable crashes for the given aircraft type. In many cases the derived likelihood of a survivable crash occurring has not been representative of future crash rates. Usually, simple extrapolation of the historical accident rates is not indicative of future crash rates of an aircraft. A critical analysis of the accident data can dramatically improve the accuracy of predicted survivable crashes. There will always be uncertainty in predicting future events and a sound analysis of the likelihood should clearly identify and communicate any uncertainty in the predicted crash rate. Poor examples are seen where the crash rate utilised for CP risk analysis is the raw number of accidents experienced divided by the total operational hours flown. This approach can be very misleading, as it usually takes into account accidents that occurred many years into the past which are likely not relevant to the current and future airworthiness framework or the aircraft's current CRE.

6.10.6.7 A survivable crash is difficult to define and it is almost impossible, in most cases, to obtain detailed crash data to determine which crashes were survivable or not. Therefore, it is very difficult to establish an accurate prediction of future survivable crash rates. As a minimum, the preferred approach is to apply a 'reasonable estimate' of the survivable crash rates. However, if this cannot be established then the analysis may assume that most crashes or serious accidents and incidents included in data sets are survivable in order to determine the most applicable likelihood from one of the five definitions in Table 3. That is, an estimation of the accident rate of the aircraft is the 'best estimation' for the CP risk analysis. Careful assessment and judgement is required to filter applicable data, when considering aspects such as the nature of the crash, deaths versus injuries, world-wide versus single operator data and categories of aircraft damage.

6.10.6.8 The crash rate should be expressed as a likelihood of a survivable crash occurring on a per annum basis. This is important because the exposure of the risk to occupants is directly related to the rate of effort of the aircraft. The more hours the aircraft operates, the greater the exposure and the greater the likelihood of an accident occurring per year. The converse applies.

6.10.6.9 Both the qualitative and quantitative guidance in the Guidance columns in Table 3 should be considered by the technical and operational representatives, together with their informed knowledge of the operating context, to determine the likelihood level. The qualitative guidance should be used to assist the evaluation of the likelihood in conjunction with the predicted future crash rate to provide an outcome that suitably reflects the risk level to occupants in the event of a survivable crash.

6.10.6.10 **Establish the CP risk level.** Apply the established likelihood and consequence determinations to the Defence Harmonised Risk Matrix to establish the pre-treatment CP risk level (Very Low, Low, Medium, High, Very High).

CP Risk Treatment

Superseded

6.10.6.11 Assess the availability and suitability of risk reduction options (controls) according to the standard risk management hierarchy of controls, for each shortfall identified against the CCPDR. The assessment is to consider the controls in order of most to least effective, per the standard hierarchy of controls described in DASR SMS. The end-state for this step is an approved list of additional controls to be implemented for the aircraft system. The key activities to be completed include:

1. Perform a joint airworthiness and operational assessment to review all design based controls, review the current operational controls, and identify possible new controls as per the hierarchy of control options, including any known 'good practice'.

2. Assess the implementation cost (financial, capability, etc.) for each proposed control.

3. Determine the treatments to be implemented in order to reduce the pre-treatment CP risk level SFARP. In determining the practicability of implementing a control, the applicable Capability Manager should be consulted to ensure there is no unacceptable degradation in the aircraft's operational performance/capability, and a Cost Benefit Analysis (CBA) should be produced to support the decision process. A CBA may be as simple as a basic cost versus benefit statement, through to a comprehensive and detailed analysis. This could include consideration of factors such as capability impact, effect on crew training/workload, etc.

6.10.6.12 The focus of the CP risk assessment to this point has been in the 'safety' dimension using the Defence Harmonised Risk Matrix. The other dimensions of the risk management process (Mission, Capability, Reputation, Financial and Environment) should also be reviewed to assess the wider implications of the controls being applied for CP. Changes to the risk profile in other risk management dimensions may drive changes to the proposed controls for the safety risk. Accordingly, there will be an iterative approach to the assessment to ensure an appropriate balance between safety and mission, capability reputation, financial and environment as deemed appropriate by Commanders, Managers and the Authority. Risk Registers, which are currently managed for each aircraft type, should be reviewed for possible flow-on changes to other risks being managed. Where necessary, risks should be updated to consider flow-on impacts to other risk management dimensions, i.e. the controls to be implemented for CP may impact other aspects of the aviation system, and flow-on impacts managed under DASR SMS.

6.10.6.13 **Treatment Decision.** Decide, at the appropriate management levels, on the controls to be applied, the priority, and the organisation to implement each control. In making this determination, the decision process for the CP risk analysis and evaluation is to be documented, including the reasons for accepting or rejecting the assessed treatment options, and presented to management to inform risk treatment decisions.

6.10.6.14 **Post-treatment Risk Assessment.** Similar to the pre-treatment risk assessment, the key activities are re-establishment of the overall CP level (Table 1), re-establishment of the consequence (Table 2) and likelihood (Table 3) levels, and finally, determination of the post-treatment CP risk level using the Defence Harmonised Risk Matrix.

6.10.6.15 **Risk Management Decision.** Risk management authorities (RMA) reside within the Chain of Command. Unless the relevant Service Chief directs otherwise, based on the final (post-treatment) CP risk level, the CP risk should be processed and retained as per DASR SMS 'Safety accountability and responsibilities'. This is to include the proposed controls (Treatment Plan), action agencies, and timeframes for implementation (priority). Additionally, updates to other risk dimension risks should also be presented to the appropriate Risk Management Authority (RMA).

Superseded

6.10.6.16 **Risk documentation.** In accordance with DASR SMS Regulation, CP risk treatment documentation should be produced, reviewed and stored by the responsible organisation as part of their SMS structure.

Superseded

7. Initial and Continued Airworthiness

7.1 Introduction

7.1.1 Background

7.1.1.1 While there is no internationally-accepted definition for Initial Airworthiness, common definitions for 'initial' (happening at the beginning) and 'airworthiness' (the fact of an aircraft being safe to fly) are helpful. After all, Initial Airworthiness does indeed focus extensively on whether a new aircraft is initially safe to fly - that is, whether it has been suitably designed and manufactured.

7.1.1.2 However, by convention, Initial Airworthiness also encompasses any design changes subsequently made to the new aircraft (including the certification of those changes) and the design of repairs. Furthermore, it includes the activities needed to ensure the design remains safe throughout its lifecycle, although this activity is often termed 'continued' airworthiness (not to be confused with 'continuing' airworthiness, per chapter 8).

7.1.1.3 This chapter presents an overview of the DASR approach to aircraft design, production and certification, which are the activities commonly associated with initial and continued airworthiness. The subsequent chapters will then explore several of these concepts in more detail.

7.1.1.4 Note this chapter is relevant only to Defence Registered aircraft; for non-Defence Registered aircraft, all initial and continued airworthiness functions are conducted per the requirements of the relevant Civil or military Aviation Authority (normally CASA).

7.1.2 DASR 21 – Aircraft Design, Production and Certification

7.1.2.1 From an Initial and Continued Airworthiness (INCA) perspective, an aircraft's lifecycle might follow a progression something like this:

a. To start, an engineering organisation demonstrates its professional ability to produce an aircraft design ('design organisation approval').

b. Next, the organisation produces a new aircraft design, and an Aviation Authority certifies that the design is suitably safe ('aircraft design and certification').

c. Individual aircraft are then produced, and an Aviation Authority certifies each as conforming to the certified design ('aircraft production and certification').

d. Over the following decades of fleet operation, numerous Minor and Major design changes and repairs will be made to the aircraft ('aircraft design changes and repairs').

e. Occasionally, there may be a need for limited flying of a possibly unairworthy aircraft, either to demonstrate a new capability or to avoid grounding an important asset ('permit to fly').

f. Critically, throughout this complex lifecycle, an engineering organisation will need to monitor for defects in the design, facilitate risk management of the design, and so on ('type certificate holder').

Superseded

g. Finally, an Aviation Authority might occasionally mandate certain remediation actions in the interests of fleet safety ('airworthiness directives').

7.1.2.2 Each of these seven functions, and several others, is regulated under DASR Pt 21– *Aircraft Design, Production and Certification.* The remainder of this chapter provides a brief summary of these functions.

7.1.2.3 **Design organisation approval.** Deficiencies in an aircraft's design can range from those with immediate catastrophic consequences (eg inadequate structural strength), to an erosion of safety margins (eg misleading navigation information), to an annoyance (eg a Minor human-machine interface flaw). Designing an aircraft where risks have been eliminated or otherwise minimised so far as is reasonably practicable (SFARP) is a particularly complex endeavour.

7.1.2.4 Consequently, the initial design of Defence aircraft should only be undertaken by skilled individuals within professional aircraft design organisations. DASRs make provision for DASA to issue Military Design Organisation Approval (MDOA) status to organisations who have demonstrated that they are able to maintain a design assurance system for the control and supervision of the design, and of design changes, of aircraft products, parts and appliances.

7.1.2.5 DASA's default expectation is that a new Defence aircraft will be designed by a MDOA of suitable scope. As a matter of pragmatism, however, DASR also make provision for Defence to accept designs that have been certified by a DASA-recognised civil or military Aviation Authority (CAA/MAA), without the need for the design organisation to be a DASA-approved MDOA, within certain bounds. This approach, often called 'prior acceptance' is explored in Chapter 7.2, *Product Certification*. These same provisions apply for design changes to an extant aircraft.

7.1.2.6 MDOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.7 **Initial aircraft design and certification.** Defence periodically acquires aircraft to meet a capability need. In practice, Defence usually acquires its new aircraft as off-the-shelf designs, and then incorporates design changes to cater for Defence's unique roles and operating environment. The entire design will meet a set of airworthiness requirements - commonly called a Type Certification Basis (TCB) - and the designer(s) will produce extensive evidence (via analysis, test and other means) to demonstrate that their design meets the TCB.

7.1.2.8 As noted in paragraph 7.1.2.5, these designs will be produced by a DASA-approved MDOA, or a design organisation whose design is certified by a DASA-recognised CAA/MAA, or sometimes both. Regardless, the final design will always be certified by DASA, signified by the issue of a Military Type Certificate (MTC)[1] for the aircraft.

7.1.2.9 In the absence of a pertinent CAA/MAA certification, DASA's certification for a new aircraft would be an immense undertaking for both DASA and the Defence acquisition organisation. More commonly, however, there will be a pertinent CAA/MAA certification, and leveraging off this certification can substantially reduce the impost on both organisations. In that case, much of the effort focuses on whether the certified design is compatible with Defence's intended Configuration, Role and Environment (CRE). Chapter 7.2, Product Certification, explores the certification process in detail.

7.1.2.10 **Aircraft production and certification.** An expertly designed and certified aircraft provides the basis for safe aircraft operation. However, just as importantly, that design must be accurately implemented on the Defence aircraft.

Superseded

7.1.2.11 DASR make provision for DASA to issue a Military Production Organisation Approval (MPOA) to an organisation when assured they have the ability to manufacture aircraft parts and appliances in conformity with approved data. DASR also make provision for Defence to accept an aircraft produced under the systems of a DASA-recognised CAA/MAA. This latter approach is used for most new Defence aircraft.

7.1.2.112 Following production of an individual aircraft, DASA must certify that the aircraft is in a state of airworthiness per the inherent level of safety specified on the MTC. This certification is signified by the DASA issue of a Military Certificate of Airworthiness (MCoA)[2] for each individual Defence aircraft.

7.1.2.13 Aircraft production and MCoAs are explored in Chapter 7.3, Production. MPOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.14 **Aircraft design changes and repairs.** Defence aircraft will usually be in service for several decades. During this time, numerous design changes will inevitably be implemented, either to enhance military capability or to address design or obsolescence problems. These design changes are classified under DASR as either Minor of Major, differentiated by the degree of airworthiness effect of the design change.

7.1.2.15 The DASR approach for Minor and Major design changes is very similar. They will both be performed by a DASA-approved MDOA or another design organisation whose design is certified by a recognised CAA/MAA, and both should preserve the level of airworthiness of the aircraft. For Major design changes, however, DASA will usually provide a proportionate level of independent assurance, and DASA itself will usually certify the design as safe. This certification is usually via an amendment to the MTC, although occasionally a Military Supplemental Type Certificate (MSTC) may be issued. Chapter 7.2, Product Certification, explores the certification process in detail.

7.1.2.16 Throughout an aircraft's life, degradation (damage) of the systems/structures integrity supporting safe flight may be compromised through direct (accidental impact and battle damage) overload, or insidious (fatigue, corrosion, moisture ingress, dis-bond, ultraviolet light etc) environmental sources. Repairs are those actions developed and implemented to restore damaged products to a suitably airworthy state. Similar to aircraft design changes, aircraft repairs are classified under DASR as Minor or Major, must be designed by a MDOA or other organisation agreed by DASA, and may be subjected to a proportionate level of DASA independent assurance.

7.1.2.17 **Permit to fly.** A Military Permit to Fly (MPTF) may be issued by DASA for an aircraft that does not meet, or has not been shown to meet, the requirements of its TCB, but is nonetheless capable of safe flight under defined conditions and for specified purposes. MPTFs are most commonly used for flight test (for aircraft development or role expansion activities), for flights where the design has not yet been certified, or for flights where the aircraft temporarily does not conform to the Type Design (eg due to unrepaired damaged, overdue maintenance, etc).

7.1.2.18 An MPTF may or may not entail an elevated level of risk, and is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application. Chapter 7.5, Flight Conditions and Military Permits to Fly, explores this in more detail.

7.1.2.19 **Type certificate holder.** As noted earlier in this chapter, DASA issues an MTC for Defence Registered aircraft types. This MTC is issued to a suitable Commonwealth government organisation (usually the relevant Defence Systems Program Office), who are then charged with 'holding' the MTC.

Superseded

7.1.2.20 Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed, and the level of safety inherent in the TCB is maintained. This includes, for a particular aircraft type, collecting aviation safety information (both locally and from external sources), ensuring operators are aware of extant hazards, ensuring that essential risk controls remain effective, leading local efforts to eliminate or further minimise known risks, and many other important roles.

7.1.2.21 These expansive holding responsibilities are often beyond the capacity and capability of the government organisation holding the MTC. Consequently, responsibility for the conduct of MTCH obligations is often vested with various support organisations, for example contractors, foreign project offices and other military operators. The government organisation remains accountable for all activities undertaken by those organisations.

7.1.2.22 Chapter 7.4, Continued Airworthiness, explores the MTCH role in more detail.

7.1.2.23 **Airworthiness directives.** In the Australian Defence context, the WHS Act and DASR place responsibility and obligation solely on the regulated community for managing the day-to-day safety of their aircraft, and for ensuring risks are eliminated or otherwise minimised so far as is reasonably practicable. DASR do, however, still make provision for DASA to mandate actions and/or impose conditions on aircraft operation in certain circumstances. This is achieved through the issue of an Airworthiness Directive (AD).

7.1.2.24 Like its civil counterpart, ADs under DASR provide a means to mandate an action in order to restore an aircraft to an acceptable level of safety, where that safety level may be otherwise compromised. However, due to Defence's unique context, DASA issues ADs infrequently, particularly in comparison to civil aviation.

7.1.2.25 Chapter 7.4, Continued Airworthiness, explores DASR ADs in more detail.

7.1.2.26 **Other.** In addition to the seven common INCA functions mentioned above, DASR 21 also makes provision for a number of niche functions. Since this chapter aims to provide an overview of INCA that is consumable to a wide audience, these niche functions will not be explored here. They include: Australian Military Technical Standard Order (AUSMTSO) authorisations, restricted type certificates, restricted certificates of airworthiness, approval of parts and appliances, and the identification of parts and appliances.

Structure of these chapters

7.1.2.27 This chapter has provided a brief overview of the functions encompassed within Initial and Continued Airworthiness. The subsequent chapters explore several of these functions in greater detail, as follows:

a. Chapter 7.2: Product certification

b. Chapter 7.3: Production and military certificates of airworthiness

c. Chapter 7.4: Continued airworthiness (including military type certificate holders, occurrence reporting, airworthiness directives and other organisational approvals)

d. Chapter 7.5: Flight conditions and military permits to fly

e. Chapter 7.6: Design and production organisations.

Superseded

7.2.1 – Introduction

7.2.1.1. Product certification authorisations represent DASA's assurance that an individual product complies with the applicable airworthiness[3] requirements. These are issued following review of compliance evidence presented by the applicant seeking product certification. Product certification authorisations covered under this chapter are MTCs, Changes to MTCs, MSTCs, and Repair Designs.

7.2.1.2. Product certification authorisations are built around four pillars of safety assurance; Organisational Capability, Compliance demonstration, Compliance Verification, and Obligations of the holder

7.2.1.3. **Organisational Capability.** Before an organisation can apply for a product certification, they need to be eligible. Eligibility is based on an assessment of whether the organisation is equipped/ resourced to achieve a successful authorisation.

7.2.1.4. **Compliance Demonstration.** The applicant for a product certification authorisation must show that their product complies with the applicable airworthiness requirements.

7.2.1.5. **Compliance Verification.** The authority must independently verify that compliance has been achieved to the applicable airworthiness requirements. As compliance demonstration and compliance verification are intrinsically linked, a certification programme is put in place to document the means by which the applicant will demonstrate compliance and the authority will verify compliance.

7.2.1.6. **Obligations of the Holder.** Following issue of a certification approval, the certificate holder must continue to carry out obligations outlined under the DASRs to ensure the product certification remains safe.

7.2.1.7. The following sections expand upon these safety assurance areas for each product certification authorisation.

7.2.2 – Type Certification – Military Type Certificates (DASR 21 Subpart B)

Overview

7.2.2.1 **Scope of Section.** Section 7.2.2 describes the DASR type certification process for obtaining a Military Type Certificate (MTC). Military Restricted Type Certificates (MRTCs) are not yet employed by DASA, and are not addressed herein.

7.2.2.2 **Military Type Certificate.** An MTC is issued by DASA to certify that a product's type design complies with the applicable Type Certification Basis (TCB) when operated within specified conditions and limitations. Further description of the MTC authorisation can be found in Section 5.3 Annex K.

Eligibility

7.2.2.3 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the MTC.

Superseded

7.2.2.4 DASR 21.A.13 (Eligibility), and by extension DASR 21.A.14 (Demonstration of Capability), define which organisations can apply for an MTC under DASR 21. As per DASR 21.A.14, applicants for an MTC can be:

1. A DASR 21 Subpart J approved Military Design Organisation (MDO) (21.A.14(a)). Holding a DASR 21J approval provides an organisation with the eligibility to apply directly to DASA for an MTC. However, given the scope of the Australian aviation industry, development and certification of a new aircraft wholly under a DASR 21J MDO will be a rare occurrence.

2. An organisation demonstrating its capability through alternative procedures (21.A.14(b)). An applicant may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to comply with this DASR. This eligibility provision is ostensibly aimed at products with simple or limited scope of design, or organisations starting toward a MDO approval or limited duration of design activities. Use of this provision to demonstrate capability to apply for an MTC would only be considered by DASA by exception.

3. A government organisation who has an agreement in place with a design organisation that has access to the type design data (21.A.14(c)). Any government organisation applying for an MTC may demonstrate its capability by having an agreement in place, accepted by DASA, with a design organisation that has access to the necessary type design data. This is the normal provision through which DASA expects government organisations (usually the relevant CASG System Program Office (SPO)) to demonstrate their capability to apply for an MTC. The agreement with the relevant design organisation shall include detailed statements how the actions and obligations are delegated to enable the government organisation, in cooperation with the contracted organisation, to comply with the requirements of Subpart J and DASR 21.A.44 (holder obligations). AMC and GM to 21.A.14(c) provide further information on demonstration of capability under this provision.

7.2.2.5 **MTC Applications by CASG SPOs (Project Offices).** To be issued an MTC by DASA, a CASG project office develops a Type Continued-Airworthiness Exposition (TCAE) for DASA review. The TCAE details the CASG arrangements with the design organisation(s) that has access to the type-design data and through which the provision of holder obligation functions occur. Further guidance on holder obligations and arrangements can be found in Section 7.4.1.

7.2.2.6 CASG project offices seeking issue of an MTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended acquisition program.

7.2.2.7 The eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J. Since a CASG project office scope of responsibility is usually limited to a single application, and does not include the through-life holder responsibilities, the CASG project office eligibility information is not required to be delivered as a single document and can instead be contained within Project or Acquisition documentation. The documentation requires review by DASA prior to the project office becoming eligible to act as an applicant. However, the CASG project office must include a transition plan to manage delivery of the Type Design to the MTC holder, and where the MTC holder organisation is being created, include plans for assessment of eligibility of the MTC holder, by DASA.

Superseded

7.2.2.8 Additional guidance with respect to MTC applicant eligibility when CASG project offices wish to leverage recognition provisions is as follows:

1. Application will be exclusively based upon an aircraft type-design that has been certified by a recognised CAA/MAA. In this situation, the project office, in conjunction with any associated design organisation(s), can gain eligibility by demonstrating its ability to conduct the required certification programme activities (develop CPP, conduct applicability assessment against Defence context, develop the Defence TCB, and provide a declaration of compliance), rather than demonstrate full adherence to the DASR 21 Subpart J requirements.

2. Application will be based on a design that has not been certified, but was developed using a design system (organisation, people, processes, data, and tools) external to the DASR, and where that system is used to produce designs for certification by a recognised CAA/MAA. In this situation, the DASA recognition framework[4] must be leveraged by the project office to assist in demonstrating to DASA that the arrangements with the external DO provides an acceptable equivalence to the DASR 21 Subpart J requirements. Activities to meet the eligibility requirements should be completed prior to initial engagement with DASA and throughout certification programme activities. The project office is to address the following expectations in their respective eligibility submission:

   i. Confirm that the external design organisation is normally oversighted by a CAA/MAA recognised by DASA[5].

   ii. Confirm that the external design organisation has appropriate technical scope and expertise for the intended design(s).

   iii. Confirm that the systems, processes and personnel used in developing other designs for certification by the parent CAA/MAA will be used in the design development or holder activities associated with the ADF design.

   iv. Confirm that the design organisation is able to provide an attestation of compliance against the Defence TCB for any provided design product.

   Note: In some circumstances, the PO or MTC holder may wish to allow the external design organisation to engage directly with DASA for Defence TCB agreement, development and conduct of the CCP, and provision of a declaration of compliance to the Defence TCB. In this case, the eligibility documentation shall demonstrate that the external design organisation systems and process are sufficiently similar to the DASR 21J requirements to support such delegation.

   v. Confirm any expected oversight by the DO's parent CAA/MAA is appropriate.

   vi. Confirm where applicable, arrangements for DASA oversight are in place.

   vii. Articulate how the recognition arrangements as per paragraphs 7.2.2.8.(b)(iii), (iv) and (v) will be monitored and ensured during the design development and submission process[6].

Certification Programme

Superseded

7.2.2.9 **Overview.** Under DASR 21, a certification programme is required for all applications for an MTC, and the certification programme requires formal acceptance by DASA.

7.2.2.10 The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a Certification Program Plan (CPP).

7.2.2.11 Two CPP templates are published on the DASA Website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the MTC CPP template.

7.2.2.12 The organisation(s) involved in the development and submission of a certification program for an MTC application will vary depending upon the acquisition arrangements. GM1 21.A.15(b) provides further guidance based on some common acquisition scenarios.

7.2.2.13 **Contents of a Certification Programme.** DASR 21.A.15(b) outlines the requirements for content of a certification programme for an MTC. Certification programmes must be tailored to meet the requirements of the certification activity.

7.2.2.14 The certification programme should be presented as a CPP containing the information required by DASR 21.A.15(b) and the supporting AMC. The MTC CPP template published by DASA will assist in meeting the required outcomes.

7.2.2.15 Two key outcomes are achieved through the development and DASA acceptance of the certification programme:

1. Applicant development and DASA agreement of the Defence TCB for the MTC[7].
2. Formalising and agreement on the approach to be taken for demonstrating compliance against the Defence TCB, and the DASA Level of Involvement (LoI) in compliance demonstration activities.

7.2.2.16 **Proposed Compliance Demonstration Items (CDIs)**. DASR 21.A.15(b)(5) requires that the CPP proposes a breakdown of the certification programme into meaningful groups of compliance demonstration activities and data, and a proposal for the means of compliance and related compliance documents.

7.2.2.17 A CDI is a meaningful group of compliance demonstration activities and data that can be considered, in isolation, for the purpose of performing the risk assessment that allows DASA to determine its LoI.

7.2.2.18 Applicants should follow AMC 21.A.15(b)(5) when proposing the CDIs, and the DASA MTC CPP template contains further guidance and tabular templates for presenting proposed CDIs.

7.2.2.19 **Proposed DASA LoI.** As outlined in AMC 21.A.15(b)(6), the Authority's LoI is a list of activities and data, in which the Authority retains the verification of compliance demonstration (e.g. review and acceptance of compliance data, witnessing of tests, etc.), as well as the depth of the verification. The depth of the verification for individual compliance reports, data, test witnessing, etc., may range from spot checks to extensive reviews. DASA will respond to those retained compliance demonstration activities and data with corresponding comments or a 'statement of no objection'. DASR 21.A.15(b)(6) requires that the CPP proposes the DASA LoI associated with compliance demonstration activities, noting that LoI should normally be proposed at the CDI level. As per DASR 21.A.15(b)(6), the DASA LoI must address the likelihood of an unidentified non-compliance with the

Superseded

TCB requirements and the potential impact of that non-compliance on safety (ie a risk-based determination). In practice, this is achieved through taking into consideration:

1. any novel or unusual features of the certification project, including operational, organisational and knowledge management aspects
2. the complexity of the design and/or demonstration of compliance
3. the criticality of the design or technology and the related safety risks, including those identified on similar designs
4. the performance and experience of the design organisation of the applicant in the domain concerned.

7.2.2.20 AMC 21.A.15(b)(6) contains a step-by-step process and extensive information that applicants should follow when determining the proposed DASA LoI. The DASA MTC CPP template also includes complementary guidance and tables. The three main steps that culminate in determining the DASA LoI are:

1. Step 1: Identification of the likelihood of an unidentified non-compliance. This includes taking into consideration novelty, complexity and the performance of the design organisation. Refer to Section 3.2 of AMC 21.A.15(b)(6) for details.
2. Step 2: Identification of the 'risk class'. This includes determining whether the potential impact of the non-compliance within a compliance demonstration activity (ie CDI) is critical or non-critical. This is then combined with the likelihood of an unidentified non-compliance (step 1) to determine the risk class. Refer to Sections 3.3-3.4 of AMC 21.A.15(b)(6) for details.
3. Step 3: Determination of the DASA LoI. Based on the qualitative risk class identified for each compliance demonstration activity (ie CDI), the applicant should propose a DASA LoI. Refer to Section 3.5 of AMC 21.A.15(b)(6) for details.

7.2.2.21 DASA will determine the depth and extent of its inspections for each CDI, based on the information provided in the certification programme and the applicant's proposal. DASA determination of LoI will be confirmed as part of DASA's acceptance of the CPP. Note that the depth and extent of DASA LoI may change throughout the project in order to account for changes that affect the basis of the initial LoI determination.

7.2.2.22 **Certification Programme Acceptance.** DASA acceptance of the certification programme is required for all MTC applications. Early engagement with DASA, and agreement on the key certification programme content, will reduce schedule and resource risks for the project. Delaying presentation of certification programmes to DASA until after compliance demonstration has commenced may result in delays, additional work, or additional resources, due to DASA:

1. determining that the proposed airworthiness requirements or means of compliance are unsuitable for the certification activity
2. identifying a need for a LoI in compliance demonstration activities that have already been completed, therefore resulting in a need to repeat the compliance demonstration
3. identifying LoI that requires travel (eg for compliance demonstration being completed overseas) and insufficient time is available to organise funding and travel prior to the planned activity, resulting in a need to delay the activity

Superseded

4. identifying a need for data access that was not accounted for prior to contracting or establishing government to government agreements for the activity, resulting in a need for contract changes or alternate workarounds.

7.2.2.23 DASA acceptance of a certification programme can be achieved incrementally, if some aspects are unknown at the beginning of the project or are expected to change throughout the project. A caveated acceptance may be possible to achieve agreement with DASA on specific aspects of the programme prior to full details being known. For an initial or caveated acceptance, the following is required:

1. identification of the applicant and any design organisations involved
2. broad detail on the design and aircraft intended use
3. an initial proposal for the TCB, including identification of the Primary Certification Code and identification of whether any TCB tailoring (including Military Certification Review Items (MCRIs)) will be required. Note: the TCB does not have to be fully defined at this point.
4. broad detail on the certification approach (i.e. whether there will be reliance on prior certification, or whether compliance demonstration evidence with be developed specifically for the DASA certification).

7.2.2.24 Where an incremental approach is taken to developing and achieving acceptance of the certification programme, the scope of acceptance intended by each version must be clearly understood and documented. A point at which the next update is required must be identified, this may be date based or linked to a specific project stage or milestone.

7.2.2.25 DASA acceptance of the certification programme will be agreed by formal communication, which will include confirmation of the DASA LoI for the activity, and any caveats on DASA acceptance.

7.2.2.26 **Certification Programme Updates.** In accordance with DASR 21.A.15(c), the certification programme is to be updated when there are changes to any of the content required under DASR 21.A.15(b). Key aspects that require the certification programme to be re-accepted by DASA are:

1. any changes that may impact on DASA LoI, such as:
   i. change to the design or intended use
   ii. change to compliance demonstration approach (including the means of compliance)
   iii. change to the CRE Assessment (CREA) or its outcomes for a program that is leveraging prior certification
   iv. change to design organisation resources or approvals
2. any changes to the proposed TCB (except those achieving separate agreement via an MCRI)
3. significant changes to schedule that may impact on DASA LoI activities

7.2.2.27 Changes to the certification programme can be presented as an update to the original CPP, or via a supplement, depending on the scope of the changes.

Superseded

7.2.2.28 Applicants should engage early with DASA (nominally DIA) staff and remain closely engaged with CPP development and subsequent amendment, heeding advice to prevent nugatory drafting and rewriting. The DASR Form 31 can be used to notify DASA of an upcoming certification project, to initiate discussions. A face-to-face session, before any CPP drafting occurs, is strongly recommended for for complex programs.

Type Certification Basis

7.2.2.29 **Contents of a TCB.** The TCB is an agreed set of airworthiness requirements that a product must be compliant with in order to obtain an MTC. The following DASR and concepts apply to the contents of a TCB:

1. DASR 21.A.16A (Airworthiness Codes). This regulation requires that DASA shall approve the use of Airworthiness Codes[8] and other detailed specifications that may be used to demonstrate compliance of products, parts and appliances. As noted in GM 21.A.16A, rather than define a Defence-unique Airworthiness Code, DASA has elected to recognise the Airworthiness Codes prescribed by several other CAAs and MAAs that have been demonstrated to achieve safe flight, and then prescribe supplementation as required. The Defence Aviation Safety Design Requirements Manual (DASDRM) identifies the Airworthiness Codes recognised by DASA.

2. DASR 21.A.16B (Special Conditions). This regulation requires that DASA shall approve any special detailed technical specification ('special conditions') if the related Airworthiness Code or specifications do not contain adequate or appropriate safety standards. As per 21.A.16B, the need for special conditions may arise due to:

   i. novel or unusual design features (relative to the design practices on which the applicable Airworthiness Code is based)

   ii. intended use of the product is unconventional

   iii. experience from other similar products in service or products having similar design features or newly identified hazards have shown that unsafe conditions may develop

   iv. applicable airworthiness codes do not exist for the concerned product class or do not address the requested kind of operations.

   In the Defence context, special conditions are required when the primary Airworthiness Code selected may contain deficiencies against contemporary airworthiness requirements and / or may not account for Defence's unique CRE. DASA uses the Defence Aviation Safety Design Requirements Manual (DASDRM) to define those 'essential' design requirements and standards that must be applied as special conditions to supplement Airworthiness Codes due to deficiencies in the Codes or to account for the Defence CRE. The DASDRM also defines a number of 'recommended' design requirements and standards for which compliance is not prescribed, but which should be applied where reasonably practicable.

3. DASR 21.A.17A (Type Certification Basis). This regulation defines the scope of the Defence TCB. The airworthiness requirements specified in the TCB include:

   i. the applicable requirements from the DASA recognised Airworthiness Code selected as a basis for the Defence aircraft certification (the Primary Certification Code (PCC))

Superseded

ii. the applicable 'essential' requirements prescribed in the Defence Aviation Safety Design Requirements Manual (DASDRM)

iii. any supplementation or tailoring agreed to by DASA.

7.2.2.30 **Development of a Defence TCB.** Development of a Defence TCB is a joint activity between the applicant and DASA and is guided by the DASR listed above and the Defence Aviation Safety Design Requirements Manual (DASDRM). TCB agreement is obtained through acceptance of the certification programme in accordance with DASR 21.A.15(b).

7.2.2.31 The TCB for a new Defence aircraft type should be developed and agreed as early as practicable in the aircraft acquisition life-cycle. While a DASA-agreed TCB should be pursued prior to entering into an acquisition contract, this will not always be possible. In those cases, the acquisition project office may elect to present a draft TCB for DASA assessment as a cost and schedule risk reduction measure.

7.2.2.32 In most cases, DASR and the DASDRM allow the Defence TCB to be based on the recognised design standards used by the parent CAA/MAA under which the aircraft was initially designed and certified.

7.2.2.33 The TCB for a Defence aircraft must be consistent with Defence's intended role and operating environment for the aircraft. In the aircraft Type Certification domain, CRE is a pivotal concept. Where an ab-initio Type Certification programme is proposed for a Defence aircraft, defining the CRE is essential to ensure that the basis of certification is consistent with the intended Defence use of the aircraft.

7.2.2.34 Where the Defence Type Certification programme intends to leverage prior certification from a recognised CAA/MAA to any extent, a CRE Assessment (CREA) is required to confirm the applicability of that prior certification to the intended Defence use. Areas where the prior certification is not entirely applicable to the Defence CRE must be addressed through further compliance demonstration evidence, inclusion of additional requirements in the TCB, or tailoring of requirements for the TCB. Further guidance on leveraging prior certification is contained in Annex B to Section 7.2, and further guidance on the conduct of a CREA is contained in Annex C to Section 7.2.

7.2.2.35 **Tailoring the PCC.** During a certification program, there may be a need to tailor the PCC when seeking an MTC. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

7.2.2.36 Tailoring of the PCC may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.2.37 Tailoring of the PCC can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a Military Certification Review Item (MCRI).

7.2.2.38 Annex A to Section 7.2 provides further guidance on tailoring the PCC, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support PCC tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Compliance Demonstration

7.2.2.39 **Overview.** Compliance demonstration evidence comprises of reports, engineering tool outputs, drawings, specifications, calculations, analysis etc. and provides a record of the means by

Superseded

which compliance with the applicable TCB is demonstrated. The applicant shall demonstrate compliance with the type-certification basis either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or

2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.2.40 The agreed certification programme will include details of how compliance demonstration is being achieved for each project. Where difficulty arises in meeting the agreed certification programme activities or outcomes, engagement with DASA as early as practicable is recommended. This phase may identify issues in compliance demonstration evidence against the agreed Defence TCB that require equivalent safety finding arguments, processing of exceptions underpinned by an Airworthiness Issue Paper (AwIP) or equivalent, or introducing new interpretations or means of compliance. In these cases an MCRI, and an AwIP as required, should be raised and submitted by the applicant for DASA consideration.

7.2.2.41 **Leveraging Prior Certification.** Defence is rarely the prime customer for new aircraft, so most acquisitions will be based on an aircraft design that has or will be certified by another CAA/ MAA. DASR 21.A.20 enables an applicant for an MTC to leverage prior certification from a recognised CAA/MAA[9] to gain relief from developing compliance demonstration evidence.

7.2.2.42 The fundamental principle of leveraging prior certification is that any requisite Authority review of evidence; testing, or witnessing of testing; or inspections (refer DASR 21.A.33(b)) have already been performed by a competent Authority (ie a CAA/MAA recognised by DASA). Therefore, duplicate effort in terms of DASA also conducting inspections / analyses / tests is unnecessary. However, as per DASR AMC 21.A.20, in order to leverage the prior certification, the applicant for the MTC must ensure:

1. the certification is within the scope, conditions and caveats specific to DASA Recognition of the certifying CAA/MAA

2. the CAA/MAA is sufficiently experienced in certification of the particular design activity

3. the certification requirements employed by the CAA/MAA are understood and any deltas from the Defence TCB have been addressed

4. the CRE applied to the prior certification is understood and any deltas from the intended Defence CRE have been addressed

5. any safety risks associated with the CAA / MAA certification have been identified, and have been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) for the Defence CRE.

7.2.2.43 Annex B to Section 7.2 provides additional guidance on the AMC 21.A.20 requirements for leveraging prior certification, and discusses common issues encountered with leveraging prior certification. Annex C to Section 7.2 provides further guidance on the conduct of a CREA to support relief from presenting CDE when leveraging prior recognition.

7.2.2.44 **Structures and Propulsion System Specific Guidance.** Guidance on the conduct of structures and propulsion system CREAs when leveraging prior certification can be found in GM1 21.A.20 and Chapter 6.6.2. Guidance to support AMC 21.A.41 (Structural and Propulsion System Critical Parts and Airworthiness Limitations (AUS)) can be found in Chapter 6.6.2.

Superseded

MTC Application, Issuance and Type Certificate Data Sheet (TCDS)

7.2.2.45 **Application.** Upon completion of all activities identified within the CPP, including development of compliance demonstration evidence and completion of DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for issuance of an MTC. The exact format of the application for an MTC will differ depending upon each project, and should be agreed within the CPP.

7.2.2.46 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will issue the MTC.

7.2.2.47 For acquisitions of new aircraft types, the Defence Aviation Authority (Defence AA) will generally elect to convene an Airworthiness Board (AwB). Aircraft acquisition AwBs, including applicant and DASA submission of documents to support the AwB, are separate to the DASR type certification process outlined within this section. AwBs are discussed further in Section 6.1.2 and Section 13.

7.2.2.48 **Type Certificate Data Sheet (TCDS).** A TCDS will accompany each MTC. The TCDS contains all information (or reference thereto) about the type certification of the product including the TCB, the type design, operating limitations, the Aircraft Flight Manual (AFM), Instructions for Continuing Airworthiness (ICA), Airworthiness Limitations (AwLs), Certification Maintenance Requirements (CMRs), critical parts list (if applicable) and any other data necessary for the continued safe operation of the product.

7.2.2.49 DASA will develop and issue the TCDS concurrently with the MTC.

DASA Assurance

7.2.2.50 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining an MTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).
2. DASA agreement of the TCB, including tailoring (refer 'Type Certification Basis' section above).
3. DASA LoI in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme' section above). In all cases, DASA LoI activities should be successfully completed prior to the applicant's declaration of compliance.
4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer below for more detailed information).

Superseded

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, and issue of the MTC and TCDS.

7.2.2.51 **DASA Assurance when Leveraging Prior Certification.** Where the certification programme indicates that an applicant is proposing to leverage prior certification from a recognised CAA/MAA, then DASA assurance activities will focus on the criteria outlined in AMC 21.A.20. The guidance outlined in Annex B to Section 7.2 provides an indication of the considerations that DASA will examine as part its assurance activities.

7.2.2.52 For certain aspects, the CPP will only be providing a proposal for how the applicant intends to address the criteria for leveraging prior certification outlined in AMC 21.A.20. For example, the applicant may need to conduct further activities to confirm that the CAA/MAA is sufficiently experienced in certification of the particular design activity, conduct further analysis to show that the design is compliant for the Defence CRE, and conduct sovereign assessments for safety risk decisions or risk retention made by an MAA. Therefore, DASA will typically request the applicant provide relevant documentation prior to, or as part of, the final application.

7.2.2.53 Note that while leveraging prior certification may provide relief from the need to develop new compliance demonstration evidence, it does not provide relief from the need to present compliance demonstration evidence to DASA. As such, DASA may request to review evidence that supported the prior certification where it is deemed necessary. Where it is not possible for the applicant to provide this evidence to DASA, for example due to limitations on access to OEM data, this will be negotiated between the applicant and DASA on a case-by-case basis.

MTC Holder Obligations

7.2.2.54 MTC holder obligations are outlined in DASR 21.A.44. Refer to Section 7.4.1 for detailed guidance on MTC holder obligations.

7.2.3 – Changes to Type Certificates and Military Supplemental Type Certificates (DASR 21 Subpart D and E)

Overview

7.2.3.1 **Scope of Section.** Section 7.2.3 primarily describes the DASR type certification process for major changes to the type certificate and obtaining a Military Supplemental Type Certificates (MSTC). Minor changes to the type certificate are only briefly addressed herein.

7.2.3.2 **Change to a Type Certificate.** As defined by DASR 21.A.41, the type certificate includes:

1. The Type Design, which includes[10]:
   i. The drawings and specifications, and a listing of those drawings and specifications, necessary to define the configuration and the design features of the product shown to comply with the applicable TCB;
   ii. Information on materials and processes and on methods of manufacture and assembly of the product necessary to ensure the conformity of the product;
   iii. An approved Airworthiness Limitations Section (ALS) of the ICA as defined by the applicable airworthiness codes; and

Superseded

iv. Any other data allowing by comparison the determination of the airworthiness of later products of the same type.

2. Operating Limitations

3. The TCDS

4. The applicable TCB

5. Any other conditions or limitations prescribed for the product in the applicable airworthiness requirements.

7.2.3.3 A change to any aspect of the items listed above is considered a change to the type certificate, and must be undertaken in accordance with DASR 21 Subpart D or E.

7.2.3.4 Note that DASR M.A.304(d) allows for the Operator to directly consume data for minor changes that has been approved within the framework of Authorities recognised by DASA. Under this pathway, the requirements of DASR 21 are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. Data for major changes cannot be directly consumed via recognition, and must be processed in accordance with DASR 21 Subpart D or E. Refer to Section 8.2 for further information on the direct consumption of data via recognition. Consumption of data for minor changes via recognition is not discussed any further within this section.

Classification

7.2.3.5 In accordance with DASR 21.A.91, all changes to the type certificate must be classified as minor or major.

7.2.3.6 A minor change is defined as a change that has no appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product. All other changes are defined as major. Guidance on classification of changes to type certificates, including examples of changes that should be classified as major, can be found in DASR GM 21.A.91.

7.2.3.7 DASR 21J MDO approval holders will typically have the privilege to classify changes that are within the scope (e.g. technology or platform types) of their terms of approval. As noted in DASR GM 21.A.91, DASA should be consulted for clarification wherever there is doubt as to the classification of a change. Furthermore, when the strict application of the DASR GM 21.A.91 paragraph 3.4 criteria results in a major classification, the applicant may request reclassification, if justified, and DASA can take the responsibility in reclassifying the change.

Processing of Minor Changes

7.2.3.8 Minor changes to the type certificate must be undertaken in accordance with DASR 21 Subpart D, and can be approved by DASA or a DASR 21J MDO approval holder with the necessary privilege and scope. DASA expects that in the Defence context, minor changes to type certificates undertaken in accordance with DASR 21 Subpart D will be developed and approved by a DASR 21J MDO[11].

Processing of Major Changes

7.2.3.9 Changes that are classified as major can be processed and approved as a:

Superseded

1. major change to the existing MTC under DASR 21 Subpart D, or

2. a MSTC under DASR 21 Subpart E.

7.2.3.10 The decision to apply for a major change (DASR 21 Subpart D) versus a MSTC (DASR 21 Subpart E) will depend upon the specific context. Under the DASR construct, both these authorisations will be issued to the government MTC holder. The default approach is usually issue a major change to the existing MTC, however, as discussed in the following sub-section, there may be cases where an MSTC is more appropriate.

Use of Military Supplemental Type Certificates (MSTCs)

7.2.3.11 The reasons for using an MSTC are different in the Defence context from in the civilian context. This sub-section provides guidance on when an MSTC should be used under the DASR.

7.2.3.12 **Civil use of Supplemental Type Certificates (STCs).** In the civil context, STCs are generally used for commercial purposes. They are used where a designer (either the OEM or another designer) alters the aircraft to provide a new capability that they can sell separately to the original Type Certificate. Of note, designers who are not the holder of the original Type Certificate can only ever apply for STCs for design changes that are classified as major, as it is not possible to apply for a major change to a certificate you do not hold.

7.2.3.13 Major changes to the Type Certificate are limited to changes done by the Type Certificate Holder, and are mostly (though not always) mandatory Service Bulletins and Airworthiness Directives to address safety issues identified in service as part of the holder obligations (eg DASR 21.A.3A).

7.2.3.14 **Use of MSTCs Under DASR.** Under the DASR the reasons for using an MSTC are different to the civil context. The following are the reasons that an MSTC (as opposed to a major change to the MTC) would be used under the DASR:

1. Sub-fleet: An MSTC may be used to manage a sub-fleet. This would be where there is one or more aircraft in the fleet that are intended to be configured or operated in a significantly different manner to the remainder of the fleet. Note, sub-fleets can also be managed via major changes to the MTC, so an MSTC may be used but is not the only option for management of sub-fleets.

2. Significant Change to the TCB: An MSTC may be used to manage a change that involves a distinct change to the TCB. Generally this will be the result of reliance on prior certification which has adopted a different PCC than that used for the original MTC. While the change to the PCC may be able to be managed via MCRI(s), it may reduce the complexity of ongoing management of the authorisations by covering the change under an MSTC.

3. Large and Complex Changes: An MSTC may be used for large and complex changes. While the process for review and approval of a major change or an MSTC is the same, use of an MSTC provides greater visibility, and as a result greater clarity, of the precise nature and scope of the change. MSTCs are often understood by Defence Operators as being a change of more significance, which warrants greater operational consideration.

4. Management Reasons: An MSTC may be used for ease of management from the perspective of the MTC holder. This may be required to provide alignment between the DASR authorisations and authorisations being leveraged via recognition. It may be

Superseded

simpler for an MTC holder to manage their obligations if the Defence authorisations are aligned with the OEM authorisations.

7.2.3.15 Note that when changes are applied to the MTC for a platform that also has MSTC(s), the compatibility of the change with the existing MSTC(s) must be explicitly addressed. Under the civil system, a change to the Type Certificate does not need to explicitly consider compatibility with potential STCs. It is the Operator's responsibility to consider the impact of change to the Type Certificate against any STCs applied to their aircraft, and to engage the STC holder as required. However, in the DASR context, the MTC and MSTCs are frequently more integrated and less able to be clearly separated from each other. In addition, the MTC and MSTCs are all held by the same organisation so separating consideration of the MTC and MSTCs is unnecessary and adds confusion for no benefit. As such, it is not appropriate to progress a major change to the MTC without considering the impact on existing MSTCs.

Eligibility

7.2.3.16 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the relevant authorisation.

7.2.3.17 **Major Change to the MTC.** In accordance with DASR 21.A.92, only the MTC holder can apply for a major change to the MTC. However, as noted by DASR GM 21.A.92(a), this includes any organisation acting on behalf of the MTC holder. DASA considers it appropriate for a design organisation to act as the applicant for a major change (on behalf of the MTC holder) where:

1. the agreement between the MTC holder and design organisation required by DASR 21.A.14(c) permits,
2. the TCAE reflects the agreement and arrangements under which such applications may occur, and
3. the proposed design change is within the scope of the design organisation's approval.

7.2.3.18 In all cases, the MTC holder must sign the final application for the major change (ie Form 31A) to confirm that they have been consulted on, and have no objection to, the major change, and will carry out holder responsibilities.

7.2.3.19 During sustainment, additional design organisations may be engaged by the MTC holder to support new modifications or reflect expanding design support agreements. In these cases, the MTC holder should inform DASA of the proposed support arrangements and define additional oversight requirements to support specific applications.

7.2.3.20 **MSTC.** In accordance with DASR 21.A.112A, any organisation that has demonstrated, or is in the process of demonstrating, its capability under DASR 21.A.112B shall be eligible as an applicant for an MSTC. The DASR 21.A.112B demonstration of capability requirements are essentially the same as those of DASR 21.A.14 (refer to the 'Eligibility' guidance in Section 7.2.2, and relevant AMC and GM for further information).

7.2.3.21 However, as noted by DASR GM 21.A.115, DASA will issue all MSTCs to the relevant government MTC holder organisation. This means that, in effect, all applications for MSTC are being made on behalf of the MTC holder who will be the eventual holder of the MSTC. Applicants for MSTCs must be able to demonstrate that they are acting on behalf of the MTC holder.

Superseded

7.2.3.22 **Major Change or MSTC Applications by CASG Project Offices.** In some cases, the CASG project office may act as the applicant for a major change or MSTC for larger or more complex modifications to an existing aircraft, such as for a mid-life upgrade program or significant capability upgrades.

7.2.3.23 Since only the MTC holder can apply for major changes to the existing MTC, the CASG project office would be considered to be applying for the approval on behalf of the MTC holder. For MSTC applications, the CASG project office could be considered the applicant under the DASR 21.A.112B(c) exception clause. In either case, the eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J.

7.2.3.24 Also refer to the 'MTC Applications by CASG SPOs (Project Offices)' guidance in Section 7.2.2 for further information, including guidance on applicant eligibility when CASG project offices wish to leverage recognition provisions.

7.2.3.25 CASG project offices seeking to apply for a major change or MSTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended program.

Certification Programme

7.2.3.26 **Overview.** Under DASR 21, a certification programme is required for all changes to type certificates and MSTCs. The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a CPP.

7.2.3.27 For MSTC and 'complex'[12] major change programs, the certification programme must be presented to DASA for formal acceptance prior to the final application and declaration of compliance, and it is recommended that it be presented as a CPP. For other certification activities, the certification programme may be documented through the design pack or final application, and does not require formal DASA acceptance. Table 7.1 summarises the certification programme requirements for different design activities.

Certification Activity	DASR Reference	Formal DASA Acceptance Required?	Comments
Application for an MSTC	21.A.113(b) 21.A.93(b)	Yes	Certification programme should be presented as a CPP containing the information required by 21.A.93(b) and the supporting AMC. The DASA major change/MSTC CPP template will assist in meeting the required outcomes.
Application for a 'complex' major change	21.A.93(b)	Yes	

Superseded

Application for a 'simple' major change	21.A.93(b)	Yes	Certification programme can be provided with the final application for approval of the change.
Minor change to type-certificate	21.A.93(b)[13]	No	

Table 1: Certification Programme Requirements for Design Change Activities

7.2.3.28 Two CPP templates are published on the DASA website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the major change/MSTC CPP template.

7.2.3.29 The organisation(s) involved in the development and submission of a certification program for a major change or an MSTC application will vary depending upon the platform support arrangements. As noted above, the design organisation that supports the MTC holder functions may act as the applicant on behalf of the MTC holder in certain circumstances. In these cases, the design organisation will usually develop the CPP and engage with DASA for formal acceptance when required.

7.2.3.30 **Simple Major Changes.** For 'simple'[14] major changes, the certification programme may be presented with the final application (ie with the Form 31a pack). This approach introduces a risk that if DASA identifies issues with the certification programme, or with the decision to treat the change as simple, there may be a requirement for rework of compliance demonstration activities, resulting in a delay to the program. As such, this approach should only be followed where the change is straightforward; for example, OEM Service Bulletins that have received CAA/MAA certification. If there is doubt as to whether a change would meet the definition of 'simple', DASA Type Certification section should be contacted for advice.

7.2.3.31 **Contents of a Certification Programme.** DASR 21.A.93(b) outlines the requirements for content of a certification programme for a major change or an MSTC.

7.2.3.32 Certification programmes must be tailored to meet the requirements of the certification activity. If a change has been assessed as 'simple', then there is no need to do a full breakdown of the programme into CDIs or to provide a detailed LoI proposal, as the LoI must be assessed as nil to meet the definition of a simple change. For changes that rely on prior certification, the breakdown of the programme into CDIs is only required for areas that are not able to fully leverage prior certification (ie where additional compliance demonstration evidence is being developed).

7.2.3.33 For 'complex' major changes and MSTC, the certification programme should be presented as a CPP containing the information required by DASR 21.A.93(b) and the supporting AMC and GM. The major change/MSTC CPP template published by DASA will assist in meeting the required outcomes.

7.2.3.34 **Further Guidance.** Refer to the certification programme information in Section 7.2.2 for further guidance on proposal of CDIs and DASA LoI, as well as certification programme acceptance and updates.

Certification Basis

7.2.3.35 For all changes to a product, the design organisation must identify the areas affected by the change and the corresponding certification basis (airworthiness requirements) for those areas. The

Superseded

applicable airworthiness requirements will depend upon the nature of the change, and can be generalised as follows:

1. **Substantial changes.** Some changes are so extensive that a new type certificate is required (refer DASR 21.A.19), and therefore would require an entirely new TCB to be established. Substantial changes for an existing aircraft type are unlikely within the Defence context.

2. **Significant (major) changes.** For major changes that are categorised as significant[15] under DASR 21.A.101, then the latest amendment level of the airworthiness requirements referenced in the TCB should be used for the change.

3. **Non-significant (major) changes.** For major changes that are not categorised as significant, then the DASR 21.A.101(b) exception clause allows the existing airworthiness requirements in the TCB to be used for the change. DASR 21.A.101(b) also allows the existing airworthiness requirements to be used for a significant change in cases where use of the latest amendment of the airworthiness requirements referenced in the TCB would not contribute materially to the level of safety, or is impractical.

4. **Minor changes.** Minor changes, by definition, do not affect the airworthiness of the product. This means that it is appropriate to use the existing airworthiness requirements in the TCB for the change (refer DASR 21.A.95(b)(1) and DASR AMC 21.A.95).

7.2.3.36 As stated above, using the existing airworthiness requirements in the TCB is usually considered adequate for minor changes and non-significant major changes. However, as noted in DASR GM 21.A.93(b)(2), Australia's WHS Act levies additional obligations on designers, namely to exercise 'reasonable knowledge' when determining that any risk inherent in designs has been minimised SFARP. Updates (later amendments) to applicable standards may provide insight into hazards and potential controls that are not identified in the existing TCB. The requirements prescribed in the DASDRM also provide a source of requirements and standards that can assist engineers to satisfy their obligation to exercise reasonable knowledge of hazards and associated controls in aircraft design.

7.2.3.37 The certification programme for the change should identify the proposed certification basis (ie existing or latest amendment level, with justification as required) and any 'reinvestigations' required[16].

7.2.3.38 **Changed Product Rule.** DASR 21.A.101 is commonly referred to as the 'changed product rule' and is used by applicants and DASA to establish the certification basis for major changes and MSTCs. The primary decision under the changed product rule is whether the latest amendment of the airworthiness requirements referenced in the TCB must be used (ie significant major change), or whether the nature of the major change allows the existing airworthiness requirements to be used (ie non-significant major change). If an applicant elects to comply with the latest amendment for a major change that could otherwise be categorised as non-significant, then the change will be compliant with DASR 21.A.101(a) and no further justification would be required.

7.2.3.39 DASR GM 21.A.101 contains extensive guidance and a step-by-step process for applicants to follow in order to establish the proposed certification basis for the major change. A summary of the changed product rule criteria and outcomes is shown below in Table 7.2. Table 7.2 is taken from Appendix B to GM 21.A.101, and only provides a brief summary of the extensive guidance and step-by-step process contained in DASR GM 21.A.101. A number of the Appendices to GM 21.A.101 refer

Superseded

to the EASA GM 21.A.101, including Appendix A of EASA GM 21.A.101 which provides examples of changes that EASA, the FAA and other Authorities considered to be 'substantial', 'significant' and 'non-significant'.

<table>

</table>

Table 2: Establishing Certification Basis for Changed Products

7.2.3.40 Significant major changes shall also comply with the relevant 'essential' design requirements defined in the DASDRM (refer DASR AMC 21.A.101).

7.2.3.41 Note that for major changes, DASR 21.A.101(e) is a further exception clause that allows applicants to propose an alternative to the airworthiness requirements in the TCB. DASA may agree to the use of an alternative set of airworthiness requirements provided the alternative provides at least an equivalent level of safety to the existing TCB.

7.2.3.42 The process and justification used to comply with DASR 21.A.101 should be included within the certification programme, and the DASA major change/MSTC CPP template contains specific headings to include this information.

7.2.3.43 When applicants believe that the major change under consideration may be significant, or have questions about application of DASR 21.A.101, then engagement with DASA as early as practicable is recommended.

7.2.3.44 **Tailoring the TCB.** During a certification program, there may be a need to tailor the TCB when seeking a major change approval. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

7.2.3.45 Tailoring of the TCB may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.3.46 Tailoring of the TCB can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a MCRI.

Superseded

7.2.3.47 Annex A to Section 7.2 provides further guidance on tailoring the TCB, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support TCB tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Reclassification of Changes Requiring TCB Tailoring

7.2.3.48 Occasionally, changes to type certificates that would otherwise be classified as minor, are required to be classified as major only because of the need to tailor the TCB. This section outlines an approach to enable these changes to be reclassified to minor, once the TCB tailoring has been agreed. This approach will allow greater use of DASR 21J MDO privileges, and reduce DASA assurance in areas where there is not a clear safety benefit.

7.2.3.49 **Reclassification Justification.** DASR GM 21.A.91 states that any changes that require an adjustment of the TCB, other than electing to comply with a later amendment of a requirement, must be classified as major. However, it also states that when the strict application of the classification criteria for a design change results in a major classification, the applicant may request re-classification, if justified, and DASA can take the responsibility in re-classifying the change.

7.2.3.50 DASA has identified that, for changes that are classified as major solely due to a need to tailor the TCB, continuing to process these as major changes once the tailoring of the TCB has been agreed imposes additional administrative burden without commensurate safety benefit, and can result in a delay to the introduction of safety improvements or capability upgrades. As such, DASA considers it appropriate for these changes to be re-classified to minor, as allowed by DASR GM 21.A.91, and either directly consumed (if subject to prior certification) or approved by a DASR 21J approved organisation holding appropriate privileges.

7.2.3.51 **Reclassification Process** (Figure1). Reclassification is only possible once the tailoring of the TCB has been agreed. An applicant may submit the requests for TCB tailoring and reclassification concurrently, allowing a single DASA response, or the reclassification request may be submitted after the tailoring has been agreed. Requests for reclassification are to be submitted via Letter or Minute to DASA via the DIA Type Certification mailbox (dasa.typecert@defence.gov.au). Requests must be submitted by an organisation that meets the eligibility requirements to apply for a major change under DASR 21 Subpart D (ie the MTC holder or a design organisation that provides MTC holder functions as part of establishing holder capability).[17]

7.2.3.52 The applicant must provide confirmation that the design would meet the requirements to be classified as minor if not for the tailoring of the TCB. This may be provided as an assessment from a DASR 21J approved organisation that has privileges to classify changes, or by providing evidence of approval as a minor change under the system of a recognised CAA/MAA with an equivalent classification system.

Superseded

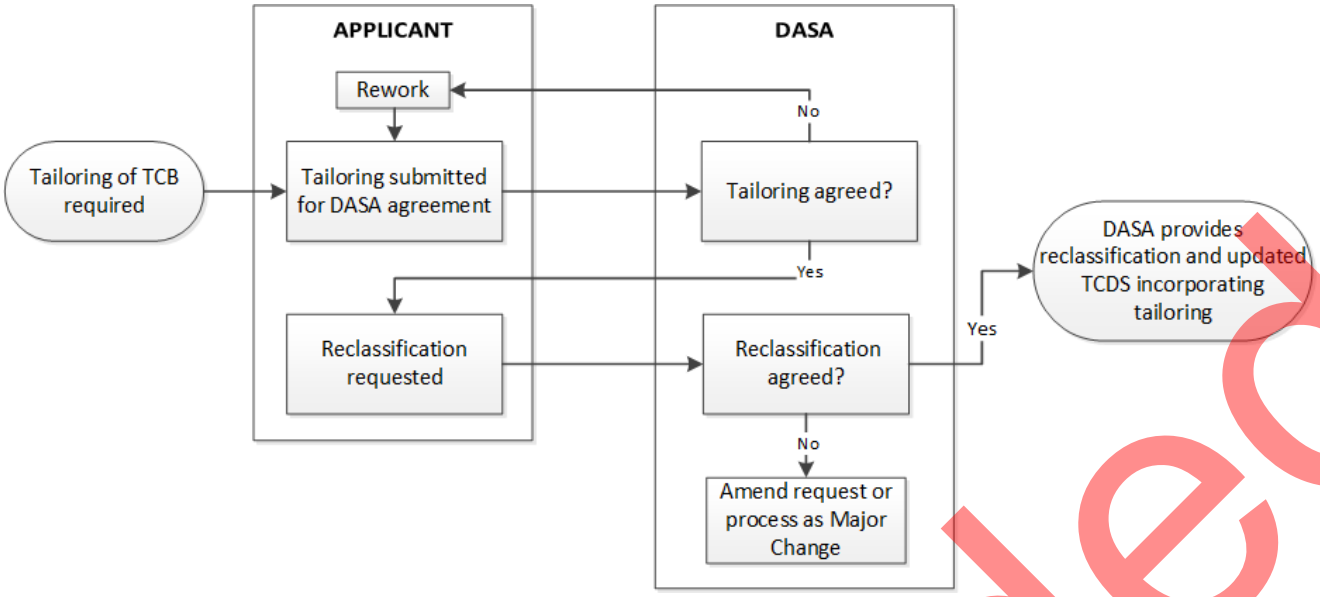

Figure 1: Process for reclassification when TCB tailoring is required

Compliance Demonstration

7.2.3.53 Compliance demonstration evidence comprises of reports, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the TCB requirements applicable to the change / MSTC is demonstrated. The applicant shall demonstrate compliance with the applicable TCB requirements either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.3.54 Refer to the 'Compliance Demonstration' evidence guidance in Section 7.2.2 for further information.

Application, Approval / Issue and TCDS Update

7.2.3.55 **Application.** Upon completion of all activities identified within the certification programme, including development of compliance demonstration evidence and DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for approval of a major change, or issuance of an MSTC, using the DASR Form 31A.

7.2.3.56 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will approve the major change or issue the MSTC.

7.2.3.57 **TCDS.** As required, DASA will develop and issue the TCDS update concurrently with the major change approval or MSTC issuance.

DASA Assurance

7.2.3.58 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining a major change or MSTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).

Superseded

2. DASA agreement of the TCB, including tailoring (refer 'Certification Basis' section above).

3. DASA Level of Involvement (LoI) in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme' section above). In all cases, DASA LoI activities must be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer to the 'DASA Assurance' guidance in Section 7.2.2 for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, approval of the major change or issue of the MTC, and update of the TCDS as required.

Holder Obligations

7.2.3.59 Given the DASR only allows the MTC holder to be the applicant for a major change to an existing MTC, there are no separate DASR holder obligations for major changes, and the MTC holder must undertake the obligations laid out in DASR 21.A.44 for the MTC, including and all major changes thereto.

7.2.3.60 Obligations for holders of an MSTC are laid out in DASR 21.A.118A . However, given DASA's policy of issuing all MSTCs to the government MTC holder organisation, and the fact that the DASR 21.A.118A obligations are essentially the same as those ofDASR 21.A.44, the MTC holder simply needs to continue to undertake all obligation laid out in DASR 21.A.44 for the MTC and all MSTCs they hold.

7.2.3.61 Refer to Section 7.4.1 for detailed guidance on the DASR 21.A.44 MTC holder obligations.

7.2.4 – Repair Designs (DASR 21 Subpart M)

Overview

7.2.4.1 Data that is used to accomplish repairs needs to be approved by a suitable and competent organisation. Data may be approved through a repair design approval process where DASA is the certifying authority, or through a process where recognition is used. These two broad pathways are covered by DASR M.A.304, which provides the requirements for data that is used to carry out repairs and modifications:

1. DASR M.A.304(a) and (b) allow data to be used that has been approved by DASA, and by a Design Organisation approved under DASR 21, respectively. In both cases DASA is the certifying authority and the requirements of DASR 21 Subpart M (Repairs) are applicable.

Superseded

2. DASR M.A.304(d) allows for the consumption of data that has been approved within the framework of Authorities recognised by DASA. In this instance the repair approval requirements of DASR 21 Subpart M (Repairs) are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate.

7.2.4.2 This section is relevant to data for repairs conforming to DASR M.A.304(a) and (b) and provides:

1. an overview of the repair approval process in accordance with DASR 21 Subpart M (Repairs)
2. guidance for design organisations and MTC holders regarding DASA's expectations for repair design development and approval
3. more detailed guidance in the form of a number of common repair scenarios.

7.2.4.3 Guidance regarding use of repair data in accordance with DASR M.A.304, including consumption of data using recognition provisions, is provided in the Section 8.2.

7.2.4.4 Note that additional general information about Repair Design authorisations is contained in Section 5.3 Annex R.

DASR 21 Repair Design Privileges

7.2.4.5 DASR 21 Subpart J privileges related to repair designs include the privilege to:

1. classify repairs (DASR 21.A.263(c)(1)),
2. approve minor repairs (DASR 21.A.263(c)(2)), and
3. approve certain[18] major repairs (DASR 21.A.263(c)(5)).

7.2.4.6 These privileges require the design organisation to have procedures agreed to by DASA, usually by issue of a Military Design Organisation Approval (MDOA). These procedures would normally be documented in a Design Organisation Handbook[19].

Repair Process

7.2.4.7 The overall process for development, approval and embodiment of repairs where DASA is the certifying authority is outlined in Table 7.3. Further guidance, in the form of specific scenarios are outlined in Annex D to Section 7.2 Repair Design Approval Scenarios. Note that the scenarios in Annex D are defined as an aid for explanation, rather than as a series of strict processes.

Stage	Description	Responsibility
Identify and Assess Damage	Damage identified for which there is no existing pre-approved solution.	CAMO
Develop Repair Design	Repair design data is developed.	Design organisation

Superseded

Repair Classification	Repair classified in accordance with the requirements of DASR 21.A.435a.	DASA or an appropriately approved design organisation under a procedure agreed with DASA
Repair Certification	Establish Certification Basis (CB). Demonstrate compliance with required CB elements, Compliance Verification, Declare Compliance. Submit application for approval if required.	Applicant that meets the eligibility criteria[20]
Repair Approval	Approval of Repair. The assignment of obligations to the repair approval holder (dependent on classification).	DASA or an appropriately approved design organisation under a procedure agreed with DASA.
Repair Configuration Management	Manage the accomplishment of repairs and maintain a record of aircraft configuration, which includes repairs.	CAMO
Production of Repair Parts	Produce repair parts.	Appropriately approved production organisation, under DASR 21 Subpart G or Subpart F, or an appropriately approved maintenance organisation under DASR 145
Repair Embodiment	Embody repair.	Appropriately approved maintenance organisation under DASR 145 or appropriately approved production organisation under DASR 21 Subpart G
Ongoing Holder Obligations		Repair design approval holder

Table 3: Repair Process where DASA is the Certifying Authority

Repair Design Classification

7.2.4.8 As per DASR 21.A.435a – Classification and approval of Repairs – a repair must be classified as either minor or major in accordance with the criteria laid out in DASR 21.A.435a. Classification of repairs guides DASA to apply appropriate assurance oversight and allows for the obligations of the holder of a repair design approval to be identified. Classification does not affect the certification basis, demonstration of compliance, independent checking or declaration of compliance and, as such, whether a repair is classified as major or minor does not affect the engineering rigour applied to the repair. Repair classification may be made by either DASA or by an appropriately privileged design organisation under a procedure agreed to with DASA[21].

7.2.4.9 DASR GM 21.A.435a states that a new repair – a repair that has not previously been approved for the application being considered on the individual aircraft in question – is classified as major if it has an appreciable effect on structural performance, weight, balance, systems, operational characteristics or other characteristics affecting airworthiness. This is elaborated on to highlight that repairs needing extensive static, fatigue or damage tolerance justification or testing, or requiring

Superseded

methods, techniques or practices that are unusual, are to be classified as major. This GM identifies repairs that require permanent changes to Airworthiness Limitations (AwLs) to be classified as major.

7.2.4.10 The paragraphs below give examples of what may need to be considered in developing a repair classification procedure. Each organisation must develop its own procedure which meets the requirements of DASR 21.A.435a, 21.A.239, 21.A.263 and 21.A.243 and is tailored to the organisations scope of work. However, the considerations below, based on the guidance provided in the GM 21.A.435a and GM 21.A.91, are provided to further clarify DASA's expectations of such a procedure.

7.2.4.11 For clarity, classification may consider the following three characteristics of the repair design:

1. Severity – the effect of the repair on airworthiness.
2. Complexity – the complexity of the design and the certification requirements.
3. Novelty – whether the design has been developed in accordance with established methods and practices for the repair application in question.

7.2.4.12 Generally repairs may be classified as major except when all of the following criteria are met:

1. Severity is low. Examples of the types of details that would be expected from repairs of low severity include:
    i. Structural performance, in terms of static strength, fatigue performance, damage tolerance performance, flutter and stiffness characteristics, is unaffected by the repair.
    ii. Load paths and load sharing in the vicinity of the repair are unaffected by the repair.
    iii. Weight and balance change is not greater than that allowed in the weight and balance manual or Original Equipment Manufacturer (OEM) repair guidance for weight and balance. This includes changes in centre of gravity and load distribution. Weight and balance of control surfaces can be particularly affected by even small changes.
    iv. Changes do not affect the operation or redundancy of a system, or an adjacent system.
    v. Changes do not affect operational characteristics.
    vi. Other characteristics related to airworthiness, or to environmental characteristics of the platform (such as noise, fuel venting and exhaust characteristics), are not affected including, but not limited to, fire protection, propulsion systems integrity and crashworthiness.
2. The repair design and the certification requirements are not complex. Examples of the types of details that would be expected from repairs of low complexity include:
    i. Repair requires no or minimal re-assessment or re-evaluation of original certification substantiation data
    ii. Repair design elements are straightforward.

Superseded

iii. Original type certification data is available, or if not available appropriate data can be established without complex engineering, and no assumptions are required in the definition of the certification requirements.

3. There are no new or novel features to the repair. Examples of the types of details that would be expected from a repair that does not have new or novel features include:

   i. Techniques, methods and practices are those employed in the regular management of the platform and type of defect.

   ii. Techniques, methods and practices are those accounted for in the platform Type Design.

7.2.4.13 It is recognised that in some cases not all data will be available at the time of initial repair classification, and so, judgement must be exercised. In the case where later data indicates that the initial classification is no longer valid, a repair may be reclassified. In this case, consultation with DASA and, where necessary, reconsideration of the Certification Programme (CP), is expected.

7.2.4.14 These classification considerations are outlined in Figure 2.

Superseded

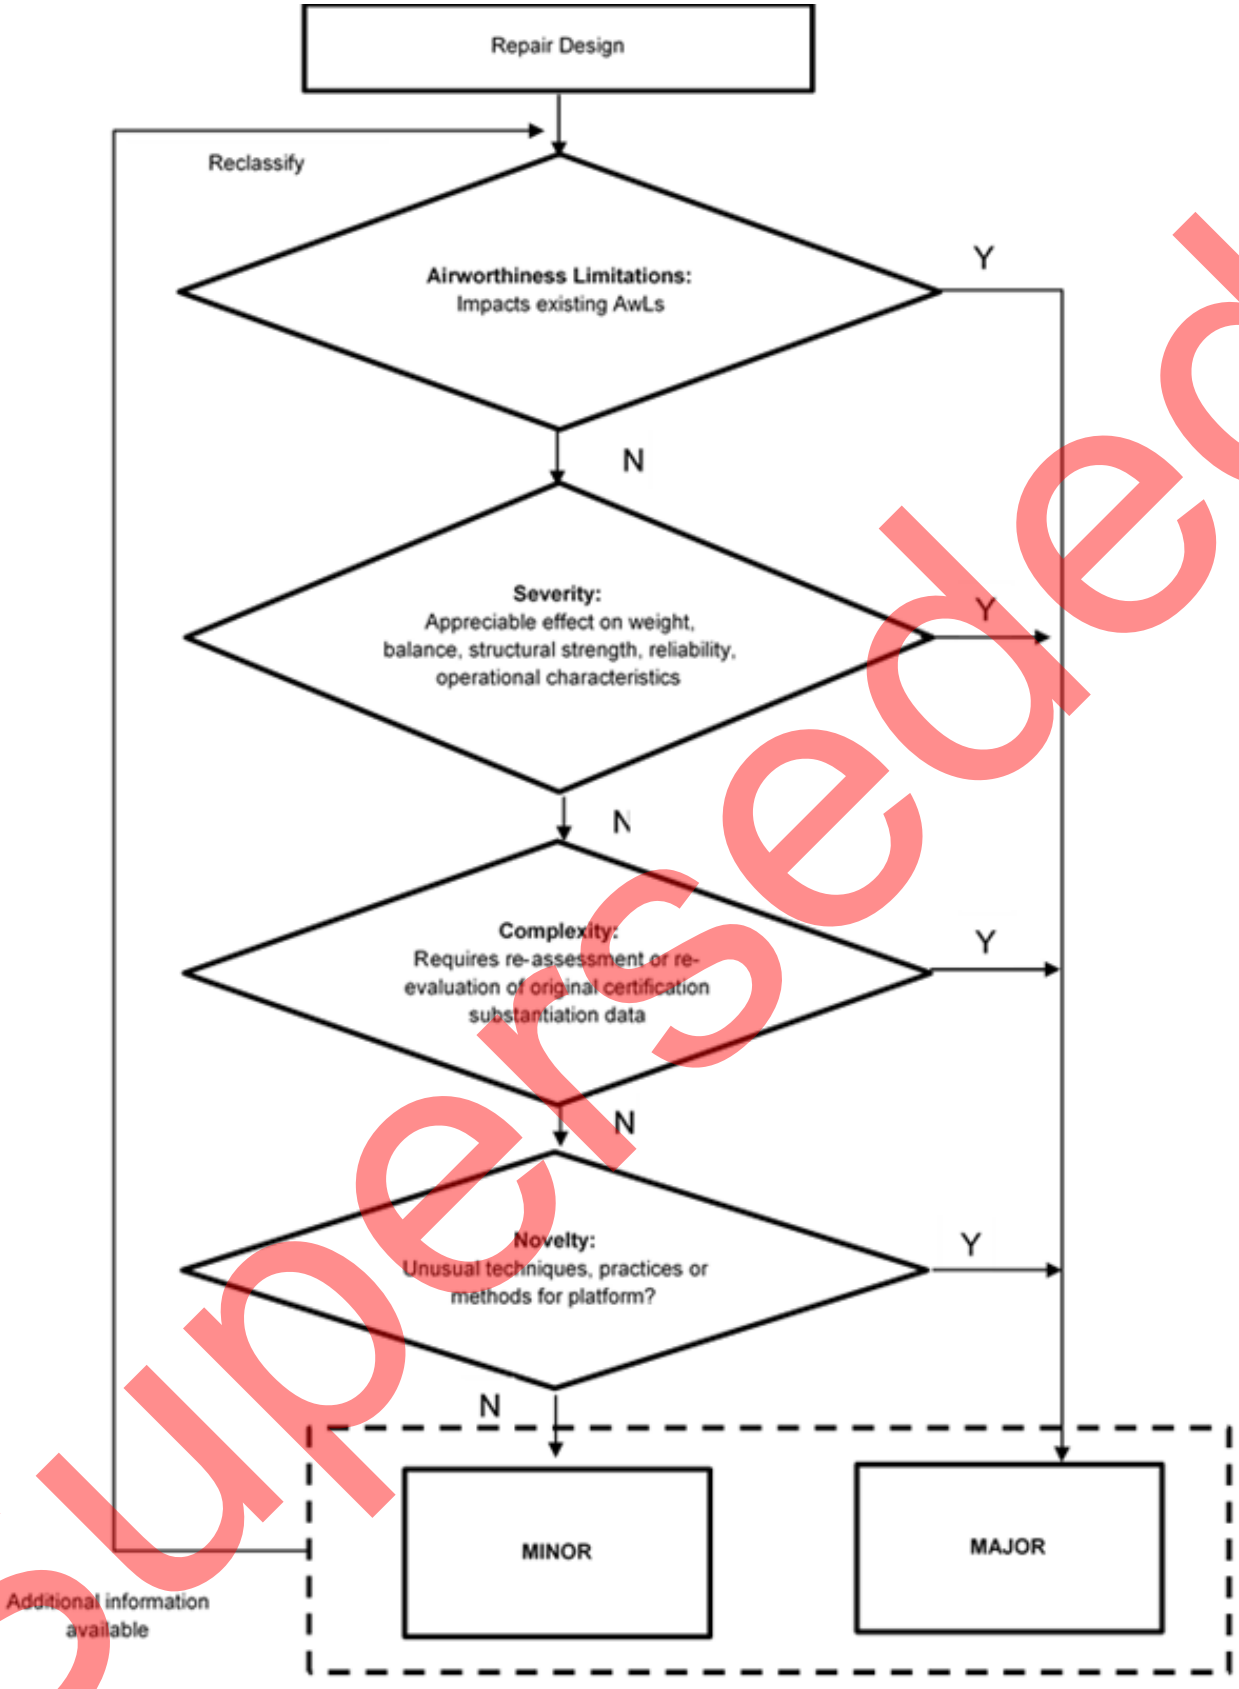

Figure 2 : Repair Classification Principles

Eligibility

7.2.4.15 Applicant eligibility requirements exist to control how designs are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance documents, artefacts

Superseded

and how the declaration of compliance is made. This provides DASA with confidence in the applicant's ability to fulfil the obligations of the repair approval holder where applicable. As such applicants for repairs must meet eligibility criteria as defined in DASR 21.A.432A.

7.2.4.16 To be eligible as an applicant for a major repair design approval, the applicant is to either hold an approval under DASR 21 Subpart J, or may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to demonstrate capability, or may be a government organisation which has agreements in place with a design organisation with access to the type design data.

7.2.4.17 Any organisation is eligible to apply for approval of a minor repair design. It is recommended that an organisation considering applying for DASA approval of a minor repair design seeks approval through an organisation holding a minor repair approval privilege under DASR 21 Subpart J, as DASA priorities will likely lead to delays in the approval of minor repairs.

Approval

7.2.4.18 Repair design approvals may be issued by DASA or an appropriately privileged design organisation, in accordance with DASR 21.A.435b.

7.2.4.19 In the case where DASA is issuing a major repair design approval, DASA receipt of a DASR Form 31B should signify the completion of a period of engagement between the applicant and DASA during which the certification activities agreed within the CP have been undertaken[22], including satisfactory DASA inspection of compliance documents. Upon receipt of the application, DASA assures itself that agreed CP activities have been completed, and if assured, DASA issues to the designated major repair design approval holder a signed DASR Form 31B for major repairs under DASR 21 Subpart M.

7.2.4.20 Design organisations approved under DASR 21 Subpart J can approve designs for minor repairs and certain major repairs, subject to the scope and privileges recorded in their terms of approval, and subject to their internal procedures agreed to by DASA. Further guidance based on repair classification is as follows:

1. **Minor Repairs.** Most MDOA holders approved by DASA will have the privilege to approve minor repairs that are within the scope of their terms of approval (privilege DASR 21.A.263(c)(2)).

2. **Major Repairs.** Some MDOA holders approved by DASA may also have the privilege to approve certain major repair designs that are within the scope of their terms of approval (privilege DASR AMC1 21.A.263(c)(5). The definition of 'certain major repairs' is provided in DASR AMC1 21.A.263(c)(5), (8) and (9), and depends upon whether or not the MDOA holder holds the relevant MTC, MSTC or Australian Military Technical Standard Order Authorisation (AUSMTSOA). In all cases, the ability to exercise the major repair approval privilege is subject to additional criteria and limits based on the characteristics of each individual repair design. For MDOA holders who do not hold the MTC, MSTC or AUSMTSOA, each new major repair design should be assessed against the 'List associated with the privilege' and the relevant 'Justification document' to determine whether the privilege can be exercised. Refer to AMC1 and AMC2 to DASR 21.A.263(c)(5), (8) and (9) for further information on award of, and exercising, the privilege to approve certain major changes.

Holder Obligations

Superseded

7.2.4.20 Following approval of the repair design, the obligations for the repair are assigned to the holder of the repair design approval in accordance with DASR 21.A.451. For both minor and major repairs these obligations include:

1. DASR 21.A.4 – Coordination between Design and Production.
2. DASR 21.A.447 – Record Keeping.
3. DASR 21.A.449 – Instructions for Continuing Airworthiness.
4. DASR 21.A.451(a)2 – Specify the markings in accordance within accordance with DASR 21.A.804(a).

7.2.4.21 For major repairs additional obligations of the holder of the repair design approval include:

1. DASR 21.A.3A – Failures, Malfunctions and Defects.
2. DASR 21.A.3B – Airworthiness Directives.
3. DASR 21.A.439 – Production of Repair Parts.
4. DASR 21.A.441 – Repair Embodiment.
5. DASR 21.A.443 – Limitations.
6. DASR 21.A.433(b) – Substantiation Data.

Superseded

7.2.5 – Instructions for Continuing Airworthiness (ICA)

Basic Principles of ICA

7.2.5.1 **ICA and maintenance data.** ICA is only a subset of all maintenance data that must be complied with in the conduct of maintenance[23]. Other sources of maintenance data include Airworthiness Directives (or other applicable requirements or operational directives issued by DASA), modification and repair implementation instructions and applicable maintenance standard practices. ICA should not be used as a collective term for all maintenance data as other sources of maintenance data are derived from different sources and subject to different regulation. This section deals only with ICA, not all forms of maintenance data.

7.2.5.2 **Airworthiness requirement.** The applicant for an MTC must develop ICA as required by the Type Certification Basis (TCB). Civil primary certification codes used for military products contain clauses (e.g. FAR/CS 23/25/27/29.1529 (aircraft), FAR 33.4 and CS-E 25 (engines), and FAR 35.4 and CS-P 40 (propellers)) that prescribe the content and format of ICA. Products with a military-derived TCB (e.g. from MIL-HDBK-516) have equivalent requirements for the development of maintenance instructions that achieve a similar intent to the civil airworthiness requirements above.

7.2.5.3 **Content and scope of ICA.** To meet the ICA requirements of a civil airworthiness code (or equivalent requirements of a military-derived TCB), the applicant for an MTC must provide:

1. Scheduling information for all recommended maintenance tasks. This information is normally contained in a Maintenance Review Board Report (MRBR) (or equivalent document).

2. Maintenance instructions including those required for servicing, troubleshooting, the methods of removing and replacing items, system testing, ground running, symmetry checks, weighing, towing, jacking, storage limitations etc. This will typically be provided in the form of an Aircraft Maintenance Manual(s), Structural Repair Manual, Fault Isolation Manual, Illustrated Parts Catalogue etc. This information can be amended by the MTC holder (broad scope to amend the master copy) or maintenance organisations approved under DASR 145 (very narrow scope to modify).

3. Mandatory maintenance requirements in a segregated and clearly distinguishable section of the ICA, typically called the Airworthiness Limitation Section (ALS). The ALS contains the mandatory maintenance tasks and intervals, identified in the type certification process. Specific terminology and requirements for the ALS content will vary depending upon the PCC, however, the ALS will generally include mandatory requirements such as:

   i. Airworthiness Limitations (AwLs). AwLs encompass mandatory retirement / replacement intervals and mandatory inspection requirements (including inspection interval(s) and the inspection method). The term AwLs is most often associated with structural life limits and structural inspections that result from FAR/CS 2x.571 or the equivalent fatigue/damage tolerance requirements in military certification standards. However, the term AwL may also be used for other aircraft systems, such as mandatory replacement times for Electrical Wiring and Interconnect System (EWIS) components. As noted within AMC 21.A.41, the definition of an AwL 'interval' includes the interval metric (e.g. flight hours, landings, Equivalent Flight Hours (EFH), Fatigue Index (FI) / Fatigue Life Expended Index (FLEI), engine cycles, etc), and any algorithm, equation, factor(s) or other engineering data which must be used to calculate life accrual against the interval.

   ii. Critical Design Configuration Control Limitations (CDCCLs). CDCCLs identify the critical design features such as proper wire separation, proper installation of a panel gasket, minimum bonding jumper resistance levels, etc., that must be maintained in exactly the same manner throughout the life of the aircraft in order to comply with the type certificate and maintain airworthiness. The purpose of CDCCLs is to provide instructions to ensure these critical features are present throughout the life of the aircraft and are inspected and verified when alterations, repairs, or maintenance actions occur in the area. Design features that are CDCCLs are defined and controlled by FAA Special Federal Aviation Regulation (SFAR) 88 and preserves critical features of the aircraft needed for the Flammability Reduction Means to perform their intended function and prevent the occurrence of an unsafe condition.

   iii. Certification Maintenance Requirements (CMRs)[24]. CMRs are required inspections or maintenance tasks, and associated intervals, developed to achieve compliance with safety analysis requirements (e.g. FAR/CS 25.1309/29.1309, other discrete safety analyses requirements such as FAR/CS 25.671, 25.783, 25.901, and 25.933, and FAR/CS 29 equivalents). A CMR is intended to detect safety-significant latent failures (failures not known to the flight or ground crew) that would, in combination with one or more other specific failures or events, result in a hazardous or catastrophic failure condition. A CMR can also be used to establish a required task to detect an

Superseded

impending wear-out of an item whose failure is associated with a hazardous or catastrophic failure condition.

7.2.5.4 **ICA and the MTC.** Even though a complete set of ICA is required to obtain an MTC, only the ALS of the ICA (or equivalent terminology including CDCCLs and CMRs) forms part of the type design[25] however, they do form part of the Type Certificate. Stand-alone amendments to ICA, other than the ALS, are allowed to be changed by the MTC holder using a procedure agreed with DASA. Note: when completing a stand-alone change to ICA other than the ALS, the MTC holder is not exercising a privilege, but is instead fulfilling their obligation to keep the ICA current[26]. Changes to the ALS of the ICA must be processed as a change to the MTC, and should be classified as a major change[27].

7.2.5.5 **Identification of ICA.** The complete set of ICA for any product should be identified on the TCDS. Other information or instructions required for continuing airworthiness or safe operation of the aircraft, e.g. the approved Aircraft Maintenance Programme (AMP) or a Minimum Equipment List (MEL), is not ICA and is not subject to regulation applicable to ICA.

7.2.5.6 **ICA supplements.** Some major changes to an MTC, MSTCs, minor changes or minor/major repair designs may require variations to the product's ICA[28]. Variations to ICA arising from these design changes or repairs stand-alone from the product's master ICA and are published as an ICA supplement[29]. This gives the aircraft operating organisation the flexibility in managing the ICA applicable to their aircraft, depending on which approved changes and repairs they have chosen to embody. The approval of ICA supplements (including any changed or additional mandatory maintenance requirements) are encapsulated in the approval of the design change or repair. ICA supplements should be identified on the Supplemental Type Certificate Data Sheet, or on the minor change or repair design approval.

7.2.5.7 **ICA and the AMP.** The approved AMP in and of itself is not ICA for the simple reason the ICA requirements of the TCB do not mandate an AMP to be developed by the applicant for an MTC. The recommended maintenance tasks and intervals in the MRBR and the mandatory maintenance requirements identified in the ALS, combined with other requirements unique to each operator's role and usage (including data from a reliability programme) forms the basis for approval of each operator's AMP.

7.2.5.8 The maintenance instructions provided by the MTC holder (or ICA supplements provided by other design approval holders) will provide detail on how to carry out the tasks and inspections in the AMP and should only be amended by the MTC holder (or other relevant design/repair approval holder for ICA supplements) – see paragraph 7.2.5.4 above. Mandatory maintenance requirements must be clearly identified as mandatory in the AMP and cannot be extended without a corresponding approval of a major change to the MTC, or issue of an MSTC. Other ICA must be changed by the MTC holder using DASA agreed procedures. Changes to other recommended task and inspection intervals in the AMP can be approved by a CAMO using a procedure agreed with DASA, without requiring approval of a change to the MTC[30].

Responsibilities for ICA

7.2.5.9 **MTC holders**. The MTC holder is Defence's custodian of the product's ICA regardless of its original author. The MTC holder is responsible for the ICA's content, amendment and distribution to all organisations that operate the aircraft. The MTC holder can amend the ICA (in accordance with approval processes) and must distribute amendments to those organisations affected. If a change to a mandatory maintenance requirement is required, the change must be approved by DASA before

Superseded

distribution of the amendment. The MTC holder's processes for discharging its responsibilities for ICA (even if exercised through external organisations) must be included in the MTC holder's Type Continued Airworthiness Exposition (TCAE). Regardless of a product's TCB, the MTC holder should be able to identify all ICA and have that documented in the TCDS.

7.2.5.10 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their ICA supplements as the MTC holder has for the product's master ICA.

7.2.5.11 **Aircraft operating organisations.** Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided.

7.2.5.12 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable ICA and relevant ICA supplements. Maintenance organisations may locally modify ICA or ICA supplements using an approved procedure specified in their Maintenance Organisation Exposition (MOE) only for the purposes of efficiency, achieving the intent of the ICA when the instructions are deficient, or for the use of alternative tools/equipment[31]. A maintenance organisation must notify the MTC holder (or relevant design approval holder in the case of ICA supplements) when it has locally modified ICA, so consideration can be given to amending the master copy for wider distribution. A maintenance organisation modifying ICA for the purposes stated above does not constitute approving an amendment to the ICA (i.e. the source document) held by the MTC holder (or ICA supplement held by another design approval holder). Only the MTC holder or holder of the ICA supplement can approve amendments to ICA, noting the need to also seek approval of a major change to the type certificate if the amendment alters any mandatory maintenance requirements.

Non-Destructive Testing (NDT) ICA

7.2.5.13 NDT ICA are applied to ensure the airworthiness of aircraft through the inspection of aircraft structure and components. NDT ICA is often used as part of damage tolerance inspection regimes to ensure structural integrity. Consequently, it is critical to ensure that NDT ICA is developed by competent staff and provides sufficient information to enable NDT staff to perform inspections effectively.

7.2.5.14 NDT ICA provided to a DASR 145 Maintenance Organisation should include the following minimum information:

1. the inspection procedure to be used
2. the inspection area
3. the material type of the inspection area
4. the type of discontinuities to be detected.

7.2.5.15 Those organisations responsible for developing NDT ICA (DASR 21J Design Organisations, MTC holder) should consider using NDT Level 3 staff (as defined in EN4179) to verify that inspections are achievable, repeatable and meet the expected detection requirements of the design or repair. This is especially important where NDT ICA is used to support an AwL.

7.2.5.16 The procedure for approving or modifying NDT ICA should be documented in the relevant organisation exposition. DASA recommends that personnel certified to NDT Level 3 in the relevant

Superseded

method be employed to approve and/or modify existing NDT ICA for application in specific circumstances. This accords with the requirements of European Standard EN4179.

Master Minimum Equipment List (MMEL)

7.2.5.17 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable / inoperative under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL cannot, in itself, be regarded as providing operational permission. It, however, can be the basis for the development of an individual Operator's Minimum Equipment List (MEL).

7.2.5.18 An MMEL forms part of the MTC. Approval of new MMEL or an MMEL amendment should be undertaken in accordance with the relevant DASR 21 Subpart[32]. Further guidance on MMEL development and approval in contained in Chapter 8.2.2, including information on:

1. typical characteristics and contents of an MMEL
2. options for developing an MMEL
3. suitable certification specifications for an MMEL
4. classification (major/minor) for changes to an MMEL
5. the DASA MMEL approval process.

7.2.5.19 Note that DASA is currently evaluating EMAR 21 version 2.0 changes that introduce the Operational Suitability Data (OSD) concept and requirements. MMELs are considered a category of OSD, and therefore, this section will be updated in the future once the relevant DASR 21 updates have been incorporated.

7.2.6 – Manuals

Basic Principles for Manuals

7.2.6.1 T**ypes of Manuals.** As per DASR 21.A.57, the holder of a type-certificate shall produce, maintain and update master copies of all manuals required by the applicable TCB.

7.2.6.2 Manuals (for the purpose of DASR 21.A.57) will fall into one of two broad categories:

1. **Aircraft Flight Manual (AFM).** The AFM is an authoritative source of information necessary for the safe operation of an aircraft. It contains the aircraft's operating limitations, operating procedures, performance information and other information and instructions necessary to operate the aircraft safely. Note that this information may be contained in several documents that contain limitations, information and instructions to ensure safe aircraft operation. Examples of other documents/ publications (in addition to the AFM) may include a Flight Crew Operating Manual, Mission Crew Operating Manuals and Pilot Handling Notes.

2. **Manuals Containing ICA.** Certification codes require that the ICA must be published in the form of a manual or manuals[33]. The relevant certification code requirements will dictate the specific ICA content that must be published. Due to the broad and varied type of information that must be published, ICA for a particular aircraft type will usually be distributed through a variety of manuals, such as Aircraft / Engine /

Superseded

Propeller Maintenance Manual, Structural Repair Manual, Engine / Propeller Installation Manual. As noted above at paragraph 7.2.5.5, the MTC holder should be able to identify the publications and manuals that meet the intent of ICA requirements.

7.2.6.3 **AFM Guidance.** DASA AC 008/2020 contains detailed information on AFM content and approval, amending AFM content and use of AFM supplements. Further information specific to changes to type certificates which affect AFMs include:

1. DASR GM 21.A.91 which contains guidance for the classification of changes to AFMs
2. DASR AMC3 21.A.263(c)(2) which contains information on approval of minor changes to the type certificate which affect the AFM.

7.2.6.4 **Approval of Manuals.** Even though particular manuals are required by the TCB and therefore required to obtain an MTC, only certain contents of manuals will form part of the enduring MTC and / or require DASA approval. Contents of manuals that requires DASA approval includes:

1. The ALS of the ICA[34] (i.e. as published within a maintenance manual). Refer Section 7.2.5 for further guidance.
2. Mandatory AFM content (Operating Limitations, Operating Procedures and Performance Information). Refer DASA AC 008/2020 for further guidance.
   7.2.6.5 Consequently, amendments to other manual contents is not a change to the MTC and can be undertaken by the MTC holder using a procedure agreed with DASA. Furthermore, as noted by AMC1 21.A.57, the process to update a manual may be separate from the process to approve or authorise the content of the manual[35].

7.2.6.5 **Manuals in the Context of Defence Aviation Orders, Instructions and Procedures (OIP) Management.** Manuals (for the purpose DASR 21.A.57) are part of the Defence Aviation OIP for the platform type. Lifecycle management of Defence Aviation OIP is discussed further in Section 6.7. A key message of Section 6.7 is that in addition to accuracy and completeness of OIP (a well-established principle in DASR 21), the usability / readability of OIP can cause or contribute to aviation safety hazards. Therefore, aviation safety hazards related to Defence Aviation OIP should be managed through an organisation's SMS. Note that this principle is consistent with DASR GM1 21.A.239(a) paragraph 3.1.5 which states that design organisations should "establish a system to collect in-service experience to be used for the improvement of the [maintenance and operating] instructions".

Responsibilities for Manuals

7.2.6.6 **MTC Holder.** In order to meet their obligation under DASR 21.A.57, the MTC holder should establish a system to produce, maintain and update manuals. As per DASR AMC 21.A.57, this system should ensure:

1. manuals are complete, current, and uniquely identified;
2. manuals contain their authority for use, document name, date of issue, and document/amendment status details;
3. manuals are provided in a medium compatible with user requirements;
4. new issues, re-issues and/or amendments are approved and/or endorsed by appropriate appointments prior to their release, noting that the process to update a

Superseded

manual may be separate from the process to approve or authorise the content of the manual, eg approve AwL in ICA;

5. manual management records are accurately maintained, controlled, traceable and are accessible; and

6. manuals can be reproduced to any previous amendment status.

7.2.6.7 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their manuals or manual supplements as the MTC holder has for the product's master set of manuals.

7.2.6.8 **Aircraft operating organisations.** The operating organisations must manage and distribute the AFM and all other relevant manuals as part of their OIP Management System[36]. Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to all relevant manuals to the extent necessary for the scope of maintenance services being provided. The operating organisation should manage any aviation OIP related hazards through their SMS, and coordinate with the MTC holder, or applicable design organisation, as required to effect any necessary updates or improvements to manuals.

7.2.6.9 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable manuals. Maintenance organisations shall establish procedures to ensure that if found, any inaccurate, incomplete or ambiguous procedure, practice, information or maintenance instruction contained in the maintenance data used by maintenance personnel is recorded and notified to the author of the maintenance data[37].

7.3 Production and Military Certificates of Airworthiness

7.3.1 Production Assurance in the Defence Aviation Safety Program

Aim

7.3.1.1 This chapter details how the production of aircraft components is assured in the Defence Aviation Safety Program (DASP). This includes what release documentation is acceptable under DASRs, and the means through which that documentation is obtained. This chapter only covers aircraft components and does not include whole aircraft. For whole aircraft see MCoA - Chapter 5.3 Annex O and MPO – Chapter 7.6.

Introduction

7.3.1.2 Production of Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured.

Acceptable release documentation

7.3.1.3 The purpose of release documentation is to provide evidence that the manufactured component conforms to approved design data. Aircraft components to be installed on Defence registered aircraft must be accompanied by one of the following release documents:

Superseded

a. DASR Form 1—Authorised Release Certificate.

b. A native or alternate component Certificate of Release to Service (CRS) issued within a recognised airworthiness framework (refer to Chapter 6.5 —Recognition of other Aviation Authorities for identification of a native and alternate component CRS).

c. For standard parts or items designated as specific equipment under DASR 21.A.303, a Certificate of Conformity from the item's manufacturer (refer AMC to DASR 145.A.42(a)(4)).

d. For components fabricated under DASR 145.A.42(c), certificates of conformity produced by the fabricating maintenance organisation that are acceptable to DASA.

7.3.1.4 Release documentation under (a), (b) or (c) above enables that component to cross organisational (and possibly national) boundaries between its manufacture and installation. Manufactured components that do not need to cross organisational boundaries can be installed with locally produced certificates of conformity that contain all of the technical information found on a DASR Form 1 per item (d) above.

DASA production assurance

7.3.1.5 DASA assures production of all Defence aircraft components using one of three mechanisms depending on the release documents required by continuing airworthiness regulations. This is depicted below in Figure 3.

Assurance through Recognition Frameworks

7.3.1.6 The majority of aircraft and aircraft component manufacture for Defence occurs outside Australia and is assured through DASA's recognition framework. To be installed on a Defence registered aircraft, these components must be accompanied by a recognised native (Form 1 equivalent) or alternate release certificate. Each DASA Recognition Certificate provides details on the unique conditions and caveats to be applied to validate the native or alternate release certificates. Production of components assured through recognition do not require a DASR Form 1 as it provides no additional safety assurance above what is inherent under the recognition framework.

Assurance through DASR 21 – production by Military Production Organisation Approval (MPOA) or letter of agreement holder

7.3.1.7 Components manufactured outside of a recognised airworthiness framework (other than standard parts, specific equipment or components fabricated under DASR 145.A.42(c)) require a DASR Form 1 for installation. To issue a DASR Form 1 an organisation must hold a Military Production Organisation Approval (MPOA) under DASR 21 Subpart G, or a letter of agreement to manufacture under DASR 21 Subpart F . In this instance, the award and oversight of MPOA is DASA's assurance mechanism for the production of such components.

7.3.1.8 The only organisations that DASA will consider for award of MPOA are those that do not hold a recognised approval that enables release of the manufactured components under a native or alternate artefact (see Chapter 6.5 —Recognition of other Aviation Authorities). That is, the requirements of DASR 21 Subparts G will be imposed on an organisation for the sole purpose of issuing a DASR Form 1 for the manufactured components.

Assurance through DASR 145 – fabrication by maintenance organisations

Superseded

7.3.1.9 DASR Form 1 must not be used for components fabricated by maintenance organisations under their DASR 145 approval. A locally produced certificate of conformity must be used instead. DASA's assurance of this production is via the issue and oversight of the organisation's DASR 145 approval. A DASR 145 MO will only have this activity included in the scope of their DASR 145 approval if they can sufficiently demonstrate their capability to perform such fabrication. Note that unless otherwise approved by DASA, only the DASR 145 MO who fabricated the component can install this component.

Figure 3: Production Assurance and Release Documentation under DASP

Manufacture and release of test articles

7.3.1.10 If a test article is manufactured to gather certification evidence, the responsibility to control the manufacture of that article and ensure it accurately reflects the proposed design data rests entirely with the organisation seeking certification of the design. For test article manufacture required to achieve certification of a major change, the Certification Programme should describe the production control processes that will be used by the applicant in producing the test articles. If DASR

Superseded

Form 1 is used to release a test article for trial installation in an aircraft, Block 12 of the DASR Form 1 must clearly state that the article is in conformity with non-approved design data. The manufacture of test articles for certification does not require MPOA under DASR 21 Subparts G or a letter of agreement under DASR 21 Subpart F. These principles also apply for minor changes being approved under MDOA privilege.

Manufacture of modification kits

7.3.1.11 Maintenance organisations approved under DASR 145 may fabricate modification kits and issue certificates of conformity provided (a) the scope of their DASR 145 approval allows it, and (b) the completed modification kit will be installed by the same maintenance organisation (and under the same DASR 145 approval) issuing the certificate of conformity. Modification kits meeting both criteria above must not be released using DASR Form 1, but must still be manufactured to the approved design data and have locally produced certificates of conformity attesting to that fact. Fabrication of modification kits for onward supply cannot be performed under a DASR 145 approval and constitutes series production that must be assured by either recognition or through DASR 21. Modification kits manufactured external to the installing maintenance organisation must be accompanied by a DASR Form 1, or release documentation acceptable to DASA through recognition.

7.3.1.16 DASR 21 Subpart G – Military Production Organisation Approval

7.3.2 Military Certificate of Airworthiness (MCoA)

Introduction

7.3.2.1 This section supplements the DASP policy and provides guidance in support of DASR 21, Subpart H relating to MCoAs, their purpose, and their issue. The guidance included in this section discusses the MCoA concept and application from both an Australian Defence context, and where appropriate for the purposes of description, a civil aviation context.

7.3.2.2 Restricted MCoAs are also discussed where appropriate; however, such MCoAs are of limited utility in the Australian Defence context, and unlikely to be issued.

Purpose

7.3.2.3 A MCoA is an aircraft operating authorisation issued against an airframe tail that has the purpose to validate that the airframe conforms to the type design as specified on the Military Type Certificate (MTC). It serves as the final assurance artefact that the airframe is in a state of airworthiness per the inherent level of safety afforded by the type design and the underlying MTC basis. It is enabled by an organisation or operator, who has registered the airframe on the Australian Defence register, and has ensured conformity through meeting various requirements.

Superseded

7.3.2.4 A restricted MCoA will follow the same rules albeit that the airframe shall conform to a restricted MTC and to specific airworthiness requirements ensuring adequate safety.

Application

7.3.2.5 MCoAs in the Australian Defence context can only be issued by the DASA or a Delegate of the Safety Authority (DoSA). The release document is via a DASR Form 25 Military Certificate Of Airworthiness and applies only to aircraft that are registered on the Defence register in Australia.

7.3.2.6 An application for a MCoA shall be made by an eligible organisation via DASR Form 25a - Application for Certificate Of Airworthiness. In the Australian Defence context, the MAO and/or their CAMO are eligible to be applicants for a MCoA as holders of a MAOC. Aircraft that are Non-Defence Registered (NDR) are not subject to Airworthiness DASRs, and are subject to a separate airworthiness requirements, typically under the applicable airworthiness Civil Aviation Safety Regulations. See further DASP Vol 3 guidance on NDR at Chapter 6.1.3.

7.3.2.7 A MCoA application shall be made in a form and manner established by the Authority (DASA in Australia) of the State of Registry[38], per DASR.21.A.174(a). When considering a MCoA application, the Authority will consider all documentation in support of the state of the airframe at application. This has particular significance for used aircraft, where records of usage, maintenance, modifications and repairs may not be to the standard normally required by Defence.

7.3.2.8 The MCoA application presents documentation that the aircraft conforms to the type design approved under the relevant MTC. The required documentation, artefacts, reports and historical evidence (if applicable) to support the application shall be in accordance with DASR.21.A.174(b). Any deviations from the certified type design must be approved by an appropriately authorised design organisation.

7.3.2.9 For used aircraft, DASA will require a Military Airworthiness Review Certificate (MARC) conducted in accordance with DASR Part M regulations before issuing an MCoA. The MARC review is a physical survey of the aircraft and supports issue of the MCoA to satisfy DASA that the submitted documentation is reflective of the physical aircraft. The MARC process is further discussed as part of paragraphs 7.3.2.15 and 7.3.2.16 of this section.

Issue of a MCoA

7.3.2.10 A MCoA can only be approved and issued if all modifications, repairs and/or production deviations implemented on the airframe are approved under DASR 21, or under a recognised national civil or military airworthiness framework.

7.3.2.11 For new civil or commercial derivative aircraft (CDA) delivered to Defence, the acquisition project should seek a civil export CoA from the Civil Aviation Authority (CAA), via the prime aircraft OEM, where a civil Type Certificate (TC) is in place. This export CoA needs to be obtained prior to transfer to the Defence register, and forms the foundation for the issue of an Australian MCoA. Failure to obtain an export CoA for a civil or CDA may limit DASA's ability to issue an evidence based MCoA.

7.3.2.12 For instances where a civil Type Certificate (TC) is not in force or Defence is leasing an aircraft that has been in civilian use, the requirement for a CAA CoA can be demonstrated if a CAA authorised delegate provides a document that attests the aircraft would be eligible for issue of a Standard or Export CoA, if the aircraft was to be registered by a Civil Aviation Authority. Defence will accept only a Standard CoA under DASR 21.A.172, DASR 21.A.173 and DASR 21.A.174. DASA-DIA staff should be consulted for specific advice.

Superseded

Validity and Amendment

7.3.2.13 The MCoA Holder (typically the MAO) is responsible for the continuing validity of an MCoA. A MCoA may be amended or modified only by the Authority (DASA in Australia) of the State of registry[39]. A MCoA may be issued for an unlimited duration, and remains valid subject to the conditions described in DASR.21.A.181.

7.3.2.14 Additionally, the ongoing validity of a MCoA requires that damage be assessed, and all applicable modifications and repairs carried out, using as appropriate the data requirements of DASR.M.A.304.

7.3.2.15 The validity of a MCoA is periodically renewed via the MARC process, as per DASR.M.A.901. This involves an airworthiness review of the aircraft and its continuing airworthiness records. The initial airworthiness review is due within 12 months of the issue date of the aircraft's initial MCoA. The validity of MARCs issued by a CAMO may be extended twice for a period of one year each time if the aircraft has been in a controlled environment.

7.3.2.16 The MAO is accountable for the continuing airworthiness of an aircraft and shall ensure that no flight takes place unless the MCoA and the MARC remain valid, as per DASR.M.A.201. If a MCoA becomes invalid, the MAO must return the aircraft to an airworthy condition before operating the aircraft or seek an alternate flying authorisation. A new MCoA is only required if the aircraft is being returned to the Defence register after removal, or the certificate is revoked by the Authority (DASA in Australia) of the State of registry[40]

7.4 Continued Airworthiness

7.4.1 Military Type Certificate Holders

Introduction

7.4.1.1 A Military Type Certificate Holder within the DASR framework provides Defence a suitable entity to 'hold' the Type Certificate. Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed and that the inherent safety that the platform type certification basis affords is maintained.

7.4.1.2 Unlike civil TC obligations, Defence MTC obligations are not enforceable via national legislation, meaning there is no enduring obligation under law for foreign organisations to manage the basis of certification through the product's life cycle. Therefore, in the application of DASRs, the Defence MTCH is a government organisation, most likely the organisation that acquired the product under contract.

Application of DASR provisions for the MTCH

Superseded

7.4.1.3 The following principles guide the application of the above regulatory provisions:

a. **Principle 1.** DASA issues an MTC for Defence registered aircraft types. Unlike the civil context, a separate TC for the aircraft power plant and/or propeller has not been issued thus far and is nominally included as part of the platform TC.

b. **Principle 2.** DASA shall only issue MTCs to suitable Commonwealth government organisations (the holding organisation) to hold the MTC. The holder is responsible for ensuring that holder functions/obligations are executed. In the Defence context, the MTCH is able to achieve the regulatory intent via a direct or indirect arrangement with the aircraft/engine OEM.

c. **Principle 3.** Military Supplemental Type Certificates (MSTCs) will also be held by the MTCH or holding organisation, with the MTCH responsible for carrying out all MSTC functions/obligations. An MSTC in the Defence context can supplement the MTC for managing sub-fleets, significant changes to the TCB, large and complex changes. They are not used to achieve a commercial outcome such as in the civil design domain.

MTCH Safety Objectives

7.4.1.4 The MTCH has two aviation safety objectives:

a. To support the safe operation of the aircraft type by command units. Achieving Defence strategic objectives requires continuous capability enhancement, and at times, the conduct of operations at markedly elevated levels of risk. In addition, operators of aircraft will require explanatory information, advice and data to operate the type safely. The MTCH must have access to type design data, or support arrangements with the aircraft/engine OEM for the provision of designs and advice to support safe operation of the type.

b. To continuously monitor the type in service and ensure the ongoing validity of the Type Certificate, by investigating issues and providing corrective actions where required. The initial certification of a type establishes the known and understood level of safety inherent in the standards against which it was certified. Through the life of the type, latent hazards within the certified design, not identified during initial certification, may emerge requiring some action to address. Similarly, the use of the aircraft may vary and new designs be incorporated. Regardless, the MTCH has the high level objective to maintain the level of safety intended during initial certification.

Australian Context

7.4.1.5 The MTCH must account for the unique Defence context where the MTCH is not the OEM of the type and noting that the DASR are an amplification of the broader Work Health and Safety[41] obligations for the Defence aviation environment. In this context, the MTCH is the steward of the Defence type in service. To fulfil this role:

1. The MTCH should be broadly aware of all historic and emerging hazards relevant to their type[42]. This awareness requires:

   i. The collection of relevant aviation safety information (occurrences etc.) from within the Defence aviation system;

Superseded

ii. The collection of relevant aviation safety information (occurrences, service bulletins, airworthiness directives etc.) from operators and authorities of similar types; and

iii. Consideration and conduct of additional verification activities(such as test programs) to generate further data independently and as necessary.

2. The MTCH is to lead the risk management of the type for the life of type, from initial certification to withdrawal from service. This leadership includes:

i. Ensuring operators are made, and remain, aware of the hazards extant in their type;

ii. Ensuring that essential risk controls (both technical and operational) pertaining to the safety of the type are, and remain, effective;

iii. Leading local efforts to eliminate or further minimise known hazards;

iv. Influencing external organisations (such as OEMs, joint user groups, co-operative partnerships etc.) to eliminate or further minimise known hazards.

MTCH Structure

7.4.1.6 To support these safety objectives, the MTCH organisation is broadly structured around two key systems, as detailed in Figure 4. These systems are responsible for the interactions regulated by DASA and are required elements of the MTCH supporting organisation.[43] They are:

a. The Safety Management System (SMS). This system ensures that the MTCH will collect operational data, analyse that data, investigate potential safety concerns and provide corrective actions.

b. The Design Assurance System (DAS). This system provides products (for example Service Bulletins correcting deficiencies, publication updates etc.) to operators of the Type.

Superseded

Figure 4: Safety Structure pyramid

7.4.1.7 Note that the safety management and design assurance systems are generic and are broadly applicable to all MTCH structures and implementations noting their varying constructs. It is likely that in implementing the systems, each MTCH through their partner organisation will employ business processes specific to their context. For example, the MTCH may rely upon long standing Defence engineering processes such as Technical Information Review, System Safety Working Groups and Configuration Control Boards to achieve the SMS intent. Similarly, the DAS of a foreign design organisation may not be entirely aligned with the requirements described in DASR 21.A.239 invoking the need to utilise Authority recognition arrangements.

7.4.1.8 Each organisation that holds a Type Certificate will be different and the model outlined in Figure 4 will not be a one-size fits all construct. It is appropriate that each organisation will implement these functions with different size, scale, or complexity, dependent on their need. For example, a CDA

Superseded

may rely on a large portion of sub-contractor products from civil aircraft OEMs operating under legislated civil safety constructs, and thus will not require a large compliance verification element.

MTCH Responsibilities

7.4.1.9 In the Australian Defence context, the government organisation holding the MTC is usually relatively small and is supported by one or more other organisations (contractors, foreign Defence organisation, OEMs etc.). As a result, responsibility for the conduct of MTCH obligations is often vested with these support organisations. This has led to confusion regarding accountabilities. To clarify:

a. Regardless of the organisational construct, the government organisation is the MTCH, and is accountable for all activities undertaken by its partners with respect to the obligations of the MTCH.

b. As such, it is unlikely that a passive compliance assurance relationship between the government organisation and its partners will suffice. DASA needs to be assured that the MTCH is able to meet its obligations – this may require the government organisation to lead key MTCH activities and be active in resourcing, prioritising, and implementing MTCH activities to ensure continued airworthiness and supporting safe operation of the type by the operator.

Eligibility to hold an MTC

7.4.1.10 A government organisation can be eligible to hold an *MTCH* under one of three regulatory provisions when applying for an MTC:

a. DASR 21.A.14(a). This provision is applicable where the government organisation has demonstrated its capability by holding a Military Design Organisation Approval (MDOA), and thus meets the requirements of DASR Subpart J and is capable of performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources.

b. DASR 21.A.14(b). This provision is an exception to subpart (a) where the organisation has no demonstrated capability, but may be able to obtain an MDOA in the future, and thus alternative procedures can be used in the starting phase as an organisation moves toward an MDOA or where there are limited duration design activities that may be required (such as initial certification of a platform).

c. DASR 21.A.14(c). This provision is an exception to subparts (a) and (b) where the government organisation is not capable of meeting the requirements of Subpart J and/or performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources. In this instance, the government organisation is entirely reliant upon partners to meet the requirements of Subpart J.

Initial Assessment of MTCH capability

7.4.1.11 In the Defence context, assessment of the capability of the MTCH occurs in parallel to certification of the aircraft type, but must be completed before a Type Certificate can be awarded to the MTCH. DASA assessment of MTCH capability will include:

Superseded

a. An initial assessment of the organisation's personnel, processes, resources and support arrangements to establish that the MTCH will be able to perform/carry out the MTCH obligations outlined in DASR 21 and that the processes are present and suitable.

b. Supplementary on-site activities such as observing System Safety Working Groups, or reviewing Failure, Malfunction, and Defect data collected, in order to establish that the organisation is operating and effective.

c. An assessment of the MTCH Type Continued Airworthiness Exposition (TCAE). The TCAE describes all MTCH arrangements in order to execute the holder obligations and maintain the integrity of the type certificate. The broad content of the TCAE shall include, but is not limited to the description of the MTCH framework, design support arrangements, processes, procedures, governance, resources, and MAO/CAMO interfaces in place to meet the regulatory intent for the platform. In addition, the TCAE should include a detailed compliance matrix explicitly describing their arrangements in place to execute each MTCH obligation. The TCAE is the appropriate document where nuances particular to the platform and/or MTCH arrangements shall be described for Authority awareness and/or proposed alternative means of compliance.

MTCH Oversight & Enforcement

7.4.1.12 Oversight and Enforcement on the MTCH will be conducted by DASA as assurance activities in either a routine or a targeted format. The activities will have the objective to assess a MTCH organisation in their execution of MTCH obligations and functions. The scope of the assessment may involve any of the explicit and/or implicit obligations and may be a result of feedback received to warrant an assurance activity. Findings will be issued for non-compliances; however, the DASA team carrying out the assessment also looks to provide outcomes aiming to improve the overall effectiveness of the MTCH organisation. Oversight and enforcement on the MTCH arrangement will be based on the MTCH executing their obligations in accordance with the regulatory intent and their TCAE.

7.4.1.13 Further guidance on the DASA oversight and enforcement framework is provided in DASP Vol 3, section 4-1-5

MTCH Obligations

7.4.1.14 Within the DASRs the MTCH have the following obligations.

DASR 21.A.3A – Failures Malfunctions and Defects

7.4.1.15 This has three aspects which must be undertaken:

1. DASR 21.A.3A(a). Have a system for the collection, investigation and analysis of data relating to failures, malfunctions, defects or other occurrences, which cause or might cause adverse effects on the airworthiness of the product.

b. DASR 21.A.3A(b). Report to DASA occurrences, which may result in an unsafe condition.

c. DASR 21.A.3A(c). Investigate the root cause of occurrences and implement actions to eliminate or otherwise minimize any resulting hazards and their associated risks

Superseded

SFARP. If DASA finds action is required to correct the deficiency, the MTCH shall submit the relevant data to DASA.

7.4.1.16 **Reporting to DASA.** Where the MTCH assesses that an occurrence of a failure, malfunction or defect "may result in an unsafe condition[44]" that occurrence must be reported to DASA. Note this is a more limited and very specific subset of all occurrences that must be collected and considered by the MTCH. For these 'reportable occurrences' the MTCH must also report the results of MTCH investigations and any proposed action by the MTCH to DASA.

7.4.1.17 **Investigate and implement actions.** In the event that an unsafe condition may exist, the MTCH is obliged to take appropriate actions and be pro-active to eliminate and/or minimise the associated risks so far as reasonably practical. DASR 21.A.3A does not require the MTCH to consult DASA for review or approval prior to initiating any analysis, investigation and/or remediation actions. DASA provides additional, external and independent assurance of the actions of the MTCH but does not lead the MTCH in satisfying DASR 21.A.3A.

7.4.1.18 Further guidance on Occurrence reporting is provided in DASP Vol 3, section 7-4-2 and section 6-3

DASR 21.A.3B Airworthiness Directives

7.4.1.19 Where DASA determines an Airworthiness Directive (AD) is required for mandating actions for remediating an unsafe condition the MTCH must:

1. propose appropriate corrective actions and/or inspections

b. provide operators of the type all data required to comply with the AD

c. provide solutions/data to DASA to correct the deficiency and restore aircraft safety. This may include additional data to that provided under DASR 21.A.3A, specifically to support the release of an AD.

7.4.1.20 DASA's decision to release an AD may occur immediately following an occurrence or many weeks, months, or even years later. Per paragraph 7.4.1.17, the MTCH is to proceed with actions to eliminate the hazard or minimise the risks independently of DASA. This provision exists to support DASA mandating action proposed by the MTCH, not to direct the MTCH in the execution of their role.

7.4.1.21 Further guidance on Airworthiness Directives in the ADF context is provided in DASP Vol 3, section 7-4-3

DASR 21.A.4 Coordination between Design and production.

7.4.1.22 The MTCH shall coordinate between design and production organisations, to provide production data, as well as receive failure/malfunction/defect data from production organisations.

7.4.1.23 Where whole aircraft, parts and/or modification kits etc. are being produced, the MTCH arrangements are to ensure that the design and produced article align. For example, if the design is changing (materials/dimensions/finishing etc.) then that information will be provided to the organisation producing the item. Similarly, there cannot be changes to the item being produced without the knowledge of the MTCH and/or the responsible design organisation supporting the platform. Finally, this agreement must ensure the communication of occurrences, especially from the production organisation to the MTCH and/or their design organisation.

DASR 21.A.42 Integration

Superseded

7.4.1.24 The MTCH shall be responsible for the integration of Products, Weapons and other Systems onto the aircraft type.

7.4.1.25 This requirement places the obligation on the MTCH to consider the impact to airworthiness on integrating products, weapons or other systems, onto the aircraft. As the MTCH is also the only organisation eligible to apply for a major change to the type, the DAS of the MTCH (in cooperation with their partner organisations) must be sufficient to enable this. This obligation is not limited to aircraft components, but as expanded upon in Paragraph 7.4.1.49 for role equipment as well.

DASR 21.A.55 Record Keeping

7.4.1.26 The MTCH shall hold all relevant design information necessary to ensure the continued airworthiness of the type and make this available to DASA as required.

7.4.1.27 In the Defence context, the MTCH will not be the OEM, and the regulations cannot assume the MTCH created the type design data. Thus, this regulation ensures that the MTCH can access all data necessary to support the type design and ensure that major changes to the type continue to meet the appropriate airworthiness requirements.

DASR 21.A.57 Manuals

7.4.1.28 The MTCH shall produce, maintain and update master copies of all manuals required by the TCB and provide copies, on request, to DASA.

7.4.1.29 A manual under this regulation is part of the type design considered during type certification. It follows that any manual assessed during certification is therefore required by the TCB under this regulation. Such manuals contain content critical to keep the type airworthy or to operate the type safely within its designed limits. An example of a manual is the Aircraft flight manual, an engine manual[45] or a propeller manual[46].

7.4.1.30 For the purpose of initial certification, the MTCH is to provide manuals applicable to the ADF type. Thus, manuals produced for aircraft/products certified under other airworthiness authorities must be evaluated prior to releasing under the DASR. For the purpose of maintaining initial airworthiness in line with OEM issued updates, the MTCH must maintain and update master copies by enabling changes to be evaluated. Prior to promulgation, such change proposals will;

a. consider applicability to any unique ADF aspects or environment.

b. classify the content being considered.

7.4.1.31 The regulation implies that the MTCH will execute the obligation in a timely manner commensurate to the (safety) criticality of the update and any OEM advice.

7.4.1.32 Further guidance on the Aircraft Flight manual in the ADF context can be found in AC 008/2020

DASR 21.A.61 Instructions for Continuing Airworthiness

7.4.1.33 The MTCH shall provide the Instructions for Continuing Airworthiness (ICA) required by the TCB to operators. Changes to that ICA will also be provided to all operators.

7.4.1.34 ICA detail the methods, inspections, processes, and procedures necessary to maintain the aircraft and/or products in an airworthy condition and within the usage parameters of the aircraft

Superseded

design. ICA are an airworthiness requirement of the TCB and are prepared at initial certification by the appropriate manufacturer for each product, part or appliance. The regulation requires the MTCH to furnish the complete set of ICA to the Operator and to maintain the currency of the ICA for the ADF Type.

7.4.1.35 In the Defence context, this has particular relevance for the MTCH as often type design data will be produced under other regulatory systems and ICA will not be clearly identified. Part of the responsibility of the MTCH under this regulation is to identify and manage the ICA for a type where the OEM documentation has not explicitly referenced which instructions are ICA. This is usually where the aircraft is largely of military design, and in these cases, the MTCH will require an established relationship with the OEMs to enable clarification of maintenance documentation, when it cannot be determined from inspection what maintenance data is ICA.

DASR 21.A.44(b) - Identification of Products, parts and Appliances (DASR 21 Subpart Q)

7.4.1.36 Identification of products, parts and appliances. The MTCH shall:

a. specify how parts are to be identified.

b. specify how identification data (plates/etchings etc.) are to be handled.

c. identify critical parts.

7.4.1.37 In the context of EMAR, this obligation leverages a responsibility onto the MTCH to specify part marking schemes to their production organisations, who in the European context could be located in multiple countries. However in the Defence context the MTCH will in most cases rely on existing design organisation/production organisation arrangements in foreign countries with part identification already in place. To achieve the intent, the MTCH will appropriately leverage the OEMs part identification systems/schemes and only if applicable, specify the manner in which locally produced products, parts and appliances are identified.

7.4.1.38 Further guidance on Production in the ADF context is provided in DASP Vol 3, section 7-3-1.

DASR 21.A.44(c) - Continued Integrity of the Aircraft Structure and Propulsion System

7.4.1.39 DASR 21.A.44(c) requires that the MTCH shall ensure the continued integrity of the aircraft structure and propulsion system through ongoing monitoring and periodic assessment. Acceptable means of compliance for this regulation is provided in AMC 21.A.44(c). Chapter 6.6.3 provides extensive guidance to support application of AMC 21.A.44(c).

MTCH Obligations– Implicit Obligations

What is an implicit obligation?

7.4.1.40 In addition to the eligibility criteria listed at DASR 21.A.14(c) and the obligations listed at DASR 21.A.44(c), the regulations also include implicit obligations and expectations for the MTCH. That is, while an obligation has not been expressed, as “the MTCH must….” the operation of a regulation (or the AMC to that regulation) clearly depends upon the MTCH performing a function to ensure the continued airworthiness of the type or the safe operation of that type.

DASR 21.A.113 and 115

7.4.1.41 An applicant for a Supplemental Type Certificate (STC) shall prepare data to support the application independently or as part of an arrangement with the MTCH. In the defence context, the MTCH will hold all STCs and is therefore pivotal to enable an STC application through a ‘no technical

Superseded

objection' assessment and to provide the necessary design data. The advice provided by the MTCH shall enable for the safe integration by multiple design organisations of STCs onto the platform.

DASR 21.A.445 Subpart M Repairs

7.4.1.42 The MTCH is to support organisations performing major and minor repairs including unrepaired damage assessments by providing adequate information to enable their evaluation.

7.4.1.43 The MTCH may commission/initiate the activities through their supporting design organisation with appropriate approvals in place to design structural repairs. The MTCH will enable the provision of sufficient technical data where necessary.

AMC 21.A.709(b)(3) Approval of Flight Conditions

7.4.1.44 Flight Conditions underpin the issue of MPTFs as alternate authorisations assuring operations outside the strict requirements of the TCB and DASR M requirements and often at elevated levels of risk.

7.4.1.45 To make sure all reasonable knowledge is considered in the risk assessment supporting Flight Conditions and MPTF, the MTCH should be consulted to provide technical assessment inputs given access arrangements to type design data. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support/facilitate these assessments.

7.4.1.46 While not specifically identified, the reference to 'a design or engineering organisation suitably knowledgeable of the certified Type Design and with access to Type Design information' is usually read to mean the MTCH or OEM.

GM M.A.301(a)(2).2 Credible Data

7.4.1.47 Where operations are not at elevated levels of risk, but a defect remains preventing the release of the aircraft back to service, an operator may use 'credible data' for the deferral of defects in accordance with DASR M.A.301. Since the list of credible data includes type certification data, the MTCH would be a likely source of such information and be expected to provide it to operators as required. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support these assessments.

GM ORO.75 Use of Role Equipment

7.4.1.48 The MTCH is expected to support operators in the determination as to whether a piece of equipment is considered role equipment or a certified part.

7.4.1.49 Whilst the MAO has direct responsibility for integrating role equipment onto their aircraft, it is expected that they utilise technical assessments when appropriate. As the MTCH has access arrangements for assessments using type design data, the MTCH shall support the operator to ensure the part or equipment is integrated onto the type with appropriate consideration.

DASR AO.GEN.05(c) Management of Orders Instructions & Publications (OIP)

7.4.1.50 The MAO is required to have a documented agreement with the MTCH and seek MTCH support for control of air operational OIP and the use of Foreign Source Data (FSD).

7.4.1.51 This introduces an implicit requirement upon the MTCH to collaborate with the MAO via an agreement for review and appropriate approval of aviation operational OIP and FSD prior to use. This has particular relevance to the Aircraft Flight Manual (AFM). In the Defence context, the management of the AFM is complex with the one document having multiple uses and regulatory requirements. As

Superseded

a result, the MTCH shall be pivotal to ensure aviation operational OIP and FSD activities do not inadvertently alter content critical to compliance with the type certification basis.

7.4.1.52 Chapter 6.7 of the DASP Manual Volume 3 provides further guidance for OIP.

7.4.2 Continued Airworthiness Occurrence Reporting

Introduction

7.4.2.1 This section provides guidance to Occurrence reporting (OR) in the continued airworthiness domain (for design and production). This section is subordinate to the wider OR guidance provided as part of DASP Vol 3, chapter 6.3 which describes the wider OR framework.

7.4.2.2 Under DASR Part 21, organisations holding an approval have a requirement levied onto them to collect data on, conduct investigations of and provide analysis on any Failures, Malfunctions, Defects (FMD) or other occurrences, which creates or has the potential to create an unsafe condition. An unsafe condition is a state where an adverse effect on airworthiness exists being the result of a compromised or potentially compromised type design. Any occurrence that is assessed to have resulted in, or may result in, an unsafe condition[47],[48] must be reported to DASA and other organisations required by the implementing regulations.

7.4.2.3 Occurrence reporting by DASR 21 approval holder(s) is an essential continued airworthiness activity and enables risks and hazards associated with the type design to be identified and addressed in accordance with DASR 21.A.3A(a). All organisations that hold a DASR Part 21 approval including (but not limited to) the platform Military Type Certificate Holder (MTCH), Subpart J design organisations, Subpart F/G production organisations are obligated to have systems in place to achieve the regulatory intent of occurrence reporting.

Collecting FMD Data

7.4.2.4 The holder organisations operating under the DASR Part 21 regulations are expected to have arrangements in place that collects technical information from a spectrum of local and international sources/networks (civil and military) relevant to their platform. This has the primary purpose to access real time (critical) design related safety information for the product/part or appliance. The technical data may be directly applicable to types operated by the ADF or may require some applicability assessment before being considered for further consumption.

7.4.2.5 Collection of FMD data either directly from the ADF fleet or indirectly from other operators also has the purpose to provide the Holders with ongoing data that can be evaluated for patterns and/or reoccurrences. Such evaluation may identify failure issues that present as disparate, but may be linked. This level of analysis has the objective to identify latent design or manufacturing defects before they are realised during operation.

Occurrence Investigations in the DASR Part 21 Domain

7.4.2.6 In the Defence context, investigations involving FMD directly attributable to the type design and/or manufacturing are conducted by the platform MTCH under obligations in DASR 21.A.3A. Under this regulation, the MTCH must with all reasonable practicality initiate appropriate levels of investigation within their design support network to determine the root cause. This may take the form of reaching back into the OEM to evaluate the circumstances and determine the likely cause. Similarly, the production organisation or the part/component OEM may be consulted where a manufacturing issue needs analysis.

Superseded

What constitutes a reportable Occurrence?

7.4.2.7 A FMD occurrence may originate from an issue identified on the ADF type or from a foreign fleet that is closely related to the ADF type. However, the immediate type design/airworthiness impacts from an FMD occurrence in the Part 21 domain are not always apparent and often requires detailed investigation to be completed. An occurrence may not be identifiable until investigation results are reported.

7.4.2.8 Similarly, there are instances where a failure, malfunction or defect, or analysis of failures, malfunctions or defects represents some level of shortfall to the type design but may not result in a reportable occurrence in accordance with DASR 21.A.3A(b) based on an assessment of the available information at that time. In these situations, the holder ought to make a judgement as to whether the shortfall constitutes a risk or not and what actions/advice is required to manage the risk (perceived or real). The Authority always encourages the community to be conservative in their judgements and provide an occurrence report - voluntary occurrence reports are an option.

7.4.2.9 In the Defence construct, the MTCH organisation is expected to receive relevant technical information (TI) from a range of sources including other operators (military or civilian, where relevant). In assessing the external TI, the MTCH must verify applicability to the ADF type and consider the ADF CRE. Once verified as applicable, a reportable occurrence is warranted satisfying any of the following conditions where the incoming technical information;

1. describes a design issue (real or potential) that leads to an unsafe condition; or
2. describes a safety concern that has a real or perceived airworthiness impact and requires some time compliance action; or
3. originates from the type OEM or Civil Aviation Authority (CAA) /Military Aviation Authority (MAA) regulator mandating an action with an accompanying risk assessment.

7.4.2.10 An occurrence on an ADF aircraft may require the outcome of an investigation before a determination can be made to report under DASR 21.A.3A. However, once the locally sourced TI is received, the same conditions of sub-paras 9a and 9b apply to determine if a reportable occurrence is warranted.

When and how to Report

7.4.2.11 Reporting occurrences to the Authority has the intent to make the Authority aware of an event that has caused or has potential to cause an unsafe condition in the current timeframe. This enables the Authority to begin their assurance function in real time and allow for intervention (where necessary) without undue delay. The reporting time period for the MTCH community is 72 hours for an occurrence once deemed reportable. It is acknowledged that the time between the actual occurrence and the MTCH being fully informed of an unsafe condition existing on their type can vary depending on many factors. Therefore, the 72 hour timeframe begins at the point where the MTCH organisation has enough information to make an informed determination of the airworthiness impact, based on the root cause (if known), type applicability, CRE considerations, etc.

7.4.2.12 The form and manner of which reportable occurrences are provided to the Authority from a MTCH organisation is via a DASR Form 44. The report shall contain (where practicable) all available information on the manufacturing or design deficiency, the results of any investigation to date, any actions they are taking or propose to take in order to correct the deficiency along with the submission of relevant data to support the actions.

Superseded

MTCH Actions to address an unsafe condition resulting from FMD

7.4.2.13 The immediate actions that the MTCH organisation may take to eliminate and/or minimise the risks associated with the type design hazard will vary on a number of factors. However, the likelihood/consequence risk assessment will ultimately dictate the level of attention, timeliness, advice and resources that are attributed to the actions. Actions taken by the MTCH to address an unsafe condition should never rely on an Authority decision gate to implement.

7.4.2.14 The Authority will review the occurrence details and MTCH actions to gauge that the risk to aviation safety has been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) by the MTCH. This is not a one-off assessment; rather the unsafe condition determination by the MTCH organisation is an ongoing safety assurance activity conducted by DASA. It commences upon receipt of the occurrence and closes upon DASA's decision that the risk no longer warrants on-going monitoring by DASA.

7.4.2.15 Where the Authority does not have confidence that the design hazard has been eliminated or otherwise minimised SFARP, or if addressing the hazard requires development of a modification and subsequent fleetwide incorporation, then the DASA Airworthiness Directive (AD) process under DASR 21.A.3B may be invoked.

Structures and Propulsion Systems Guidance.

7.4.2.16 Structures and propulsion system specific considerations for the collection, investigation and analysis of failure, malfunctions, defects and other occurrences are addressed in AMC1 21.A.3A(a). Supporting guidance can be found in Chapter 6.6.3.

7.4.2.17 Specific guidance regarding risk analysis for propulsion systems (as could be used to develop the proposed corrective action(s) for a design- or manufacturing-related unsafe condition) is contained in Annex E to Chapter 7.2.

7.4.3 Airworthiness Directives (AD) in the DASP

Introduction

7.4.3.1 An Airworthiness Directive (AD) is *'a document issued (or adopted) by the Authority which mandates actions to be performed on an aircraft to restore an acceptable level of safety, when evidence shows that the safety level of this aircraft may otherwise be compromised'* [50]. Therefore, an AD is a key mechanism available to DASA to communicate mandatory action, in instances when an unsafe condition is determined to exist in an aircraft (and is likely to exist or develop in other aircraft) as a result of a deficiency in an aircraft's type design or conformance thereto.

7.4.3.2 This chapter sets out guidance for the use of ADs in the DASP. The guidance leverages civil practice, and expands on the regulatory criteria for the issue of an AD and key elements to execute the policy for the Defence aviation context.

Occurrence Reporting and Airworthiness Directives

7.4.3.3 Whilst Defence-registered State aircraft are type-certified within the DASP (via the issue of a Military Type-Certificate (MTC)), and individual aircraft that conform to that type are awarded a Military Certificate of Airworthiness (MCoA), this is not a guarantee of enduring safety from a continued (and continuing) airworthiness perspective. This therefore necessitates that the potential for any unsafe condition (that may arise in-service) must be carefully monitored and managed.

Superseded

7.4.3.4 Further to Chapter 7.4.2 (Continued Airworthiness Occurrence Reporting), respective Approval Holders[51] under the DASP have certain obligations[52] to DASA for the identification, communication and rectification of safety-related issues. DASA's role is to independently assure that the actions of the regulated community, in response to reportable/reported in-service occurrences affecting Defence-registered aircraft, are commensurate with the safety risk, and credible and defensible. This directly supports continued assessment of the validity of DASA-issued MTCs (/MSTCs) and/or MCoAs, and in certain instances, DASA's oversight of safety-related occurrences will need to consider if a DASA-issued AD is necessary to assure the safety of Defence aircraft (by explicitly approving and mandating the required corrective action to address an unsafe condition).

7.4.3.5 The nature of these occurrences, and the attendant severity and risk, vary considerably. In a practical sense, not every reported occurrence will (or should) result in an AD. In certain situations, it is entirely appropriate that lower-level safety-related issues reported to DASA by a sustainment enterprise (under DASR 21.A.3A) are just monitored (until defined closure criteria is met), if they do not actually constitute an unsafe condition *perse*.

Unsafe Condition Assessments (UCAs)

7.4.3.6 During the conduct of DASA's 'spectrum of assurance' for reported occurrences, the airworthiness impact to either the type, or individual aircraft of that type, must be considered. In every instance, what is unequivocally required is the determination of whether an unsafe condition exists (or not). Therefore, investigations and assessments conducted by Approval Holders within the regulated community must consider whether an unsafe condition exists; for this is not only DASA's function, but a shared responsibility. DASA's role is to be engaged with Approval Holders and determine/confirm[53] whether (or not) an unsafe condition exists (based on reports, investigations and assessments by, and engagement with, the regulated community[54]). DASA should generally not be conducting the UCA itself; for this is best-placed with respective Approval Holders[55] under DASRs (based upon type knowledge and understanding). That said, DASA always reserves the right to do so (if required).

Unsafe Conditions

7.4.3.7 Whilst DASR 21.A.3B(b) provides AMC and GM for what constitutes an unsafe condition, practical application is not always straight-forward in every instance, for discerning (and agreeing) which conditions are truly unsafe requires the exercise of professional judgement (by both Approval Holders and DASA). Moreover, the determination of what is truly an unsafe condition cannot be defined for every situation and scenario, for each platform (and DASA's assurance thereof). Generic aspects that will need to be considered are the:

1. nature of the deficiency/condition (and the associated consequence/likelihood of hazards)
2. elevated level of risk attributed to the deficiency (above that inherent in the type-certified design)
3. urgency for required mitigations, inspections and/or corrective action
4. corresponding risk exposure period of (and any complexity within) required terminating action to resolve the deficiency.

7.4.3.8 It is important to understand that DASA (as the independent regulator) is not, and should never be, on the critical path to manage the day-to-day safety of aircraft. Under the DASRs (and the

Superseded

WHS Act 2011), regulated entities have obligations to ensure safety is not compromised and to alert DASA as the situations warrants. Therefore, regulated entities should not wait for DASA to provide a position before taking any appropriate action in response to an identified unsafe condition.

Criteria for issue of an AD

7.4.3.9 During the conduct of DASA's assurance of reported occurrences, and regardless of whether the actions of the Approval Holder are deemed to be credible and defensible, DASA will consider (on a case-by-case basis) the issue of an AD[56] when:

1. an unsafe condition has been determined by the Authority to exist in an aircraft, as a result of a deficiency in the aircraft, or an engine, propeller, part or appliance installed on this aircraft.
2. that condition is likely to exist or develop in other aircraft, including engine, propeller, part or appliance installed on those aircraft that may be affected by this unsafe condition.

7.4.3.10 In these instances, the 'safety benchmark' for the type or individual aircraft has (or potentially has) been compromised, and the continued validity of an aircraft's MCoA (and/or MTC) may be brought into question (via the presence of an unsafe condition). Therefore, DASA-approved inspection and/or remediation is necessary to restore an acceptable level of safety, via the issue of an AD.

7.4.3.11 Given an AD may be applicable to either all aircraft of a certified Defence type, or only certain individual aircraft of that type, ADs are by definition either type- or tail-related, issued to address identified in-service deficiencies pertaining to continued or continuing airworthiness (and potentially a hybrid thereof).

Purpose of an AD

7.4.3.12 The fundamental purpose of an AD is to:

1. approve corrective action and/or required inspections (proposed by the relevant Approval Holder under the DASRs)
2. communicate the presence of an unsafe condition affecting a Defence type and/or individual aircraft (that endangers flight safety) to the MAO/CAMO
3. mandate required action by the MAO/CAMO[57].

7.4.3.13 Regulated community compliance with DASA-issued ADs (to restore an acceptable level of safety) is mandatory within the DASP[58], which invokes the implementation of required action from a continuing airworthiness perspective under DASR Parts M and 145 (including military aircraft airworthiness review activities under DASR M Subpart I)[59].

Defence aviation context and considerations

7.4.3.14 Since (EMAR-based) DASRs have a civil lineage – albeit adapted for the military context – fundamental aspects underpinning the intended application of DASR 21.A.3A and .3B are derived from ICAO-based concepts and civil regulations. That said, whilst DASA's assurance functions for reported unsafe conditions and the corresponding use of ADs within the DASP are *prima facie* the

Superseded

same, the combination of a number of inter-related features of the Defence aviation context requires additional policy considerations. In particular, how to pragmatically deal with the reality of:

1. sovereign government MTC Holder arrangements, that typically only coordinate the execution of holder obligations[60] and almost entirely leverage and recognise a much-broader (initial/) continued and continuing airworthiness management framework in place for a foreign type the same as, or similar to, the Defence type.
2. the general lack of centrality of the OEMs (as the original 'Approval Holders' for design and production that are not directly regulated under DASRs).
3. the nature of DASA as a relatively-small 'validating' Authority when issuing sovereign MTCs for Defence-registered aircraft (and most major changes to type-certificate (TC) thereafter).

7.4.3.15 Therefore, there is a strong reliance on the sustainment support arrangements established by CASG SPOs for the ongoing execution of sovereign MTC Holder functions required by DASR 21.A.3A and .3B [61], either with the actual OEM(s) and/or by leveraging the framework and actions of a foreign Civil/Military Aviation Authority (C/MAA), to support the identification and management of unsafe conditions applicable to Defence aircraft.

Sovereign MTC Holder support arrangements

7.4.3.16 The various in-service sustainment support arrangements implemented by CASG SPOs to support respective MTC Holder obligations, have differing degrees of OEM and/or foreign C/MAA involvement. Therefore, the extent to which sovereign MTC Holders leverage the initial, continued and continuing airworthiness management framework of a DASA-recognised foreign C/MAA, in direct support to the management of Defence types, will strongly influence the extent of sovereign decision-making required by MTC Holders (in the determination of required sovereign action to address an unsafe condition). In particular, those support arrangements that include a foreign C/MAA that acted as the primary certifying authority for an aircraft type similar to, or the same as, that operated by Defence.

7.4.3.17 Moreover, given the much-larger global fleets being oversighted and assured by respective foreign C/MAAs, the reality is that the vast majority of FMD/occurrences, assessments of any associated unsafe conditions, and the corresponding mandatory actions (to restore the safety benchmark) will be determined overseas (generally without sovereign MTC Holder and DASA involvement). However, FMD/occurrences for Defence aircraft do still arise, which may not be addressed by foreign type management arrangements. In particular, any design or part production deficiency that may be attributable to a military design or production organisation (MDO/MPO) approved by DASA under the DASP[62]. In these instances, the full intent of DASR 21.A.3A and .3B is required by respective Approval Holders and DASA.

7.4.3.18 Therefore, the degree of 'type management sovereignty' for Defence-registered aircraft – and therefore the extent to which sovereign decisions are required – will commensurately govern DASA's assurance of unsafe conditions affecting Defence-registered types (and the oversight of corresponding actions). That is, when more airworthiness-related 'type management' activity and decision-making is conducted in Australia, the greater DASA's involvement will be in the application of DASR 21.A.3A and .3B.

Sovereign Approval Holders propose required action to support the issue of an AD

Superseded

7.4.3.19 When DASA decides that an AD needs to be issued within the DASP[63], the MTC Holder organisation (and/or other relevant Approval Holders under DASRs) should propose[64] appropriate corrective action and/or required inspections to DASA. Given sovereign MTC Holder organisations are primarily a coordinating (and not a design) organisation, OEM input should be considered mandatory, as well as C/MAA oversight and involvement (as appropriate)[65]. This therefore connects the original 'applicant' and the 'holder' of the design, as well as the primary certifying authority (that established the safety benchmark with the original 'OEM applicant' within their airworthiness management framework), which therefore executes the actual intent of DASR 21.A.3A and .3B.

7.4.3.20 Upon receipt, DASA's independent safety assurance function is to approve the holder's proposal, including required inspection(s) and/or rectification interval(s), and the associated risk exposure. DASA will engage with the Approval Holder and amend the proposal, if and as required. When satisfied that the AD's content (as proposed by the holder) provides appropriate terminating action to eliminate the unsafe condition (and to restore the 'safety benchmark'), and the associated risk during the exposure period will be otherwise minimised SFARP, DASA will issue an AD accordingly[66]. In doing so, DASA is explicitly approving the corrective action to address the unsafe condition and the corresponding exposure period.

Foreign ADs (or equivalent)

7.4.3.21 When sovereign MTC Holders receive relevant foreign ADs (or equivalent[67]) for assessment, and report this to DASA[68], the DASP is the beneficiary of relevant C/MAA assurance of the same/similar type to that operated by Defence. This broadly meets the intent of DASR 21.A.3A and .3B; for the 'problem' and the 'solution' is provided, that usually leverages the inputs of the actual OEM and recognises what the relevant C/MAA deemed mandatory. Therefore, a sovereign MTC Holder will need to consider the following:

1. the applicability of a foreign AD (or equivalent) to a Defence-registered type.
2. the availability and suitability of controls and corrective actions provided by a relevant foreign C/MAA that can be 'adopted' (including whether full (or partial) compliance and implementation is intended).
3. the extent to which a Defence type's Configuration, Role and Environment (CRE) considerations require necessary/appropriate variations to adapt the content of a foreign AD (or equivalent); and in particular, necessary/appropriate variations to risk controls, terminating action(s) and/or implementation timeframes/risk exposure periods.
4. the need to amplify other foreign-source safety advice for required actions and timeframes to rectify an unsafe condition[69].

7.4.3.22 Given the 'sovereignty' of DASA-issued MTCs (/MSTCs) and MCoAs for Defence-registered aircraft, the assessment of unsafe (or potentially unsafe) conditions identified for foreign aircraft that may affect Defence aircraft is fundamental to support the ongoing validity of these DASA-issued authorisations. However, it is important to note that these foreign ADs (or equivalent) are not automatically applicable and mandatory under the DASP, and despite the AD definition cited within DASR 21.A.3B(a), there is no regulatory mechanism within DASR 21 to 'adopt' foreign ADs (or equivalent)[70]. Therefore, whilst the regulated community may indeed decide to implement the required actions of a foreign AD (or equivalent) as a 'credible and defensible' means to address an unsafe condition for a Defence-registered aircraft, DASA nonetheless requires that applicable critical

Superseded

foreign safety-related information (and in particular, that issued by the primary certifying authority) is formally 'brought into the DASP' and actioned accordingly. The only way for this to occuris for DASA to issue an AD in the DASP[71], to mandate the same/similar action for Defence-registered aircraft.

Foreign ADs (or equivalent) issued by the primary certifying authority are mandatory when applicable to Defence-registered aircraft

7.4.3.23 DASA functions largely and almost exclusively as a 'validating authority', when issuing a sovereign MTC to establish the initial airworthiness of Defence types (and approving most major changes to TC thereafter), based upon recognition and leverage of the previous type-certification efforts of foreign C/MAAs. Similarly, the DASP should also recognise and leverage the type knowledge and understanding of the relevant C/MAA's management of continued and continuing airworthiness, for aircraft the same as/similar to Defence types.

7.4.3.24 Therefore, DASA's default policy position is that compliance with the technical content of foreign ADs (or equivalent) – issued by the primary certifying authority that DASA leveraged to underpin the award of a DASA MTC – is mandatory (when applicable to Defence-registered aircraft). If the primary certifying authority deemed a condition unsafe, then in near-all instances, their required mandatory action to address compromised airworthiness should be equally-applicable to Defence aircraft (notwithstanding any unique CRE considerations in certain situations).

7.4.3.25 The act of 'validating' the applicability and corresponding mandatory action within a foreign AD (or equivalent) for a Defence type is pragmatic and efficient. DASA issue of an AD when 'validating' a foreign AD (or equivalent) will in most instances be as simple as placing a DASA AD cover page on the foreign artefact(s) (if no changes are required), which may also include any minor adaption (that does not change the intent[72]), and promulgating this to the relevant MAO/CAMO for implementation.

7.4.3.26 Whilst this policy consideration would likely cater for many foreign ADs (or equivalent), DASA acknowledges there may be exceptions and complexities in certain situations, that require professional judgement. In particular, there may be compelling reasons why applicable foreign ADs are not intended for compliance (or only partial compliance), or there are substantial required and/or proposed variations on account of Defence CRE considerations (or otherwise) that will alter the intent and/or attendant risk. This will therefore require a much-greater degree of engagement between the relevant Approval Holder and DASA, to agree the content of the DASA AD (if issued).

Traceability with required mandatory action issued by the primary certifying authority

7.4.3.27 DASA's expectation is that sovereign MTC Holder arrangements implemented for each Defence type will monitor safety-related information from respective OEMs and C/MAAs (including other operators), to support required obligations under DASR 21.A.3A and .3B) (and DASR 21.A.44). In particular, this should include the documented methods and means to record the traceability of all actions mandated by the primary certifying authority[73], and the alignment with that implemented within the DASP.

7.4.3.28 For civil-derivative military aircraft, certified by a foreign MAA yet underpinned substantially by a foreign CAA's certification of the 'green aircraft', the applicability of foreign civil ADs would ideally be assessed and actioned by the relevant foreign MAA (that oversights the overseas fleet the same as/similar to a Defence type), but this may not always occur as expected. Therefore, due consideration should also be given to record the traceability (or otherwise) to Emergency or Alert Service Bulletins (issued by civil OEMs) and ADs (issued by the relevant CAA) that may not be mandated by the relevant MAA.

Superseded

Platform DoSAs may issue ADs (for validated foreign ADs (or equivalent))

7.4.3.29 When a DASA AD needs to be issued within the DASP, and in instances where the relevant Platform Delegate of the Safety Authority (DoSA) is not developing the technical content therein – but rather only validating that a foreign AD (or equivalent) is applicable to, and should be mandatory for, Defence-registered aircraft – the Platform DoSA is the most-appropriate release authority (for, and on behalf of, DASA[74]). This is pragmatic and efficient, and is the most-responsive and agile arrangement (particularly for exigent circumstances), which is also aligned with a Platform DoSA's safety-related role and functions.

7.4.3.30 Moreover, this also fully aligns with the distributed model established for each Defence type to monitor, review and assess foreign safety-related data that may impact Defence aircraft, and should be invoked to the greatest extent possible[75]. The only caveat is that if the risk exposure is DHRM MEDIUM (or higher) until terminating action is accomplished, this should default to DASA (yet supported and staffed by the Platform DoSA).

AD issue in the absence of a foreign AD (or equivalent)

7.4.3.31 For the Defence aviation context, and in addition to the aforementioned, DASA will also consider (on a case-by-case basis) the issue of an AD in the DASP, in advance of a primary certifying authority's release of a foreign AD (or equivalent). DASA's expectation is that whenever continued operations are intended with protracted exposure to a (post-mitigation) residual risk to airworthiness – on account of an unsafe condition associated with catastrophic and hazardous consequences that cannot be eliminated or fully-controlled immediately by design – an AD in the DASP should be issued. This will usually manifest in situations where foreign MAAs have conducted a risk assessment and recommended initial treatment/controls for continued operations (due to the presence of an unsafe condition), yet the design solution and the attendant foreign AD (or equivalent) does not (and will not) exist for a significant period of time (to detail required terminating action and compliance timeframe to restore an acceptable level of safety).

7.4.3.32 This therefore sets a default position for compromised airworthiness associated with long-standing exposure to an elevated level of residual risk (whilst design solutions are being devised). In this instance, a DASA-issued AD therefore provides a means to formally communicate instances of elevated levels of risk within the DASP (bounded by a date for terminating action and compliance to be implemented), which will also provide improved Command awareness, visibility and traceability of required actions.

DASA-issued ADs associated with elevated risk should be underpinned by 7-Step Risk Management

7.4.3.33 By definition, continued (post-mitigation) operations with an unsafe condition that cannot be eliminated immediately constitutes an elevated level of risk to airworthiness during the exposure period, until terminating action detailed within an AD restores an acceptable level of safety.

7.4.3.34 Therefore, consistent with a MAO's DASR and WHS obligations, the elevated level of risk attributed to a deficiency (above that inherent in the certified design) and the corresponding residual risk exposure period should be underpinned by a MAO's Risk-Decision Brief (RDB). In particular, for instances that:

1. deviate significantly from compliance requirements with 'validated and adopted' foreign ADs (or equivalent).

Superseded

2. where there is markedly-elevated risk being retained, and the corresponding design solution required to address the deficiency will not be available for an extended period of time[76].

7.4.3.35 This policy position will primarily affect military aircraft (and likely not affect Defence-registered aircraft that are ostensibly civil). The need for an RDB for lower-level risks should be considered on a case-by-case basis (aligned with a MAO's Safety Management System (SMS)), and may not be required at all – particularly for instances where DASA leverages and 'adopts' foreign CAA ADs with no variations to risk controls and exposure periods.

7.4.3.36 MAO RDBs (that underpin DASA-issued ADs) will need to consider and disposition all available and suitable technical and operational risk controls, to support appropriate operating conditions and/or limitations. This therefore ensures and requires that MAO Hazard Tracking Authorities (HTAs) and Risk Management Authorities (RMAs) are suitably-engaged for airworthiness issues, and the corresponding DASA AD is a mechanism to communicate and document DASA's independent safety assurance for an agreed risk management strategy.

7.4.4 Other Design Approval Holders

7.4.4.1 This section addresses other design approval holders under the DASR framework. This primarily covers any Australian Military Technical Standard Order Authorisations (AUSMTSO) under DASR 21 Subpart O. AUSMTSO Authorisations are not expected to be widely used in the Defence regulatory framework and will only be issued by exception. The Authorisation is common in the civil domain under the term Technical Standard Order (TSO) and TSO Authorisations and encourages competition across the industry through novel design which does readily translate across into the military domain.

7.4.4.2 An AUSMTSO under DASR is considered equal in concept to the civil use where a TSO is defined as a minimum performance standard for specified materials, parts, and appliances used on civil aircraft. An AUSMTSO Authorisation enables the holder to manufacture a material, part, or appliances to a TSO standard. Receiving an AUSMTSO Authorisation is both a design and production approval, but importantly does not extend to installing and using the article in the aircraft.

7.4.4.3 In the civil domain, a TSO Authorisation enables the manufacture of articles that may be installed on an aircraft only after showing that the article meets the specific airworthiness requirements (certification basis) of a particular aircraft model. Receiving a TSO Authorisation verifies that an article meets a minimum performance requirement independent of the article's intended installation on an aircraft. Under the DASR, using the AUSMTSO Authorisation will be more nuanced and will not be issued on a competitive basis.

7.4.4.4 Common articles on modern day aircraft including Military aircraft that have their genesis through the civil TSO provisions include Embedded GPS and INS Units (EGIs), Auxiliary Power Units, Tires, seat belts, crew oxygen masks, seat assemblies, brake assemblies, antennae, various instrumentation, cargo containers along with many more. Under the DASR framework, the use of AUSMTSO has been very limited.

7.4.4.5 Under DASR 21, Subpart O, the holder of an AUSMTSO has obligations to ensure that the article continually conforms to its design and is manufactured accordingly per regulations detailed under production (Subpart G). The holder is also subject to a number of other initial airworthiness regulations such as occurrence reporting and part marking with respect to their article. Although the Defence MTC construct results in a nuanced use, the AUSMTSO holder is required to engage with the

Superseded

aircraft Type certificate holder to integrate their article into the aircraft type or where design changes impact the integration.

7.5.1 Introduction

7.5.1.1 A Military Permit to Fly (MPTF) is a 'product authorisation' issued by DASA to aircraft that do not meet, or have not been shown to meet, the requirements of the Type-Certification Basis (TCB) and/or Military Air Operator Certificate (MAOC), but are nonetheless capable of safe flight under defined conditions and for specified purposes. An MPTF is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application.

7.5.1.2 An MPTF is a risk-based authorisation, within the suite of Defence aviation flexibility provisions provided under DASR GR.80, to facilitate military flexibility in support of a capability imperative, which is valid for a defined period of time, underpinned by a seven-step risk assessment with both technical and operational input.

7.5.1.3 Further to the overview of the Flight Conditions and MPTF authorisations provided at Chapter 5.3 Annex N, this chapter details DASR implementation of applications for, and approval of, Flight Conditions and MPTF (and the associated risk management aspects).

Audience

7.5.1.4 This chapter applies to DASR-regulated entities exercising roles or responsibilities when applying for an MPTF under DASR 21 Subpart P Military Permit To Fly. Whilst this will primarily be Military Air Operators (MAOs) – including Continuing Airworthiness Management Organisations (CAMOs) and service providers – it also extends to any organisation engaged to assist with the preparation of the application, such as: Military Type-Certificate (MTC) holders; design organisations (DASR Military Design Organisations (MDOs) and equivalents) and organisations involved in managing the configuration of Defence aircraft (CASG Systems Program Offices (SPOs) and Through-Life Support (TLS) contractors).

7.5.1.5 While cognisant of the above, the application for (and holding of) an MPTF within the DASR environment will almost exclusively be a MAO requirement for the subject aircraft defined within the MAOC Operations Specification (OpSpec)[77]. The MAO should therefore establish in-service procedures to implement attendant MPTF regulation and Acceptable Means of Compliance (AMC) that reflects the central role of the MAO Accountable Manager (AM) and authorised staff within the MPTF process.

Purpose

7.5.1.6 This chapter provides guidance in relation to Initial Airworthiness requirements under DASR 21 Subpart P, for developing MPTF applications, inclusive of: collating substantiation documentation; gaining operational endorsement; signing the declaration of safety; engaging with the Authority (inclusive of the Delegate of the Safety Authority (DoSA)) for approval and issue of the MPTF; and meeting MPTF holder obligations. Moreover, this chapter explains how applications for approval of flight conditions and an MPTF should follow the seven-step risk management process detailed in DASA AC 003-2018—Risk Management in the Defence Aviation Safety Program, and describes the key

Superseded

elements of safety risk management that must be implemented by organisations to ensure compliance with the Work Health and Safety Act 2011 (WHS Act).

Background

7.5.1.7 Within civilian aviation regulations, a permit to fly is predominately used to support development, certification, production and delivery of new aircraft and major modifications, and to support in-service operation outside the bounds of the Certificate of Airworthiness (CoA); such as ferry flights to a suitable maintenance venue for defect rectification or the conduct of an overdue scheduled servicing.

7.5.1.8 The use of MPTFs within the DASR context is subtly different. Design, certification and production of a new aircraft solely within a DASR MDO/MPO has not yet occurred, and flight test for development of major modifications will likely occur for Defence-registered aircraft operated by a MAO (rather than a DASR MDO/MPO at this stage). Furthermore, as recognised and afforded by DASR GR.80 Flexibility Provisions, Defence aviation requires flexibility to support capability imperatives for certain operational circumstances that would not be allowed within the civilian aviation domain.

7.5.1.9 Under normal circumstances, all Defence-registered aircraft should only be operated with a valid Military CoA (MCoA) issued by DASA. An MCoA is issued when the aircraft was shown, at the time of issue, to conform to its MTC awarded post-certification. Whilst in-service, the validity of the aircraft's MCoA is maintained by meeting the continuing airworthiness requirements of DASR M[78]. A valid MCoA represents a baseline level of airworthiness, aligning to both civil and military global conventions. Importantly, in the Defence context, an MPTF authorisation supplements, rather than replaces, the MCoA.

7.5.1.10 However, as stated, military aviation requires flexibility for Commanders to operate aircraft in certain circumstances without having met all the prescribed initial, continued or continuing airworthiness or aviation safety requirements, but are nonetheless capable of safe flight under defined conditions. In these circumstances, and without the necessary flexibility provisions in DASRs, the MAO would be unable to operate under the regulations. To accommodate Defence aviation flexibility, DASRs include provisions for issue of either of the following, to facilitate operation when the prescribed airworthiness or aviation safety requirements are not met:

1. MPTF under DASR 21 Subpart P Military Permit To Fly, which is augmented with AUS-unique AMC and Guidance Material (GM), which stipulate specific application requirements and include additional expectations for the holders of an MPTF, or
2. Command Clearance (CC) under DASR Specific Purpose Approval – SPA.10 *Command Clearance*[79].

7.5.2 Difference between MPTF and CC

7.5.2.1 The DASR SPA.10 CC provides for a similar outcome to that of an MPTF, in so far as the CC may also be used to authorise flight(s) where the MCoA's Instructions for Continuing Airworthiness (ICA) conditions are unable to be met. However, the key difference between the MPTF and CC is that the MPTF is an initial airworthiness authorisation subject to DASA approval and issue, whereas a CC is an operational authorisation via the command chain. In ideal circumstances, conditions that require an MPTF would be managed via an MPTF; however, in the event of compelling time-critical capability imperatives or emergencies, and where there is insufficient time to process an MPTF application, a DASR SPA.10 CC may be exercised.

Superseded

7.5.2.2 Regardless of whether MPTF or CC provisions are used, the operating organisation remains responsible for meeting WHS obligations to eliminate or otherwise minimise risk to aviation safety, so far as reasonably practicable (SFARP). Therefore, both the MPTF application process and issue of a CC require the MAO to exercise the seven-step risk management process detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. However, an MPTF provides the MAO with independent assurance over the discharge of their obligations and should be sought whenever reasonably practicable. Should the requirement for operation of an aircraft under DASR SPA.10 be for an extended period, an MPTF or other appropriate authorisation must replace the CC.

7.5.3 Defence use of MPTFs

7.5.3.1 Whilst DASR 21.A.701(a) provides a non-exhaustive list of examples illustrating situations when an MPTF should be used, the majority of those examples are EASA/EMAR-based, and focused more on development of aircraft design, production, delivery and initial training within an OEM organisation (operating under privilege), as opposed to in-service scenarios that are typical for Defence aviation. For the Defence context, and as outlined within GM to DASR GR.80(c), aircraft operation in the following circumstances potentially entails flight at an elevated level of risk that may require an MPTF:

1. **Prior to initial issue of an MTC and MCoA.** DASR 21 precludes the issue of an MCoA if an MTC has not yet been issued. This will typically be due to the requirement to operate new aircraft prior to completion of the type-certification programme.

2. **Aircraft operation while continuing airworthiness requirements are not satisfied.** The aircraft has been issued an MCoA and is required for operational tasking; however, any of the following continuing airworthiness requirements have not been met:

    i. a defect that cannot be deferred as it has been assessed to endanger flight safety

    ii. scheduled maintenance in the Aircraft Maintenance Programme (AMP) has not been carried out

    iii. an Airworthiness Limitation (AwL) or Certification Maintenance Requirement (CMR) has been reached

    iv. an Airworthiness Directive (AD) has not been incorporated.

3. **Aircraft not conforming to an approved design configuration for the purpose of flight test.** Installation of a yet-to-be-approved modification for flight test, in order to gather compliance demonstration evidence to support approval of a change to type-certificate (or subsequent flights prior to the design change approval being issued).

4. **Aircraft operation outside approved limitations.** The aircraft has been issued an MCoA but is intended to be flown beyond the approved operating limitations in the Aircraft Flight Manual (AFM), or outside the approved role and/or environment detailed within the MAOC OpSpec. These circumstances can arise from either operational tasking or for the purpose of flight test (to support role expansion activities).

Superseded

7.5.4 Overview of Organisational Responsibilities

7.5.4.1 The following organisations have specific responsibilities with respect to the application for, and issue of, MPTFs:

1. MAOs. MAOs are responsible for applying to DASA for the approval of flight conditions and the issue of an MPTF. They must fulfil the responsibilities of the applicant, including the conduct of a risk assessment that fully integrates all technical and operational considerations. MAOs should engage relevant external organisations in the course of preparing the application in order to effectively conduct an integrated risk assessment. These organisations may include the product's MTC holder, design organisations, CAMOs (and service providers), flight test organisations, and/or relevant maintenance organisations. All MPTFs are issued to MAOs who are then responsible for discharging the obligations of the holder of a MPTF.

2. DASA. Upon receipt of an application(s), DASA will provide independent assurance that there is evidence that the MAO met their obligations and has eliminated or otherwise minimised all risks SFARP. DASA assurance will focus on credible and defensible risk management, which provides advice to Commanders if the capability imperative has been sufficiently described and would support a decision-to-proceed with the identified Elevated Level of Risk (ELOR); however the decision-to-proceed always remains with the applicant.

7.5.5 Overview of MPTF Process and DASR Forms

7.5.5.1 The application process to obtain an MPTF is relatively straightforward, but does require clear identification of the participants and an understanding of the associated responsibilities. Whilst two separate applications are required, DASRs do not prohibit both being submitted to DASA concurrently. Relevant DASR Forms are as follows:

1. DASR Form 18b. Application for, and approval of, flight conditions that enable the aircraft to operate safely. This form is raised and submitted by an applicant to DASA. DASA approves the application and returns the approved form to the applicant.

2. DASR Form 21. Application for issue of an MPTF. Raised by the applicant and submitted to DASA. This may reference pre-existing and approved flight conditions within DASR Form 18b.

3. DASR Form 20a. Issue of an MPTF in response to a DASR Form 21 application. Raised by DASA and issued to the applicant; that is, the organisation responsible for conducting the associated flight(s) and ensuring the flight conditions are adhered to.

7.5.5.2 Further to GM to DASR 21 Subpart P, Annex A provides a 'swim-lane' flowchart illustrating the application process within organisational responsibilities. Reiterating, the approval of flight conditions is separate from the issue of an MPTF to give the applicant flexibility. Reasons include:

1. One set of flight conditions may underpin a number of MPTFs.

2. The approval of flight conditions and the issue of an MPTF may be separated in time.

3. The issue of an MPTF by a local DoSA, in instances where DASA has previously approved flight conditions that are beyond the DoSA's delegation, may improve flexibility and timeliness.

Superseded

4. The approval of flight conditions and issue of an MPTF represent different steps in the seven-step risk management process, and therefore address different WHS Act requirements.

7.5.6 Summary of the Seven-Step Risk Management Process

7.5.6.1 GM to DASR SMS.A.25(b)(2)(2.2) outlines Defence's seven-step risk management process (depicted in Figure 5), with further aviation-specific guidance detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. AC 003/2018 describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the WHS Act.

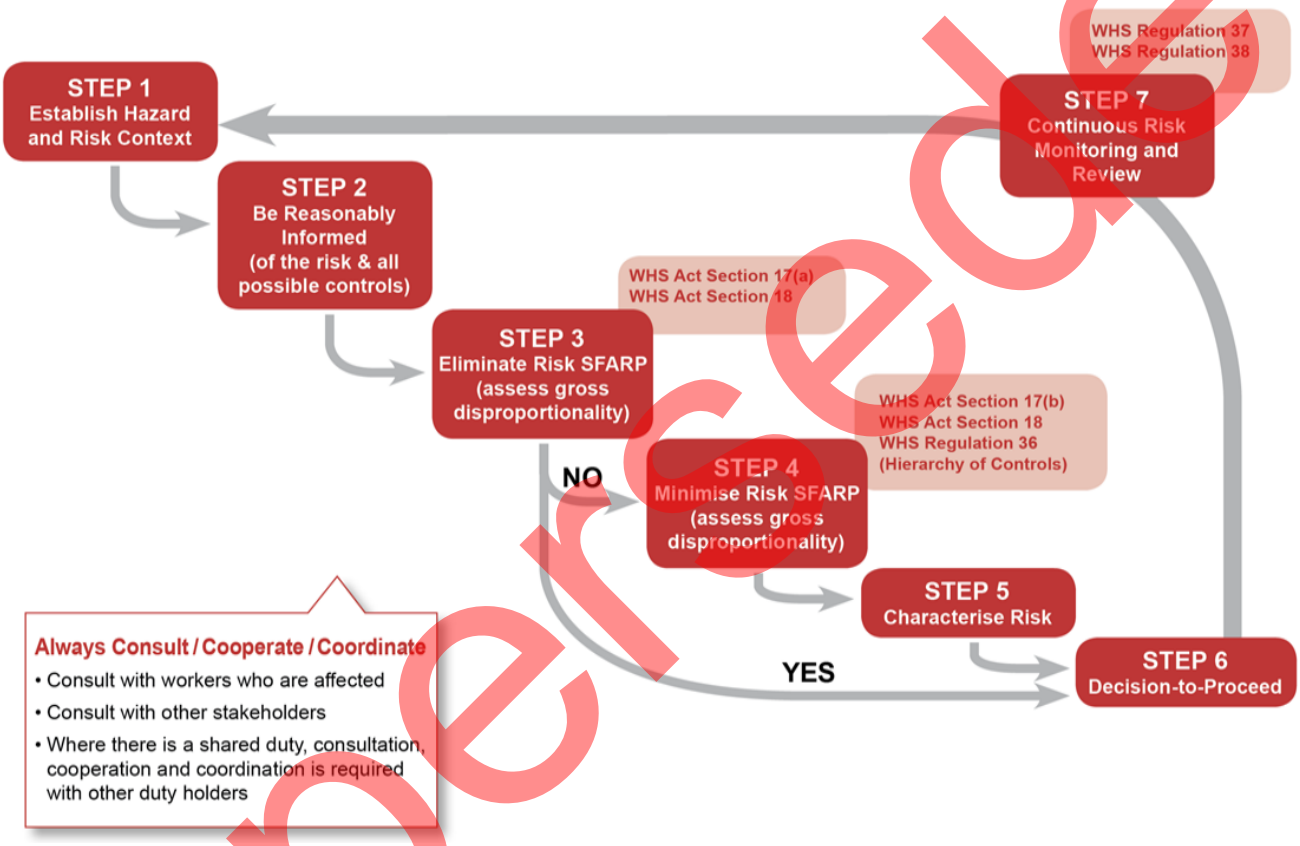

Figure 5: Safety Risk Management Process

7.5.6.1.2 DASR application forms for the approval of flight conditions and the issue of an MPTF collectively cover all of the required steps in the safety risk management process. DASR Forms 18b and 21 should summarise key information arising from the seven-step risk management process. Additional detail may be included in separate documents.

7.5.7 Application for Approval of Flight Conditions

7.5.7.1 An approved set of flight conditions underpins every MPTF, which are the risk controls required to eliminate or otherwise minimise the risk SFARP. In applying for the approval of flight conditions, the applicant should execute and document Steps 1–5 of the seven-step risk management process. A single set of approved flight conditions may be applied to several MPTFs.

Superseded

7.5.7.2 The specific application of these steps in applying for the approval of flight conditions are as follows:

1. **Step 1 – Establishing the risk context.** The applicant must define the task objective(s) including a clear strategic, operational or tactical imperative for the task and why it is necessary to fly with an ELOR. In defining task objective(s), the applicant should consider whether the task is new or existing, the discretionary/non-discretionary nature of the task and its urgency. The applicant should also identify and engage relevant stakeholders to ensure the risk assessment fully integrates all technical and operational factors. The risk context establishes the depth of risk assessment required and informs all reasonably practicable judgements. Establishing the context, also includes the duration of the activity. Retention of ELOR must be for the minimum possible duration to remain defensible within the WHS obligations and DASRs. As such, long-term MPTFs are unlikely to be defensible[80].

2. **Step 2.a – Being reasonably informed of the risks.** The applicant must proactively take steps to gain reasonable knowledge of the exact nature of all hazards and risks (both technical and operational). This may include use of existing OIP, the AFM, ICA or the provision of specialist advice from appropriate support organisations. This could include design organisations, technology or operational specialists, flight test specialists or the aircraft's OEM. There is no fixed list of who must be consulted for each application; instead, the applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context.

3. **Step 2.b – Being reasonably informed of all possible controls.** The applicant must take steps to gain reasonable knowledge of all possible controls (both technical and operational) in order to identify which ones are available and potentially suitable. Per Step 2.a, the applicant must seek relevant specialist advice where appropriate. Again, there is no fixed list of who must be consulted for each application. The applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context. The applicant must not discard any controls at this stage, as all identified controls should be used as inputs to Steps 3 and 4 in the risk management process.

4. **Steps 3 and 4 – Eliminate or otherwise minimise risk SFARP.** There is an explicit requirement to eliminate risk SFARP in the first instance and only if not reasonably practicable to do so (informed by the risk context established at Step 1), implement risk controls to minimise the risk SFARP. The applicant should systematically work through every control identified in Step 2 to determine if they are reasonably practicable to implement. The applicant must also address any additional hazards introduced by the risk controls. The integrated set of technical and operational risk controls that are reasonably practicable to implement, form the proposed flight conditions that will underpin the MPTF.

5. **Step 5 – Characterising and communicating residual risk.** The applicant must characterise the residual risk using their safety risk management system (Note: DASA anticipates the residual risk will be characterised using the Defence Harmonised Risk Matrix (DHRM) in the Defence Aviation Safety Manual (DASM), but does not mandate its use). This step must include a declaration from the applicant that the flight conditions are a set of risk controls, integrated from a technical and operational perspective, which eliminates or otherwise minimises the risk SFARP.

Superseded

7.5.7.3 Specific detail of the information and supporting documentation required to complete DASR Form 18b- *Application for Approval of Flight Conditions* is provided in the instruction sheets covering the form. See also DASR 21.A.708 and 21.A.709.

7.5.7.4 Flight Test. When an MPTF relates to flight test activity, DASRs require that flight conditions and operational endorsement must be provided by a competent MAO staff member, as determined by a DoSA-Flight Test (DoSA-FT)[81]. MAOs may apply to a DoSA-FT for a determination of competence for nominated MAO staff.

7.5.8 Approval of Flight Conditions

7.5.8.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can approve flight conditions. DASA will approve flight conditions if it has sufficient confidence that:

1. The applicant has given due consideration to the risk context, including the objectives and significance of the flying activity.
2. Elimination of the risk by restoring the aircraft to an airworthy condition IAW existing approved data, or deferring a defect, is not reasonably practicable.
3. Proposed flight conditions represent a set of risk controls that provide a credible and defensible level of safety for the flights/duration requested.
4. The applicant has appropriately characterised and communicated the residual risk.
5. The applicant has made an explicit declaration that the flight conditions, when implemented effectively, will eliminate or otherwise minimise the risk SFARP. The risk context of the application must support the depth of risk assessment undertaken and reasonably practicable judgements made by the applicant.

7.5.8.2 In assessing the application, DASA reviews the information supplied by the applicant and independently assures that it demonstrates the risk has been eliminated or minimised SFARP, and has been characterised accurately. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

7.5.9 Application for an MPTF

7.5.9.1 Applications to DASA for the issue of an MPTF are made for specific aircraft and tasking using DASR Form 21 - *Application for a Military Permit to Fly*. All applications must reference an approved set of flight conditions, or an accompanying application for their approval. DASR Form 21 supports and records the applicant's 'decision-to-proceed' at Step 6 in the seven-step risk management process.

7.5.9.2 Note, in submitting an application for an MPTF and making the decision-to-proceed, the applicant also revisits Step 1 – Establishing the Risk Context, for that application. The test of SFARP is contextual and temporal; so this return to the risk context for the MPTF application is necessary to ensure that the applicant has made the decision-to-proceed based on the characterisation of risk in

Superseded

the flight conditions and in the context defined by the MPTF application, at the time of that application.

7.5.9.3 For example, the risk context of the flight conditions may be broad and enduring, covering activities such as 'deployed or directed operations'. However, the context of an application for an MPTF referencing those flight conditions must justify proceeding with the risk characterised in those flight conditions in its own right. As a result, an MPTF for a flight which itself is discretionary with little or no military capability imperative, relying upon flight conditions with a broad context such as 'deployed operations', may not be credible or defensible with the risk characterised in the referenced flight conditions, despite occurring while 'deployed'.

7.5.9.4 The key information required to support this step in the risk management process is the applicant's justification that:

1. The purpose of flight for this application is within the risk context of the referenced flight conditions and the specific task in this application warrants proceeding with the residual risk at the time of application.
2. The specific aircraft to be tasked meet(s) the configuration required by the approved flight conditions.
3. The conditions and restrictions (risk controls) in the approved flight conditions will be implemented on the subject aircraft for the subject flight(s).

7.5.9.5 The applicant must identify a suitable delegate within their organisation who has capacity to make the decision-to-proceed with the flight(s) (i.e. retain the risk). In making the decision-to-proceed, the applicant must act within their safety risk management system. Specific details of the information and supporting documentation required to complete DASR Form 21 - *Application for a Military Permit to Fly* is provided in the instruction sheets covering the form. See also DASR 21.A.707.

7.5.9.6 Flight Test. Within specialist Service Flight Test Organisations (FTOs), procedures exist to streamline MPTF applications and approvals for a range of flight test activities, such as:

1. Flight test activities on any Defence aircraft type to be conducted by, or under the direct supervision of, a Defence Aviation Authority (DAA)-approved FTO (all CAT 1 and 2 flight test and some CAT 4 tests)
2. Where Flight Test Instrumentation (FTI) or modifications are to be used, or
3. Where flight test operational substantiation and/or endorsement is required.

7.5.9.7 MAOs considering flight test activities are encouraged to engage their respective Service FTO or a DoSA-FT, who will advise on the process to use. See also DASR FT–Flight Test.

7.5.10 Issue of a MPTF

7.5.10.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can issue an MPTF. DASA will issue an MPTF (via DASR Form 20a) if it has sufficient confidence that:

1. The decision-to-proceed has been made by an appropriate person within the applicant's organisation, given the characterisation of the residual risk (Note: DASA does not prescribe what this level is, nor what organisational authorisations they must hold).

Superseded

2. The assignment of the responsibilities to implement and monitor risk controls (i.e. adherence to the approved flight conditions) is clear.

3. If applicable, there has been consideration that the flight conditions are compatible with any other MPTFs currently in effect for that aircraft (Note: The applicant is responsible for managing the implementation of multiple or concurrent MPTFs).

4. The risk context of the MPTF application is within that of the referenced flight conditions and supports the decision-to-proceed with the risk characterised by those flight conditions.

7.5.10.2 In assessing the application for an MPTF, DASA reviews the information supplied by the applicant and independently assures that it supports flying with an aircraft that does not meet the prescribed airworthiness or aviation safety requirements and may be operating at an ELOR. This will include whether the period of risk retention (the context) is defensible. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

7.5.10.3 Flight Test. When the MPTF relates to a flight test activity categorised IAW DASR.FT.05, flight conditions must be endorsed by competent staff of a MAO (as per para 22), and for a CAT 1 or 2 activity, Authority approval of flight conditions and issuing of the MPTF must be conducted by a DoSA-FT.

7.5.11 Obligations of the holder of an MPTF

7.5.11.1 As the holder of an MPTF, the MAO is responsible for ensuring the flight conditions are implemented and remain effective for the duration of the MPTF. This satisfies Step 7 of the seven-step risk management process and includes ensuring the risk context supporting the approved flight conditions remains applicable for the duration of the MPTF. See also DASR 21.A.727 and DASR 21.A.708.

7.5.11.2 Configuration management. An MPTF may introduce specific aircraft configuration management requirements, especially if an MPTF covers a yet-to-be-approved modification for operational use or flight test activity. MPTF conditions may include information such as: incorporation and maintenance instructions for new modifications; periodic inspections for non-standard damage; or increased usage data recording requirements. The CAMO must be aware of MPTFs that are applicable to a given aircraft to ensure overlapping continuing airworthiness requirements are resolved or coordinated, to ensure no loss of configuration management and the appropriate aircraft technical log and maintenance documentation remains accurate.

7.5.11.3 Operation by another MAO. The holder of an MPTF is responsible for ensuring the DASR 21.A.708 flight conditions are met. However, in instances where aircraft may be transferred between MAOs, this situation requires the holder to establish suitable arrangements for the transfer of holder obligations for an aircraft (that is subject to one or more MPTFs) when operated by another MAO.

7.5.12 MPTF Examples within DASR Context

7.5.12.1 Annex B provides a non-exhaustive list of examples intended to illustrate the conduct of the MPTF process within the DASR environment. Where uncertainty exists, contact a DASA Desk Officer (DIA-TC or DAVENG), the platform DoSA, or a DoSA-FT (for MPTFs related to flight test). In

Superseded

addition, Annex C provides a comprehensive guide to good practice and common issues pertaining to applications for flight conditions and MPTFs.

Chapter 7.6 Design and Production Organisations.

7.6.1 Military Design Organisations

Aim

7.6.1.1 This chapter details the approval and ongoing oversight of a Military Design Organisation (MDO). A MDO is approved under DASR Part21J and can only undertake design work related to the privileges granted under that approval and within the scope of that approval. Often the scope restricts what platforms a design can be applied to and can impose further limitations to aspects of their design work if required.

Introduction

Superseded

7.6.1.2 Design organisation means an organisation responsible for the design of aircraft, aircraft engines, propellers, auxiliary power units, or related parts and appliances, and holding, or applying for, type-certificates, supplemental type-certificates, changes or repair design approvals. These design organisations that design aircraft, make changes to aircraft or design repairs of aircraft, and parts and appliances, need to fulfil the requirements as defined in DASR Part 21. Such organisations need to demonstrate that they have the right organisation, procedures, competencies and resources to effectively produce the design.

Obligations

7.6.1.3 DASA impose regulatory obligations on Design Organisations as part of the approval to ensure the airworthiness of aircraft and aviation products being designed within Defence. These obligations are intended to maintain high standards of design, engineering, and manufacturing processes throughout the defence aviation industry.

7.6.4 By placing obligations on design organisations, DASA aims to assure that the design, modification, and production of aircraft, components, and systems meet appropriate airworthiness standards.

Privileges

7.6.1.5 Under the DASR construct, the authority is the controlling signatory for all product released related to the type certificate. To reduce the burden on DASA, approved organisations are typically awarded privileges that allow work to be approved on behalf of the authority. For example, a design organisation may be privileged to approve minor changes to type design as well as minor and major repairs.

7.6.1.6 Granted privileges are documented on a Form 83. The Form 83 outlines the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

7.6.1.7 An organisation attains a DASR 21 MDO Approval by submitting a Form 80 Application for Military Design Organisation Approval (MDOA) for DASA consideration, or a Form 82 Application for Significant Changes to Design Organisation Approval where a MDOA is already held but scope change is needed. Along with the application, the organisation must furnish a handbook (formerly an exposition) whereby all the processes utilised under the established Design Assurance System (DAS) are detailed. The Design Organisation Handbook Requirements are outlined in Appendix 1 of Chapter 5.3 of DASP Manual Volume 3.

DASA Design organisation assurance

7.6.1.8 Once a design organisation has gained an approval to conduct design activity, DASA will schedule oversight activities in order to assure that the MDO has maintained / is maintaining their approval to the standard as governed by the DASR Pt21 regulations. For organisations maintaining a Part21 approval, DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, and Resources as detailed in the approved Design organisation handbook, as well as consideration of the quality of design products.

7.6.1.9 The DAS is effectively the Quality Management System (QMS) specific to the output of designs against the scope issued under the Form 83. The DAS can utilise elements of the organisation

Superseded

QMS to satisfy requirements of the DAS. The DAS and the QMS are not the same and oversight of the DAS will be conducted specifically to design products produced.

Further information

1. DASP Manual Vol 3 Chapter 5.3 Annex E
2. DASR 21 Subpart J – Military Design Organisation Approval

7.6.2 Military Production Organisations

Aim

7.6.2.1 This chapter details the approval and ongoing oversight of a Military Production Organisation (MPO). A MPO is approved under DASR Part21 G and can only undertake production work related to the privileges granted under that approval. This includes what release documentation is acceptable under DASRs.

Introduction

7.6.2.2 Production for Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured. Acceptable release documentation is outlined at Chapter 7.3.2.

Obligations

7.6.2.3 With a Production Organisation Approval, DASA impose a set of obligations as part of the approval and as part of its regulatory framework to ensure the safety and airworthiness of aircraft and aviation products being utilised within Defence. By placing obligations on production organisations, DASA aims to assure that the production of aircraft, components, and systems meet rigorous safety and airworthiness standards.

Privileges

7.6.2.4 Under the DASR construct, an approved MPO will be granted privileges to conduct design work to support changes to the type certificate for which the MTCH manages. Granted privileges are documented on a Form 55. The Form 55 is the certificate outlining the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

7.6.2.5 An organisation attains a DASR 21 MPO Approval by submitting a Form 55 Application for Military Production Organisation Approval (MDOA) for DASA consideration, or a Form 51 Application for Significant Changes to Production Organisation Approval where an MPOA is already held but scope change is needed. Along with the application, the organisation must furnish an exposition, whereby all the processes utilised to produce the category items under the ToA are documented.

7.6.2.6 Currently, DASA will not accept applications for production without a Military Production Organisation Approval as the authority is not resourced adequately to oversight this type of approval.

DASA production organisation assurance

Superseded

7.6.2.7 Once a production organisation has gained an approval to produce category items, DASA will schedule oversight activities in order to assure the MPO has maintained/is maintaining their approval to the standard as governed by the DASR 21 regulations. DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, Resources which is detailed in the approved Production Organisation Exposition.

7.6.5 Guidance for Organisations Developing and Producing Aviation Software

Introduction

7.6.5.1 This section provides guidance for the design and production of aviation software under DASR 21. This guidance does not apply to software designed or produced under recognition as defined in DASP Vol 3 Chapter 7.3.1 Production

7.6.5.2 Aviation software is classified as a 'part or appliance' and subject to the same rules applicable to all 'tangible' parts and appliances.

7.6.5.3 Aviation software refers only to software installed in an aircraft used for operating and controlling the aircraft and does not include mission system software, condition monitoring software, aeronautical information or ground-based aircraft diagnostic systems.

7.6.5.4 For the context of aviation software, the following definitions apply:

1. **Manufacturing** – is the development of aviation software, including compiling of source code into executable object code.
2. **Production** – is the process of preparing aviation software for distribution, including packaging the executable object code and associated engineering and technical data on distribution media.
3. **Replication** – is the process of copying aviation software (executable object code) that has been authorised through a production process.

Certification of Aviation Software

Superseded

7.6.5.5 Organisations manufacturing software for installation on Defence registered aircraft must hold a Military Design Organisation Approval (MDOA) under DASR 21 Subpart J. The development of new (or the modification of existing) aviation software is a change to a product's type design and must be approved under DASR 21 Subpart D or E. For changes to aviation software classified as minor, a minor change approval can be issued by an organisation holding an MDOA in accordance with its Terms of Approval. For changes to aviation software classified as major, the approval must be issued by DASA as either an amended Military Type Certificate (MTC) or a Military Supplemental Type Certificate (MSTC).

Production of Aviation Software

7.6.5.6 The production of software is the responsibility of an organisation holding an appropriate Military Production Organisation Approval (MPOA) and the release of aviation software for installation on a Defence registered aircraft is via a DASR Form 1. The software's 'part' number (version) should be marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

7.6.5.7 DASR 21 does not allow the production of aviation software under an organisation's MDOA Terms of Approval. Organisations producing aviation software for installation in Defence registered aircraft must meet the requirements of DASR 21 Subpart G—Military Production Organisation Approval in order to obtain privileges to release the software for installation.

Replication of Aviation Software

7.6.5.8 Software authorised for installation on a Defence registered aircraft via a DASR Form 1 and provided to the Continuing Airworthiness Maintenance Organisation (CAMO) may be replicated by an Approved Maintenance Organisation (AMO) in accordance with OEM or DASR 21 MDO approved procedures. It is the responsibility of the CAMO or AMO to ensure that their quality systems have processes in place to manage and verify the integrity of the replicated software. This is typically done using a checksum value that is generated during production of software and provided to the CAMO or AMO alongside the produced software.

7.6.5.9 Any software replication process should also include a step to ensure the software's 'part' number (version) is marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

Organisation Approval Requirements

7.6.5.10 Development and production of software are often done by the same organisation. In this case, the organisation must hold both a MDOA under DASR 21 Subpart J and a MPOA under DASR 21 Subpart G in order to obtain the necessary privileges to approve the development and production of aviation software. Typically, there are no organisations with an MPOA with software scope without a corresponding MDOA with software scope.

7.6.5.11 Underpinning these organisation approvals and privileges are a Design Assurance System documented in a Handbook (Design Organisation Exposition/DOE), and a Production Quality System documented in a Production Organisation Exposition (POE). For a software development and production organisation, it is not necessary to have discrete and dedicated stand-alone procedures manuals entitled 'DOE' or 'POE' to meet both sets of organisation approval requirements. A single manual, document (irrespective of its title) or set of procedures that covers the development and production of software may simultaneously meet the requirements of both a DOE and POE.

Superseded

7.6.5.12 The regulatory requirements of a DOE (DASR 21.A.243) and a POE (DASR 21.A.143) are the minimum required of such a manual or document to be awarded the relevant organisation approval and privileges. Any manual or document(s) identified as a DOE/POE (or both simultaneously) should be a working level document(s) published for use by personnel working in the organisation. The DOE/ POE should not be written purely to satisfy regulatory requirements, although this aspect will be assessed by DASA when reviewing the working level documentation and the organisation's staff's understanding of it.

7.6.6 GUIDANCE ON CONSIDERING EXPLOSIVES IN AVIATION DESIGNS

Introduction

7.6.6.1 This DASPMAN section explains what Military Design Organisations (MDO) and Military Type Certification Holders (MTCH) must consider when performing design activities on aircraft systems containing explosives and integrating air-launched stores containing explosives onto aircraft[82]. Such design activities include physical design changes to systems and equipment containing explosives, assessments that unrelated design changes do not adversely impact explosive safety, changes to Airworthiness Limitations (AwL), changes to explosives-related Instructions for Continuing Airworthiness (ICA), monitoring for new explosive-related hazards within safety management systems (SMS), and aircraft stores compatibility engineering activities.

What is an explosive?

7.6.6.2 An explosive is '… a substance manufactured with a view to producing an explosion or pyrotechnic effect[83].'Many Defence aircraft contain explosives, either forming part of an aircraft system (such as ejection seats) and within air-launched stores such as bombs, missiles and gun ammunition[84].

Explosives requirements within Type Certification Basis

7.6.6.3 In deciding what type of explosive requirements should be included in an aircraft's Type Certification Basis (TCB) the key document is the *European Military Airworthiness Certification Criteria* (EMACC) published by the European Defence Agency. The EMACC indicates that all explosives forming part of an aircraft system should be considered when developing TCB requirements. Accordingly, the TCB should include explosive-related requirements during initial certification and when MDOs develop major or minor changes to the type design.

7.6.6.4 For aircraft stores containing explosives the EMACC implies that the TCB should only consider requirements relevant to the installation, integration and interface of the aircraft and stores. That is, the TCB should only include explosive-related design requirements to the extent they affect the store's installation, integration and interface. Any subsequent major or minor changes to the type design should also only consider the installation, integration and interface of the store.

Legislative requirements

Superseded

7.6.6.5 The legislation relevant to the safe design, maintenance and operation of Defence aircraft containing explosives is the Work Health and Safety Act (Cth) 2011 (the WHS Act), the Explosives Act (Cth) 1961, and their subordinate regulations.

Explosive Safety Regulatory Framework

7.6.6.6 To comply with their explosive-related obligations under all this legislation, MDOs and MTCHs must understand Defence's *Explosive Safety Regulatory Framework* (ESRF), which amplifies this legislation for the explosives context. The ESRF purpose is to provide a Defence-wide explosive safety risk management framework which ensures explosives safety risks are effectively managed. Explosives safety aims to '… prevent premature, unintentional, or unauthorised initiation of explosives and devices containing explosives; and with minimising the effects of explosions, combustion, toxicity, and any other deleterious effects'[85].Within the ESRF, Director General Explosive Ordnance (DGEO) is the Explosive Ordnance Safety Regulator (EOSR), supported by the Director of Ordnance Safety (DOS).

7.6.6.7 Under the ESRF, the safe conduct of activities involving explosives (including design) requires adherence to the following three fundamental concepts:

1. Explosives must be designed and manufactured to design requirements so as to eliminate or minimise explosives safety hazards so far as is reasonably practicable. This concept is referred to as 'safety and suitability for service' (S3).

2. Activities involving explosives must be conducted at locations where the consequence of an explosives safety mishap is understood, and risks are minimised (referred to as a 'safe location').

3. Activities involving explosives must be conducted through safe work practices, conducted by trained and competent personnel, which will minimise both the likelihood and consequences of an explosives safety mishap (referred to as 'safe work practices').

7.6.6.8 In applying these three concepts, the ESRF provides requirements (12 principles and 28 regulations) and guidance relevant to the design, production, operation, maintenance, handling, storage and transport of explosives throughout its lifecycle.

7.6.6.9 The ESRF is documented within the following Defence Explosive Ordnance Publications (DEOP):

1. DEOP 100 comprises three volumes of which only Volume 2 Defence Explosives Safety Regulatory Framework has been issued. Volume 2 describes the 12 mandatory principles of the ESRF, not all of which are relevant to aviation design activities. For each principle, information is provided on its rationale, the expected outcome, the constraints, obligations, external requirements and controls. DEOP 100 Volume 2 also describes the ESRF risk management and assurance processes. The ESRF relies on organisational compliance with its mandatory requirements but does not provide organisational certifications.

2. DEOP 101 provides the 28 ESRF regulations with not all applying to aviation design activities. The regulations are not in a standard format, but most comprise a general overview, the requirements, responsibilities and any accompanying procedures. Each of the 28 regulations contain some mandatory requirements.

Superseded

3. DEOP 102 provides information relevant to assessing the 'Safety and Suitability for Service of Defence Explosive Ordnance'. The publication mentions the 12 principles and the 28 regulations, while providing no further requirements relevant to aviation design activities. This DEOP also discusses several explosive-related hazards[86].

7.6.6.10 Within the ESRF, the EOSR releases Defence Explosives Safety Advisory Circulars (ESAC) to promulgate important safety information. ESACs do not mandate any actions, but provide informed, well-considered safety advice and guidance. ESACs can be accessed at: drnet/JCG/JLC/ExplosiveOrdnance/DOS/Pages/ESRF.aspx (Available on DPN Only)

Relationship between the DASF and ESRF

7.6.6.11 The ESRF is specifically intended to integrate with and support other Defence regulatory frameworks that aim to achieve safety outcomes, including aviation safety. Comparison of the DASF and ESRF demonstrates that regulated organisations within the DASF can comply with both the Defence Aviation Safety Regulations (DASR) and relevant ESRF requirements, with no inconsistencies between the two safety frameworks. Importantly, both safety frameworks are subject to the WHS Act's concept of shared duty holders (s16), who must consult, co-operate and co-ordinate their activities (s46) to ensure explosive-related risks are eliminated or otherwise minimised so far as is reasonably practicable (s17).

7.6.6.12 DASA regulates the design of aircraft systems and the integration of all air-launched stores onto a type. Complementing these regulations, DGEO provides mandatory explosive-related requirements (both principles and regulations) for the design of aircraft systems containing explosives and air-launched stores containing explosives.

7.6.6.13 The S3 construct within the ESRF requires consideration of the hazards posed to explosives safety by carriage environments. Accordingly, the ESRF requires designers to consider whether the failure or partial performance of the non-explosive components of aircraft stores adversely affects the safety of the explosives within the store. Forms of component failure or partial performance that do not affect explosive safety are outside the ESRF scope, but are considered by Guided Weapons and Explosive Ordnance Group (GWEO) as part of its broader safety responsibilities.

ESRF applicability to DASR 21 scope

7.6.6.14 Several ESRF principles and regulations fall within the scope of DASR 21. Specifically:

1. ten of the 12 ESRF principles (Principles 1-10) impose obligations on aircraft designers within MDOs and MTCH organisations
2. all of these ten principles fall within the scope of DASR 21
3. compliance with DASR 21 provides total compliance with one principle (Principle 1), partial compliance with eight principles (Principles 2, 3, 5, 6, 7, 8, 9 and 10) and no compliance with one principle (Principle 4)
4. only four of the 28 ESRF regulations (1.1, 1.2, 1.5 and 2.5) within DEOP 101 impose obligations on aviation designers within MDOs and MTCH organisations
5. of these four regulations, three fall within the scope of DASR 21 (1.1, 1.5 and 2.5)
6. compliance with DASR 21 provides only partial compliance with these three regulations.

Superseded

7.6.6.15 These principles and regulations within the scope of DASR 21 provide no limits or constraints on which individuals or organisations within Defence may perform design activities for aircraft systems and aircraft stores containing explosives.

Satisfying applicable ESRF requirements

7.6.6.16 Compliance with DASR 21 provides total or partial compliance with several mandatory ESRF principles and regulations. To achieve full compliance, MDOs and MTCHs must:

1. obtain explosives safety hazard and risk management advice from personnel and organisations competent in explosives safety management (refer paragraph 7.6.6.18)
2. when complying with DASR SMS, ensure that consideration is given to explosive-specific hazards and risks
3. ensure that explosives safety hazards and residual risks of explosives are identified and communicated to affected Services, Groups and others (including non-Defence entities)
4. aim to reduce the consequences of on-aircraft explosive hazards through careful design of where explosives are located in the aircraft and the quantity of explosives used
5. ensure that personnel performing design activities on aircraft systems and air-launched stores containing explosives receive explosive-related training compliant with ESRF Regulation 1.1 (eDEOP 101)[87]
6. when creating Instructions for Continuing Airworthiness (ICA) for aircraft systems and air-launched stores containing explosives, be aware of the inspection requirements in ESRF Regulation 1.5 (eDEOP 101)
7. when engaged in the process for the initial certification of explosives installed in aircraft systems and amendments to their life limits, comply with the process described in Annex B.

7.6.6.17 While outside the scope of DASR 21, where MDOs handle explosives as part of the design process, they should ensure their sites, platforms and facilities have the necessary facility certifications, and that the minimum number of people are exposed and are aware of the risks.

Explosives safety hazard and risk management advice

7.6.6.18 MDOs and MTCHs can obtain explosives safety hazard and risk management advice from the following organisations competent in explosives safety management:

1. the Directorate of Ordnance Safety within Joint Logistics Command
2. Joint Proof and Experimental Unit within Joint Logistics Command
3. Aerospace Explosive Ordnance Systems Program Office within GWEO
4. Directorate of Engineering and Technical within GWEO's Systems Division.

7.6.6.19 MDOs and MTCHs should have confidence in the explosives safety hazard and risk management advice provided by these organisations because they:

Superseded

1. have roles (either regulatory or in-practice) that require them to comprehensively understand explosive safety hazards and risks

2. are subject to the requirements of the well-established ESRF and will provide advice compliant with all relevant ESRF principles and regulations

3. have an extensive demonstrated history of providing safe explosives advice across Defence, including to the aviation community

4. work within well-developed engineering frameworks that have evolved over several years.

7.6.6.20 MDOs and MTCHs can consume explosives safety hazard and risk management advice from these specified organisations, without the need to invoke DASR 21.A.239. That is, they do not need to consider these organisations as a '… partner or subcontractor' and are not obliged to specify the manner in which the MDO/MTCH design assurance system accounts for the acceptability of the advice provided by these external organisations or specialist personnel within them.

7.6.6.21 Some forms of advice may not need be obtained case-by-case but could be obtained as a 'standing' advice relevant to a particular type of design change whenever it occurred (for example a proposed change to a component throwaway life or maintenance interval). The relevance of specific 'standing' advice to a new circumstance would depend on the aircraft type, the form of explosives, the aircraft's operating environment and its specific sustainment arrangements.

7.6.6.22 The relationships that MDOs establish with specialist explosives organisations should be documented in the Handbook (Design Organisation Exposition), required by DASR 21.A.243. Similarly, MTCHs should documents their relationships in the Type Continued Airworthiness Exposition required by GM 21.A.14(c) and discussed at DASPMAN Chapter 5.3 Annex J Appendix 1.

Other guidance

7.6.6.23 A variety of other Defence stakeholders can contribute to the safe design of aircraft systems containing explosives and the safe integration of air-launched stores containing explosives. Such organisations include:

1. **Maintenance organisations** - to understand the maintenance implications of design decisions and the utility of proposed ICA relating to explosives

2. **CAMOs** - to understand the continuing airworthiness implications of explosive-related design decisions, such as the potential need for pre-flight inspections and the effect of explosive-related component lives on the aircraft maintenance program

3. **MAOs** - to understand the operational implications of explosives-related design decisions, such as preferred aircrew actions for stores release

4. **DASA** - to understand the scope of the ability to approve minor explosives-related design changes

5. **Organisations who transport and store explosives.** Organisations within various Defence Groups and Services, whose primary roles is transporting and storing explosives, would not usually be a source of explosives design safety advice. Nevertheless, there may be occasions when MDOs should seek information from them that provides necessary context for design activities.

Design activities for aircraft systems containing explosives

Superseded

7.6.6.24 An aircraft system may contain explosives, usually to separate an air-launched store from the aircraft, but sometimes to separate parts of the aircraft such as ejection seats and cockpit canopies. Specific guidance on the design activities for aircraft systems containing explosives is provided in Annex A.

Design activities for ALSE/role equipment containing explosives but not part of the aircraft's type design

7.6.6.25 ALSE/Role equipment containing explosives, but not part of the aircraft type design, are outside the scope of this chapter. Nevertheless, the ESRF requirements at 7.6.6.16 a/c/d/e still apply to organisations performing relevant design activities.

Design activities for air-launched stores containing explosives

7.6.6.26 An air-launched store is an aircraft store that is intended to be separated from an aircraft in flight. Some air-launched stores contain explosives:

1. to separate the store from the aircraft (such as some chaff, some flares, some sonobuoys and gun ammunition)[88]
2. to create an explosive effect post separation (such as bombs, missiles and flares)
3. for both purposes.

7.6.6.27 Design activities on the explosives within air-launched stores are outside an MDO's scope, performed within the scope of GWEO organisations.

7.6.6.28 Specific guidance on the integration of air-launched stores containing explosives, which is within the MDO/MTCH scopes, is provided in Annex B.

(a) Design activities for aircraft systems containing explosives

(b) Integration of air-launched stores containing explosives

Superseded

7.1. Introduction

7.1.1 Background

7.1.1.1 While there is no internationally-accepted definition for Initial Airworthiness, common definitions for 'initial' (happening at the beginning) and 'airworthiness' (the fact of an aircraft being safe to fly) are helpful. After all, Initial Airworthiness does indeed focus extensively on whether a new aircraft is initially safe to fly - that is, whether it has been suitably designed and manufactured.

7.1.1.2 However, by convention, Initial Airworthiness also encompasses any design changes subsequently made to the new aircraft (including the certification of those changes) and the design of repairs. Furthermore, it includes the activities needed to ensure the design remains safe throughout its lifecycle, although this activity is often termed 'continued' airworthiness (not to be confused with 'continuing' airworthiness, per chapter 8).

7.1.1.3 This chapter presents an overview of the DASR approach to aircraft design, production and certification, which are the activities commonly associated with initial and continued airworthiness. The subsequent chapters will then explore several of these concepts in more detail.

7.1.1.4 Note this chapter is relevant only to Defence Registered aircraft; for non-Defence Registered aircraft, all initial and continued airworthiness functions are conducted per the requirements of the relevant Civil or military Aviation Authority (normally CASA).

7.1.2 DASR 21 – Aircraft Design, Production and Certification

7.1.2.1 From an Initial and Continued Airworthiness (INCA) perspective, an aircraft's lifecycle might follow a progression something like this:

a. To start, an engineering organisation demonstrates its professional ability to produce an aircraft design ('design organisation approval').

b. Next, the organisation produces a new aircraft design, and an Aviation Authority certifies that the design is suitably safe ('aircraft design and certification').

c. Individual aircraft are then produced, and an Aviation Authority certifies each as conforming to the certified design ('aircraft production and certification').

d. Over the following decades of fleet operation, numerous Minor and Major design changes and repairs will be made to the aircraft ('aircraft design changes and repairs').

e. Occasionally, there may be a need for limited flying of a possibly unairworthy aircraft, either to demonstrate a new capability or to avoid grounding an important asset ('permit to fly').

Superseded

f. Critically, throughout this complex lifecycle, an engineering organisation will need to monitor for defects in the design, facilitate risk management of the design, and so on ('type certificate holder').

g. Finally, an Aviation Authority might occasionally mandate certain remediation actions in the interests of fleet safety ('airworthiness directives').

7.1.2.2 Each of these seven functions, and several others, is regulated under DASR Pt 21– *Aircraft Design, Production and Certification.* The remainder of this chapter provides a brief summary of these functions.

7.1.2.3 **Design organisation approval.** Deficiencies in an aircraft's design can range from those with immediate catastrophic consequences (eg inadequate structural strength), to an erosion of safety margins (eg misleading navigation information), to an annoyance (eg a Minor human-machine interface flaw). Designing an aircraft where risks have been eliminated or otherwise minimised so far as is reasonably practicable (SFARP) is a particularly complex endeavour.

7.1.2.4 Consequently, the initial design of Defence aircraft should only be undertaken by skilled individuals within professional aircraft design organisations. DASRs make provision for DASA to issue Military Design Organisation Approval (MDOA) status to organisations who have demonstrated that they are able to maintain a design assurance system for the control and supervision of the design, and of design changes, of aircraft products, parts and appliances.

7.1.2.5 DASA's default expectation is that a new Defence aircraft will be designed by a MDOA of suitable scope. As a matter of pragmatism, however, DASR also make provision for Defence to accept designs that have been certified by a DASA-recognised civil or military Aviation Authority (CAA/MAA), without the need for the design organisation to be a DASA-approved MDOA, within certain bounds. This approach, often called 'prior acceptance' is explored in Chapter 7.2, *Product Certification*. These same provisions apply for design changes to an extant aircraft.

7.1.2.6 MDOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.7 **Initial aircraft design and certification.** Defence periodically acquires aircraft to meet a capability need. In practice, Defence usually acquires its new aircraft as off-the-shelf designs, and then incorporates design changes to cater for Defence's unique roles and operating environment. The entire design will meet a set of airworthiness requirements - commonly called a Type Certification Basis (TCB) - and the designer(s) will produce extensive evidence (via analysis, test and other means) to demonstrate that their design meets the TCB.

7.1.2.8 As noted in paragraph 7.1.2.5, these designs will be produced by a DASA-approved MDOA, or a design organisation whose design is certified by a DASA-recognised CAA/MAA, or sometimes both. Regardless, the final design will always be certified by DASA, signified by the issue of a Military Type Certificate (MTC)[1] for the aircraft.

7.1.2.9 In the absence of a pertinent CAA/MAA certification, DASA's certification for a new aircraft would be an immense undertaking for both DASA and the Defence acquisition organisation. More commonly, however, there will be a pertinent CAA/MAA certification, and leveraging off this certification can substantially reduce the impost on both organisations. In that case, much of the effort focuses on whether the certified design is compatible with Defence's intended Configuration, Role and Environment (CRE). Chapter 7.2, Product Certification, explores the certification process in detail.

Superseded

7.1.2.10 **Aircraft production and certification.** An expertly designed and certified aircraft provides the basis for safe aircraft operation. However, just as importantly, that design must be accurately implemented on the Defence aircraft.

7.1.2.11 DASR make provision for DASA to issue a Military Production Organisation Approval (MPOA) to an organisation when assured they have the ability to manufacture aircraft parts and appliances in conformity with approved data. DASR also make provision for Defence to accept an aircraft produced under the systems of a DASA-recognised CAA/MAA. This latter approach is used for most new Defence aircraft.

7.1.2.112 Following production of an individual aircraft, DASA must certify that the aircraft is in a state of airworthiness per the inherent level of safety specified on the MTC. This certification is signified by the DASA issue of a Military Certificate of Airworthiness (MCoA)[2] for each individual Defence aircraft.

7.1.2.13 Aircraft production and MCoAs are explored in Chapter 7.3, Production. MPOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.14 **Aircraft design changes and repairs.** Defence aircraft will usually be in service for several decades. During this time, numerous design changes will inevitably be implemented, either to enhance military capability or to address design or obsolescence problems. These design changes are classified under DASR as either Minor of Major, differentiated by the degree of airworthiness effect of the design change.

7.1.2.15 The DASR approach for Minor and Major design changes is very similar. They will both be performed by a DASA-approved MDOA or another design organisation whose design is certified by a recognised CAA/MAA, and both should preserve the level of airworthiness of the aircraft. For Major design changes, however, DASA will usually provide a proportionate level of independent assurance, and DASA itself will usually certify the design as safe. This certification is usually via an amendment to the MTC, although occasionally a Military Supplemental Type Certificate (MSTC) may be issued. Chapter 7.2, Product Certification, explores the certification process in detail.

7.1.2.16 Throughout an aircraft's life, degradation (damage) of the systems/structures integrity supporting safe flight may be compromised through direct (accidental impact and battle damage) overload, or insidious (fatigue, corrosion, moisture ingress, dis-bond, ultraviolet light etc) environmental sources. Repairs are those actions developed and implemented to restore damaged products to a suitably airworthy state. Similar to aircraft design changes, aircraft repairs are classified under DASR as Minor or Major, must be designed by a MDOA or other organisation agreed by DASA, and may be subjected to a proportionate level of DASA independent assurance.

7.1.2.17 **Permit to fly.** A Military Permit to Fly (MPTF) may be issued by DASA for an aircraft that does not meet, or has not been shown to meet, the requirements of its TCB, but is nonetheless capable of safe flight under defined conditions and for specified purposes. MPTFs are most commonly used for flight test (for aircraft development or role expansion activities), for flights where the design has not yet been certified, or for flights where the aircraft temporarily does not conform to the Type Design (eg due to unrepaired damaged, overdue maintenance, etc).

7.1.2.18 An MPTF may or may not entail an elevated level of risk, and is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application. Chapter 7.5, Flight Conditions and Military Permits to Fly, explores this in more detail.

Superseded

7.1.2.19 **Type certificate holder.** As noted earlier in this chapter, DASA issues an MTC for Defence Registered aircraft types. This MTC is issued to a suitable Commonwealth government organisation (usually the relevant Defence Systems Program Office), who are then charged with 'holding' the MTC.

7.1.2.20 Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed, and the level of safety inherent in the TCB is maintained. This includes, for a particular aircraft type, collecting aviation safety information (both locally and from external sources), ensuring operators are aware of extant hazards, ensuring that essential risk controls remain effective, leading local efforts to eliminate or further minimise known risks, and many other important roles.

7.1.2.21 These expansive holding responsibilities are often beyond the capacity and capability of the government organisation holding the MTC. Consequently, responsibility for the conduct of MTCH obligations is often vested with various support organisations, for example contractors, foreign project offices and other military operators. The government organisation remains accountable for all activities undertaken by those organisations.

7.1.2.22 Chapter 7.4, Continued Airworthiness, explores the MTCH role in more detail.

7.1.2.23 **Airworthiness directives.** In the Australian Defence context, the WHS Act and DASR place responsibility and obligation solely on the regulated community for managing the day-to-day safety of their aircraft, and for ensuring risks are eliminated or otherwise minimised so far as is reasonably practicable. DASR do, however, still make provision for DASA to mandate actions and/or impose conditions on aircraft operation in certain circumstances. This is achieved through the issue of an Airworthiness Directive (AD).

7.1.2.24 Like its civil counterpart, ADs under DASR provide a means to mandate an action in order to restore an aircraft to an acceptable level of safety, where that safety level may be otherwise compromised. However, due to Defence's unique context, DASA issues ADs infrequently, particularly in comparison to civil aviation.

7.1.2.25 Chapter 7.4, Continued Airworthiness, explores DASR ADs in more detail.

7.1.2.26 **Other.** In addition to the seven common INCA functions mentioned above, DASR 21 also makes provision for a number of niche functions. Since this chapter aims to provide an overview of INCA that is consumable to a wide audience, these niche functions will not be explored here. They include: Australian Military Technical Standard Order (AUSMTSO) authorisations, restricted type certificates, restricted certificates of airworthiness, approval of parts and appliances, and the identification of parts and appliances.

Structure of these chapters

7.1.2.27 This chapter has provided a brief overview of the functions encompassed within Initial and Continued Airworthiness. The subsequent chapters explore several of these functions in greater detail, as follows:

a. Chapter 7.2: Product certification

b. Chapter 7.3: Production and military certificates of airworthiness

c. Chapter 7.4: Continued airworthiness (including military type certificate holders, occurrence reporting, airworthiness directives and other organisational approvals)

d. Chapter 7.5: Flight conditions and military permits to fly

Superseded

e. Chapter 7.6: Design and production organisations.

7.2 Product Certification

7.2.1 – Introduction

7.2.1.1. Product certification authorisations represent DASA's assurance that an individual product complies with the applicable airworthiness[3] requirements. These are issued following review of compliance evidence presented by the applicant seeking product certification. Product certification authorisations covered under this chapter are MTCs, Changes to MTCs, MSTCs, and Repair Designs.

7.2.1.2. Product certification authorisations are built around four pillars of safety assurance; Organisational Capability, Compliance demonstration, Compliance Verification, and Obligations of the holder

7.2.1.3. **Organisational Capability.** Before an organisation can apply for a product certification, they need to be eligible. Eligibility is based on an assessment of whether the organisation is equipped/ resourced to achieve a successful authorisation.

7.2.1.4. **Compliance Demonstration.** The applicant for a product certification authorisation must show that their product complies with the applicable airworthiness requirements.

7.2.1.5. **Compliance Verification.** The authority must independently verify that compliance has been achieved to the applicable airworthiness requirements. As compliance demonstration and compliance verification are intrinsically linked, a certification programme is put in place to document the means by which the applicant will demonstrate compliance and the authority will verify compliance.

7.2.1.6. **Obligations of the Holder.** Following issue of a certification approval, the certificate holder must continue to carry out obligations outlined under the DASRs to ensure the product certification remains safe.

7.2.1.7. The following sections expand upon these safety assurance areas for each product certification authorisation.

7.2.2 – Type Certification – Military Type Certificates (DASR 21 Subpart B)

Overview

7.2.2.1 **Scope of Section.** Section 7.2.2 describes the DASR type certification process for obtaining a Military Type Certificate (MTC). Military Restricted Type Certificates (MRTCs) are not yet employed by DASA, and are not addressed herein.

7.2.2.2 **Military Type Certificate.** An MTC is issued by DASA to certify that a product's type design complies with the applicable Type Certification Basis (TCB) when operated within specified conditions and limitations. Further description of the MTC authorisation can be found in Section 5.3 Annex K.

Eligibility

Superseded

7.2.2.3 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the MTC.

7.2.2.4 DASR 21.A.13 (Eligibility), and by extension DASR 21.A.14 (Demonstration of Capability), define which organisations can apply for an MTC under DASR 21. As per DASR 21.A.14, applicants for an MTC can be:

1. A DASR 21 Subpart J approved Military Design Organisation (MDO) (21.A.14(a)). Holding a DASR 21J approval provides an organisation with the eligibility to apply directly to DASA for an MTC. However, given the scope of the Australian aviation industry, development and certification of a new aircraft wholly under a DASR 21J MDO will be a rare occurrence.

2. An organisation demonstrating its capability through alternative procedures (21.A.14(b)). An applicant may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to comply with this DASR. This eligibility provision is ostensibly aimed at products with simple or limited scope of design, or organisations starting toward a MDO approval or limited duration of design activities. Use of this provision to demonstrate capability to apply for an MTC would only be considered by DASA by exception.

3. A government organisation who has an agreement in place with a design organisation that has access to the type design data (21.A.14(c)). Any government organisation applying for an MTC may demonstrate its capability by having an agreement in place, accepted by DASA, with a design organisation that has access to the necessary type design data. This is the normal provision through which DASA expects government organisations (usually the relevant CASG System Program Office (SPO)) to demonstrate their capability to apply for an MTC. The agreement with the relevant design organisation shall include detailed statements how the actions and obligations are delegated to enable the government organisation, in cooperation with the contracted organisation, to comply with the requirements of Subpart J and DASR 21.A.44 (holder obligations). AMC and GM to 21.A.14(c) provide further information on demonstration of capability under this provision.

7.2.2.5 **MTC Applications by CASG SPOs (Project Offices).** To be issued an MTC by DASA, a CASG project office develops a Type Continued-Airworthiness Exposition (TCAE) for DASA review. The TCAE details the CASG arrangements with the design organisation(s) that has access to the type-design data and through which the provision of holder obligation functions occur. Further guidance on holder obligations and arrangements can be found in Section 7.4.1.

7.2.2.6 CASG project offices seeking issue of an MTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended acquisition program.

7.2.2.7 The eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J. Since a CASG project office scope of responsibility is usually limited to a single application, and does not include the through-life holder responsibilities, the CASG project office eligibility information is not required to be delivered as a single document and can instead be contained within

Superseded

Project or Acquisition documentation. The documentation requires review by DASA prior to the project office becoming eligible to act as an applicant. However, the CASG project office must include a transition plan to manage delivery of the Type Design to the MTC holder, and where the MTC holder organisation is being created, include plans for assessment of eligibility of the MTC holder, by DASA.

7.2.2.8 Additional guidance with respect to MTC applicant eligibility when CASG project offices wish to leverage recognition provisions is as follows:

1. Application will be exclusively based upon an aircraft type-design that has been certified by a recognised CAA/MAA. In this situation, the project office, in conjunction with any associated design organisation(s), can gain eligibility by demonstrating its ability to conduct the required certification programme activities (develop CPP, conduct applicability assessment against Defence context, develop the Defence TCB, and provide a declaration of compliance), rather than demonstrate full adherence to the DASR 21 Subpart J requirements.

2. Application will be based on a design that has not been certified, but was developed using a design system (organisation, people, processes, data, and tools) external to the DASR, and where that system is used to produce designs for certification by a recognised CAA/MAA. In this situation, the DASA recognition framework[4] must be leveraged by the project office to assist in demonstrating to DASA that the arrangements with the external DO provides an acceptable equivalence to the DASR 21 Subpart J requirements. Activities to meet the eligibility requirements should be completed prior to initial engagement with DASA and throughout certification programme activities. The project office is to address the following expectations in their respective eligibility submission:

   i. Confirm that the external design organisation is normally oversighted by a CAA/MAA recognised by DASA[5].

   ii. Confirm that the external design organisation has appropriate technical scope and expertise for the intended design(s).

   iii. Confirm that the systems, processes and personnel used in developing other designs for certification by the parent CAA/MAA will be used in the design development or holder activities associated with the ADF design.

   iv. Confirm that the design organisation is able to provide an attestation of compliance against the Defence TCB for any provided design product.

   Note: In some circumstances, the PO or MTC holder may wish to allow the external design organisation to engage directly with DASA for Defence TCB agreement, development and conduct of the CCP, and provision of a declaration of compliance to the Defence TCB. In this case, the eligibility documentation shall demonstrate that the external design organisation systems and process are sufficiently similar to the DASR 21J requirements to support such delegation.

   v. Confirm any expected oversight by the DO's parent CAA/MAA is appropriate.

   vi. Confirm where applicable, arrangements for DASA oversight are in place.

Superseded

vii. Articulate how the recognition arrangements as per paragraphs 7.2.2.8.(b)(iii), (iv) and (v) will be monitored and ensured during the design development and submission process[6].

Certification Programme

7.2.2.9 **Overview.** Under DASR 21, a certification programme is required for all applications for an MTC, and the certification programme requires formal acceptance by DASA.

7.2.2.10 The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a Certification Program Plan (CPP).

7.2.2.11 Two CPP templates are published on the DASA Website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the MTC CPP template.

7.2.2.12 The organisation(s) involved in the development and submission of a certification program for an MTC application will vary depending upon the acquisition arrangements. GM1 21.A.15(b) provides further guidance based on some common acquisition scenarios.

7.2.2.13 **Contents of a Certification Programme.** DASR 21.A.15(b) outlines the requirements for content of a certification programme for an MTC. Certification programmes must be tailored to meet the requirements of the certification activity.

7.2.2.14 The certification programme should be presented as a CPP containing the information required by DASR 21.A.15(b) and the supporting AMC. The MTC CPP template published by DASA will assist in meeting the required outcomes.

7.2.2.15 Two key outcomes are achieved through the development and DASA acceptance of the certification programme:

1. Applicant development and DASA agreement of the Defence TCB for the MTC[7].
2. Formalising and agreement on the approach to be taken for demonstrating compliance against the Defence TCB, and the DASA Level of Involvement (LoI) in compliance demonstration activities.

7.2.2.16 **Proposed Compliance Demonstration Items (CDIs)**. DASR 21.A.15(b)(5) requires that the CPP proposes a breakdown of the certification programme into meaningful groups of compliance demonstration activities and data, and a proposal for the means of compliance and related compliance documents.

7.2.2.17 A CDI is a meaningful group of compliance demonstration activities and data that can be considered, in isolation, for the purpose of performing the risk assessment that allows DASA to determine its LoI.

7.2.2.18 Applicants should follow AMC 21.A.15(b)(5) when proposing the CDIs, and the DASA MTC CPP template contains further guidance and tabular templates for presenting proposed CDIs.

7.2.2.19 **Proposed DASA LoI.** As outlined in AMC 21.A.15(b)(6), the Authority's LoI is a list of activities and data, in which the Authority retains the verification of compliance demonstration (e.g. review and acceptance of compliance data, witnessing of tests, etc.), as well as the depth of the verification. The depth of the verification for individual compliance reports, data, test witnessing, etc., may range

Superseded

from spot checks to extensive reviews. DASA will respond to those retained compliance demonstration activities and data with corresponding comments or a 'statement of no objection'. DASR 21.A.15(b)(6) requires that the CPP proposes the DASA LoI associated with compliance demonstration activities, noting that LoI should normally be proposed at the CDI level. As per DASR 21.A.15(b)(6), the DASA LoI must address the likelihood of an unidentified non-compliance with the TCB requirements and the potential impact of that non-compliance on safety (ie a risk-based determination). In practice, this is achieved through taking into consideration:

1. any novel or unusual features of the certification project, including operational, organisational and knowledge management aspects
2. the complexity of the design and/or demonstration of compliance
3. the criticality of the design or technology and the related safety risks, including those identified on similar designs
4. the performance and experience of the design organisation of the applicant in the domain concerned.

7.2.2.20 AMC 21.A.15(b)(6) contains a step-by-step process and extensive information that applicants should follow when determining the proposed DASA LoI. The DASA MTC CPP template also includes complementary guidance and tables. The three main steps that culminate in determining the DASA LoI are:

1. Step 1: Identification of the likelihood of an unidentified non-compliance. This includes taking into consideration novelty, complexity and the performance of the design organisation. Refer to Section 3.2 of AMC 21.A.15(b)(6) for details.
2. Step 2: Identification of the 'risk class'. This includes determining whether the potential impact of the non-compliance within a compliance demonstration activity (ie CDI) is critical or non-critical. This is then combined with the likelihood of an unidentified non-compliance (step 1) to determine the risk class. Refer to Sections 3.3-3.4 of AMC 21.A.15(b)(6) for details.
3. Step 3: Determination of the DASA LoI. Based on the qualitative risk class identified for each compliance demonstration activity (ie CDI), the applicant should propose a DASA LoI. Refer to Section 3.5 of AMC 21.A.15(b)(6) for details.

7.2.2.21 DASA will determine the depth and extent of its inspections for each CDI, based on the information provided in the certification programme and the applicant's proposal. DASA determination of LoI will be confirmed as part of DASA's acceptance of the CPP. Note that the depth and extent of DASA LoI may change throughout the project in order to account for changes that affect the basis of the initial LoI determination.

7.2.2.22 **Certification Programme Acceptance.** DASA acceptance of the certification programme is required for all MTC applications. Early engagement with DASA, and agreement on the key certification programme content, will reduce schedule and resource risks for the project. Delaying presentation of certification programmes to DASA until after compliance demonstration has commenced may result in delays, additional work, or additional resources, due to DASA:

1. determining that the proposed airworthiness requirements or means of compliance are unsuitable for the certification activity

Superseded

2. identifying a need for a LoI in compliance demonstration activities that have already been completed, therefore resulting in a need to repeat the compliance demonstration

3. identifying LoI that requires travel (eg for compliance demonstration being completed overseas) and insufficient time is available to organise funding and travel prior to the planned activity, resulting in a need to delay the activity

4. identifying a need for data access that was not accounted for prior to contracting or establishing government to government agreements for the activity, resulting in a need for contract changes or alternate workarounds.

7.2.2.23 DASA acceptance of a certification programme can be achieved incrementally, if some aspects are unknown at the beginning of the project or are expected to change throughout the project. A caveated acceptance may be possible to achieve agreement with DASA on specific aspects of the programme prior to full details being known. For an initial or caveated acceptance, the following is required:

1. identification of the applicant and any design organisations involved

2. broad detail on the design and aircraft intended use

3. an initial proposal for the TCB, including identification of the Primary Certification Code and identification of whether any TCB tailoring (including Military Certification Review Items (MCRIs)) will be required. Note: the TCB does not have to be fully defined at this point.

4. broad detail on the certification approach (i.e. whether there will be reliance on prior certification, or whether compliance demonstration evidence with be developed specifically for the DASA certification).

7.2.2.24 Where an incremental approach is taken to developing and achieving acceptance of the certification programme, the scope of acceptance intended by each version must be clearly understood and documented. A point at which the next update is required must be identified, this may be date based or linked to a specific project stage or milestone.

7.2.2.25 DASA acceptance of the certification programme will be agreed by formal communication, which will include confirmation of the DASA LoI for the activity, and any caveats on DASA acceptance.

7.2.2.26 **Certification Programme Updates.** In accordance with DASR 21.A.15(c), the certification programme is to be updated when there are changes to any of the content required under DASR 21.A.15(b). Key aspects that require the certification programme to be re-accepted by DASA are:

1. any changes that may impact on DASA LoI, such as:

   i. change to the design or intended use

   ii. change to compliance demonstration approach (including the means of compliance)

   iii. change to the CRE Assessment (CREA) or its outcomes for a program that is leveraging prior certification

   iv. change to design organisation resources or approvals

Superseded

2. any changes to the proposed TCB (except those achieving separate agreement via an MCRI)

3. significant changes to schedule that may impact on DASA LoI activities

7.2.2.27 Changes to the certification programme can be presented as an update to the original CPP, or via a supplement, depending on the scope of the changes.

7.2.2.28 Applicants should engage early with DASA (nominally DIA) staff and remain closely engaged with CPP development and subsequent amendment, heeding advice to prevent nugatory drafting and rewriting. The DASR Form 31 can be used to notify DASA of an upcoming certification project, to initiate discussions. A face-to-face session, before any CPP drafting occurs, is strongly recommended for for complex programs.

Type Certification Basis

7.2.2.29 **Contents of a TCB.** The TCB is an agreed set of airworthiness requirements that a product must be compliant with in order to obtain an MTC. The following DASR and concepts apply to the contents of a TCB:

1. DASR 21.A.16A (Airworthiness Codes). This regulation requires that DASA shall approve the use of Airworthiness Codes[8] and other detailed specifications that may be used to demonstrate compliance of products, parts and appliances. As noted in GM 21.A.16A, rather than define a Defence-unique Airworthiness Code, DASA has elected to recognise the Airworthiness Codes prescribed by several other CAAs and MAAs that have been demonstrated to achieve safe flight, and then prescribe supplementation as required. The Defence Aviation Safety Design Requirements Manual (DASDRM) identifies the Airworthiness Codes recognised by DASA.

2. DASR 21.A.16B (Special Conditions). This regulation requires that DASA shall approve any special detailed technical specification ('special conditions') if the related Airworthiness Code or specifications do not contain adequate or appropriate safety standards. As per 21.A.16B, the need for special conditions may arise due to:

   i. novel or unusual design features (relative to the design practices on which the applicable Airworthiness Code is based)

   ii. intended use of the product is unconventional

   iii. experience from other similar products in service or products having similar design features or newly identified hazards have shown that unsafe conditions may develop

   iv. applicable airworthiness codes do not exist for the concerned product class or do not address the requested kind of operations.

   In the Defence context, special conditions are required when the primary Airworthiness Code selected may contain deficiencies against contemporary airworthiness requirements and / or may not account for Defence's unique CRE. DASA uses the Defence Aviation Safety Design Requirements Manual (DASDRM) to define those 'essential' design requirements and standards that must be applied as special conditions to supplement Airworthiness Codes due to deficiencies in the Codes or to account for the Defence CRE. The DASDRM also defines a number of 'recommended'

Superseded

design requirements and standards for which compliance is not prescribed, but which should be applied where reasonably practicable.

3. DASR 21.A.17A (Type Certification Basis). This regulation defines the scope of the Defence TCB. The airworthiness requirements specified in the TCB include:

   i. the applicable requirements from the DASA recognised Airworthiness Code selected as a basis for the Defence aircraft certification (the Primary Certification Code (PCC))

   ii. the applicable 'essential' requirements prescribed in the Defence Aviation Safety Design Requirements Manual (DASDRM)

   iii. any supplementation or tailoring agreed to by DASA.

7.2.2.30 **Development of a Defence TCB.** Development of a Defence TCB is a joint activity between the applicant and DASA and is guided by the DASR listed above and the Defence Aviation Safety Design Requirements Manual (DASDRM). TCB agreement is obtained through acceptance of the certification programme in accordance with DASR 21.A.15(b).

7.2.2.31 The TCB for a new Defence aircraft type should be developed and agreed as early as practicable in the aircraft acquisition life-cycle. While a DASA-agreed TCB should be pursued prior to entering into an acquisition contract, this will not always be possible. In those cases, the acquisition project office may elect to present a draft TCB for DASA assessment as a cost and schedule risk reduction measure.

7.2.2.32 In most cases, DASR and the DASDRM allow the Defence TCB to be based on the recognised design standards used by the parent CAA/MAA under which the aircraft was initially designed and certified.

7.2.2.33 The TCB for a Defence aircraft must be consistent with Defence's intended role and operating environment for the aircraft. In the aircraft Type Certification domain, CRE is a pivotal concept. Where an ab-initio Type Certification programme is proposed for a Defence aircraft, defining the CRE is essential to ensure that the basis of certification is consistent with the intended Defence use of the aircraft.

7.2.2.34 Where the Defence Type Certification programme intends to leverage prior certification from a recognised CAA/MAA to any extent, a CRE Assessment (CREA) is required to confirm the applicability of that prior certification to the intended Defence use. Areas where the prior certification is not entirely applicable to the Defence CRE must be addressed through further compliance demonstration evidence, inclusion of additional requirements in the TCB, or tailoring of requirements for the TCB. Further guidance on leveraging prior certification is contained in Annex B to Section 7.2, and further guidance on the conduct of a CREA is contained in Annex C to Section 7.2.

7.2.2.35 **Tailoring the PCC.** During a certification program, there may be a need to tailor the PCC when seeking an MTC. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

7.2.2.36 Tailoring of the PCC may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.2.37 Tailoring of the PCC can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a Military Certification Review Item (MCRI).

Superseded

7.2.2.38 Annex A to Section 7.2 provides further guidance on tailoring the PCC, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support PCC tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Compliance Demonstration

7.2.2.39 **Overview.** Compliance demonstration evidence comprises of reports, engineering tool outputs, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the applicable TCB is demonstrated. The applicant shall demonstrate compliance with the type-certification basis either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.2.40 The agreed certification programme will include details of how compliance demonstration is being achieved for each project. Where difficulty arises in meeting the agreed certification programme activities or outcomes, engagement with DASA as early as practicable is recommended. This phase may identify issues in compliance demonstration evidence against the agreed Defence TCB that require equivalent safety finding arguments, processing of exceptions underpinned by an Airworthiness Issue Paper (AwIP) or equivalent, or introducing new interpretations or means of compliance. In these cases an MCRI, and an AwIP as required, should be raised and submitted by the applicant for DASA consideration.

7.2.2.41 **Leveraging Prior Certification.** Defence is rarely the prime customer for new aircraft, so most acquisitions will be based on an aircraft design that has or will be certified by another CAA/ MAA. DASR 21.A.20 enables an applicant for an MTC to leverage prior certification from a recognised CAA/MAA[9] to gain relief from developing compliance demonstration evidence.

7.2.2.42 The fundamental principle of leveraging prior certification is that any requisite Authority review of evidence; testing, or witnessing of testing; or inspections (refer DASR 21.A.33(b)) have already been performed by a competent Authority (ie a CAA/MAA recognised by DASA). Therefore, duplicate effort in terms of DASA also conducting inspections / analyses / tests is unnecessary. However, as per DASR AMC 21.A.20, in order to leverage the prior certification, the applicant for the MTC must ensure:

1. the certification is within the scope, conditions and caveats specific to DASA Recognition of the certifying CAA/MAA
2. the CAA/MAA is sufficiently experienced in certification of the particular design activity
3. the certification requirements employed by the CAA/MAA are understood and any deltas from the Defence TCB have been addressed
4. the CRE applied to the prior certification is understood and any deltas from the intended Defence CRE have been addressed
5. any safety risks associated with the CAA / MAA certification have been identified, and have been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) for the Defence CRE.

Superseded

7.2.2.43 Annex B to Section 7.2 provides additional guidance on the AMC 21.A.20 requirements for leveraging prior certification, and discusses common issues encountered with leveraging prior certification. Annex C to Section 7.2 provides further guidance on the conduct of a CREA to support relief from presenting CDE when leveraging prior recognition.

7.2.2.44 **Structures and Propulsion System Specific Guidance.** Guidance on the conduct of structures and propulsion system CREAs when leveraging prior certification can be found in GM1 21.A.20 and Chapter 6.6.2. Guidance to support AMC 21.A.41 (Structural and Propulsion System Critical Parts and Airworthiness Limitations (AUS)) can be found in Chapter 6.6.2.

MTC Application, Issuance and Type Certificate Data Sheet (TCDS)

7.2.2.45 **Application.** Upon completion of all activities identified within the CPP, including development of compliance demonstration evidence and completion of DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for issuance of an MTC. The exact format of the application for an MTC will differ depending upon each project, and should be agreed within the CPP.

7.2.2.46 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will issue the MTC.

7.2.2.47 For acquisitions of new aircraft types, the Defence Aviation Authority (Defence AA) will generally elect to convene an Airworthiness Board (AwB). Aircraft acquisition AwBs, including applicant and DASA submission of documents to support the AwB, are separate to the DASR type certification process outlined within this section. AwBs are discussed further in Section 6.1.2 and Section 13.

7.2.2.48 **Type Certificate Data Sheet (TCDS).** A TCDS will accompany each MTC. The TCDS contains all information (or reference thereto) about the type certification of the product including the TCB, the type design, operating limitations, the Aircraft Flight Manual (AFM), Instructions for Continuing Airworthiness (ICA), Airworthiness Limitations (AwLs), Certification Maintenance Requirements (CMRs), critical parts list (if applicable) and any other data necessary for the continued safe operation of the product.

7.2.2.49 DASA will develop and issue the TCDS concurrently with the MTC.

DASA Assurance

7.2.2.50 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining an MTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).
2. DASA agreement of the TCB, including tailoring (refer 'Type Certification Basis' section above).
3. DASA LoI in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme'

Superseded

section above). In all cases, DASA LoI activities should be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer below for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, and issue of the MTC and TCDS.

7.2.2.51 **DASA Assurance when Leveraging Prior Certification.** Where the certification programme indicates that an applicant is proposing to leverage prior certification from a recognised CAA/MAA, then DASA assurance activities will focus on the criteria outlined in AMC 21.A.20. The guidance outlined in Annex B to Section 7.2 provides an indication of the considerations that DASA will examine as part its assurance activities.

7.2.2.52 For certain aspects, the CPP will only be providing a proposal for how the applicant intends to address the criteria for leveraging prior certification outlined in AMC 21.A.20. For example, the applicant may need to conduct further activities to confirm that the CAA/MAA is sufficiently experienced in certification of the particular design activity, conduct further analysis to show that the design is compliant for the Defence CRE, and conduct sovereign assessments for safety risk decisions or risk retention made by an MAA. Therefore, DASA will typically request the applicant provide relevant documentation prior to, or as part of, the final application.

7.2.2.53 Note that while leveraging prior certification may provide relief from the need to develop new compliance demonstration evidence, it does not provide relief from the need to present compliance demonstration evidence to DASA. As such, DASA may request to review evidence that supported the prior certification where it is deemed necessary. Where it is not possible for the applicant to provide this evidence to DASA, for example due to limitations on access to OEM data, this will be negotiated between the applicant and DASA on a case-by-case basis.

MTC Holder Obligations

7.2.2.54 MTC holder obligations are outlined in DASR 21.A.44. Refer to Section 7.4.1 for detailed guidance on MTC holder obligations.

7.2.3 – Changes to Type Certificates and Military Supplemental Type Certificates (DASR 21 Subpart D and E)

Overview

7.2.3.1 **Scope of Section.** Section 7.2.3 primarily describes the DASR type certification process for major changes to the type certificate and obtaining a Military Supplemental Type Certificates (MSTC). Minor changes to the type certificate are only briefly addressed herein.

7.2.3.2 **Change to a Type Certificate.** As defined by DASR 21.A.41, the type certificate includes:

1. The Type Design, which includes[10]:

Superseded

i. The drawings and specifications, and a listing of those drawings and specifications, necessary to define the configuration and the design features of the product shown to comply with the applicable TCB;

ii. Information on materials and processes and on methods of manufacture and assembly of the product necessary to ensure the conformity of the product;

iii. An approved Airworthiness Limitations Section (ALS) of the ICA as defined by the applicable airworthiness codes; and

iv. Any other data allowing by comparison the determination of the airworthiness of later products of the same type.

2. Operating Limitations

3. The TCDS

4. The applicable TCB

5. Any other conditions or limitations prescribed for the product in the applicable airworthiness requirements.

7.2.3.3 A change to any aspect of the items listed above is considered a change to the type certificate, and must be undertaken in accordance with DASR 21 Subpart D or E.

7.2.3.4 Note that DASR M.A.304(d) allows for the Operator to directly consume data for minor changes that has been approved within the framework of Authorities recognised by DASA. Under this pathway, the requirements of DASR 21 are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. Data for major changes cannot be directly consumed via recognition, and must be processed in accordance with DASR 21 Subpart D or E. Refer to Section 8.2 for further information on the direct consumption of data via recognition. Consumption of data for minor changes via recognition is not discussed any further within this section.

Classification

7.2.3.5 In accordance with DASR 21.A.91, all changes to the type certificate must be classified as minor or major.

7.2.3.6 A minor change is defined as a change that has no appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product. All other changes are defined as major. Guidance on classification of changes to type certificates, including examples of changes that should be classified as major, can be found in DASR GM 21.A.91.

7.2.3.7 DASR 21J MDO approval holders will typically have the privilege to classify changes that are within the scope (e.g. technology or platform types) of their terms of approval. As noted in DASR GM 21.A.91, DASA should be consulted for clarification wherever there is doubt as to the classification of a change. Furthermore, when the strict application of the DASR GM 21.A.91 paragraph 3.4 criteria results in a major classification, the applicant may request reclassification, if justified, and DASA can take the responsibility in reclassifying the change.

Processing of Minor Changes

Superseded

7.2.3.8 Minor changes to the type certificate must be undertaken in accordance with DASR 21 Subpart D, and can be approved by DASA or a DASR 21J MDO approval holder with the necessary privilege and scope. DASA expects that in the Defence context, minor changes to type certificates undertaken in accordance with DASR 21 Subpart D will be developed and approved by a DASR 21J MDO[11].

Processing of Major Changes

7.2.3.9 Changes that are classified as major can be processed and approved as a:

1. major change to the existing MTC under DASR 21 Subpart D, or
2. a MSTC under DASR 21 Subpart E.

7.2.3.10 The decision to apply for a major change (DASR 21 Subpart D) versus a MSTC (DASR 21 Subpart E) will depend upon the specific context. Under the DASR construct, both these authorisations will be issued to the government MTC holder. The default approach is usually issue a major change to the existing MTC, however, as discussed in the following sub-section, there may be cases where an MSTC is more appropriate.

Use of Military Supplemental Type Certificates (MSTCs)

7.2.3.11 The reasons for using an MSTC are different in the Defence context from in the civilian context. This sub-section provides guidance on when an MSTC should be used under the DASR.

7.2.3.12 **Civil use of Supplemental Type Certificates (STCs).** In the civil context, STCs are generally used for commercial purposes. They are used where a designer (either the OEM or another designer) alters the aircraft to provide a new capability that they can sell separately to the original Type Certificate. Of note, designers who are not the holder of the original Type Certificate can only ever apply for STCs for design changes that are classified as major, as it is not possible to apply for a major change to a certificate you do not hold.

7.2.3.13 Major changes to the Type Certificate are limited to changes done by the Type Certificate Holder, and are mostly (though not always) mandatory Service Bulletins and Airworthiness Directives to address safety issues identified in service as part of the holder obligations (eg DASR 21.A.3A).

7.2.3.14 **Use of MSTCs Under DASR.** Under the DASR the reasons for using an MSTC are different to the civil context. The following are the reasons that an MSTC (as opposed to a major change to the MTC) would be used under the DASR:

1. Sub-fleet: An MSTC may be used to manage a sub-fleet. This would be where there is one or more aircraft in the fleet that are intended to be configured or operated in a significantly different manner to the remainder of the fleet. Note, sub-fleets can also be managed via major changes to the MTC, so an MSTC may be used but is not the only option for management of sub-fleets.
2. Significant Change to the TCB: An MSTC may be used to manage a change that involves a distinct change to the TCB. Generally this will be the result of reliance on prior certification which has adopted a different PCC than that used for the original MTC. While the change to the PCC may be able to be managed via MCRI(s), it may reduce the complexity of ongoing management of the authorisations by covering the change under an MSTC.

Superseded

3. Large and Complex Changes: An MSTC may be used for large and complex changes. While the process for review and approval of a major change or an MSTC is the same, use of an MSTC provides greater visibility, and as a result greater clarity, of the precise nature and scope of the change. MSTCs are often understood by Defence Operators as being a change of more significance, which warrants greater operational consideration.

4. Management Reasons: An MSTC may be used for ease of management from the perspective of the MTC holder. This may be required to provide alignment between the DASR authorisations and authorisations being leveraged via recognition. It may be simpler for an MTC holder to manage their obligations if the Defence authorisations are aligned with the OEM authorisations.

7.2.3.15 Note that when changes are applied to the MTC for a platform that also has MSTC(s), the compatibility of the change with the existing MSTC(s) must be explicitly addressed. Under the civil system, a change to the Type Certificate does not need to explicitly consider compatibility with potential STCs. It is the Operator's responsibility to consider the impact of change to the Type Certificate against any STCs applied to their aircraft, and to engage the STC holder as required. However, in the DASR context, the MTC and MSTCs are frequently more integrated and less able to be clearly separated from each other. In addition, the MTC and MSTCs are all held by the same organisation so separating consideration of the MTC and MSTCs is unnecessary and adds confusion for no benefit. As such, it is not appropriate to progress a major change to the MTC without considering the impact on existing MSTCs.

Eligibility

7.2.3.16 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the relevant authorisation.

7.2.3.17 **Major Change to the MTC.** In accordance with DASR 21.A.92, only the MTC holder can apply for a major change to the MTC. However, as noted by DASR GM 21.A.92(a), this includes any organisation acting on behalf of the MTC holder. DASA considers it appropriate for a design organisation to act as the applicant for a major change (on behalf of the MTC holder) where:

1. the agreement between the MTC holder and design organisation required by DASR 21.A.14(c) permits,

2. the TCAE reflects the agreement and arrangements under which such applications may occur, and

3. the proposed design change is within the scope of the design organisation's approval.

7.2.3.18 In all cases, the MTC holder must sign the final application for the major change (ie Form 31A) to confirm that they have been consulted on, and have no objection to, the major change, and will carry out holder responsibilities.

7.2.3.19 During sustainment, additional design organisations may be engaged by the MTC holder to support new modifications or reflect expanding design support agreements. In these cases, the MTC holder should inform DASA of the proposed support arrangements and define additional oversight requirements to support specific applications.

Superseded

7.2.3.20 **MSTC.** In accordance with DASR 21.A.112A, any organisation that has demonstrated, or is in the process of demonstrating, its capability under DASR 21.A.112B shall be eligible as an applicant for an MSTC. The DASR 21.A.112B demonstration of capability requirements are essentially the same as those of DASR 21.A.14 (refer to the 'Eligibility' guidance in Section 7.2.2, and relevant AMC and GM for further information).

7.2.3.21 However, as noted by DASR GM 21.A.115, DASA will issue all MSTCs to the relevant government MTC holder organisation. This means that, in effect, all applications for MSTC are being made on behalf of the MTC holder who will be the eventual holder of the MSTC. Applicants for MSTCs must be able to demonstrate that they are acting on behalf of the MTC holder.

7.2.3.22 **Major Change or MSTC Applications by CASG Project Offices.** In some cases, the CASG project office may act as the applicant for a major change or MSTC for larger or more complex modifications to an existing aircraft, such as for a mid-life upgrade program or significant capability upgrades.

7.2.3.23 Since only the MTC holder can apply for major changes to the existing MTC, the CASG project office would be considered to be applying for the approval on behalf of the MTC holder. For MSTC applications, the CASG project office could be considered the applicant under the DASR 21.A.112B(c) exception clause. In either case, the eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J.

7.2.3.24 Also refer to the 'MTC Applications by CASG SPOs (Project Offices)' guidance in Section 7.2.2 for further information, including guidance on applicant eligibility when CASG project offices wish to leverage recognition provisions.

7.2.3.25 CASG project offices seeking to apply for a major change or MSTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended program.

Certification Programme

7.2.3.26 **Overview.** Under DASR 21, a certification programme is required for all changes to type certificates and MSTCs. The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a CPP.

7.2.3.27 For MSTC and 'complex'[12] major change programs, the certification programme must be presented to DASA for formal acceptance prior to the final application and declaration of compliance, and it is recommended that it be presented as a CPP. For other certification activities, the certification programme may be documented through the design pack or final application, and does not require formal DASA acceptance. Table 7.1 summarises the certification programme requirements for different design activities.

Certification Activity	DASR Reference	Formal DASA Acceptance Required?	Comments
Application for an MSTC	21.A.113(b)	Yes	Certification programme should be presented as a

Superseded

	21.A.93(b)		CPP containing the information required by 21.A.93(b) and the supporting AMC. The DASA major change/MSTC CPP template will assist in meeting the required outcomes.
Application for a 'complex' major change	21.A.93(b)	Yes	
Application for a 'simple' major change	21.A.93(b)	Yes	Certification programme can be provided with the final application for approval of the change.
Minor change to type-certificate	21.A.93(b)[13]	No	

Table 1: Certification Programme Requirements for Design Change Activities

7.2.3.28 Two CPP templates are published on the DASA website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the major change/MSTC CPP template.

7.2.3.29 The organisation(s) involved in the development and submission of a certification program for a major change or an MSTC application will vary depending upon the platform support arrangements. As noted above, the design organisation that supports the MTC holder functions may act as the applicant on behalf of the MTC holder in certain circumstances. In these cases, the design organisation will usually develop the CPP and engage with DASA for formal acceptance when required.

7.2.3.30 **Simple Major Changes.** For 'simple'[14] major changes, the certification programme may be presented with the final application (ie with the Form 31a pack). This approach introduces a risk that if DASA identifies issues with the certification programme, or with the decision to treat the change as simple, there may be a requirement for rework of compliance demonstration activities, resulting in a delay to the program. As such, this approach should only be followed where the change is straightforward; for example, OEM Service Bulletins that have received CAA/MAA certification. If there is doubt as to whether a change would meet the definition of 'simple', DASA Type Certification section should be contacted for advice.

7.2.3.31 **Contents of a Certification Programme.** DASR 21.A.93(b) outlines the requirements for content of a certification programme for a major change or an MSTC.

7.2.3.32 Certification programmes must be tailored to meet the requirements of the certification activity. If a change has been assessed as 'simple', then there is no need to do a full breakdown of the programme into CDIs or to provide a detailed LoI proposal, as the LoI must be assessed as nil to meet the definition of a simple change. For changes that rely on prior certification, the breakdown of the programme into CDIs is only required for areas that are not able to fully leverage prior certification (ie where additional compliance demonstration evidence is being developed).

7.2.3.33 For 'complex' major changes and MSTC, the certification programme should be presented as a CPP containing the information required by DASR 21.A.93(b) and the supporting AMC and GM. The major change/MSTC CPP template published by DASA will assist in meeting the required outcomes.

Superseded

7.2.3.34 **Further Guidance.** Refer to the certification programme information in Section 7.2.2 for further guidance on proposal of CDIs and DASA LoI, as well as certification programme acceptance and updates.

Certification Basis

7.2.3.35 For all changes to a product, the design organisation must identify the areas affected by the change and the corresponding certification basis (airworthiness requirements) for those areas. The applicable airworthiness requirements will depend upon the nature of the change, and can be generalised as follows:

1. **Substantial changes.** Some changes are so extensive that a new type certificate is required (refer DASR 21.A.19), and therefore would require an entirely new TCB to be established. Substantial changes for an existing aircraft type are unlikely within the Defence context.

2. **Significant (major) changes.** For major changes that are categorised as significant[15] under DASR 21.A.101, then the latest amendment level of the airworthiness requirements referenced in the TCB should be used for the change.

3. **Non-significant (major) changes.** For major changes that are not categorised as significant, then the DASR 21.A.101(b) exception clause allows the existing airworthiness requirements in the TCB to be used for the change. DASR 21.A.101(b) also allows the existing airworthiness requirements to be used for a significant change in cases where use of the latest amendment of the airworthiness requirements referenced in the TCB would not contribute materially to the level of safety, or is impractical.

4. **Minor changes.** Minor changes, by definition, do not affect the airworthiness of the product. This means that it is appropriate to use the existing airworthiness requirements in the TCB for the change (refer DASR 21.A.95(b)(1) and DASR AMC 21.A.95).

7.2.3.36 As stated above, using the existing airworthiness requirements in the TCB is usually considered adequate for minor changes and non-significant major changes. However, as noted in DASR GM 21.A.93(b)(2), Australia's WHS Act levies additional obligations on designers, namely to exercise 'reasonable knowledge' when determining that any risk inherent in designs has been minimised SFARP. Updates (later amendments) to applicable standards may provide insight into hazards and potential controls that are not identified in the existing TCB. The requirements prescribed in the DASDRM also provide a source of requirements and standards that can assist engineers to satisfy their obligation to exercise reasonable knowledge of hazards and associated controls in aircraft design.

7.2.3.37 The certification programme for the change should identify the proposed certification basis (ie existing or latest amendment level, with justification as required) and any 'reinvestigations' required[16].

7.2.3.38 **Changed Product Rule.** DASR 21.A.101 is commonly referred to as the 'changed product rule' and is used by applicants and DASA to establish the certification basis for major changes and MSTCs. The primary decision under the changed product rule is whether the latest amendment of the airworthiness requirements referenced in the TCB must be used (ie significant major change), or whether the nature of the major change allows the existing airworthiness requirements to be used (ie non-significant major change). If an applicant elects to comply with the latest amendment for a major

Superseded

change that could otherwise be categorised as non-significant, then the change will be compliant with DASR 21.A.101(a) and no further justification would be required.

7.2.3.39 DASR GM 21.A.101 contains extensive guidance and a step-by-step process for applicants to follow in order to establish the proposed certification basis for the major change. A summary of the changed product rule criteria and outcomes is shown below in Table 7.2. Table 7.2 is taken from Appendix B to GM 21.A.101, and only provides a brief summary of the extensive guidance and step-by-step process contained in DASR GM 21.A.101. A number of the Appendices to GM 21.A.101 refer to the EASA GM 21.A.101, including Appendix A of EASA GM 21.A.101 which provides examples of changes that EASA, the FAA and other Authorities considered to be 'substantial', 'significant' and 'non-significant'.

<table>

</table>

Table 2: Establishing Certification Basis for Changed Products

7.2.3.40 Significant major changes shall also comply with the relevant 'essential' design requirements defined in the DASDRM (refer DASR AMC 21.A.101).

7.2.3.41 Note that for major changes, DASR 21.A.101(e) is a further exception clause that allows applicants to propose an alternative to the airworthiness requirements in the TCB. DASA may agree to the use of an alternative set of airworthiness requirements provided the alternative provides at least an equivalent level of safety to the existing TCB.

7.2.3.42 The process and justification used to comply with DASR 21.A.101 should be included within the certification programme, and the DASA major change/MSTC CPP template contains specific headings to include this information.

7.2.3.43 When applicants believe that the major change under consideration may be significant, or have questions about application of DASR 21.A.101, then engagement with DASA as early as practicable is recommended.

7.2.3.44 **Tailoring the TCB.** During a certification program, there may be a need to tailor the TCB when seeking a major change approval. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

Superseded

7.2.3.45 Tailoring of the TCB may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.3.46 Tailoring of the TCB can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a MCRI.

7.2.3.47 Annex A to Section 7.2 provides further guidance on tailoring the TCB, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support TCB tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Reclassification of Changes Requiring TCB Tailoring

7.2.3.48 Occasionally, changes to type certificates that would otherwise be classified as minor, are required to be classified as major only because of the need to tailor the TCB. This section outlines an approach to enable these changes to be reclassified to minor, once the TCB tailoring has been agreed. This approach will allow greater use of DASR 21J MDO privileges, and reduce DASA assurance in areas where there is not a clear safety benefit.

7.2.3.49 **Reclassification Justification.** DASR GM 21.A.91 states that any changes that require an adjustment of the TCB, other than electing to comply with a later amendment of a requirement, must be classified as major. However, it also states that when the strict application of the classification criteria for a design change results in a major classification, the applicant may request re-classification, if justified, and DASA can take the responsibility in re-classifying the change.

7.2.3.50 DASA has identified that, for changes that are classified as major solely due to a need to tailor the TCB, continuing to process these as major changes once the tailoring of the TCB has been agreed imposes additional administrative burden without commensurate safety benefit, and can result in a delay to the introduction of safety improvements or capability upgrades. As such, DASA considers it appropriate for these changes to be re-classified to minor, as allowed by DASR GM 21.A.91, and either directly consumed (if subject to prior certification) or approved by a DASR 21J approved organisation holding appropriate privileges.

7.2.3.51 **Reclassification Process** (Figure1). Reclassification is only possible once the tailoring of the TCB has been agreed. An applicant may submit the requests for TCB tailoring and reclassification concurrently, allowing a single DASA response, or the reclassification request may be submitted after the tailoring has been agreed. Requests for reclassification are to be submitted via Letter or Minute to DASA via the DIA Type Certification mailbox (dasa.typecert@defence.gov.au). Requests must be submitted by an organisation that meets the eligibility requirements to apply for a major change under DASR 21 Subpart D (ie the MTC holder or a design organisation that provides MTC holder functions as part of establishing holder capability).[17]

7.2.3.52 The applicant must provide confirmation that the design would meet the requirements to be classified as minor if not for the tailoring of the TCB. This may be provided as an assessment from a DASR 21J approved organisation that has privileges to classify changes, or by providing evidence of approval as a minor change under the system of a recognised CAA/MAA with an equivalent classification system.

Superseded

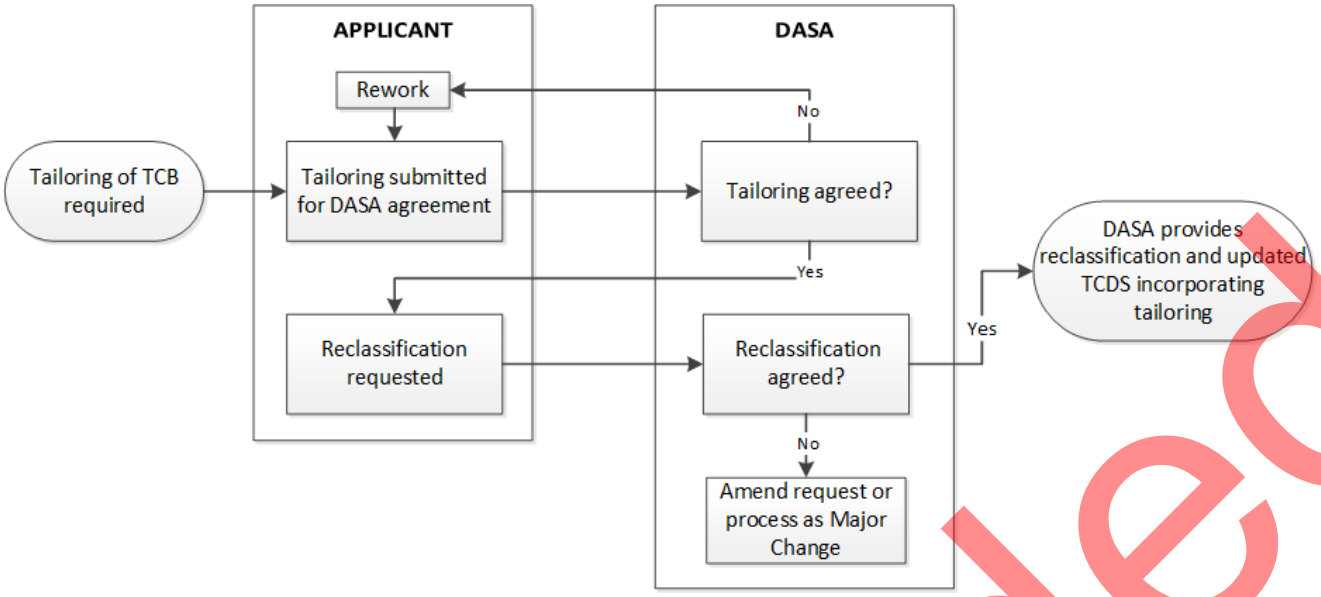

Figure 1: Process for reclassification when TCB tailoring is required

Compliance Demonstration

7.2.3.53 Compliance demonstration evidence comprises of reports, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the TCB requirements applicable to the change / MSTC is demonstrated. The applicant shall demonstrate compliance with the applicable TCB requirements either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.3.54 Refer to the 'Compliance Demonstration' evidence guidance in Section 7.2.2 for further information.

Application, Approval / Issue and TCDS Update

7.2.3.55 **Application.** Upon completion of all activities identified within the certification programme, including development of compliance demonstration evidence and DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for approval of a major change, or issuance of an MSTC, using the DASR Form 31A.

7.2.3.56 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will approve the major change or issue the MSTC.

7.2.3.57 **TCDS.** As required, DASA will develop and issue the TCDS update concurrently with the major change approval or MSTC issuance.

DASA Assurance

7.2.3.58 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining a major change or MSTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).

Superseded

2. DASA agreement of the TCB, including tailoring (refer 'Certification Basis' section above).

3. DASA Level of Involvement (LoI) in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme' section above). In all cases, DASA LoI activities must be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer to the 'DASA Assurance' guidance in Section 7.2.2 for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, approval of the major change or issue of the MTC, and update of the TCDS as required.

Holder Obligations

7.2.3.59 Given the DASR only allows the MTC holder to be the applicant for a major change to an existing MTC, there are no separate DASR holder obligations for major changes, and the MTC holder must undertake the obligations laid out in DASR 21.A.44 for the MTC, including and all major changes thereto.

7.2.3.60 Obligations for holders of an MSTC are laid out in DASR 21.A.118A . However, given DASA's policy of issuing all MSTCs to the government MTC holder organisation, and the fact that the DASR 21.A.118A obligations are essentially the same as those ofDASR 21.A.44, the MTC holder simply needs to continue to undertake all obligation laid out in DASR 21.A.44 for the MTC and all MSTCs they hold.

7.2.3.61 Refer to Section 7.4.1 for detailed guidance on the DASR 21.A.44 MTC holder obligations.

7.2.4 – Repair Designs (DASR 21 Subpart M)

Overview

7.2.4.1 Data that is used to accomplish repairs needs to be approved by a suitable and competent organisation. Data may be approved through a repair design approval process where DASA is the certifying authority, or through a process where recognition is used. These two broad pathways are covered by DASR M.A.304, which provides the requirements for data that is used to carry out repairs and modifications:

1. DASR M.A.304(a) and (b) allow data to be used that has been approved by DASA, and by a Design Organisation approved under DASR 21, respectively. In both cases DASA is the certifying authority and the requirements of DASR 21 Subpart M (Repairs) are applicable.

Superseded

2. DASR M.A.304(d) allows for the consumption of data that has been approved within the framework of Authorities recognised by DASA. In this instance the repair approval requirements of DASR 21 Subpart M (Repairs) are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate.

7.2.4.2 This section is relevant to data for repairs conforming to DASR M.A.304(a) and (b) and provides:

1. an overview of the repair approval process in accordance with DASR 21 Subpart M (Repairs)
2. guidance for design organisations and MTC holders regarding DASA's expectations for repair design development and approval
3. more detailed guidance in the form of a number of common repair scenarios.

7.2.4.3 Guidance regarding use of repair data in accordance with DASR M.A.304, including consumption of data using recognition provisions, is provided in the Section 8.2.

7.2.4.4 Note that additional general information about Repair Design authorisations is contained in Section 5.3 Annex R.

DASR 21 Repair Design Privileges

7.2.4.5 DASR 21 Subpart J privileges related to repair designs include the privilege to:

1. classify repairs (DASR 21.A.263(c)(1)),
2. approve minor repairs (DASR 21.A.263(c)(2)), and
3. approve certain[18] major repairs (DASR 21.A.263(c)(5)).

7.2.4.6 These privileges require the design organisation to have procedures agreed to by DASA, usually by issue of a Military Design Organisation Approval (MDOA). These procedures would normally be documented in a Design Organisation Handbook[19].

Repair Process

7.2.4.7 The overall process for development, approval and embodiment of repairs where DASA is the certifying authority is outlined in Table 7.3. Further guidance, in the form of specific scenarios are outlined in Annex D to Section 7.2 Repair Design Approval Scenarios. Note that the scenarios in Annex D are defined as an aid for explanation, rather than as a series of strict processes.

Stage	Description	Responsibility
Identify and Assess Damage	Damage identified for which there is no existing pre-approved solution.	CAMO
Develop Repair Design	Repair design data is developed.	Design organisation

Superseded

Repair Classification	Repair classified in accordance with the requirements of DASR 21.A.435a.	DASA or an appropriately approved design organisation under a procedure agreed with DASA
Repair Certification	Establish Certification Basis (CB). Demonstrate compliance with required CB elements, Compliance Verification, Declare Compliance. Submit application for approval if required.	Applicant that meets the eligibility criteria[20]
Repair Approval	Approval of Repair. The assignment of obligations to the repair approval holder (dependent on classification).	DASA or an appropriately approved design organisation under a procedure agreed with DASA.
Repair Configuration Management	Manage the accomplishment of repairs and maintain a record of aircraft configuration, which includes repairs.	CAMO
Production of Repair Parts	Produce repair parts.	Appropriately approved production organisation, under DASR 21 Subpart G or Subpart F, or an appropriately approved maintenance organisation under DASR 145
Repair Embodiment	Embody repair.	Appropriately approved maintenance organisation under DASR 145 or appropriately approved production organisation under DASR 21 Subpart G
Ongoing Holder Obligations		Repair design approval holder

Table 3: Repair Process where DASA is the Certifying Authority

Repair Design Classification

7.2.4.8 As per DASR 21.A.435a – Classification and approval of Repairs – a repair must be classified as either minor or major in accordance with the criteria laid out in DASR 21.A.435a. Classification of repairs guides DASA to apply appropriate assurance oversight and allows for the obligations of the holder of a repair design approval to be identified. Classification does not affect the certification basis, demonstration of compliance, independent checking or declaration of compliance and, as such, whether a repair is classified as major or minor does not affect the engineering rigour applied to the repair. Repair classification may be made by either DASA or by an appropriately privileged design organisation under a procedure agreed to with DASA[21].

7.2.4.9 DASR GM 21.A.435a states that a new repair – a repair that has not previously been approved for the application being considered on the individual aircraft in question – is classified as major if it has an appreciable effect on structural performance, weight, balance, systems, operational characteristics or other characteristics affecting airworthiness. This is elaborated on to highlight that repairs needing extensive static, fatigue or damage tolerance justification or testing, or requiring

Superseded

methods, techniques or practices that are unusual, are to be classified as major. This GM identifies repairs that require permanent changes to Airworthiness Limitations (AwLs) to be classified as major.

7.2.4.10 The paragraphs below give examples of what may need to be considered in developing a repair classification procedure. Each organisation must develop its own procedure which meets the requirements of DASR 21.A.435a, 21.A.239, 21.A.263 and 21.A.243 and is tailored to the organisations scope of work. However, the considerations below, based on the guidance provided in the GM 21.A.435a and GM 21.A.91, are provided to further clarify DASA's expectations of such a procedure.

7.2.4.11 For clarity, classification may consider the following three characteristics of the repair design:

1. Severity – the effect of the repair on airworthiness.
2. Complexity – the complexity of the design and the certification requirements.
3. Novelty – whether the design has been developed in accordance with established methods and practices for the repair application in question.

7.2.4.12 Generally repairs may be classified as major except when all of the following criteria are met:

1. Severity is low. Examples of the types of details that would be expected from repairs of low severity include:
    i. Structural performance, in terms of static strength, fatigue performance, damage tolerance performance, flutter and stiffness characteristics, is unaffected by the repair.
    ii. Load paths and load sharing in the vicinity of the repair are unaffected by the repair.
    iii. Weight and balance change is not greater than that allowed in the weight and balance manual or Original Equipment Manufacturer (OEM) repair guidance for weight and balance. This includes changes in centre of gravity and load distribution. Weight and balance of control surfaces can be particularly affected by even small changes.
    iv. Changes do not affect the operation or redundancy of a system, or an adjacent system.
    v. Changes do not affect operational characteristics.
    vi. Other characteristics related to airworthiness, or to environmental characteristics of the platform (such as noise, fuel venting and exhaust characteristics), are not affected including, but not limited to, fire protection, propulsion systems integrity and crashworthiness.
2. The repair design and the certification requirements are not complex. Examples of the types of details that would be expected from repairs of low complexity include:
    i. Repair requires no or minimal re-assessment or re-evaluation of original certification substantiation data
    ii. Repair design elements are straightforward.

Superseded

iii. Original type certification data is available, or if not available appropriate data can be established without complex engineering, and no assumptions are required in the definition of the certification requirements.

3. There are no new or novel features to the repair. Examples of the types of details that would be expected from a repair that does not have new or novel features include:

   i. Techniques, methods and practices are those employed in the regular management of the platform and type of defect.

   ii. Techniques, methods and practices are those accounted for in the platform Type Design.

7.2.4.13 It is recognised that in some cases not all data will be available at the time of initial repair classification, and so, judgement must be exercised. In the case where later data indicates that the initial classification is no longer valid, a repair may be reclassified. In this case, consultation with DASA and, where necessary, reconsideration of the Certification Programme (CP), is expected.

7.2.4.14 These classification considerations are outlined in Figure 2.

Superseded

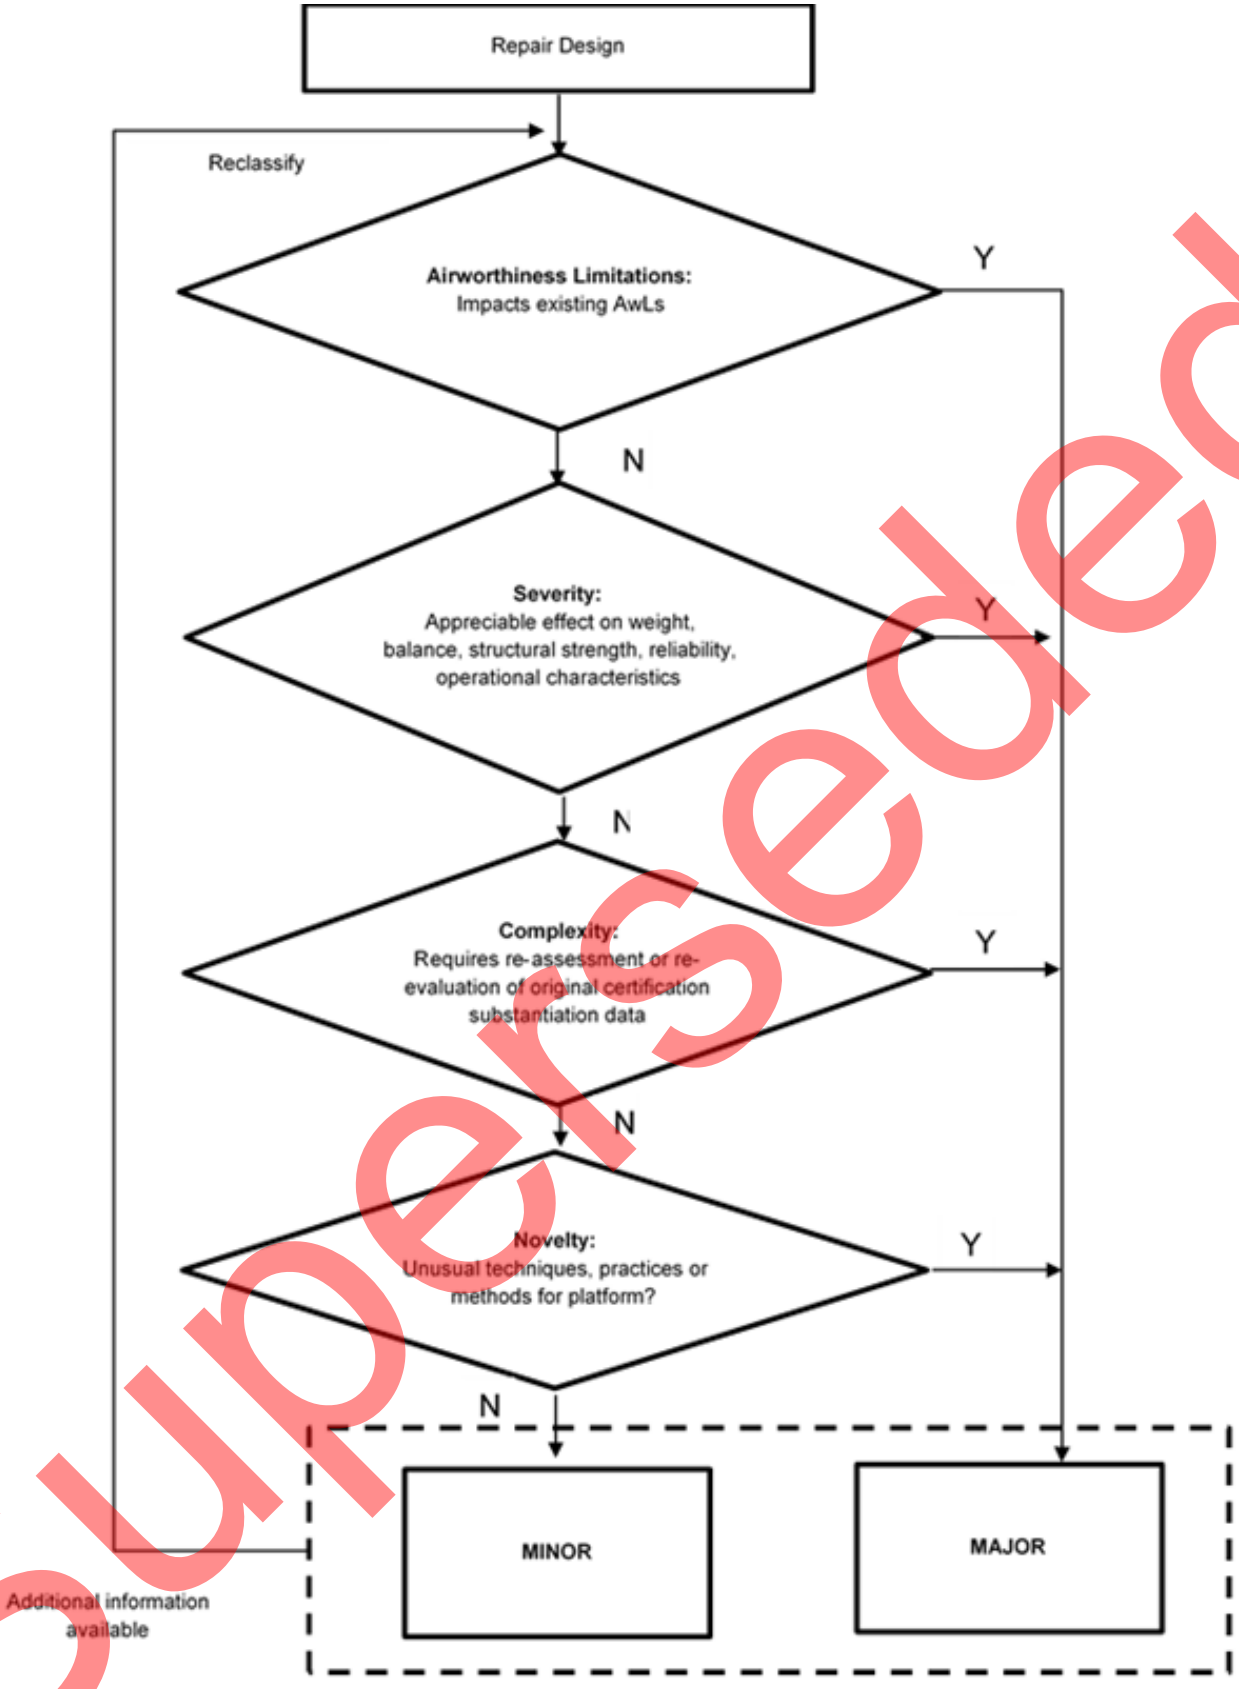

Figure 2 : Repair Classification Principles

Eligibility

7.2.4.15 Applicant eligibility requirements exist to control how designs are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance documents, artefacts

Superseded

and how the declaration of compliance is made. This provides DASA with confidence in the applicant's ability to fulfil the obligations of the repair approval holder where applicable. As such applicants for repairs must meet eligibility criteria as defined in DASR 21.A.432A.

7.2.4.16 To be eligible as an applicant for a major repair design approval, the applicant is to either hold an approval under DASR 21 Subpart J, or may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to demonstrate capability, or may be a government organisation which has agreements in place with a design organisation with access to the type design data.

7.2.4.17 Any organisation is eligible to apply for approval of a minor repair design. It is recommended that an organisation considering applying for DASA approval of a minor repair design seeks approval through an organisation holding a minor repair approval privilege under DASR 21 Subpart J, as DASA priorities will likely lead to delays in the approval of minor repairs.

Approval

7.2.4.18 Repair design approvals may be issued by DASA or an appropriately privileged design organisation, in accordance with DASR 21.A.435b.

7.2.4.19 In the case where DASA is issuing a major repair design approval, DASA receipt of a DASR Form 31B should signify the completion of a period of engagement between the applicant and DASA during which the certification activities agreed within the CP have been undertaken[22], including satisfactory DASA inspection of compliance documents. Upon receipt of the application, DASA assures itself that agreed CP activities have been completed, and if assured, DASA issues to the designated major repair design approval holder a signed DASR Form 31B for major repairs under DASR 21 Subpart M.

7.2.4.20 Design organisations approved under DASR 21 Subpart J can approve designs for minor repairs and certain major repairs, subject to the scope and privileges recorded in their terms of approval, and subject to their internal procedures agreed to by DASA. Further guidance based on repair classification is as follows:

1. **Minor Repairs.** Most MDOA holders approved by DASA will have the privilege to approve minor repairs that are within the scope of their terms of approval (privilege DASR 21.A.263(c)(2)).

2. **Major Repairs.** Some MDOA holders approved by DASA may also have the privilege to approve certain major repair designs that are within the scope of their terms of approval (privilege DASR AMC1 21.A.263(c)(5). The definition of 'certain major repairs' is provided in DASR AMC1 21.A.263(c)(5), (8) and (9), and depends upon whether or not the MDOA holder holds the relevant MTC, MSTC or Australian Military Technical Standard Order Authorisation (AUSMTSOA). In all cases, the ability to exercise the major repair approval privilege is subject to additional criteria and limits based on the characteristics of each individual repair design. For MDOA holders who do not hold the MTC, MSTC or AUSMTSOA, each new major repair design should be assessed against the 'List associated with the privilege' and the relevant 'Justification document' to determine whether the privilege can be exercised. Refer to AMC1 and AMC2 to DASR 21.A.263(c)(5), (8) and (9) for further information on award of, and exercising, the privilege to approve certain major changes.

Holder Obligations

Superseded

7.2.4.20 Following approval of the repair design, the obligations for the repair are assigned to the holder of the repair design approval in accordance with DASR 21.A.451. For both minor and major repairs these obligations include:

1. DASR 21.A.4 – Coordination between Design and Production.
2. DASR 21.A.447 – Record Keeping.
3. DASR 21.A.449 – Instructions for Continuing Airworthiness.
4. DASR 21.A.451(a)2 – Specify the markings in accordance within accordance with DASR 21.A.804(a).

7.2.4.21 For major repairs additional obligations of the holder of the repair design approval include:

1. DASR 21.A.3A – Failures, Malfunctions and Defects.
2. DASR 21.A.3B – Airworthiness Directives.
3. DASR 21.A.439 – Production of Repair Parts.
4. DASR 21.A.441 – Repair Embodiment.
5. DASR 21.A.443 – Limitations.
6. DASR 21.A.433(b) – Substantiation Data.

Superseded

7.2.5 – Instructions for Continuing Airworthiness (ICA)

Basic Principles of ICA

7.2.5.1 **ICA and maintenance data.** ICA is only a subset of all maintenance data that must be complied with in the conduct of maintenance[23]. Other sources of maintenance data include Airworthiness Directives (or other applicable requirements or operational directives issued by DASA), modification and repair implementation instructions and applicable maintenance standard practices. ICA should not be used as a collective term for all maintenance data as other sources of maintenance data are derived from different sources and subject to different regulation. This section deals only with ICA, not all forms of maintenance data.

7.2.5.2 **Airworthiness requirement.** The applicant for an MTC must develop ICA as required by the Type Certification Basis (TCB). Civil primary certification codes used for military products contain clauses (e.g. FAR/CS 23/25/27/29.1529 (aircraft), FAR 33.4 and CS-E 25 (engines), and FAR 35.4 and CS-P 40 (propellers)) that prescribe the content and format of ICA. Products with a military-derived TCB (e.g. from MIL-HDBK-516) have equivalent requirements for the development of maintenance instructions that achieve a similar intent to the civil airworthiness requirements above.

7.2.5.3 **Content and scope of ICA.** To meet the ICA requirements of a civil airworthiness code (or equivalent requirements of a military-derived TCB), the applicant for an MTC must provide:

1. Scheduling information for all recommended maintenance tasks. This information is normally contained in a Maintenance Review Board Report (MRBR) (or equivalent document).

2. Maintenance instructions including those required for servicing, troubleshooting, the methods of removing and replacing items, system testing, ground running, symmetry checks, weighing, towing, jacking, storage limitations etc. This will typically be provided in the form of an Aircraft Maintenance Manual(s), Structural Repair Manual, Fault Isolation Manual, Illustrated Parts Catalogue etc. This information can be amended by the MTC holder (broad scope to amend the master copy) or maintenance organisations approved under DASR 145 (very narrow scope to modify).

3. Mandatory maintenance requirements in a segregated and clearly distinguishable section of the ICA, typically called the Airworthiness Limitation Section (ALS). The ALS contains the mandatory maintenance tasks and intervals, identified in the type certification process. Specific terminology and requirements for the ALS content will vary depending upon the PCC, however, the ALS will generally include mandatory requirements such as:

   i. Airworthiness Limitations (AwLs). AwLs encompass mandatory retirement / replacement intervals and mandatory inspection requirements (including inspection interval(s) and the inspection method). The term AwLs is most often associated with structural life limits and structural inspections that result from FAR/CS 2x.571 or the equivalent fatigue/damage tolerance requirements in military certification standards. However, the term AwL may also be used for other aircraft systems, such as mandatory replacement times for Electrical Wiring and Interconnect System (EWIS) components. As noted within AMC 21.A.41, the definition of an AwL 'interval' includes the interval metric (e.g. flight hours, landings, Equivalent Flight Hours (EFH), Fatigue Index (FI) / Fatigue Life Expended Index (FLEI), engine cycles, etc), and any algorithm, equation, factor(s) or other engineering data which must be used to calculate life accrual against the interval.

   ii. Critical Design Configuration Control Limitations (CDCCLs). CDCCLs identify the critical design features such as proper wire separation, proper installation of a panel gasket, minimum bonding jumper resistance levels, etc., that must be maintained in exactly the same manner throughout the life of the aircraft in order to comply with the type certificate and maintain airworthiness. The purpose of CDCCLs is to provide instructions to ensure these critical features are present throughout the life of the aircraft and are inspected and verified when alterations, repairs, or maintenance actions occur in the area. Design features that are CDCCLs are defined and controlled by FAA Special Federal Aviation Regulation (SFAR) 88 and preserves critical features of the aircraft needed for the Flammability Reduction Means to perform their intended function and prevent the occurrence of an unsafe condition.

   iii. Certification Maintenance Requirements (CMRs)[24]. CMRs are required inspections or maintenance tasks, and associated intervals, developed to achieve compliance with safety analysis requirements (e.g. FAR/CS 25.1309/29.1309, other discrete safety analyses requirements such as FAR/CS 25.671, 25.783, 25.901, and 25.933, and FAR/CS 29 equivalents). A CMR is intended to detect safety-significant latent failures (failures not known to the flight or ground crew) that would, in combination with one or more other

Superseded

specific failures or events, result in a hazardous or catastrophic failure condition. A CMR can also be used to establish a required task to detect an impending wear-out of an item whose failure is associated with a hazardous or catastrophic failure condition.

7.2.5.4 **ICA and the MTC.** Even though a complete set of ICA is required to obtain an MTC, only the ALS of the ICA (or equivalent terminology including CDCCLs and CMRs) forms part of the type design[25] however, they do form part of the Type Certificate. Stand-alone amendments to ICA, other than the ALS, are allowed to be changed by the MTC holder using a procedure agreed with DASA. Note: when completing a stand-alone change to ICA other than the ALS, the MTC holder is not exercising a privilege, but is instead fulfilling their obligation to keep the ICA current[26]. Changes to the ALS of the ICA must be processed as a change to the MTC, and should be classified as a major change[27].

7.2.5.5 **Identification of ICA.** The complete set of ICA for any product should be identified on the TCDS. Other information or instructions required for continuing airworthiness or safe operation of the aircraft, e.g. the approved Aircraft Maintenance Programme (AMP) or a Minimum Equipment List (MEL), is not ICA and is not subject to regulation applicable to ICA.

7.2.5.6 **ICA supplements.** Some major changes to an MTC, MSTCs, minor changes or minor/major repair designs may require variations to the product's ICA[28]. Variations to ICA arising from these design changes or repairs stand-alone from the product's master ICA and are published as an ICA supplement[29]. This gives the aircraft operating organisation the flexibility in managing the ICA applicable to their aircraft, depending on which approved changes and repairs they have chosen to embody. The approval of ICA supplements (including any changed or additional mandatory maintenance requirements) are encapsulated in the approval of the design change or repair. ICA supplements should be identified on the Supplemental Type Certificate Data Sheet, or on the minor change or repair design approval.

7.2.5.7 **ICA and the AMP.** The approved AMP in and of itself is not ICA for the simple reason the ICA requirements of the TCB do not mandate an AMP to be developed by the applicant for an MTC. The recommended maintenance tasks and intervals in the MRBR and the mandatory maintenance requirements identified in the ALS, combined with other requirements unique to each operator's role and usage (including data from a reliability programme) forms the basis for approval of each operator's AMP.

7.2.5.8 The maintenance instructions provided by the MTC holder (or ICA supplements provided by other design approval holders) will provide detail on how to carry out the tasks and inspections in the AMP and should only be amended by the MTC holder (or other relevant design/repair approval holder for ICA supplements) – see paragraph 7.2.5.4 above. Mandatory maintenance requirements must be clearly identified as mandatory in the AMP and cannot be extended without a corresponding approval of a major change to the MTC, or issue of an MSTC. Other ICA must be changed by the MTC holder using DASA agreed procedures. Changes to other recommended task and inspection intervals in the AMP can be approved by a CAMO using a procedure agreed with DASA, without requiring approval of a change to the MTC[30].

Responsibilities for ICA

7.2.5.9 **MTC holders**. The MTC holder is Defence's custodian of the product's ICA regardless of its original author. The MTC holder is responsible for the ICA's content, amendment and distribution to all organisations that operate the aircraft. The MTC holder can amend the ICA (in accordance with

Superseded

approval processes) and must distribute amendments to those organisations affected. If a change to a mandatory maintenance requirement is required, the change must be approved by DASA before distribution of the amendment. The MTC holder's processes for discharging its responsibilities for ICA (even if exercised through external organisations) must be included in the MTC holder's Type Continued Airworthiness Exposition (TCAE). Regardless of a product's TCB, the MTC holder should be able to identify all ICA and have that documented in the TCDS.

7.2.5.10 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their ICA supplements as the MTC holder has for the product's master ICA.

7.2.5.11 **Aircraft operating organisations.** Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided.

7.2.5.12 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable ICA and relevant ICA supplements. Maintenance organisations may locally modify ICA or ICA supplements using an approved procedure specified in their Maintenance Organisation Exposition (MOE) only for the purposes of efficiency, achieving the intent of the ICA when the instructions are deficient, or for the use of alternative tools/equipment[31]. A maintenance organisation must notify the MTC holder (or relevant design approval holder in the case of ICA supplements) when it has locally modified ICA, so consideration can be given to amending the master copy for wider distribution. A maintenance organisation modifying ICA for the purposes stated above does not constitute approving an amendment to the ICA (i.e. the source document) held by the MTC holder (or ICA supplement held by another design approval holder). Only the MTC holder or holder of the ICA supplement can approve amendments to ICA, noting the need to also seek approval of a major change to the type certificate if the amendment alters any mandatory maintenance requirements.

Non-Destructive Testing (NDT) ICA

7.2.5.13 NDT ICA are applied to ensure the airworthiness of aircraft through the inspection of aircraft structure and components. NDT ICA is often used as part of damage tolerance inspection regimes to ensure structural integrity. Consequently, it is critical to ensure that NDT ICA is developed by competent staff and provides sufficient information to enable NDT staff to perform inspections effectively.

7.2.5.14 NDT ICA provided to a DASR 145 Maintenance Organisation should include the following minimum information:

1. the inspection procedure to be used
2. the inspection area
3. the material type of the inspection area
4. the type of discontinuities to be detected.

7.2.5.15 Those organisations responsible for developing NDT ICA (DASR 21J Design Organisations, MTC holder) should consider using NDT Level 3 staff (as defined in EN4179) to verify that inspections are achievable, repeatable and meet the expected detection requirements of the design or repair. This is especially important where NDT ICA is used to support an AwL.

Superseded

7.2.5.16 The procedure for approving or modifying NDT ICA should be documented in the relevant organisation exposition. DASA recommends that personnel certified to NDT Level 3 in the relevant method be employed to approve and/or modify existing NDT ICA for application in specific circumstances. This accords with the requirements of European Standard EN4179.

Master Minimum Equipment List (MMEL)

7.2.5.17 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable / inoperative under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL cannot, in itself, be regarded as providing operational permission. It, however, can be the basis for the development of an individual Operator's Minimum Equipment List (MEL).

7.2.5.18 An MMEL forms part of the MTC. Approval of new MMEL or an MMEL amendment should be undertaken in accordance with the relevant DASR 21 Subpart[32]. Further guidance on MMEL development and approval in contained in Chapter 8.2.2, including information on:

1. typical characteristics and contents of an MMEL
2. options for developing an MMEL
3. suitable certification specifications for an MMEL
4. classification (major/minor) for changes to an MMEL
5. the DASA MMEL approval process.

7.2.5.19 Note that DASA is currently evaluating EMAR 21 version 2.0 changes that introduce the Operational Suitability Data (OSD) concept and requirements. MMELs are considered a category of OSD, and therefore, this section will be updated in the future once the relevant DASR 21 updates have been incorporated.

7.2.6 – Manuals

Basic Principles for Manuals

7.2.6.1 T**ypes of Manuals.** As per DASR 21.A.57, the holder of a type-certificate shall produce, maintain and update master copies of all manuals required by the applicable TCB.

7.2.6.2 Manuals (for the purpose of DASR 21.A.57) will fall into one of two broad categories:

1. **Aircraft Flight Manual (AFM).** The AFM is an authoritative source of information necessary for the safe operation of an aircraft. It contains the aircraft's operating limitations, operating procedures, performance information and other information and instructions necessary to operate the aircraft safely. Note that this information may be contained in several documents that contain limitations, information and instructions to ensure safe aircraft operation. Examples of other documents/ publications (in addition to the AFM) may include a Flight Crew Operating Manual, Mission Crew Operating Manuals and Pilot Handling Notes.

Superseded

2. **Manuals Containing ICA.** Certification codes require that the ICA must be published in the form of a manual or manuals[33]. The relevant certification code requirements will dictate the specific ICA content that must be published. Due to the broad and varied type of information that must be published, ICA for a particular aircraft type will usually be distributed through a variety of manuals, such as Aircraft / Engine / Propeller Maintenance Manual, Structural Repair Manual, Engine / Propeller Installation Manual. As noted above at paragraph 7.2.5.5, the MTC holder should be able to identify the publications and manuals that meet the intent of ICA requirements.

7.2.6.3 **AFM Guidance.** DASA AC 008/2020 contains detailed information on AFM content and approval, amending AFM content and use of AFM supplements. Further information specific to changes to type certificates which affect AFMs include:

1. DASR GM 21.A.91 which contains guidance for the classification of changes to AFMs
2. DASR AMC3 21.A.263(c)(2) which contains information on approval of minor changes to the type certificate which affect the AFM.

7.2.6.4 **Approval of Manuals.** Even though particular manuals are required by the TCB and therefore required to obtain an MTC, only certain contents of manuals will form part of the enduring MTC and / or require DASA approval. Contents of manuals that requires DASA approval includes:

1. The ALS of the ICA[34] (i.e. as published within a maintenance manual). Refer Section 7.2.5 for further guidance.
2. Mandatory AFM content (Operating Limitations, Operating Procedures and Performance Information). Refer DASA AC 008/2020 for further guidance.

7.2.6.5 Consequently, amendments to other manual contents is not a change to the MTC and can be undertaken by the MTC holder using a procedure agreed with DASA. Furthermore, as noted by AMC1 21.A.57, the process to update a manual may be separate from the process to approve or authorise the content of the manual[35].

7.2.6.5 **Manuals in the Context of Defence Aviation Orders, Instructions and Procedures (OIP) Management.** Manuals (for the purpose DASR 21.A.57) are part of the Defence Aviation OIP for the platform type. Lifecycle management of Defence Aviation OIP is discussed further in Section 6.7. A key message of Section 6.7 is that in addition to accuracy and completeness of OIP (a well-established principle in DASR 21), the usability / readability of OIP can cause or contribute to aviation safety hazards. Therefore, aviation safety hazards related to Defence Aviation OIP should be managed through an organisation's SMS. Note that this principle is consistent with DASR GM1 21.A.239(a) paragraph 3.1.5 which states that design organisations should "establish a system to collect in-service experience to be used for the improvement of the [maintenance and operating] instructions".

Responsibilities for Manuals

7.2.6.6 **MTC Holder.** In order to meet their obligation under DASR 21.A.57, the MTC holder should establish a system to produce, maintain and update manuals. As per DASR AMC 21.A.57, this system should ensure:

1. manuals are complete, current, and uniquely identified;
2. manuals contain their authority for use, document name, date of issue, and document/amendment status details;

Superseded

3. manuals are provided in a medium compatible with user requirements;

4. new issues, re-issues and/or amendments are approved and/or endorsed by appropriate appointments prior to their release, noting that the process to update a manual may be separate from the process to approve or authorise the content of the manual, eg approve AwL in ICA;

5. manual management records are accurately maintained, controlled, traceable and are accessible; and

6. manuals can be reproduced to any previous amendment status.

7.2.6.7 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their manuals or manual supplements as the MTC holder has for the product's master set of manuals.

7.2.6.8 **Aircraft operating organisations.** The operating organisations must manage and distribute the AFM and all other relevant manuals as part of their OIP Management System[36]. Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to all relevant manuals to the extent necessary for the scope of maintenance services being provided. The operating organisation should manage any aviation OIP related hazards through their SMS, and coordinate with the MTC holder, or applicable design organisation, as required to effect any necessary updates or improvements to manuals.

7.2.6.9 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable manuals. Maintenance organisations shall establish procedures to ensure that if found, any inaccurate, incomplete or ambiguous procedure, practice, information or maintenance instruction contained in the maintenance data used by maintenance personnel is recorded and notified to the author of the maintenance data[37].

7.3 Production and Military Certificates of Airworthiness

7.3.1 Production Assurance in the Defence Aviation Safety Program

Aim

7.3.1.1 This chapter details how the production of aircraft components is assured in the Defence Aviation Safety Program (DASP). This includes what release documentation is acceptable under DASRs, and the means through which that documentation is obtained. This chapter only covers aircraft components and does not include whole aircraft. For whole aircraft see MCoA - Chapter 5.3 Annex O and MPO – Chapter 7.6.

Introduction

7.3.1.2 Production of Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured.

Superseded

Acceptable release documentation

7.3.1.3 The purpose of release documentation is to provide evidence that the manufactured component conforms to approved design data. Aircraft components to be installed on Defence registered aircraft must be accompanied by one of the following release documents:

a. DASR Form 1—Authorised Release Certificate.

b. A native or alternate component Certificate of Release to Service (CRS) issued within a recognised airworthiness framework (refer to Chapter 6.5 —Recognition of other Aviation Authorities for identification of a native and alternate component CRS).

c. For standard parts or items designated as specific equipment under DASR 21.A.303, a Certificate of Conformity from the item's manufacturer (refer AMC to DASR 145.A.42(a)(4)).

d. For components fabricated under DASR 145.A.42(c), certificates of conformity produced by the fabricating maintenance organisation that are acceptable to DASA.

7.3.1.4 Release documentation under (a), (b) or (c) above enables that component to cross organisational (and possibly national) boundaries between its manufacture and installation. Manufactured components that do not need to cross organisational boundaries can be installed with locally produced certificates of conformity that contain all of the technical information found on a DASR Form 1 per item (d) above.

DASA production assurance

7.3.1.5 DASA assures production of all Defence aircraft components using one of three mechanisms depending on the release documents required by continuing airworthiness regulations. This is depicted below in Figure 3.

Assurance through Recognition Frameworks

7.3.1.6 The majority of aircraft and aircraft component manufacture for Defence occurs outside Australia and is assured through DASA's recognition framework. To be installed on a Defence registered aircraft, these components must be accompanied by a recognised native (Form 1 equivalent) or alternate release certificate. Each DASA Recognition Certificate provides details on the unique conditions and caveats to be applied to validate the native or alternate release certificates. Production of components assured through recognition do not require a DASR Form 1 as it provides no additional safety assurance above what is inherent under the recognition framework.

Assurance through DASR 21 – production by Military Production Organisation Approval (MPOA) or letter of agreement holder

7.3.1.7 Components manufactured outside of a recognised airworthiness framework (other than standard parts, specific equipment or components fabricated under DASR 145.A.42(c)) require a DASR Form 1 for installation. To issue a DASR Form 1 an organisation must hold a Military Production Organisation Approval (MPOA) under DASR 21 Subpart G, or a letter of agreement to manufacture under DASR 21 Subpart F . In this instance, the award and oversight of MPOA is DASA's assurance mechanism for the production of such components.

7.3.1.8 The only organisations that DASA will consider for award of MPOA are those that do not hold a recognised approval that enables release of the manufactured components under a native or alternate artefact (see Chapter 6.5 —Recognition of other Aviation Authorities). That is, the

Superseded

requirements of DASR 21 Subparts G will be imposed on an organisation for the sole purpose of issuing a DASR Form 1 for the manufactured components.

Assurance through DASR 145 – fabrication by maintenance organisations

7.3.1.9 DASR Form 1 must not be used for components fabricated by maintenance organisations under their DASR 145 approval. A locally produced certificate of conformity must be used instead. DASA's assurance of this production is via the issue and oversight of the organisation's DASR 145 approval. A DASR 145 MO will only have this activity included in the scope of their DASR 145 approval if they can sufficiently demonstrate their capability to perform such fabrication. Note that unless otherwise approved by DASA, only the DASR 145 MO who fabricated the component can install this component.

Figure 3: Production Assurance and Release Documentation under DASP

Manufacture and release of test articles

Superseded

7.3.1.10 If a test article is manufactured to gather certification evidence, the responsibility to control the manufacture of that article and ensure it accurately reflects the proposed design data rests entirely with the organisation seeking certification of the design. For test article manufacture required to achieve certification of a major change, the Certification Programme should describe the production control processes that will be used by the applicant in producing the test articles. If DASR Form 1 is used to release a test article for trial installation in an aircraft, Block 12 of the DASR Form 1 must clearly state that the article is in conformity with non-approved design data. The manufacture of test articles for certification does not require MPOA under DASR 21 Subparts G or a letter of agreement under DASR 21 Subpart F. These principles also apply for minor changes being approved under MDOA privilege.

Manufacture of modification kits

7.3.1.11 Maintenance organisations approved under DASR 145 may fabricate modification kits and issue certificates of conformity provided (a) the scope of their DASR 145 approval allows it, and (b) the completed modification kit will be installed by the same maintenance organisation (and under the same DASR 145 approval) issuing the certificate of conformity. Modification kits meeting both criteria above must not be released using DASR Form 1, but must still be manufactured to the approved design data and have locally produced certificates of conformity attesting to that fact. Fabrication of modification kits for onward supply cannot be performed under a DASR 145 approval and constitutes series production that must be assured by either recognition or through DASR 21. Modification kits manufactured external to the installing maintenance organisation must be accompanied by a DASR Form 1, or release documentation acceptable to DASA through recognition.

7.3.1.16 DASR 21 Subpart G – Military Production Organisation Approval

7.3.2 Military Certificate of Airworthiness (MCoA)

Introduction

7.3.2.1 This section supplements the DASP policy and provides guidance in support of DASR 21, Subpart H relating to MCoAs, their purpose, and their issue. The guidance included in this section discusses the MCoA concept and application from both an Australian Defence context, and where appropriate for the purposes of description, a civil aviation context.

7.3.2.2 Restricted MCoAs are also discussed where appropriate; however, such MCoAs are of limited utility in the Australian Defence context, and unlikely to be issued.

Purpose

7.3.2.3 A MCoA is an aircraft operating authorisation issued against an airframe tail that has the purpose to validate that the airframe conforms to the type design as specified on the Military Type

Superseded

Certificate (MTC). It serves as the final assurance artefact that the airframe is in a state of airworthiness per the inherent level of safety afforded by the type design and the underlying MTC basis. It is enabled by an organisation or operator, who has registered the airframe on the Australian Defence register, and has ensured conformity through meeting various requirements.

7.3.2.4 A restricted MCoA will follow the same rules albeit that the airframe shall conform to a restricted MTC and to specific airworthiness requirements ensuring adequate safety.

Application

7.3.2.5 MCoAs in the Australian Defence context can only be issued by the DASA or a Delegate of the Safety Authority (DoSA). The release document is via a DASR Form 25 Military Certificate Of Airworthiness and applies only to aircraft that are registered on the Defence register in Australia.

7.3.2.6 An application for a MCoA shall be made by an eligible organisation via DASR Form 25a - Application for Certificate Of Airworthiness. In the Australian Defence context, the MAO and/or their CAMO are eligible to be applicants for a MCoA as holders of a MAOC. Aircraft that are Non-Defence Registered (NDR) are not subject to Airworthiness DASRs, and are subject to a separate airworthiness requirements, typically under the applicable airworthiness Civil Aviation Safety Regulations. See further DASP Vol 3 guidance on NDR at Chapter 6.1.3.

7.3.2.7 A MCoA application shall be made in a form and manner established by the Authority (DASA in Australia) of the State of Registry[38], per DASR.21.A.174(a). When considering a MCoA application, the Authority will consider all documentation in support of the state of the airframe at application. This has particular significance for used aircraft, where records of usage, maintenance, modifications and repairs may not be to the standard normally required by Defence.

7.3.2.8 The MCoA application presents documentation that the aircraft conforms to the type design approved under the relevant MTC. The required documentation, artefacts, reports and historical evidence (if applicable) to support the application shall be in accordance with DASR.21.A.174(b). Any deviations from the certified type design must be approved by an appropriately authorised design organisation.

7.3.2.9 For used aircraft, DASA will require a Military Airworthiness Review Certificate (MARC) conducted in accordance with DASR Part M regulations before issuing an MCoA. The MARC review is a physical survey of the aircraft and supports issue of the MCoA to satisfy DASA that the submitted documentation is reflective of the physical aircraft. The MARC process is further discussed as part of paragraphs 7.3.2.15 and 7.3.2.16 of this section.

Issue of a MCoA

7.3.2.10 A MCoA can only be approved and issued if all modifications, repairs and/or production deviations implemented on the airframe are approved under DASR 21, or under a recognised national civil or military airworthiness framework.

7.3.2.11 For new civil or commercial derivative aircraft (CDA) delivered to Defence, the acquisition project should seek a civil export CoA from the Civil Aviation Authority (CAA), via the prime aircraft OEM, where a civil Type Certificate (TC) is in place. This export CoA needs to be obtained prior to transfer to the Defence register, and forms the foundation for the issue of an Australian MCoA. Failure to obtain an export CoA for a civil or CDA may limit DASA's ability to issue an evidence based MCoA.

7.3.2.12 For instances where a civil Type Certificate (TC) is not in force or Defence is leasing an aircraft that has been in civilian use, the requirement for a CAA CoA can be demonstrated if a CAA

Superseded

authorised delegate provides a document that attests the aircraft would be eligible for issue of a Standard or Export CoA, if the aircraft was to be registered by a Civil Aviation Authority. Defence will accept only a Standard CoA under DASR 21.A.172, DASR 21.A.173 and DASR 21.A.174. DASA-DIA staff should be consulted for specific advice.

Validity and Amendment

7.3.2.13 The MCoA Holder (typically the MAO) is responsible for the continuing validity of an MCoA. A MCoA may be amended or modified only by the Authority (DASA in Australia) of the State of registry[39]. A MCoA may be issued for an unlimited duration, and remains valid subject to the conditions described in DASR.21.A.181.

7.3.2.14 Additionally, the ongoing validity of a MCoA requires that damage be assessed, and all applicable modifications and repairs carried out, using as appropriate the data requirements of DASR.M.A.304.

7.3.2.15 The validity of a MCoA is periodically renewed via the MARC process, as per DASR.M.A.901. This involves an airworthiness review of the aircraft and its continuing airworthiness records. The initial airworthiness review is due within 12 months of the issue date of the aircraft's initial MCoA. The validity of MARCs issued by a CAMO may be extended twice for a period of one year each time if the aircraft has been in a controlled environment.

7.3.2.16 The MAO is accountable for the continuing airworthiness of an aircraft and shall ensure that no flight takes place unless the MCoA and the MARC remain valid, as per DASR.M.A.201. If a MCoA becomes invalid, the MAO must return the aircraft to an airworthy condition before operating the aircraft or seek an alternate flying authorisation. A new MCoA is only required if the aircraft is being returned to the Defence register after removal, or the certificate is revoked by the Authority (DASA in Australia) of the State of registry[40]

7.4.1 Military Type Certificate Holders

Introduction

7.4.1.1 A Military Type Certificate Holder within the DASR framework provides Defence a suitable entity to 'hold' the Type Certificate. Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed and that the inherent safety that the platform type certification basis affords is maintained.

7.4.1.2 Unlike civil TC obligations, Defence MTC obligations are not enforceable via national legislation, meaning there is no enduring obligation under law for foreign organisations to manage

Superseded

the basis of certification through the product's life cycle. Therefore, in the application of DASRs, the Defence MTCH is a government organisation, most likely the organisation that acquired the product under contract.

Application of DASR provisions for the MTCH

7.4.1.3 The following principles guide the application of the above regulatory provisions:

a. **Principle 1.** DASA issues an MTC for Defence registered aircraft types. Unlike the civil context, a separate TC for the aircraft power plant and/or propeller has not been issued thus far and is nominally included as part of the platform TC.

b. **Principle 2.** DASA shall only issue MTCs to suitable Commonwealth government organisations (the holding organisation) to hold the MTC. The holder is responsible for ensuring that holder functions/obligations are executed. In the Defence context, the MTCH is able to achieve the regulatory intent via a direct or indirect arrangement with the aircraft/engine OEM.

c. **Principle 3.** Military Supplemental Type Certificates (MSTCs) will also be held by the MTCH or holding organisation, with the MTCH responsible for carrying out all MSTC functions/obligations. An MSTC in the Defence context can supplement the MTC for managing sub-fleets, significant changes to the TCB, large and complex changes. They are not used to achieve a commercial outcome such as in the civil design domain.

MTCH Safety Objectives

7.4.1.4 The MTCH has two aviation safety objectives:

a. To support the safe operation of the aircraft type by command units. Achieving Defence strategic objectives requires continuous capability enhancement, and at times, the conduct of operations at markedly elevated levels of risk. In addition, operators of aircraft will require explanatory information, advice and data to operate the type safely. The MTCH must have access to type design data, or support arrangements with the aircraft/engine OEM for the provision of designs and advice to support safe operation of the type.

b. To continuously monitor the type in service and ensure the ongoing validity of the Type Certificate, by investigating issues and providing corrective actions where required. The initial certification of a type establishes the known and understood level of safety inherent in the standards against which it was certified. Through the life of the type, latent hazards within the certified design, not identified during initial certification, may emerge requiring some action to address. Similarly, the use of the aircraft may vary and new designs be incorporated. Regardless, the MTCH has the high level objective to maintain the level of safety intended during initial certification.

Australian Context

7.4.1.5 The MTCH must account for the unique Defence context where the MTCH is not the OEM of the type and noting that the DASR are an amplification of the broader Work Health and Safety[41] obligations for the Defence aviation environment. In this context, the MTCH is the steward of the Defence type in service. To fulfil this role:

1. The MTCH should be broadly aware of all historic and emerging hazards relevant to their type[42]. This awareness requires:

Superseded

i. The collection of relevant aviation safety information (occurrences etc.) from within the Defence aviation system;

ii. The collection of relevant aviation safety information (occurrences, service bulletins, airworthiness directives etc.) from operators and authorities of similar types; and

iii. Consideration and conduct of additional verification activities(such as test programs) to generate further data independently and as necessary.

2. The MTCH is to lead the risk management of the type for the life of type, from initial certification to withdrawal from service. This leadership includes:

i. Ensuring operators are made, and remain, aware of the hazards extant in their type;

ii. Ensuring that essential risk controls (both technical and operational) pertaining to the safety of the type are, and remain, effective;

iii. Leading local efforts to eliminate or further minimise known hazards;

iv. Influencing external organisations (such as OEMs, joint user groups, co-operative partnerships etc.) to eliminate or further minimise known hazards.

MTCH Structure

7.4.1.6 To support these safety objectives, the MTCH organisation is broadly structured around two key systems, as detailed in Figure 4. These systems are responsible for the interactions regulated by DASA and are required elements of the MTCH supporting organisation.[43] They are:

a. The Safety Management System (SMS). This system ensures that the MTCH will collect operational data, analyse that data, investigate potential safety concerns and provide corrective actions.

b. The Design Assurance System (DAS). This system provides products (for example Service Bulletins correcting deficiencies, publication updates etc.) to operators of the Type.

Superseded

Figure 4: Safety Structure pyramid

7.4.1.7 Note that the safety management and design assurance systems are generic and are broadly applicable to all MTCH structures and implementations noting their varying constructs. It is likely that in implementing the systems, each MTCH through their partner organisation will employ business processes specific to their context. For example, the MTCH may rely upon long standing Defence engineering processes such as Technical Information Review, System Safety Working Groups and Configuration Control Boards to achieve the SMS intent. Similarly, the DAS of a foreign design organisation may not be entirely aligned with the requirements described in DASR 21.A.239 invoking the need to utilise Authority recognition arrangements.

7.4.1.8 Each organisation that holds a Type Certificate will be different and the model outlined in Figure 4 will not be a one-size fits all construct. It is appropriate that each organisation will implement these functions with different size, scale, or complexity, dependent on their need. For example, a CDA

Superseded

may rely on a large portion of sub-contractor products from civil aircraft OEMs operating under legislated civil safety constructs, and thus will not require a large compliance verification element.

MTCH Responsibilities

7.4.1.9 In the Australian Defence context, the government organisation holding the MTC is usually relatively small and is supported by one or more other organisations (contractors, foreign Defence organisation, OEMs etc.). As a result, responsibility for the conduct of MTCH obligations is often vested with these support organisations. This has led to confusion regarding accountabilities. To clarify:

a. Regardless of the organisational construct, the government organisation is the MTCH, and is accountable for all activities undertaken by its partners with respect to the obligations of the MTCH.

b. As such, it is unlikely that a passive compliance assurance relationship between the government organisation and its partners will suffice. DASA needs to be assured that the MTCH is able to meet its obligations – this may require the government organisation to lead key MTCH activities and be active in resourcing, prioritising, and implementing MTCH activities to ensure continued airworthiness and supporting safe operation of the type by the operator.

Eligibility to hold an MTC

7.4.1.10 A government organisation can be eligible to hold an *MTCH* under one of three regulatory provisions when applying for an MTC:

a. DASR 21.A.14(a). This provision is applicable where the government organisation has demonstrated its capability by holding a Military Design Organisation Approval (MDOA), and thus meets the requirements of DASR Subpart J and is capable of performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources.

b. DASR 21.A.14(b). This provision is an exception to subpart (a) where the organisation has no demonstrated capability, but may be able to obtain an MDOA in the future, and thus alternative procedures can be used in the starting phase as an organisation moves toward an MDOA or where there are limited duration design activities that may be required (such as initial certification of a platform).

c. DASR 21.A.14(c). This provision is an exception to subparts (a) and (b) where the government organisation is not capable of meeting the requirements of Subpart J and/or performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources. In this instance, the government organisation is entirely reliant upon partners to meet the requirements of Subpart J.

Initial Assessment of MTCH capability

7.4.1.11 In the Defence context, assessment of the capability of the MTCH occurs in parallel to certification of the aircraft type, but must be completed before a Type Certificate can be awarded to the MTCH. DASA assessment of MTCH capability will include:

Superseded

a. An initial assessment of the organisation's personnel, processes, resources and support arrangements to establish that the MTCH will be able to perform/carry out the MTCH obligations outlined in DASR 21 and that the processes are present and suitable.

b. Supplementary on-site activities such as observing System Safety Working Groups, or reviewing Failure, Malfunction, and Defect data collected, in order to establish that the organisation is operating and effective.

c. An assessment of the MTCH Type Continued Airworthiness Exposition (TCAE). The TCAE describes all MTCH arrangements in order to execute the holder obligations and maintain the integrity of the type certificate. The broad content of the TCAE shall include, but is not limited to the description of the MTCH framework, design support arrangements, processes, procedures, governance, resources, and MAO/CAMO interfaces in place to meet the regulatory intent for the platform. In addition, the TCAE should include a detailed compliance matrix explicitly describing their arrangements in place to execute each MTCH obligation. The TCAE is the appropriate document where nuances particular to the platform and/or MTCH arrangements shall be described for Authority awareness and/or proposed alternative means of compliance.

MTCH Oversight & Enforcement

7.4.1.12 Oversight and Enforcement on the MTCH will be conducted by DASA as assurance activities in either a routine or a targeted format. The activities will have the objective to assess a MTCH organisation in their execution of MTCH obligations and functions. The scope of the assessment may involve any of the explicit and/or implicit obligations and may be a result of feedback received to warrant an assurance activity. Findings will be issued for non-compliances; however, the DASA team carrying out the assessment also looks to provide outcomes aiming to improve the overall effectiveness of the MTCH organisation. Oversight and enforcement on the MTCH arrangement will be based on the MTCH executing their obligations in accordance with the regulatory intent and their TCAE.

7.4.1.13 Further guidance on the DASA oversight and enforcement framework is provided in DASP Vol 3, section 4-1-5

MTCH Obligations

7.4.1.14 Within the DASRs the MTCH have the following obligations.

DASR 21.A.3A – Failures Malfunctions and Defects

7.4.1.15 This has three aspects which must be undertaken:

1. DASR 21.A.3A(a). Have a system for the collection, investigation and analysis of data relating to failures, malfunctions, defects or other occurrences, which cause or might cause adverse effects on the airworthiness of the product.

b. DASR 21.A.3A(b). Report to DASA occurrences, which may result in an unsafe condition.

c. DASR 21.A.3A(c). Investigate the root cause of occurrences and implement actions to eliminate or otherwise minimize any resulting hazards and their associated risks

Superseded

SFARP. If DASA finds action is required to correct the deficiency, the MTCH shall submit the relevant data to DASA.

7.4.1.16 **Reporting to DASA.** Where the MTCH assesses that an occurrence of a failure, malfunction or defect "may result in an unsafe condition[44]" that occurrence must be reported to DASA. Note this is a more limited and very specific subset of all occurrences that must be collected and considered by the MTCH. For these 'reportable occurrences' the MTCH must also report the results of MTCH investigations and any proposed action by the MTCH to DASA.

7.4.1.17 **Investigate and implement actions.** In the event that an unsafe condition may exist, the MTCH is obliged to take appropriate actions and be pro-active to eliminate and/or minimise the associated risks so far as reasonably practical. DASR 21.A.3A does not require the MTCH to consult DASA for review or approval prior to initiating any analysis, investigation and/or remediation actions. DASA provides additional, external and independent assurance of the actions of the MTCH but does not lead the MTCH in satisfying DASR 21.A.3A.

7.4.1.18 Further guidance on Occurrence reporting is provided in DASP Vol 3, section 7-4-2 and section 6-3

DASR 21.A.3B Airworthiness Directives

7.4.1.19 Where DASA determines an Airworthiness Directive (AD) is required for mandating actions for remediating an unsafe condition the MTCH must:

1. propose appropriate corrective actions and/or inspections

b. provide operators of the type all data required to comply with the AD

c. provide solutions/data to DASA to correct the deficiency and restore aircraft safety. This may include additional data to that provided under DASR 21.A.3A, specifically to support the release of an AD.

7.4.1.20 DASA's decision to release an AD may occur immediately following an occurrence or many weeks, months, or even years later. Per paragraph 7.4.1.17, the MTCH is to proceed with actions to eliminate the hazard or minimise the risks independently of DASA. This provision exists to support DASA mandating action proposed by the MTCH, not to direct the MTCH in the execution of their role.

7.4.1.21 Further guidance on Airworthiness Directives in the ADF context is provided in DASP Vol 3, section 7-4-3

DASR 21.A.4 Coordination between Design and production.

7.4.1.22 The MTCH shall coordinate between design and production organisations, to provide production data, as well as receive failure/malfunction/defect data from production organisations.

7.4.1.23 Where whole aircraft, parts and/or modification kits etc. are being produced, the MTCH arrangements are to ensure that the design and produced article align. For example, if the design is changing (materials/dimensions/finishing etc.) then that information will be provided to the organisation producing the item. Similarly, there cannot be changes to the item being produced without the knowledge of the MTCH and/or the responsible design organisation supporting the platform. Finally, this agreement must ensure the communication of occurrences, especially from the production organisation to the MTCH and/or their design organisation.

DASR 21.A.42 Integration

Superseded

7.4.1.24 The MTCH shall be responsible for the integration of Products, Weapons and other Systems onto the aircraft type.

7.4.1.25 This requirement places the obligation on the MTCH to consider the impact to airworthiness on integrating products, weapons or other systems, onto the aircraft. As the MTCH is also the only organisation eligible to apply for a major change to the type, the DAS of the MTCH (in cooperation with their partner organisations) must be sufficient to enable this. This obligation is not limited to aircraft components, but as expanded upon in Paragraph 7.4.1.49 for role equipment as well.

DASR 21.A.55 Record Keeping

7.4.1.26 The MTCH shall hold all relevant design information necessary to ensure the continued airworthiness of the type and make this available to DASA as required.

7.4.1.27 In the Defence context, the MTCH will not be the OEM, and the regulations cannot assume the MTCH created the type design data. Thus, this regulation ensures that the MTCH can access all data necessary to support the type design and ensure that major changes to the type continue to meet the appropriate airworthiness requirements.

DASR 21.A.57 Manuals

7.4.1.28 The MTCH shall produce, maintain and update master copies of all manuals required by the TCB and provide copies, on request, to DASA.

7.4.1.29 A manual under this regulation is part of the type design considered during type certification. It follows that any manual assessed during certification is therefore required by the TCB under this regulation. Such manuals contain content critical to keep the type airworthy or to operate the type safely within its designed limits. An example of a manual is the Aircraft flight manual, an engine manual[45] or a propeller manual[46] .

7.4.1.30 For the purpose of initial certification, the MTCH is to provide manuals applicable to the ADF type. Thus, manuals produced for aircraft/products certified under other airworthiness authorities must be evaluated prior to releasing under the DASR. For the purpose of maintaining initial airworthiness in line with OEM issued updates, the MTCH must maintain and update master copies by enabling changes to be evaluated. Prior to promulgation, such change proposals will;

a. consider applicability to any unique ADF aspects or environment.

b. classify the content being considered.

7.4.1.31 The regulation implies that the MTCH will execute the obligation in a timely manner commensurate to the (safety) criticality of the update and any OEM advice.

7.4.1.32 Further guidance on the Aircraft Flight manual in the ADF context can be found in AC 008/2020

DASR 21.A.61 Instructions for Continuing Airworthiness

7.4.1.33 The MTCH shall provide the Instructions for Continuing Airworthiness (ICA) required by the TCB to operators. Changes to that ICA will also be provided to all operators.

7.4.1.34 ICA detail the methods, inspections, processes, and procedures necessary to maintain the aircraft and/or products in an airworthy condition and within the usage parameters of the aircraft

Superseded

design. ICA are an airworthiness requirement of the TCB and are prepared at initial certification by the appropriate manufacturer for each product, part or appliance. The regulation requires the MTCH to furnish the complete set of ICA to the Operator and to maintain the currency of the ICA for the ADF Type.

7.4.1.35 In the Defence context, this has particular relevance for the MTCH as often type design data will be produced under other regulatory systems and ICA will not be clearly identified. Part of the responsibility of the MTCH under this regulation is to identify and manage the ICA for a type where the OEM documentation has not explicitly referenced which instructions are ICA. This is usually where the aircraft is largely of military design, and in these cases, the MTCH will require an established relationship with the OEMs to enable clarification of maintenance documentation, when it cannot be determined from inspection what maintenance data is ICA.

DASR 21.A.44(b) - Identification of Products, parts and Appliances (DASR 21 Subpart Q)

7.4.1.36 Identification of products, parts and appliances. The MTCH shall:

a. specify how parts are to be identified.

b. specify how identification data (plates/etchings etc.) are to be handled.

c. identify critical parts.

7.4.1.37 In the context of EMAR, this obligation leverages a responsibility onto the MTCH to specify part marking schemes to their production organisations, who in the European context could be located in multiple countries. However in the Defence context the MTCH will in most cases rely on existing design organisation/production organisation arrangements in foreign countries with part identification already in place. To achieve the intent, the MTCH will appropriately leverage the OEMs part identification systems/schemes and only if applicable, specify the manner in which locally produced products, parts and appliances are identified.

7.4.1.38 Further guidance on Production in the ADF context is provided in DASP Vol 3, section 7-3-1.

DASR 21.A.44(c) - Continued Integrity of the Aircraft Structure and Propulsion System

7.4.1.39 DASR 21.A.44(c) requires that the MTCH shall ensure the continued integrity of the aircraft structure and propulsion system through ongoing monitoring and periodic assessment. Acceptable means of compliance for this regulation is provided in AMC 21.A.44(c). Chapter 6.6.3 provides extensive guidance to support application of AMC 21.A.44(c).

MTCH Obligations– Implicit Obligations

What is an implicit obligation?

7.4.1.40 In addition to the eligibility criteria listed at DASR 21.A.14(c) and the obligations listed at DASR 21.A.44(c), the regulations also include implicit obligations and expectations for the MTCH. That is, while an obligation has not been expressed, as “the MTCH must….” the operation of a regulation (or the AMC to that regulation) clearly depends upon the MTCH performing a function to ensure the continued airworthiness of the type or the safe operation of that type.

DASR 21.A.113 and 115

7.4.1.41 An applicant for a Supplemental Type Certificate (STC) shall prepare data to support the application independently or as part of an arrangement with the MTCH. In the defence context, the MTCH will hold all STCs and is therefore pivotal to enable an STC application through a ‘no technical

Superseded

objection' assessment and to provide the necessary design data. The advice provided by the MTCH shall enable for the safe integration by multiple design organisations of STCs onto the platform.

DASR 21.A.445 Subpart M Repairs

7.4.1.42 The MTCH is to support organisations performing major and minor repairs including unrepaired damage assessments by providing adequate information to enable their evaluation.

7.4.1.43 The MTCH may commission/initiate the activities through their supporting design organisation with appropriate approvals in place to design structural repairs. The MTCH will enable the provision of sufficient technical data where necessary.

AMC 21.A.709(b)(3) Approval of Flight Conditions

7.4.1.44 Flight Conditions underpin the issue of MPTFs as alternate authorisations assuring operations outside the strict requirements of the TCB and DASR M requirements and often at elevated levels of risk.

7.4.1.45 To make sure all reasonable knowledge is considered in the risk assessment supporting Flight Conditions and MPTF, the MTCH should be consulted to provide technical assessment inputs given access arrangements to type design data. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support/facilitate these assessments.

7.4.1.46 While not specifically identified, the reference to 'a design or engineering organisation suitably knowledgeable of the certified Type Design and with access to Type Design information' is usually read to mean the MTCH or OEM.

GM M.A.301(a)(2).2 Credible Data

7.4.1.47 Where operations are not at elevated levels of risk, but a defect remains preventing the release of the aircraft back to service, an operator may use 'credible data' for the deferral of defects in accordance with DASR M.A.301. Since the list of credible data includes type certification data, the MTCH would be a likely source of such information and be expected to provide it to operators as required. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support these assessments.

GM ORO.75 Use of Role Equipment

7.4.1.48 The MTCH is expected to support operators in the determination as to whether a piece of equipment is considered role equipment or a certified part.

7.4.1.49 Whilst the MAO has direct responsibility for integrating role equipment onto their aircraft, it is expected that they utilise technical assessments when appropriate. As the MTCH has access arrangements for assessments using type design data, the MTCH shall support the operator to ensure the part or equipment is integrated onto the type with appropriate consideration.

DASR AO.GEN.05(c) Management of Orders Instructions & Publications (OIP)

7.4.1.50 The MAO is required to have a documented agreement with the MTCH and seek MTCH support for control of air operational OIP and the use of Foreign Source Data (FSD).

7.4.1.51 This introduces an implicit requirement upon the MTCH to collaborate with the MAO via an agreement for review and appropriate approval of aviation operational OIP and FSD prior to use. This has particular relevance to the Aircraft Flight Manual (AFM). In the Defence context, the management of the AFM is complex with the one document having multiple uses and regulatory requirements. As

Superseded

a result, the MTCH shall be pivotal to ensure aviation operational OIP and FSD activities do not inadvertently alter content critical to compliance with the type certification basis.

7.4.1.52 Chapter 6.7 of the DASP Manual Volume 3 provides further guidance for OIP.

7.4.2 Continued Airworthiness Occurrence Reporting

Introduction

7.4.2.1 This section provides guidance to Occurrence reporting (OR) in the continued airworthiness domain (for design and production). This section is subordinate to the wider OR guidance provided as part of DASP Vol 3, chapter 6.3 which describes the wider OR framework.

7.4.2.2 Under DASR Part 21, organisations holding an approval have a requirement levied onto them to collect data on, conduct investigations of and provide analysis on any Failures, Malfunctions, Defects (FMD) or other occurrences, which creates or has the potential to create an unsafe condition. An unsafe condition is a state where an adverse effect on airworthiness exists being the result of a compromised or potentially compromised type design. Any occurrence that is assessed to have resulted in, or may result in, an unsafe condition[47],[48] must be reported to DASA and other organisations required by the implementing regulations.

7.4.2.3 Occurrence reporting by DASR 21 approval holder(s) is an essential continued airworthiness activity and enables risks and hazards associated with the type design to be identified and addressed in accordance with DASR 21.A.3A(a). All organisations that hold a DASR Part 21 approval including (but not limited to) the platform Military Type Certificate Holder (MTCH), Subpart J design organisations, Subpart F/G production organisations are obligated to have systems in place to achieve the regulatory intent of occurrence reporting.

Collecting FMD Data

7.4.2.4 The holder organisations operating under the DASR Part 21 regulations are expected to have arrangements in place that collects technical information from a spectrum of local and international sources/networks (civil and military) relevant to their platform. This has the primary purpose to access real time (critical) design related safety information for the product/part or appliance. The technical data may be directly applicable to types operated by the ADF or may require some applicability assessment before being considered for further consumption.

7.4.2.5 Collection of FMD data either directly from the ADF fleet or indirectly from other operators also has the purpose to provide the Holders with ongoing data that can be evaluated for patterns and/or reoccurrences. Such evaluation may identify failure issues that present as disparate, but may be linked. This level of analysis has the objective to identify latent design or manufacturing defects before they are realised during operation.

Occurrence Investigations in the DASR Part 21 Domain

7.4.2.6 In the Defence context, investigations involving FMD directly attributable to the type design and/or manufacturing are conducted by the platform MTCH under obligations in DASR 21.A.3A. Under this regulation, the MTCH must with all reasonable practicality initiate appropriate levels of investigation within their design support network to determine the root cause. This may take the form of reaching back into the OEM to evaluate the circumstances and determine the likely cause.

Superseded

Similarly, the production organisation or the part/component OEM may be consulted where a manufacturing issue needs analysis.

What constitutes a reportable Occurrence?

7.4.2.7 A FMD occurrence may originate from an issue identified on the ADF type or from a foreign fleet that is closely related to the ADF type. However, the immediate type design/airworthiness impacts from an FMD occurrence in the Part 21 domain are not always apparent and often requires detailed investigation to be completed. An occurrence may not be identifiable until investigation results are reported.

7.4.2.8 Similarly, there are instances where a failure, malfunction or defect, or analysis of failures, malfunctions or defects represents some level of shortfall to the type design but may not result in a reportable occurrence in accordance with DASR 21.A.3A(b) based on an assessment of the available information at that time. In these situations, the holder ought to make a judgement as to whether the shortfall constitutes a risk or not and what actions/advice is required to manage the risk (perceived or real). The Authority always encourages the community to be conservative in their judgements and provide an occurrence report - voluntary occurrence reports are an option.

7.4.2.9 In the Defence construct, the MTCH organisation is expected to receive relevant technical information (TI) from a range of sources including other operators (military or civilian, where relevant). In assessing the external TI, the MTCH must verify applicability to the ADF type and consider the ADF CRE. Once verified as applicable, a reportable occurrence is warranted satisfying any of the following conditions where the incoming technical information;

1. describes a design issue (real or potential) that leads to an unsafe condition; or
2. describes a safety concern that has a real or perceived airworthiness impact and requires some time compliance action; or
3. originates from the type OEM or Civil Aviation Authority (CAA) /Military Aviation Authority (MAA) regulator mandating an action with an accompanying risk assessment.

7.4.2.10 An occurrence on an ADF aircraft may require the outcome of an investigation before a determination can be made to report under DASR 21.A.3A. However, once the locally sourced TI is received, the same conditions of sub-paras 9a and 9b apply to determine if a reportable occurrence is warranted.

When and how to Report

7.4.2.11 Reporting occurrences to the Authority has the intent to make the Authority aware of an event that has caused or has potential to cause an unsafe condition in the current timeframe. This enables the Authority to begin their assurance function in real time and allow for intervention (where necessary) without undue delay. The reporting time period for the MTCH community is 72 hours for an occurrence once deemed reportable. It is acknowledged that the time between the actual occurrence and the MTCH being fully informed of an unsafe condition existing on their type can vary depending on many factors. Therefore, the 72 hour timeframe begins at the point where the MTCH organisation has enough information to make an informed determination of the airworthiness impact, based on the root cause (if known), type applicability, CRE considerations, etc.

7.4.2.12 The form and manner of which reportable occurrences are provided to the Authority from a MTCH organisation is via a DASR Form 44. The report shall contain (where practicable) all available information on the manufacturing or design deficiency, the results of any investigation to date, any

Superseded

actions they are taking or propose to take in order to correct the deficiency along with the submission of relevant data to support the actions.

MTCH Actions to address an unsafe condition resulting from FMD

7.4.2.13 The immediate actions that the MTCH organisation may take to eliminate and/or minimise the risks associated with the type design hazard will vary on a number of factors. However, the likelihood/consequence risk assessment will ultimately dictate the level of attention, timeliness, advice and resources that are attributed to the actions. Actions taken by the MTCH to address an unsafe condition should never rely on an Authority decision gate to implement.

7.4.2.14 The Authority will review the occurrence details and MTCH actions to gauge that the risk to aviation safety has been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) by the MTCH. This is not a one-off assessment; rather the unsafe condition determination by the MTCH organisation is an ongoing safety assurance activity conducted by DASA. It commences upon receipt of the occurrence and closes upon DASA's decision that the risk no longer warrants on-going monitoring by DASA.

7.4.2.15 Where the Authority does not have confidence that the design hazard has been eliminated or otherwise minimised SFARP, or if addressing the hazard requires development of a modification and subsequent fleetwide incorporation, then the DASA Airworthiness Directive (AD) process under DASR 21.A.3B may be invoked.

Structures and Propulsion Systems Guidance.

7.4.2.16 Structures and propulsion system specific considerations for the collection, investigation and analysis of failure, malfunctions, defects and other occurrences are addressed in AMC1 21.A.3A(a). Supporting guidance can be found in Chapter 6.6.3.

7.4.2.17 Specific guidance regarding risk analysis for propulsion systems (as could be used to develop the proposed corrective action(s) for a design- or manufacturing-related unsafe condition) is contained in Annex E to Chapter 7.2.

7.4.3 Airworthiness Directives (AD) in the DASP

Introduction

7.4.3.1 An Airworthiness Directive (AD) is *'a document issued (or adopted) by the Authority which mandates actions to be performed on an aircraft to restore an acceptable level of safety, when evidence shows that the safety level of this aircraft may otherwise be compromised'* [50]. Therefore, an AD is a key mechanism available to DASA to communicate mandatory action, in instances when an unsafe condition is determined to exist in an aircraft (and is likely to exist or develop in other aircraft) as a result of a deficiency in an aircraft's type design or conformance thereto.

7.4.3.2 This chapter sets out guidance for the use of ADs in the DASP. The guidance leverages civil practice, and expands on the regulatory criteria for the issue of an AD and key elements to execute the policy for the Defence aviation context.

Occurrence Reporting and Airworthiness Directives

Superseded

7.4.3.3 Whilst Defence-registered State aircraft are type-certified within the DASP (via the issue of a Military Type-Certificate (MTC)), and individual aircraft that conform to that type are awarded a Military Certificate of Airworthiness (MCoA), this is not a guarantee of enduring safety from a continued (and continuing) airworthiness perspective. This therefore necessitates that the potential for any unsafe condition (that may arise in-service) must be carefully monitored and managed.

7.4.3.4 Further to Chapter 7.4.2 (Continued Airworthiness Occurrence Reporting), respective Approval Holders[51] under the DASP have certain obligations[52] to DASA for the identification, communication and rectification of safety-related issues. DASA's role is to independently assure that the actions of the regulated community, in response to reportable/reported in-service occurrences affecting Defence-registered aircraft, are commensurate with the safety risk, and credible and defensible. This directly supports continued assessment of the validity of DASA-issued MTCs (/MSTCs) and/or MCoAs, and in certain instances, DASA's oversight of safety-related occurrences will need to consider if a DASA-issued AD is necessary to assure the safety of Defence aircraft (by explicitly approving and mandating the required corrective action to address an unsafe condition).

7.4.3.5 The nature of these occurrences, and the attendant severity and risk, vary considerably. In a practical sense, not every reported occurrence will (or should) result in an AD. In certain situations, it is entirely appropriate that lower-level safety-related issues reported to DASA by a sustainment enterprise (under DASR 21.A.3A) are just monitored (until defined closure criteria is met), if they do not actually constitute an unsafe condition *perse*.

Unsafe Condition Assessments (UCAs)

7.4.3.6 During the conduct of DASA's 'spectrum of assurance' for reported occurrences, the airworthiness impact to either the type, or individual aircraft of that type, must be considered. In every instance, what is unequivocally required is the determination of whether an unsafe condition exists (or not). Therefore, investigations and assessments conducted by Approval Holders within the regulated community must consider whether an unsafe condition exists; for this is not only DASA's function, but a shared responsibility. DASA's role is to be engaged with Approval Holders and determine/confirm[53] whether (or not) an unsafe condition exists (based on reports, investigations and assessments by, and engagement with, the regulated community[54]). DASA should generally not be conducting the UCA itself; for this is best-placed with respective Approval Holders[55] under DASRs (based upon type knowledge and understanding). That said, DASA always reserves the right to do so (if required).

Unsafe Conditions

7.4.3.7 Whilst DASR 21.A.3B(b) provides AMC and GM for what constitutes an unsafe condition, practical application is not always straight-forward in every instance, for discerning (and agreeing) which conditions are truly unsafe requires the exercise of professional judgement (by both Approval Holders and DASA). Moreover, the determination of what is truly an unsafe condition cannot be defined for every situation and scenario, for each platform (and DASA's assurance thereof). Generic aspects that will need to be considered are the:

1. nature of the deficiency/condition (and the associated consequence/likelihood of hazards)
2. elevated level of risk attributed to the deficiency (above that inherent in the type-certified design)
3. urgency for required mitigations, inspections and/or corrective action

Superseded

4. corresponding risk exposure period of (and any complexity within) required terminating action to resolve the deficiency.

7.4.3.8 It is important to understand that DASA (as the independent regulator) is not, and should never be, on the critical path to manage the day-to-day safety of aircraft. Under the DASRs (and the WHS Act 2011), regulated entities have obligations to ensure safety is not compromised and to alert DASA as the situations warrants. Therefore, regulated entities should not wait for DASA to provide a position before taking any appropriate action in response to an identified unsafe condition.

Criteria for issue of an AD

7.4.3.9 During the conduct of DASA's assurance of reported occurrences, and regardless of whether the actions of the Approval Holder are deemed to be credible and defensible, DASA will consider (on a case-by-case basis) the issue of an AD[56] when:

1. an unsafe condition has been determined by the Authority to exist in an aircraft, as a result of a deficiency in the aircraft, or an engine, propeller, part or appliance installed on this aircraft.

2. that condition is likely to exist or develop in other aircraft, including engine, propeller, part or appliance installed on those aircraft that may be affected by this unsafe condition.

7.4.3.10 In these instances, the 'safety benchmark' for the type or individual aircraft has (or potentially has) been compromised, and the continued validity of an aircraft's MCoA (and/or MTC) may be brought into question (via the presence of an unsafe condition). Therefore, DASA-approved inspection and/or remediation is necessary to restore an acceptable level of safety, via the issue of an AD.

7.4.3.11 Given an AD may be applicable to either all aircraft of a certified Defence type, or only certain individual aircraft of that type, ADs are by definition either type- or tail-related, issued to address identified in-service deficiencies pertaining to continued or continuing airworthiness (and potentially a hybrid thereof).

Purpose of an AD

7.4.3.12 The fundamental purpose of an AD is to:

1. approve corrective action and/or required inspections (proposed by the relevant Approval Holder under the DASRs)

2. communicate the presence of an unsafe condition affecting a Defence type and/or individual aircraft (that endangers flight safety) to the MAO/CAMO

3. mandate required action by the MAO/CAMO[57].

7.4.3.13 Regulated community compliance with DASA-issued ADs (to restore an acceptable level of safety) is mandatory within the DASP[58], which invokes the implementation of required action from a continuing airworthiness perspective under DASR Parts M and 145 (including military aircraft airworthiness review activities under DASR M Subpart I)[59].

Defence aviation context and considerations

Superseded

7.4.3.14 Since (EMAR-based) DASRs have a civil lineage – albeit adapted for the military context – fundamental aspects underpinning the intended application of DASR 21.A.3A and .3B are derived from ICAO-based concepts and civil regulations. That said, whilst DASA's assurance functions for reported unsafe conditions and the corresponding use of ADs within the DASP are *prima facie* the same, the combination of a number of inter-related features of the Defence aviation context requires additional policy considerations. In particular, how to pragmatically deal with the reality of:

1. sovereign government MTC Holder arrangements, that typically only coordinate the execution of holder obligations[60] and almost entirely leverage and recognise a much-broader (initial/) continued and continuing airworthiness management framework in place for a foreign type the same as, or similar to, the Defence type.
2. the general lack of centrality of the OEMs (as the original 'Approval Holders' for design and production that are not directly regulated under DASRs).
3. the nature of DASA as a relatively-small 'validating' Authority when issuing sovereign MTCs for Defence-registered aircraft (and most major changes to type-certificate (TC) thereafter).

7.4.3.15 Therefore, there is a strong reliance on the sustainment support arrangements established by CASG SPOs for the ongoing execution of sovereign MTC Holder functions required by DASR 21.A.3A and .3B [61], either with the actual OEM(s) and/or by leveraging the framework and actions of a foreign Civil/Military Aviation Authority (C/MAA), to support the identification and management of unsafe conditions applicable to Defence aircraft.

Sovereign MTC Holder support arrangements

7.4.3.16 The various in-service sustainment support arrangements implemented by CASG SPOs to support respective MTC Holder obligations, have differing degrees of OEM and/or foreign C/MAA involvement. Therefore, the extent to which sovereign MTC Holders leverage the initial, continued and continuing airworthiness management framework of a DASA-recognised foreign C/MAA, in direct support to the management of Defence types, will strongly influence the extent of sovereign decision-making required by MTC Holders (in the determination of required sovereign action to address an unsafe condition). In particular, those support arrangements that include a foreign C/MAA that acted as the primary certifying authority for an aircraft type similar to, or the same as, that operated by Defence.

7.4.3.17 Moreover, given the much-larger global fleets being oversighted and assured by respective foreign C/MAAs, the reality is that the vast majority of FMD/occurrences, assessments of any associated unsafe conditions, and the corresponding mandatory actions (to restore the safety benchmark) will be determined overseas (generally without sovereign MTC Holder and DASA involvement). However, FMD/occurrences for Defence aircraft do still arise, which may not be addressed by foreign type management arrangements. In particular, any design or part production deficiency that may be attributable to a military design or production organisation (MDO/MPO) approved by DASA under the DASP[62]. In these instances, the full intent of DASR 21.A.3A and .3B is required by respective Approval Holders and DASA.

7.4.3.18 Therefore, the degree of 'type management sovereignty' for Defence-registered aircraft – and therefore the extent to which sovereign decisions are required – will commensurately govern DASA's assurance of unsafe conditions affecting Defence-registered types (and the oversight of corresponding actions). That is, when more airworthiness-related 'type management' activity and

Superseded

decision-making is conducted in Australia, the greater DASA's involvement will be in the application of DASR 21.A.3A and .3B.

Sovereign Approval Holders propose required action to support the issue of an AD

7.4.3.19 When DASA decides that an AD needs to be issued within the DASP[63], the MTC Holder organisation (and/or other relevant Approval Holders under DASRs) should propose[64] appropriate corrective action and/or required inspections to DASA. Given sovereign MTC Holder organisations are primarily a coordinating (and not a design) organisation, OEM input should be considered mandatory, as well as C/MAA oversight and involvement (as appropriate)[65]. This therefore connects the original 'applicant' and the 'holder' of the design, as well as the primary certifying authority (that established the safety benchmark with the original 'OEM applicant' within their airworthiness management framework), which therefore executes the actual intent of DASR 21.A.3A and .3B.

7.4.3.20 Upon receipt, DASA's independent safety assurance function is to approve the holder's proposal, including required inspection(s) and/or rectification interval(s), and the associated risk exposure. DASA will engage with the Approval Holder and amend the proposal, if and as required. When satisfied that the AD's content (as proposed by the holder) provides appropriate terminating action to eliminate the unsafe condition (and to restore the 'safety benchmark'), and the associated risk during the exposure period will be otherwise minimised SFARP, DASA will issue an AD accordingly[66]. In doing so, DASA is explicitly approving the corrective action to address the unsafe condition and the corresponding exposure period.

Foreign ADs (or equivalent)

7.4.3.21 When sovereign MTC Holders receive relevant foreign ADs (or equivalent[67]) for assessment, and report this to DASA[68], the DASP is the beneficiary of relevant C/MAA assurance of the same/similar type to that operated by Defence. This broadly meets the intent of DASR 21.A.3A and .3B; for the 'problem' and the 'solution' is provided, that usually leverages the inputs of the actual OEM and recognises what the relevant C/MAA deemed mandatory. Therefore, a sovereign MTC Holder will need to consider the following:

1. the applicability of a foreign AD (or equivalent) to a Defence-registered type.
2. the availability and suitability of controls and corrective actions provided by a relevant foreign C/MAA that can be 'adopted' (including whether full (or partial) compliance and implementation is intended).
3. the extent to which a Defence type's Configuration, Role and Environment (CRE) considerations require necessary/appropriate variations to adapt the content of a foreign AD (or equivalent); and in particular, necessary/appropriate variations to risk controls, terminating action(s) and/or implementation timeframes/risk exposure periods.
4. the need to amplify other foreign-source safety advice for required actions and timeframes to rectify an unsafe condition[69].

7.4.3.22 Given the 'sovereignty' of DASA-issued MTCs (/MSTCs) and MCoAs for Defence-registered aircraft, the assessment of unsafe (or potentially unsafe) conditions identified for foreign aircraft that may affect Defence aircraft is fundamental to support the ongoing validity of these DASA-issued authorisations. However, it is important to note that these foreign ADs (or equivalent) are not automatically applicable and mandatory under the DASP, and despite the AD definition cited within

Superseded

DASR 21.A.3B(a), there is no regulatory mechanism within DASR 21 to 'adopt' foreign ADs (or equivalent)[70]. Therefore, whilst the regulated community may indeed decide to implement the required actions of a foreign AD (or equivalent) as a 'credible and defensible' means to address an unsafe condition for a Defence-registered aircraft, DASA nonetheless requires that applicable critical foreign safety-related information (and in particular, that issued by the primary certifying authority) is formally 'brought into the DASP' and actioned accordingly. The only way for this to occuris for DASA to issue an AD in the DASP[71], to mandate the same/similar action for Defence-registered aircraft.

Foreign ADs (or equivalent) issued by the primary certifying authority are mandatory when applicable to Defence-registered aircraft

7.4.3.23 DASA functions largely and almost exclusively as a 'validating authority', when issuing a sovereign MTC to establish the initial airworthiness of Defence types (and approving most major changes to TC thereafter), based upon recognition and leverage of the previous type-certification efforts of foreign C/MAAs. Similarly, the DASP should also recognise and leverage the type knowledge and understanding of the relevant C/MAA's management of continued and continuing airworthiness, for aircraft the same as/similar to Defence types.

7.4.3.24 Therefore, DASA's default policy position is that compliance with the technical content of foreign ADs (or equivalent) – issued by the primary certifying authority that DASA leveraged to underpin the award of a DASA MTC – is mandatory (when applicable to Defence-registered aircraft). If the primary certifying authority deemed a condition unsafe, then in near-all instances, their required mandatory action to address compromised airworthiness should be equally-applicable to Defence aircraft (notwithstanding any unique CRE considerations in certain situations).

7.4.3.25 The act of 'validating' the applicability and corresponding mandatory action within a foreign AD (or equivalent) for a Defence type is pragmatic and efficient. DASA issue of an AD when 'validating' a foreign AD (or equivalent) will in most instances be as simple as placing a DASA AD cover page on the foreign artefact(s) (if no changes are required), which may also include any minor adaption (that does not change the intent[72]), and promulgating this to the relevant MAO/CAMO for implementation.

7.4.3.26 Whilst this policy consideration would likely cater for many foreign ADs (or equivalent), DASA acknowledges there may be exceptions and complexities in certain situations, that require professional judgement. In particular, there may be compelling reasons why applicable foreign ADs are not intended for compliance (or only partial compliance), or there are substantial required and/or proposed variations on account of Defence CRE considerations (or otherwise) that will alter the intent and/or attendant risk. This will therefore require a much-greater degree of engagement between the relevant Approval Holder and DASA, to agree the content of the DASA AD (if issued).

Traceability with required mandatory action issued by the primary certifying authority

7.4.3.27 DASA's expectation is that sovereign MTC Holder arrangements implemented for each Defence type will monitor safety-related information from respective OEMs and C/MAAs (including other operators), to support required obligations under DASR 21.A.3A and .3B) (and DASR 21.A.44). In particular, this should include the documented methods and means to record the traceability of all actions mandated by the primary certifying authority[73], and the alignment with that implemented within the DASP.

7.4.3.28 For civil-derivative military aircraft, certified by a foreign MAA yet underpinned substantially by a foreign CAA's certification of the 'green aircraft', the applicability of foreign civil ADs would ideally be assessed and actioned by the relevant foreign MAA (that oversights the overseas

Superseded

fleet the same as/similar to a Defence type), but this may not always occur as expected. Therefore, due consideration should also be given to record the traceability (or otherwise) to Emergency or Alert Service Bulletins (issued by civil OEMs) and ADs (issued by the relevant CAA) that may not be mandated by the relevant MAA.

Platform DoSAs may issue ADs (for validated foreign ADs (or equivalent))

7.4.3.29 When a DASA AD needs to be issued within the DASP, and in instances where the relevant Platform Delegate of the Safety Authority (DoSA) is not developing the technical content therein – but rather only validating that a foreign AD (or equivalent) is applicable to, and should be mandatory for, Defence-registered aircraft – the Platform DoSA is the most-appropriate release authority (for, and on behalf of, DASA[74]). This is pragmatic and efficient, and is the most-responsive and agile arrangement (particularly for exigent circumstances), which is also aligned with a Platform DoSA's safety-related role and functions.

7.4.3.30 Moreover, this also fully aligns with the distributed model established for each Defence type to monitor, review and assess foreign safety-related data that may impact Defence aircraft, and should be invoked to the greatest extent possible[75]. The only caveat is that if the risk exposure is DHRM MEDIUM (or higher) until terminating action is accomplished, this should default to DASA (yet supported and staffed by the Platform DoSA).

AD issue in the absence of a foreign AD (or equivalent)

7.4.3.31 For the Defence aviation context, and in addition to the aforementioned, DASA will also consider (on a case-by-case basis) the issue of an AD in the DASP, in advance of a primary certifying authority's release of a foreign AD (or equivalent). DASA's expectation is that whenever continued operations are intended with protracted exposure to a (post-mitigation) residual risk to airworthiness – on account of an unsafe condition associated with catastrophic and hazardous consequences that cannot be eliminated or fully-controlled immediately by design – an AD in the DASP should be issued. This will usually manifest in situations where foreign MAAs have conducted a risk assessment and recommended initial treatment/controls for continued operations (due to the presence of an unsafe condition), yet the design solution and the attendant foreign AD (or equivalent) does not (and will not) exist for a significant period of time (to detail required terminating action and compliance timeframe to restore an acceptable level of safety).

7.4.3.32 This therefore sets a default position for compromised airworthiness associated with long-standing exposure to an elevated level of residual risk (whilst design solutions are being devised). In this instance, a DASA-issued AD therefore provides a means to formally communicate instances of elevated levels of risk within the DASP (bounded by a date for terminating action and compliance to be implemented), which will also provide improved Command awareness, visibility and traceability of required actions.

DASA-issued ADs associated with elevated risk should be underpinned by 7-Step Risk Management

7.4.3.33 By definition, continued (post-mitigation) operations with an unsafe condition that cannot be eliminated immediately constitutes an elevated level of risk to airworthiness during the exposure period, until terminating action detailed within an AD restores an acceptable level of safety.

7.4.3.34 Therefore, consistent with a MAO's DASR and WHS obligations, the elevated level of risk attributed to a deficiency (above that inherent in the certified design) and the corresponding residual risk exposure period should be underpinned by a MAO's Risk-Decision Brief (RDB). In particular, for instances that:

Superseded

1. deviate significantly from compliance requirements with 'validated and adopted' foreign ADs (or equivalent).

2. where there is markedly-elevated risk being retained, and the corresponding design solution required to address the deficiency will not be available for an extended period of time[76].

7.4.3.35 This policy position will primarily affect military aircraft (and likely not affect Defence-registered aircraft that are ostensibly civil). The need for an RDB for lower-level risks should be considered on a case-by-case basis (aligned with a MAO's Safety Management System (SMS)), and may not be required at all – particularly for instances where DASA leverages and 'adopts' foreign CAA ADs with no variations to risk controls and exposure periods.

7.4.3.36 MAO RDBs (that underpin DASA-issued ADs) will need to consider and disposition all available and suitable technical and operational risk controls, to support appropriate operating conditions and/or limitations. This therefore ensures and requires that MAO Hazard Tracking Authorities (HTAs) and Risk Management Authorities (RMAs) are suitably-engaged for airworthiness issues, and the corresponding DASA AD is a mechanism to communicate and document DASA's independent safety assurance for an agreed risk management strategy.

7.4.4 Other Design Approval Holders

7.4.4.1 This section addresses other design approval holders under the DASR framework. This primarily covers any Australian Military Technical Standard Order Authorisations (AUSMTSO) under DASR 21 Subpart O. AUSMTSO Authorisations are not expected to be widely used in the Defence regulatory framework and will only be issued by exception. The Authorisation is common in the civil domain under the term Technical Standard Order (TSO) and TSO Authorisations and encourages competition across the industry through novel design which does readily translate across into the military domain.

7.4.4.2 An AUSMTSO under DASR is considered equal in concept to the civil use where a TSO is defined as a minimum performance standard for specified materials, parts, and appliances used on civil aircraft. An AUSMTSO Authorisation enables the holder to manufacture a material, part, or appliances to a TSO standard. Receiving an AUSMTSO Authorisation is both a design and production approval, but importantly does not extend to installing and using the article in the aircraft.

7.4.4.3 In the civil domain, a TSO Authorisation enables the manufacture of articles that may be installed on an aircraft only after showing that the article meets the specific airworthiness requirements (certification basis) of a particular aircraft model. Receiving a TSO Authorisation verifies that an article meets a minimum performance requirement independent of the article's intended installation on an aircraft. Under the DASR, using the AUSMTSO Authorisation will be more nuanced and will not be issued on a competitive basis.

7.4.4.4 Common articles on modern day aircraft including Military aircraft that have their genesis through the civil TSO provisions include Embedded GPS and INS Units (EGIs), Auxiliary Power Units, Tires, seat belts, crew oxygen masks, seat assemblies, brake assemblies, antennae, various instrumentation, cargo containers along with many more. Under the DASR framework, the use of AUSMTSO has been very limited.

Superseded

7.4.4.5 Under DASR 21, Subpart O, the holder of an AUSMTSO has obligations to ensure that the article continually conforms to its design and is manufactured accordingly per regulations detailed under production (Subpart G). The holder is also subject to a number of other initial airworthiness regulations such as occurrence reporting and part marking with respect to their article. Although the Defence MTC construct results in a nuanced use, the AUSMTSO holder is required to engage with the aircraft Type certificate holder to integrate their article into the aircraft type or where design changes impact the integration.

7.5.1 Introduction

7.5.1.1 A Military Permit to Fly (MPTF) is a 'product authorisation' issued by DASA to aircraft that do not meet, or have not been shown to meet, the requirements of the Type-Certification Basis (TCB) and/or Military Air Operator Certificate (MAOC), but are nonetheless capable of safe flight under defined conditions and for specified purposes. An MPTF is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application.

7.5.1.2 An MPTF is a risk-based authorisation, within the suite of Defence aviation flexibility provisions provided under DASR GR.80, to facilitate military flexibility in support of a capability imperative, which is valid for a defined period of time, underpinned by a seven-step risk assessment with both technical and operational input.

7.5.1.3 Further to the overview of the Flight Conditions and MPTF authorisations provided at Chapter 5.3 Annex N, this chapter details DASR implementation of applications for, and approval of, Flight Conditions and MPTF (and the associated risk management aspects).

Audience

7.5.1.4 This chapter applies to DASR-regulated entities exercising roles or responsibilities when applying for an MPTF under DASR 21 Subpart P Military Permit To Fly. Whilst this will primarily be Military Air Operators (MAOs) – including Continuing Airworthiness Management Organisations (CAMOs) and service providers – it also extends to any organisation engaged to assist with the preparation of the application, such as: Military Type-Certificate (MTC) holders; design organisations (DASR Military Design Organisations (MDOs) and equivalents) and organisations involved in managing the configuration of Defence aircraft (CASG Systems Program Offices (SPOs) and Through-Life Support (TLS) contractors).

7.5.1.5 While cognisant of the above, the application for (and holding of) an MPTF within the DASR environment will almost exclusively be a MAO requirement for the subject aircraft defined within the MAOC Operations Specification (OpSpec)[77]. The MAO should therefore establish in-service procedures to implement attendant MPTF regulation and Acceptable Means of Compliance (AMC) that reflects the central role of the MAO Accountable Manager (AM) and authorised staff within the MPTF process.

Purpose

7.5.1.6 This chapter provides guidance in relation to Initial Airworthiness requirements under DASR 21 Subpart P, for developing MPTF applications, inclusive of: collating substantiation documentation; gaining operational endorsement; signing the declaration of safety; engaging with the Authority

Superseded

(inclusive of the Delegate of the Safety Authority (DoSA)) for approval and issue of the MPTF; and meeting MPTF holder obligations. Moreover, this chapter explains how applications for approval of flight conditions and an MPTF should follow the seven-step risk management process detailed in DASA AC 003-2018—Risk Management in the Defence Aviation Safety Program, and describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the Work Health and Safety Act 2011 (WHS Act).

Background

7.5.1.7 Within civilian aviation regulations, a permit to fly is predominately used to support development, certification, production and delivery of new aircraft and major modifications, and to support in-service operation outside the bounds of the Certificate of Airworthiness (CoA); such as ferry flights to a suitable maintenance venue for defect rectification or the conduct of an overdue scheduled servicing.

7.5.1.8 The use of MPTFs within the DASR context is subtly different. Design, certification and production of a new aircraft solely within a DASR MDO/MPO has not yet occurred, and flight test for development of major modifications will likely occur for Defence-registered aircraft operated by a MAO (rather than a DASR MDO/MPO at this stage). Furthermore, as recognised and afforded by DASR GR.80 Flexibility Provisions, Defence aviation requires flexibility to support capability imperatives for certain operational circumstances that would not be allowed within the civilian aviation domain.

7.5.1.9 Under normal circumstances, all Defence-registered aircraft should only be operated with a valid Military CoA (MCoA) issued by DASA. An MCoA is issued when the aircraft was shown, at the time of issue, to conform to its MTC awarded post-certification. Whilst in-service, the validity of the aircraft's MCoA is maintained by meeting the continuing airworthiness requirements of DASR M[78]. A valid MCoA represents a baseline level of airworthiness, aligning to both civil and military global conventions. Importantly, in the Defence context, an MPTF authorisation supplements, rather than replaces, the MCoA.

7.5.1.10 However, as stated, military aviation requires flexibility for Commanders to operate aircraft in certain circumstances without having met all the prescribed initial, continued or continuing airworthiness or aviation safety requirements, but are nonetheless capable of safe flight under defined conditions. In these circumstances, and without the necessary flexibility provisions in DASRs, the MAO would be unable to operate under the regulations. To accommodate Defence aviation flexibility, DASRs include provisions for issue of either of the following, to facilitate operation when the prescribed airworthiness or aviation safety requirements are not met:

1. MPTF under DASR 21 Subpart P Military Permit To Fly, which is augmented with AUS-unique AMC and Guidance Material (GM), which stipulate specific application requirements and include additional expectations for the holders of an MPTF, or
2. Command Clearance (CC) under DASR Specific Purpose Approval – SPA.10 *Command Clearance* [79].

7.5.2 Difference between MPTF and CC

7.5.2.1 The DASR SPA.10 CC provides for a similar outcome to that of an MPTF, in so far as the CC may also be used to authorise flight(s) where the MCoA's Instructions for Continuing Airworthiness (ICA) conditions are unable to be met. However, the key difference between the MPTF and CC is that the MPTF is an initial airworthiness authorisation subject to DASA approval and issue, whereas a CC is

Superseded

an operational authorisation via the command chain. In ideal circumstances, conditions that require an MPTF would be managed via an MPTF; however, in the event of compelling time-critical capability imperatives or emergencies, and where there is insufficient time to process an MPTF application, a DASR SPA.10 CC may be exercised.

7.5.2.2 Regardless of whether MPTF or CC provisions are used, the operating organisation remains responsible for meeting WHS obligations to eliminate or otherwise minimise risk to aviation safety, so far as reasonably practicable (SFARP). Therefore, both the MPTF application process and issue of a CC require the MAO to exercise the seven-step risk management process detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. However, an MPTF provides the MAO with independent assurance over the discharge of their obligations and should be sought whenever reasonably practicable. Should the requirement for operation of an aircraft under DASR SPA.10 be for an extended period, an MPTF or other appropriate authorisation must replace the CC.

7.5.3 Defence use of MPTFs

7.5.3.1 Whilst DASR 21.A.701(a) provides a non-exhaustive list of examples illustrating situations when an MPTF should be used, the majority of those examples are EASA/EMAR-based, and focused more on development of aircraft design, production, delivery and initial training within an OEM organisation (operating under privilege), as opposed to in-service scenarios that are typical for Defence aviation. For the Defence context, and as outlined within GM to DASR GR.80(c), aircraft operation in the following circumstances potentially entails flight at an elevated level of risk that may require an MPTF:

1. **Prior to initial issue of an MTC and MCoA.** DASR 21 precludes the issue of an MCoA if an MTC has not yet been issued. This will typically be due to the requirement to operate new aircraft prior to completion of the type-certification programme.

2. **Aircraft operation while continuing airworthiness requirements are not satisfied.** The aircraft has been issued an MCoA and is required for operational tasking; however, any of the following continuing airworthiness requirements have not been met:

   i. a defect that cannot be deferred as it has been assessed to endanger flight safety

   ii. scheduled maintenance in the Aircraft Maintenance Programme (AMP) has not been carried out

   iii. an Airworthiness Limitation (AwL) or Certification Maintenance Requirement (CMR) has been reached

   iv. an Airworthiness Directive (AD) has not been incorporated.

3. **Aircraft not conforming to an approved design configuration for the purpose of flight test.** Installation of a yet-to-be-approved modification for flight test, in order to gather compliance demonstration evidence to support approval of a change to type-certificate (or subsequent flights prior to the design change approval being issued).

4. **Aircraft operation outside approved limitations.** The aircraft has been issued an MCoA but is intended to be flown beyond the approved operating limitations in the Aircraft Flight Manual (AFM), or outside the approved role and/or environment detailed within the MAOC OpSpec. These circumstances can arise from either

Superseded

operational tasking or for the purpose of flight test (to support role expansion activities).

7.5.4 Overview of Organisational Responsibilities

7.5.4.1 The following organisations have specific responsibilities with respect to the application for, and issue of, MPTFs:

1. MAOs. MAOs are responsible for applying to DASA for the approval of flight conditions and the issue of an MPTF. They must fulfil the responsibilities of the applicant, including the conduct of a risk assessment that fully integrates all technical and operational considerations. MAOs should engage relevant external organisations in the course of preparing the application in order to effectively conduct an integrated risk assessment. These organisations may include the product's MTC holder, design organisations, CAMOs (and service providers), flight test organisations, and/or relevant maintenance organisations. All MPTFs are issued to MAOs who are then responsible for discharging the obligations of the holder of a MPTF.

2. DASA. Upon receipt of an application(s), DASA will provide independent assurance that there is evidence that the MAO met their obligations and has eliminated or otherwise minimised all risks SFARP. DASA assurance will focus on credible and defensible risk management, which provides advice to Commanders if the capability imperative has been sufficiently described and would support a decision-to-proceed with the identified Elevated Level of Risk (ELOR); however the decision-to-proceed always remains with the applicant.

7.5.5 Overview of MPTF Process and DASR Forms

7.5.5.1 The application process to obtain an MPTF is relatively straightforward, but does require clear identification of the participants and an understanding of the associated responsibilities. Whilst two separate applications are required, DASRs do not prohibit both being submitted to DASA concurrently. Relevant DASR Forms are as follows:

1. DASR Form 18b. Application for, and approval of, flight conditions that enable the aircraft to operate safely. This form is raised and submitted by an applicant to DASA. DASA approves the application and returns the approved form to the applicant.

2. DASR Form 21. Application for issue of an MPTF. Raised by the applicant and submitted to DASA. This may reference pre-existing and approved flight conditions within DASR Form 18b.

3. DASR Form 20a. Issue of an MPTF in response to a DASR Form 21 application. Raised by DASA and issued to the applicant; that is, the organisation responsible for conducting the associated flight(s) and ensuring the flight conditions are adhered to.

7.5.5.2 Further to GM to DASR 21 Subpart P, Annex A provides a 'swim-lane' flowchart illustrating the application process within organisational responsibilities. Reiterating, the approval of flight conditions is separate from the issue of an MPTF to give the applicant flexibility. Reasons include:

1. One set of flight conditions may underpin a number of MPTFs.

Superseded

2. The approval of flight conditions and the issue of an MPTF may be separated in time.

3. The issue of an MPTF by a local DoSA, in instances where DASA has previously approved flight conditions that are beyond the DoSA's delegation, may improve flexibility and timeliness.

4. The approval of flight conditions and issue of an MPTF represent different steps in the seven-step risk management process, and therefore address different WHS Act requirements.

7.5.6 Summary of the Seven-Step Risk Management Process

7.5.6.1 GM to DASR SMS.A.25(b)(2)(2.2) outlines Defence's seven-step risk management process (depicted in Figure 5), with further aviation-specific guidance detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. AC 003/2018 describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the WHS Act.

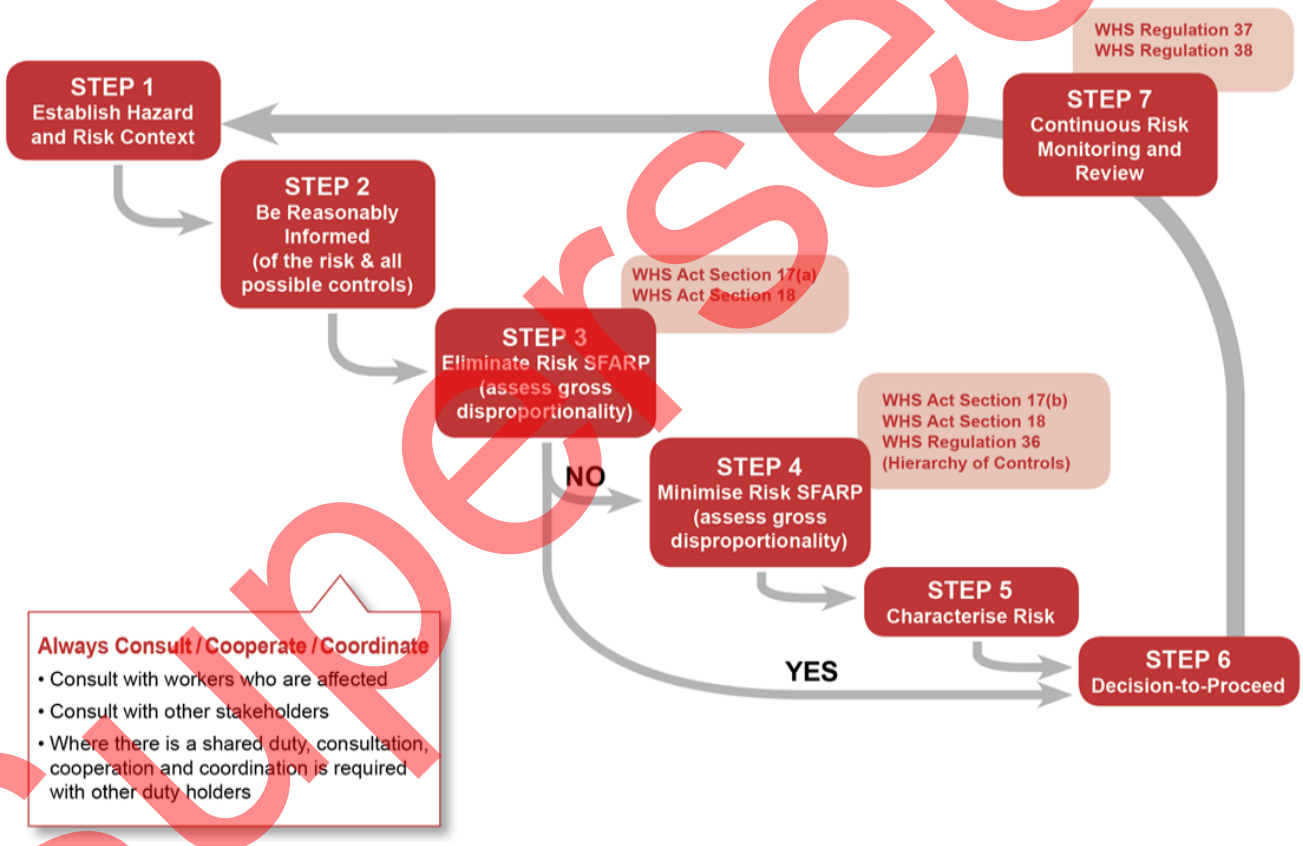

Figure 5: Safety Risk Management Process

7.5.6.1.2 DASR application forms for the approval of flight conditions and the issue of an MPTF collectively cover all of the required steps in the safety risk management process. DASR Forms 18b and 21 should summarise key information arising from the seven-step risk management process. Additional detail may be included in separate documents.

Superseded

7.5.7 Application for Approval of Flight Conditions

7.5.7.1 An approved set of flight conditions underpins every MPTF, which are the risk controls required to eliminate or otherwise minimise the risk SFARP. In applying for the approval of flight conditions, the applicant should execute and document Steps 1–5 of the seven-step risk management process. A single set of approved flight conditions may be applied to several MPTFs.

7.5.7.2 The specific application of these steps in applying for the approval of flight conditions are as follows:

1. **Step 1 – Establishing the risk context.** The applicant must define the task objective(s) including a clear strategic, operational or tactical imperative for the task and why it is necessary to fly with an ELOR. In defining task objective(s), the applicant should consider whether the task is new or existing, the discretionary/non-discretionary nature of the task and its urgency. The applicant should also identify and engage relevant stakeholders to ensure the risk assessment fully integrates all technical and operational factors. The risk context establishes the depth of risk assessment required and informs all reasonably practicable judgements. Establishing the context, also includes the duration of the activity. Retention of ELOR must be for the minimum possible duration to remain defensible within the WHS obligations and DASRs. As such, long-term MPTFs are unlikely to be defensible[80].

2. **Step 2.a – Being reasonably informed of the risks.** The applicant must proactively take steps to gain reasonable knowledge of the exact nature of all hazards and risks (both technical and operational). This may include use of existing OIP, the AFM, ICA or the provision of specialist advice from appropriate support organisations. This could include design organisations, technology or operational specialists, flight test specialists or the aircraft's OEM. There is no fixed list of who must be consulted for each application; instead, the applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context.

3. **Step 2.b – Being reasonably informed of all possible controls.** The applicant must take steps to gain reasonable knowledge of all possible controls (both technical and operational) in order to identify which ones are available and potentially suitable. Per Step 2.a, the applicant must seek relevant specialist advice where appropriate. Again, there is no fixed list of who must be consulted for each application. The applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context. The applicant must not discard any controls at this stage, as all identified controls should be used as inputs to Steps 3 and 4 in the risk management process.

4. **Steps 3 and 4 – Eliminate or otherwise minimise risk SFARP.** There is an explicit requirement to eliminate risk SFARP in the first instance and only if not reasonably practicable to do so (informed by the risk context established at Step 1), implement risk controls to minimise the risk SFARP. The applicant should systematically work through every control identified in Step 2 to determine if they are reasonably practicable to implement. The applicant must also address any additional hazards introduced by the risk controls. The integrated set of technical and operational risk controls that are reasonably practicable to implement, form the proposed flight conditions that will underpin the MPTF.

Superseded

5. **Step 5 – Characterising and communicating residual risk.** The applicant must characterise the residual risk using their safety risk management system (Note: DASA anticipates the residual risk will be characterised using the Defence Harmonised Risk Matrix (DHRM) in the Defence Aviation Safety Manual (DASM), but does not mandate its use). This step must include a declaration from the applicant that the flight conditions are a set of risk controls, integrated from a technical and operational perspective, which eliminates or otherwise minimises the risk SFARP.

7.5.7.3 Specific detail of the information and supporting documentation required to complete DASR Form 18b- *Application for Approval of Flight Conditions* is provided in the instruction sheets covering the form. See also DASR 21.A.708 and 21.A.709.

7.5.7.4 Flight Test. When an MPTF relates to flight test activity, DASRs require that flight conditions and operational endorsement must be provided by a competent MAO staff member, as determined by a DoSA-Flight Test (DoSA-FT)[81]. MAOs may apply to a DoSA-FT for a determination of competence for nominated MAO staff.

7.5.8 Approval of Flight Conditions

7.5.8.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can approve flight conditions. DASA will approve flight conditions if it has sufficient confidence that:

1. The applicant has given due consideration to the risk context, including the objectives and significance of the flying activity.
2. Elimination of the risk by restoring the aircraft to an airworthy condition IAW existing approved data, or deferring a defect, is not reasonably practicable.
3. Proposed flight conditions represent a set of risk controls that provide a credible and defensible level of safety for the flights/duration requested.
4. The applicant has appropriately characterised and communicated the residual risk.
5. The applicant has made an explicit declaration that the flight conditions, when implemented effectively, will eliminate or otherwise minimise the risk SFARP. The risk context of the application must support the depth of risk assessment undertaken and reasonably practicable judgements made by the applicant.

7.5.8.2 In assessing the application, DASA reviews the information supplied by the applicant and independently assures that it demonstrates the risk has been eliminated or minimised SFARP, and has been characterised accurately. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

Superseded

7.5.9 Application for an MPTF

7.5.9.1 Applications to DASA for the issue of an MPTF are made for specific aircraft and tasking using DASR Form 21 - *Application for a Military Permit to Fly*. All applications must reference an approved set of flight conditions, or an accompanying application for their approval. DASR Form 21 supports and records the applicant's 'decision-to-proceed' at Step 6 in the seven-step risk management process.

7.5.9.2 Note, in submitting an application for an MPTF and making the decision-to-proceed, the applicant also revisits Step 1 – Establishing the Risk Context, for that application. The test of SFARP is contextual and temporal; so this return to the risk context for the MPTF application is necessary to ensure that the applicant has made the decision-to-proceed based on the characterisation of risk in the flight conditions and in the context defined by the MPTF application, at the time of that application.

7.5.9.3 For example, the risk context of the flight conditions may be broad and enduring, covering activities such as 'deployed or directed operations'. However, the context of an application for an MPTF referencing those flight conditions must justify proceeding with the risk characterised in those flight conditions in its own right. As a result, an MPTF for a flight which itself is discretionary with little or no military capability imperative, relying upon flight conditions with a broad context such as 'deployed operations', may not be credible or defensible with the risk characterised in the referenced flight conditions, despite occurring while 'deployed'.

7.5.9.4 The key information required to support this step in the risk management process is the applicant's justification that:

1. The purpose of flight for this application is within the risk context of the referenced flight conditions and the specific task in this application warrants proceeding with the residual risk at the time of application.
2. The specific aircraft to be tasked meet(s) the configuration required by the approved flight conditions.
3. The conditions and restrictions (risk controls) in the approved flight conditions will be implemented on the subject aircraft for the subject flight(s).

7.5.9.5 The applicant must identify a suitable delegate within their organisation who has capacity to make the decision-to-proceed with the flight(s) (i.e. retain the risk). In making the decision-to-proceed, the applicant must act within their safety risk management system. Specific details of the information and supporting documentation required to complete DASR Form 21 - *Application for a Military Permit to Fly* is provided in the instruction sheets covering the form. See also DASR 21.A.707.

7.5.9.6 Flight Test. Within specialist Service Flight Test Organisations (FTOs), procedures exist to streamline MPTF applications and approvals for a range of flight test activities, such as:

1. Flight test activities on any Defence aircraft type to be conducted by, or under the direct supervision of, a Defence Aviation Authority (DAA)-approved FTO (all CAT 1 and 2 flight test and some CAT 4 tests)
2. Where Flight Test Instrumentation (FTI) or modifications are to be used, or
3. Where flight test operational substantiation and/or endorsement is required.

Superseded

7.5.9.7 MAOs considering flight test activities are encouraged to engage their respective Service FTO or a DoSA-FT, who will advise on the process to use. See also DASR FT–Flight Test.

7.5.10 Issue of a MPTF

7.5.10.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can issue an MPTF. DASA will issue an MPTF (via DASR Form 20a) if it has sufficient confidence that:

1. The decision-to-proceed has been made by an appropriate person within the applicant's organisation, given the characterisation of the residual risk (Note: DASA does not prescribe what this level is, nor what organisational authorisations they must hold).

2. The assignment of the responsibilities to implement and monitor risk controls (i.e. adherence to the approved flight conditions) is clear.

3. If applicable, there has been consideration that the flight conditions are compatible with any other MPTFs currently in effect for that aircraft (Note: The applicant is responsible for managing the implementation of multiple or concurrent MPTFs).

4. The risk context of the MPTF application is within that of the referenced flight conditions and supports the decision-to-proceed with the risk characterised by those flight conditions.

7.5.10.2 In assessing the application for an MPTF, DASA reviews the information supplied by the applicant and independently assures that it supports flying with an aircraft that does not meet the prescribed airworthiness or aviation safety requirements and may be operating at an ELOR. This will include whether the period of risk retention (the context) is defensible. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

7.5.10.3 Flight Test. When the MPTF relates to a flight test activity categorised IAW DASR.FT.05, flight conditions must be endorsed by competent staff of a MAO (as per para 22), and for a CAT 1 or 2 activity, Authority approval of flight conditions and issuing of the MPTF must be conducted by a DoSA-FT.

7.5.11 Obligations of the holder of an MPTF

7.5.11.1 As the holder of an MPTF, the MAO is responsible for ensuring the flight conditions are implemented and remain effective for the duration of the MPTF. This satisfies Step 7 of the seven-step risk management process and includes ensuring the risk context supporting the approved flight conditions remains applicable for the duration of the MPTF. See also DASR 21.A.727 and DASR 21.A.708.

7.5.11.2 Configuration management. An MPTF may introduce specific aircraft configuration management requirements, especially if an MPTF covers a yet-to-be-approved modification for operational use or flight test activity. MPTF conditions may include information such as: incorporation and maintenance instructions for new modifications; periodic inspections for non-standard damage;

Superseded

or increased usage data recording requirements. The CAMO must be aware of MPTFs that are applicable to a given aircraft to ensure overlapping continuing airworthiness requirements are resolved or coordinated, to ensure no loss of configuration management and the appropriate aircraft technical log and maintenance documentation remains accurate.

7.5.11.3 Operation by another MAO. The holder of an MPTF is responsible for ensuring the DASR 21.A.708 flight conditions are met. However, in instances where aircraft may be transferred between MAOs, this situation requires the holder to establish suitable arrangements for the transfer of holder obligations for an aircraft (that is subject to one or more MPTFs) when operated by another MAO.

7.5.12 MPTF Examples within DASR Context

7.5.12.1 Annex B provides a non-exhaustive list of examples intended to illustrate the conduct of the MPTF process within the DASR environment. Where uncertainty exists, contact a DASA Desk Officer (DIA-TC or DAVENG), the platform DoSA, or a DoSA-FT (for MPTFs related to flight test). In addition, Annex C provides a comprehensive guide to good practice and common issues pertaining to applications for flight conditions and MPTFs.

7.6.1 Military Design Organisations

Aim

7.6.1.1 This chapter details the approval and ongoing oversight of a Military Design Organisation (MDO). A MDO is approved under DASR Part21J and can only undertake design work related to the privileges granted under that approval and within the scope of that approval. Often the scope restricts what platforms a design can be applied to and can impose further limitations to aspects of their design work if required.

Introduction

7.6.1.2 Design organisation means an organisation responsible for the design of aircraft, aircraft engines, propellers, auxiliary power units, or related parts and appliances, and holding, or applying for, type-certificates, supplemental type-certificates, changes or repair design approvals. These design organisations that design aircraft, make changes to aircraft or design repairs of aircraft, and parts and appliances, need to fulfil the requirements as defined in DASR Part 21. Such organisations need to demonstrate that they have the right organisation, procedures, competencies and resources to effectively produce the design.

Obligations

7.6.1.3 DASA impose regulatory obligations on Design Organisations as part of the approval to ensure the airworthiness of aircraft and aviation products being designed within Defence. These obligations are intended to maintain high standards of design, engineering, and manufacturing processes throughout the defence aviation industry.

7.6.4 By placing obligations on design organisations, DASA aims to assure that the design, modification, and production of aircraft, components, and systems meet appropriate airworthiness standards.

Privileges

7.6.1.5 Under the DASR construct, the authority is the controlling signatory for all product released related to the type certificate. To reduce the burden on DASA, approved organisations are typically awarded privileges that allow work to be approved on behalf of the authority. For example, a design organisation may be privileged to approve minor changes to type design as well as minor and major repairs.

7.6.1.6 Granted privileges are documented on a Form 83. The Form 83 outlines the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

Superseded

7.6.1.7 An organisation attains a DASR 21 MDO Approval by submitting a Form 80 Application for Military Design Organisation Approval (MDOA) for DASA consideration, or a Form 82 Application for Significant Changes to Design Organisation Approval where a MDOA is already held but scope change is needed. Along with the application, the organisation must furnish a handbook (formerly an exposition) whereby all the processes utilised under the established Design Assurance System (DAS) are detailed. The Design Organisation Handbook Requirements are outlined in Appendix 1 of Chapter 5.3 of DASP Manual Volume 3.

DASA Design organisation assurance

7.6.1.8 Once a design organisation has gained an approval to conduct design activity, DASA will schedule oversight activities in order to assure that the MDO has maintained / is maintaining their approval to the standard as governed by the DASR Pt21 regulations. For organisations maintaining a Part21 approval, DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, and Resources as detailed in the approved Design organisation handbook, as well as consideration of the quality of design products.

7.6.1.9 The DAS is effectively the Quality Management System (QMS) specific to the output of designs against the scope issued under the Form 83. The DAS can utilise elements of the organisation QMS to satisfy requirements of the DAS. The DAS and the QMS are not the same and oversight of the DAS will be conducted specifically to design products produced.

Further information

1. DASP Manual Vol 3 Chapter 5.3 Annex E
2. DASR 21 Subpart J – Military Design Organisation Approval

7.6.2 Military Production Organisations

Aim

7.6.2.1 This chapter details the approval and ongoing oversight of a Military Production Organisation (MPO). A MPO is approved under DASR Part21 G and can only undertake production work related to the privileges granted under that approval. This includes what release documentation is acceptable under DASRs.

Introduction

7.6.2.2 Production for Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured. Acceptable release documentation is outlined at Chapter 7.3.2.

Obligations

7.6.2.3 With a Production Organisation Approval, DASA impose a set of obligations as part of the approval and as part of its regulatory framework to ensure the safety and airworthiness of aircraft and aviation products being utilised within Defence. By placing obligations on production organisations, DASA aims to assure that the production of aircraft, components, and systems meet rigorous safety and airworthiness standards.

Superseded

Privileges

7.6.2.4 Under the DASR construct, an approved MPO will be granted privileges to conduct design work to support changes to the type certificate for which the MTCH manages. Granted privileges are documented on a Form 55. The Form 55 is the certificate outlining the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

7.6.2.5 An organisation attains a DASR 21 MPO Approval by submitting a Form 55 Application for Military Production Organisation Approval (MDOA) for DASA consideration, or a Form 51 Application for Significant Changes to Production Organisation Approval where an MPOA is already held but scope change is needed. Along with the application, the organisation must furnish an exposition, whereby all the processes utilised to produce the category items under the ToA are documented.

7.6.2.6 Currently, DASA will not accept applications for production without a Military Production Organisation Approval as the authority is not resourced adequately to oversight this type of approval.

DASA production organisation assurance

7.6.2.7 Once a production organisation has gained an approval to produce category items, DASA will schedule oversight activities in order to assure the MPO has maintained/is maintaining their approval to the standard as governed by the DASR 21 regulations. DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, Resources which is detailed in the approved Production Organisation Exposition.

(Reserved)

7.6.5 Guidance for Organisations Developing and Producing Aviation Software

Introduction

Superseded

7.6.5.1 This section provides guidance for the design and production of aviation software under DASR 21. This guidance does not apply to software designed or produced under recognition as defined in DASP Vol 3 Chapter 7.3.1 Production

7.6.5.2 Aviation software is classified as a 'part or appliance' and subject to the same rules applicable to all 'tangible' parts and appliances.

7.6.5.3 Aviation software refers only to software installed in an aircraft used for operating and controlling the aircraft and does not include mission system software, condition monitoring software, aeronautical information or ground-based aircraft diagnostic systems.

7.6.5.4 For the context of aviation software, the following definitions apply:

1. **Manufacturing** – is the development of aviation software, including compiling of source code into executable object code.
2. **Production** – is the process of preparing aviation software for distribution, including packaging the executable object code and associated engineering and technical data on distribution media.
3. **Replication** – is the process of copying aviation software (executable object code) that has been authorised through a production process.

Certification of Aviation Software

7.6.5.5 Organisations manufacturing software for installation on Defence registered aircraft must hold a Military Design Organisation Approval (MDOA) under DASR 21 Subpart J. The development of new (or the modification of existing) aviation software is a change to a product's type design and must be approved under DASR 21 Subpart D or E. For changes to aviation software classified as minor, a minor change approval can be issued by an organisation holding an MDOA in accordance with its Terms of Approval. For changes to aviation software classified as major, the approval must be issued by DASA as either an amended Military Type Certificate (MTC) or a Military Supplemental Type Certificate (MSTC).

Production of Aviation Software

7.6.5.6 The production of software is the responsibility of an organisation holding an appropriate Military Production Organisation Approval (MPOA) and the release of aviation software for installation on a Defence registered aircraft is via a DASR Form 1. The software's 'part' number (version) should be marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

7.6.5.7 DASR 21 does not allow the production of aviation software under an organisation's MDOA Terms of Approval. Organisations producing aviation software for installation in Defence registered aircraft must meet the requirements of DASR 21 Subpart G—Military Production Organisation Approval in order to obtain privileges to release the software for installation.

Replication of Aviation Software

7.6.5.8 Software authorised for installation on a Defence registered aircraft via a DASR Form 1 and provided to the Continuing Airworthiness Maintenance Organisation (CAMO) may be replicated by an Approved Maintenance Organisation (AMO) in accordance with OEM or DASR 21 MDO approved procedures. It is the responsibility of the CAMO or AMO to ensure that their quality systems have processes in place to manage and verify the integrity of the replicated software. This is typically done

Superseded

using a checksum value that is generated during production of software and provided to the CAMO or AMO alongside the produced software.

7.6.5.9 Any software replication process should also include a step to ensure the software's 'part' number (version) is marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

Organisation Approval Requirements

7.6.5.10 Development and production of software are often done by the same organisation. In this case, the organisation must hold both a MDOA under DASR 21 Subpart J and a MPOA under DASR 21 Subpart G in order to obtain the necessary privileges to approve the development and production of aviation software. Typically, there are no organisations with an MPOA with software scope without a corresponding MDOA with software scope.

7.6.5.11 Underpinning these organisation approvals and privileges are a Design Assurance System documented in a Handbook (Design Organisation Exposition/DOE), and a Production Quality System documented in a Production Organisation Exposition (POE). For a software development and production organisation, it is not necessary to have discrete and dedicated stand-alone procedures manuals entitled 'DOE' or 'POE' to meet both sets of organisation approval requirements. A single manual, document (irrespective of its title) or set of procedures that covers the development and production of software may simultaneously meet the requirements of both a DOE and POE.

7.6.5.12 The regulatory requirements of a DOE (DASR 21.A.243) and a POE (DASR 21.A.143) are the minimum required of such a manual or document to be awarded the relevant organisation approval and privileges. Any manual or document(s) identified as a DOE/POE (or both simultaneously) should be a working level document(s) published for use by personnel working in the organisation. The DOE/POE should not be written purely to satisfy regulatory requirements, although this aspect will be assessed by DASA when reviewing the working level documentation and the organisation's staff's understanding of it.

7.6.6 GUIDANCE ON CONSIDERING EXPLOSIVES IN AVIATION DESIGNS

Introduction

7.6.6.1 This DASPMAN section explains what Military Design Organisations (MDO) and Military Type Certification Holders (MTCH) must consider when performing design activities on aircraft systems containing explosives and integrating air-launched stores containing explosives onto aircraft[82]. Such design activities include physical design changes to systems and equipment containing explosives, assessments that unrelated design changes do not adversely impact explosive safety, changes to Airworthiness Limitations (AwL), changes to explosives-related Instructions for Continuing Airworthiness (ICA), monitoring for new explosive-related hazards within safety management systems (SMS), and aircraft stores compatibility engineering activities.

Superseded

What is an explosive?

7.6.6.2 An explosive is '… a substance manufactured with a view to producing an explosion or pyrotechnic effect[83].'Many Defence aircraft contain explosives, either forming part of an aircraft system (such as ejection seats) and within air-launched stores such as bombs, missiles and gun ammunition[84].

Explosives requirements within Type Certification Basis

7.6.6.3 In deciding what type of explosive requirements should be included in an aircraft's Type Certification Basis (TCB) the key document is the *European Military Airworthiness Certification Criteria* (EMACC) published by the European Defence Agency. The EMACC indicates that all explosives forming part of an aircraft system should be considered when developing TCB requirements. Accordingly, the TCB should include explosive-related requirements during initial certification and when MDOs develop major or minor changes to the type design.

7.6.6.4 For aircraft stores containing explosives the EMACC implies that the TCB should only consider requirements relevant to the installation, integration and interface of the aircraft and stores. That is, the TCB should only include explosive-related design requirements to the extent they affect the store's installation, integration and interface. Any subsequent major or minor changes to the type design should also only consider the installation, integration and interface of the store.

Legislative requirements

7.6.6.5 The legislation relevant to the safe design, maintenance and operation of Defence aircraft containing explosives is the Work Health and Safety Act (Cth) 2011 (the WHS Act), the Explosives Act (Cth) 1961, and their subordinate regulations.

Explosive Safety Regulatory Framework

7.6.6.6 To comply with their explosive-related obligations under all this legislation, MDOs and MTCHs must understand Defence's *Explosive Safety Regulatory Framework* (ESRF), which amplifies this legislation for the explosives context. The ESRF purpose is to provide a Defence-wide explosive safety risk management framework which ensures explosives safety risks are effectively managed. Explosives safety aims to '… prevent premature, unintentional, or unauthorised initiation of explosives and devices containing explosives; and with minimising the effects of explosions, combustion, toxicity, and any other deleterious effects'[85].Within the ESRF, Director General Explosive Ordnance (DGEO) is the Explosive Ordnance Safety Regulator (EOSR), supported by the Director of Ordnance Safety (DOS).

7.6.6.7 Under the ESRF, the safe conduct of activities involving explosives (including design) requires adherence to the following three fundamental concepts:

1. Explosives must be designed and manufactured to design requirements so as to eliminate or minimise explosives safety hazards so far as is reasonably practicable. This concept is referred to as 'safety and suitability for service' (S3).

2. Activities involving explosives must be conducted at locations where the consequence of an explosives safety mishap is understood, and risks are minimised (referred to as a 'safe location').

Superseded

3. Activities involving explosives must be conducted through safe work practices, conducted by trained and competent personnel, which will minimise both the likelihood and consequences of an explosives safety mishap (referred to as 'safe work practices').

7.6.6.8 In applying these three concepts, the ESRF provides requirements (12 principles and 28 regulations) and guidance relevant to the design, production, operation, maintenance, handling, storage and transport of explosives throughout its lifecycle.

7.6.6.9 The ESRF is documented within the following Defence Explosive Ordnance Publications (DEOP):

1. DEOP 100 comprises three volumes of which only Volume 2 Defence Explosives Safety Regulatory Framework has been issued. Volume 2 describes the 12 mandatory principles of the ESRF, not all of which are relevant to aviation design activities. For each principle, information is provided on its rationale, the expected outcome, the constraints, obligations, external requirements and controls. DEOP 100 Volume 2 also describes the ESRF risk management and assurance processes. The ESRF relies on organisational compliance with its mandatory requirements but does not provide organisational certifications.

2. DEOP 101 provides the 28 ESRF regulations with not all applying to aviation design activities. The regulations are not in a standard format, but most comprise a general overview, the requirements, responsibilities and any accompanying procedures. Each of the 28 regulations contain some mandatory requirements.

3. DEOP 102 provides information relevant to assessing the 'Safety and Suitability for Service of Defence Explosive Ordnance'. The publication mentions the 12 principles and the 28 regulations, while providing no further requirements relevant to aviation design activities. This DEOP also discusses several explosive-related hazards[86].

7.6.6.10 Within the ESRF, the EOSR releases Defence Explosives Safety Advisory Circulars (ESAC) to promulgate important safety information. ESACs do not mandate any actions, but provide informed, well-considered safety advice and guidance. ESACs can be accessed at: drnet/JCG/JLC/ExplosiveOrdnance/DOS/Pages/ESRF.aspx (Available on DPN Only)

Relationship between the DASF and ESRF

7.6.6.11 The ESRF is specifically intended to integrate with and support other Defence regulatory frameworks that aim to achieve safety outcomes, including aviation safety. Comparison of the DASF and ESRF demonstrates that regulated organisations within the DASF can comply with both the Defence Aviation Safety Regulations (DASR) and relevant ESRF requirements, with no inconsistencies between the two safety frameworks. Importantly, both safety frameworks are subject to the WHS Act's concept of shared duty holders (s16), who must consult, co-operate and co-ordinate their activities (s46) to ensure explosive-related risks are eliminated or otherwise minimised so far as is reasonably practicable (s17).

7.6.6.12 DASA regulates the design of aircraft systems and the integration of all air-launched stores onto a type. Complementing these regulations, DGEO provides mandatory explosive-related requirements (both principles and regulations) for the design of aircraft systems containing explosives and air-launched stores containing explosives.

Superseded

7.6.6.13 The S3 construct within the ESRF requires consideration of the hazards posed to explosives safety by carriage environments. Accordingly, the ESRF requires designers to consider whether the failure or partial performance of the non-explosive components of aircraft stores adversely affects the safety of the explosives within the store. Forms of component failure or partial performance that do not affect explosive safety are outside the ESRF scope, but are considered by Guided Weapons and Explosive Ordnance Group (GWEO) as part of its broader safety responsibilities.

ESRF applicability to DASR 21 scope

7.6.6.14 Several ESRF principles and regulations fall within the scope of DASR 21. Specifically:

1. ten of the 12 ESRF principles (Principles 1-10) impose obligations on aircraft designers within MDOs and MTCH organisations
2. all of these ten principles fall within the scope of DASR 21
3. compliance with DASR 21 provides total compliance with one principle (Principle 1), partial compliance with eight principles (Principles 2, 3, 5, 6, 7, 8, 9 and 10) and no compliance with one principle (Principle 4)
4. only four of the 28 ESRF regulations (1.1, 1.2, 1.5 and 2.5) within DEOP 101 impose obligations on aviation designers within MDOs and MTCH organisations
5. of these four regulations, three fall within the scope of DASR 21 (1.1, 1.5 and 2.5)
6. compliance with DASR 21 provides only partial compliance with these three regulations.

7.6.6.15 These principles and regulations within the scope of DASR 21 provide no limits or constraints on which individuals or organisations within Defence may perform design activities for aircraft systems and aircraft stores containing explosives.

Satisfying applicable ESRF requirements

7.6.6.16 Compliance with DASR 21 provides total or partial compliance with several mandatory ESRF principles and regulations. To achieve full compliance, MDOs and MTCHs must:

1. obtain explosives safety hazard and risk management advice from personnel and organisations competent in explosives safety management (refer paragraph 7.6.6.18)
2. when complying with DASR SMS, ensure that consideration is given to explosive-specific hazards and risks
3. ensure that explosives safety hazards and residual risks of explosives are identified and communicated to affected Services, Groups and others (including non-Defence entities)
4. aim to reduce the consequences of on-aircraft explosive hazards through careful design of where explosives are located in the aircraft and the quantity of explosives used
5. ensure that personnel performing design activities on aircraft systems and air-launched stores containing explosives receive explosive-related training compliant with ESRF Regulation 1.1 (eDEOP 101)[87]

Superseded

6. when creating Instructions for Continuing Airworthiness (ICA) for aircraft systems and air-launched stores containing explosives, be aware of the inspection requirements in ESRF Regulation 1.5 (eDEOP 101)

7. when engaged in the process for the initial certification of explosives installed in aircraft systems and amendments to their life limits, comply with the process described in Annex B.

7.6.6.17 While outside the scope of DASR 21, where MDOs handle explosives as part of the design process, they should ensure their sites, platforms and facilities have the necessary facility certifications, and that the minimum number of people are exposed and are aware of the risks.

Explosives safety hazard and risk management advice

7.6.6.18 MDOs and MTCHs can obtain explosives safety hazard and risk management advice from the following organisations competent in explosives safety management:

1. the Directorate of Ordnance Safety within Joint Logistics Command

2. Joint Proof and Experimental Unit within Joint Logistics Command

3. Aerospace Explosive Ordnance Systems Program Office within GWEO

4. Directorate of Engineering and Technical within GWEO's Systems Division.

7.6.6.19 MDOs and MTCHs should have confidence in the explosives safety hazard and risk management advice provided by these organisations because they:

1. have roles (either regulatory or in-practice) that require them to comprehensively understand explosive safety hazards and risks

2. are subject to the requirements of the well-established ESRF and will provide advice compliant with all relevant ESRF principles and regulations

3. have an extensive demonstrated history of providing safe explosives advice across Defence, including to the aviation community

4. work within well-developed engineering frameworks that have evolved over several years.

7.6.6.20 MDOs and MTCHs can consume explosives safety hazard and risk management advice from these specified organisations, without the need to invoke DASR 21.A.239. That is, they do not need to consider these organisations as a '… partner or subcontractor' and are not obliged to specify the manner in which the MDO/MTCH design assurance system accounts for the acceptability of the advice provided by these external organisations or specialist personnel within them.

7.6.6.21 Some forms of advice may not need be obtained case-by-case but could be obtained as a 'standing' advice relevant to a particular type of design change whenever it occurred (for example a proposed change to a component throwaway life or maintenance interval). The relevance of specific 'standing' advice to a new circumstance would depend on the aircraft type, the form of explosives, the aircraft's operating environment and its specific sustainment arrangements.

7.6.6.22 The relationships that MDOs establish with specialist explosives organisations should be documented in the Handbook (Design Organisation Exposition), required by DASR 21.A.243. Similarly,

Superseded

MTCHs should documents their relationships in the Type Continued Airworthiness Exposition required by GM 21.A.14(c) and discussed at DASPMAN Chapter 5.3 Annex J Appendix 1.

Other guidance

7.6.6.23 A variety of other Defence stakeholders can contribute to the safe design of aircraft systems containing explosives and the safe integration of air-launched stores containing explosives. Such organisations include:

1. **Maintenance organisations** - to understand the maintenance implications of design decisions and the utility of proposed ICA relating to explosives
2. **CAMOs** - to understand the continuing airworthiness implications of explosive-related design decisions, such as the potential need for pre-flight inspections and the effect of explosive-related component lives on the aircraft maintenance program
3. **MAOs** - to understand the operational implications of explosives-related design decisions, such as preferred aircrew actions for stores release
4. **DASA** - to understand the scope of the ability to approve minor explosives-related design changes
5. **Organisations who transport and store explosives.** Organisations within various Defence Groups and Services, whose primary roles is transporting and storing explosives, would not usually be a source of explosives design safety advice. Nevertheless, there may be occasions when MDOs should seek information from them that provides necessary context for design activities.

Design activities for aircraft systems containing explosives

7.6.6.24 An aircraft system may contain explosives, usually to separate an air-launched store from the aircraft, but sometimes to separate parts of the aircraft such as ejection seats and cockpit canopies. Specific guidance on the design activities for aircraft systems containing explosives is provided in Annex A.

Design activities for ALSE/role equipment containing explosives but not part of the aircraft's type design

7.6.6.25 ALSE/Role equipment containing explosives, but not part of the aircraft type design, are outside the scope of this chapter. Nevertheless, the ESRF requirements at 7.6.6.16 a/c/d/e still apply to organisations performing relevant design activities.

Design activities for air-launched stores containing explosives

7.6.6.26 An air-launched store is an aircraft store that is intended to be separated from an aircraft in flight. Some air-launched stores contain explosives:

1. to separate the store from the aircraft (such as some chaff, some flares, some sonobuoys and gun ammunition)[88]
2. to create an explosive effect post separation (such as bombs, missiles and flares)
3. for both purposes.

Superseded

7.6.6.27 Design activities on the explosives within air-launched stores are outside an MDO's scope, performed within the scope of GWEO organisations.

7.6.6.28 Specific guidance on the integration of air-launched stores containing explosives, which is within the MDO/MTCH scopes, is provided in Annex B.

7.2. Product Certification

7.1 Introduction

7.1.1 Background

7.1.1.1 While there is no internationally-accepted definition for Initial Airworthiness, common definitions for 'initial' (happening at the beginning) and 'airworthiness' (the fact of an aircraft being safe to fly) are helpful. After all, Initial Airworthiness does indeed focus extensively on whether a new aircraft is initially safe to fly - that is, whether it has been suitably designed and manufactured.

7.1.1.2 However, by convention, Initial Airworthiness also encompasses any design changes subsequently made to the new aircraft (including the certification of those changes) and the design of repairs. Furthermore, it includes the activities needed to ensure the design remains safe throughout its lifecycle, although this activity is often termed 'continued' airworthiness (not to be confused with 'continuing' airworthiness, per chapter 8).

7.1.1.3 This chapter presents an overview of the DASR approach to aircraft design, production and certification, which are the activities commonly associated with initial and continued airworthiness. The subsequent chapters will then explore several of these concepts in more detail.

7.1.1.4 Note this chapter is relevant only to Defence Registered aircraft; for non-Defence Registered aircraft, all initial and continued airworthiness functions are conducted per the requirements of the relevant Civil or military Aviation Authority (normally CASA).

7.1.2 DASR 21 – Aircraft Design, Production and Certification

7.1.2.1 From an Initial and Continued Airworthiness (INCA) perspective, an aircraft's lifecycle might follow a progression something like this:

a. To start, an engineering organisation demonstrates its professional ability to produce an aircraft design ('design organisation approval').

b. Next, the organisation produces a new aircraft design, and an Aviation Authority certifies that the design is suitably safe ('aircraft design and certification').

c. Individual aircraft are then produced, and an Aviation Authority certifies each as conforming to the certified design ('aircraft production and certification').

d. Over the following decades of fleet operation, numerous Minor and Major design changes and repairs will be made to the aircraft ('aircraft design changes and repairs').

e. Occasionally, there may be a need for limited flying of a possibly unairworthy aircraft, either to demonstrate a new capability or to avoid grounding an important asset ('permit to fly').

Superseded

f. Critically, throughout this complex lifecycle, an engineering organisation will need to monitor for defects in the design, facilitate risk management of the design, and so on ('type certificate holder').

g. Finally, an Aviation Authority might occasionally mandate certain remediation actions in the interests of fleet safety ('airworthiness directives').

7.1.2.2 Each of these seven functions, and several others, is regulated under DASR Pt 21– *Aircraft Design, Production and Certification.* The remainder of this chapter provides a brief summary of these functions.

7.1.2.3 **Design organisation approval.** Deficiencies in an aircraft's design can range from those with immediate catastrophic consequences (eg inadequate structural strength), to an erosion of safety margins (eg misleading navigation information), to an annoyance (eg a Minor human-machine interface flaw). Designing an aircraft where risks have been eliminated or otherwise minimised so far as is reasonably practicable (SFARP) is a particularly complex endeavour.

7.1.2.4 Consequently, the initial design of Defence aircraft should only be undertaken by skilled individuals within professional aircraft design organisations. DASRs make provision for DASA to issue Military Design Organisation Approval (MDOA) status to organisations who have demonstrated that they are able to maintain a design assurance system for the control and supervision of the design, and of design changes, of aircraft products, parts and appliances.

7.1.2.5 DASA's default expectation is that a new Defence aircraft will be designed by a MDOA of suitable scope. As a matter of pragmatism, however, DASR also make provision for Defence to accept designs that have been certified by a DASA-recognised civil or military Aviation Authority (CAA/MAA), without the need for the design organisation to be a DASA-approved MDOA, within certain bounds. This approach, often called 'prior acceptance' is explored in Chapter 7.2, *Product Certification*. These same provisions apply for design changes to an extant aircraft.

7.1.2.6 MDOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.7 **Initial aircraft design and certification.** Defence periodically acquires aircraft to meet a capability need. In practice, Defence usually acquires its new aircraft as off-the-shelf designs, and then incorporates design changes to cater for Defence's unique roles and operating environment. The entire design will meet a set of airworthiness requirements - commonly called a Type Certification Basis (TCB) - and the designer(s) will produce extensive evidence (via analysis, test and other means) to demonstrate that their design meets the TCB.

7.1.2.8 As noted in paragraph 7.1.2.5, these designs will be produced by a DASA-approved MDOA, or a design organisation whose design is certified by a DASA-recognised CAA/MAA, or sometimes both. Regardless, the final design will always be certified by DASA, signified by the issue of a Military Type Certificate (MTC)[1] for the aircraft.

7.1.2.9 In the absence of a pertinent CAA/MAA certification, DASA's certification for a new aircraft would be an immense undertaking for both DASA and the Defence acquisition organisation. More commonly, however, there will be a pertinent CAA/MAA certification, and leveraging off this certification can substantially reduce the impost on both organisations. In that case, much of the effort focuses on whether the certified design is compatible with Defence's intended Configuration, Role and Environment (CRE). Chapter 7.2, Product Certification, explores the certification process in detail.

Superseded

7.1.2.10 **Aircraft production and certification.** An expertly designed and certified aircraft provides the basis for safe aircraft operation. However, just as importantly, that design must be accurately implemented on the Defence aircraft.

7.1.2.11 DASR make provision for DASA to issue a Military Production Organisation Approval (MPOA) to an organisation when assured they have the ability to manufacture aircraft parts and appliances in conformity with approved data. DASR also make provision for Defence to accept an aircraft produced under the systems of a DASA-recognised CAA/MAA. This latter approach is used for most new Defence aircraft.

7.1.2.112 Following production of an individual aircraft, DASA must certify that the aircraft is in a state of airworthiness per the inherent level of safety specified on the MTC. This certification is signified by the DASA issue of a Military Certificate of Airworthiness (MCoA)[2] for each individual Defence aircraft.

7.1.2.13 Aircraft production and MCoAs are explored in Chapter 7.3, Production. MPOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.14 **Aircraft design changes and repairs.** Defence aircraft will usually be in service for several decades. During this time, numerous design changes will inevitably be implemented, either to enhance military capability or to address design or obsolescence problems. These design changes are classified under DASR as either Minor of Major, differentiated by the degree of airworthiness effect of the design change.

7.1.2.15 The DASR approach for Minor and Major design changes is very similar. They will both be performed by a DASA-approved MDOA or another design organisation whose design is certified by a recognised CAA/MAA, and both should preserve the level of airworthiness of the aircraft. For Major design changes, however, DASA will usually provide a proportionate level of independent assurance, and DASA itself will usually certify the design as safe. This certification is usually via an amendment to the MTC, although occasionally a Military Supplemental Type Certificate (MSTC) may be issued. Chapter 7.2, Product Certification, explores the certification process in detail.

7.1.2.16 Throughout an aircraft's life, degradation (damage) of the systems/structures integrity supporting safe flight may be compromised through direct (accidental impact and battle damage) overload, or insidious (fatigue, corrosion, moisture ingress, dis-bond, ultraviolet light etc) environmental sources. Repairs are those actions developed and implemented to restore damaged products to a suitably airworthy state. Similar to aircraft design changes, aircraft repairs are classified under DASR as Minor or Major, must be designed by a MDOA or other organisation agreed by DASA, and may be subjected to a proportionate level of DASA independent assurance.

7.1.2.17 **Permit to fly.** A Military Permit to Fly (MPTF) may be issued by DASA for an aircraft that does not meet, or has not been shown to meet, the requirements of its TCB, but is nonetheless capable of safe flight under defined conditions and for specified purposes. MPTFs are most commonly used for flight test (for aircraft development or role expansion activities), for flights where the design has not yet been certified, or for flights where the aircraft temporarily does not conform to the Type Design (eg due to unrepaired damaged, overdue maintenance, etc).

7.1.2.18 An MPTF may or may not entail an elevated level of risk, and is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application. Chapter 7.5, Flight Conditions and Military Permits to Fly, explores this in more detail.

Superseded

7.1.2.19 **Type certificate holder.** As noted earlier in this chapter, DASA issues an MTC for Defence Registered aircraft types. This MTC is issued to a suitable Commonwealth government organisation (usually the relevant Defence Systems Program Office), who are then charged with 'holding' the MTC.

7.1.2.20 Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed, and the level of safety inherent in the TCB is maintained. This includes, for a particular aircraft type, collecting aviation safety information (both locally and from external sources), ensuring operators are aware of extant hazards, ensuring that essential risk controls remain effective, leading local efforts to eliminate or further minimise known risks, and many other important roles.

7.1.2.21 These expansive holding responsibilities are often beyond the capacity and capability of the government organisation holding the MTC. Consequently, responsibility for the conduct of MTCH obligations is often vested with various support organisations, for example contractors, foreign project offices and other military operators. The government organisation remains accountable for all activities undertaken by those organisations.

7.1.2.22 Chapter 7.4, Continued Airworthiness, explores the MTCH role in more detail.

7.1.2.23 **Airworthiness directives.** In the Australian Defence context, the WHS Act and DASR place responsibility and obligation solely on the regulated community for managing the day-to-day safety of their aircraft, and for ensuring risks are eliminated or otherwise minimised so far as is reasonably practicable. DASR do, however, still make provision for DASA to mandate actions and/or impose conditions on aircraft operation in certain circumstances. This is achieved through the issue of an Airworthiness Directive (AD).

7.1.2.24 Like its civil counterpart, ADs under DASR provide a means to mandate an action in order to restore an aircraft to an acceptable level of safety, where that safety level may be otherwise compromised. However, due to Defence's unique context, DASA issues ADs infrequently, particularly in comparison to civil aviation.

7.1.2.25 Chapter 7.4, Continued Airworthiness, explores DASR ADs in more detail.

7.1.2.26 **Other.** In addition to the seven common INCA functions mentioned above, DASR 21 also makes provision for a number of niche functions. Since this chapter aims to provide an overview of INCA that is consumable to a wide audience, these niche functions will not be explored here. They include: Australian Military Technical Standard Order (AUSMTSO) authorisations, restricted type certificates, restricted certificates of airworthiness, approval of parts and appliances, and the identification of parts and appliances.

Structure of these chapters

7.1.2.27 This chapter has provided a brief overview of the functions encompassed within Initial and Continued Airworthiness. The subsequent chapters explore several of these functions in greater detail, as follows:

a. Chapter 7.2: Product certification

b. Chapter 7.3: Production and military certificates of airworthiness

c. Chapter 7.4: Continued airworthiness (including military type certificate holders, occurrence reporting, airworthiness directives and other organisational approvals)

d. Chapter 7.5: Flight conditions and military permits to fly

Superseded

e. Chapter 7.6: Design and production organisations.

7.2 Product Certification

7.2.1 – Introduction

7.2.1.1. Product certification authorisations represent DASA's assurance that an individual product complies with the applicable airworthiness[3] requirements. These are issued following review of compliance evidence presented by the applicant seeking product certification. Product certification authorisations covered under this chapter are MTCs, Changes to MTCs, MSTCs, and Repair Designs.

7.2.1.2. Product certification authorisations are built around four pillars of safety assurance; Organisational Capability, Compliance demonstration, Compliance Verification, and Obligations of the holder

7.2.1.3. **Organisational Capability.** Before an organisation can apply for a product certification, they need to be eligible. Eligibility is based on an assessment of whether the organisation is equipped/ resourced to achieve a successful authorisation.

7.2.1.4. **Compliance Demonstration.** The applicant for a product certification authorisation must show that their product complies with the applicable airworthiness requirements.

7.2.1.5. **Compliance Verification.** The authority must independently verify that compliance has been achieved to the applicable airworthiness requirements. As compliance demonstration and compliance verification are intrinsically linked, a certification programme is put in place to document the means by which the applicant will demonstrate compliance and the authority will verify compliance.

7.2.1.6. **Obligations of the Holder.** Following issue of a certification approval, the certificate holder must continue to carry out obligations outlined under the DASRs to ensure the product certification remains safe.

7.2.1.7. The following sections expand upon these safety assurance areas for each product certification authorisation.

7.2.2 – Type Certification – Military Type Certificates (DASR 21 Subpart B)

Overview

7.2.2.1 **Scope of Section.** Section 7.2.2 describes the DASR type certification process for obtaining a Military Type Certificate (MTC). Military Restricted Type Certificates (MRTCs) are not yet employed by DASA, and are not addressed herein.

7.2.2.2 **Military Type Certificate.** An MTC is issued by DASA to certify that a product's type design complies with the applicable Type Certification Basis (TCB) when operated within specified conditions and limitations. Further description of the MTC authorisation can be found in Section 5.3 Annex K.

Eligibility

Superseded

7.2.2.3 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the MTC.

7.2.2.4 DASR 21.A.13 (Eligibility), and by extension DASR 21.A.14 (Demonstration of Capability), define which organisations can apply for an MTC under DASR 21. As per DASR 21.A.14, applicants for an MTC can be:

1. A DASR 21 Subpart J approved Military Design Organisation (MDO) (21.A.14(a)). Holding a DASR 21J approval provides an organisation with the eligibility to apply directly to DASA for an MTC. However, given the scope of the Australian aviation industry, development and certification of a new aircraft wholly under a DASR 21J MDO will be a rare occurrence.

2. An organisation demonstrating its capability through alternative procedures (21.A.14(b)). An applicant may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to comply with this DASR. This eligibility provision is ostensibly aimed at products with simple or limited scope of design, or organisations starting toward a MDO approval or limited duration of design activities. Use of this provision to demonstrate capability to apply for an MTC would only be considered by DASA by exception.

3. A government organisation who has an agreement in place with a design organisation that has access to the type design data (21.A.14(c)). Any government organisation applying for an MTC may demonstrate its capability by having an agreement in place, accepted by DASA, with a design organisation that has access to the necessary type design data. This is the normal provision through which DASA expects government organisations (usually the relevant CASG System Program Office (SPO)) to demonstrate their capability to apply for an MTC. The agreement with the relevant design organisation shall include detailed statements how the actions and obligations are delegated to enable the government organisation, in cooperation with the contracted organisation, to comply with the requirements of Subpart J and DASR 21.A.44 (holder obligations). AMC and GM to 21.A.14(c) provide further information on demonstration of capability under this provision.

7.2.2.5 **MTC Applications by CASG SPOs (Project Offices).** To be issued an MTC by DASA, a CASG project office develops a Type Continued-Airworthiness Exposition (TCAE) for DASA review. The TCAE details the CASG arrangements with the design organisation(s) that has access to the type-design data and through which the provision of holder obligation functions occur. Further guidance on holder obligations and arrangements can be found in Section 7.4.1.

7.2.2.6 CASG project offices seeking issue of an MTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended acquisition program.

7.2.2.7 The eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J. Since a CASG project office scope of responsibility is usually limited to a single application, and does not include the through-life holder responsibilities, the CASG project office eligibility information is not required to be delivered as a single document and can instead be contained within

Superseded

Project or Acquisition documentation. The documentation requires review by DASA prior to the project office becoming eligible to act as an applicant. However, the CASG project office must include a transition plan to manage delivery of the Type Design to the MTC holder, and where the MTC holder organisation is being created, include plans for assessment of eligibility of the MTC holder, by DASA.

7.2.2.8 Additional guidance with respect to MTC applicant eligibility when CASG project offices wish to leverage recognition provisions is as follows:

1. Application will be exclusively based upon an aircraft type-design that has been certified by a recognised CAA/MAA. In this situation, the project office, in conjunction with any associated design organisation(s), can gain eligibility by demonstrating its ability to conduct the required certification programme activities (develop CPP, conduct applicability assessment against Defence context, develop the Defence TCB, and provide a declaration of compliance), rather than demonstrate full adherence to the DASR 21 Subpart J requirements.

2. Application will be based on a design that has not been certified, but was developed using a design system (organisation, people, processes, data, and tools) external to the DASR, and where that system is used to produce designs for certification by a recognised CAA/MAA. In this situation, the DASA recognition framework[4] must be leveraged by the project office to assist in demonstrating to DASA that the arrangements with the external DO provides an acceptable equivalence to the DASR 21 Subpart J requirements. Activities to meet the eligibility requirements should be completed prior to initial engagement with DASA and throughout certification programme activities. The project office is to address the following expectations in their respective eligibility submission:

   i. Confirm that the external design organisation is normally oversighted by a CAA/MAA recognised by DASA[5].

   ii. Confirm that the external design organisation has appropriate technical scope and expertise for the intended design(s).

   iii. Confirm that the systems, processes and personnel used in developing other designs for certification by the parent CAA/MAA will be used in the design development or holder activities associated with the ADF design.

   iv. Confirm that the design organisation is able to provide an attestation of compliance against the Defence TCB for any provided design product.

   Note: In some circumstances, the PO or MTC holder may wish to allow the external design organisation to engage directly with DASA for Defence TCB agreement, development and conduct of the CCP, and provision of a declaration of compliance to the Defence TCB. In this case, the eligibility documentation shall demonstrate that the external design organisation systems and process are sufficiently similar to the DASR 21J requirements to support such delegation.

   v. Confirm any expected oversight by the DO's parent CAA/MAA is appropriate.

   vi. Confirm where applicable, arrangements for DASA oversight are in place.

Superseded

vii. Articulate how the recognition arrangements as per paragraphs 7.2.2.8.(b)(iii), (iv) and (v) will be monitored and ensured during the design development and submission process[6].

Certification Programme

7.2.2.9 **Overview.** Under DASR 21, a certification programme is required for all applications for an MTC, and the certification programme requires formal acceptance by DASA.

7.2.2.10 The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a Certification Program Plan (CPP).

7.2.2.11 Two CPP templates are published on the DASA Website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the MTC CPP template.

7.2.2.12 The organisation(s) involved in the development and submission of a certification program for an MTC application will vary depending upon the acquisition arrangements. GM1 21.A.15(b) provides further guidance based on some common acquisition scenarios.

7.2.2.13 **Contents of a Certification Programme.** DASR 21.A.15(b) outlines the requirements for content of a certification programme for an MTC. Certification programmes must be tailored to meet the requirements of the certification activity.

7.2.2.14 The certification programme should be presented as a CPP containing the information required by DASR 21.A.15(b) and the supporting AMC. The MTC CPP template published by DASA will assist in meeting the required outcomes.

7.2.2.15 Two key outcomes are achieved through the development and DASA acceptance of the certification programme:

1. Applicant development and DASA agreement of the Defence TCB for the MTC[7].
2. Formalising and agreement on the approach to be taken for demonstrating compliance against the Defence TCB, and the DASA Level of Involvement (LoI) in compliance demonstration activities.

7.2.2.16 **Proposed Compliance Demonstration Items (CDIs)**. DASR 21.A.15(b)(5) requires that the CPP proposes a breakdown of the certification programme into meaningful groups of compliance demonstration activities and data, and a proposal for the means of compliance and related compliance documents.

7.2.2.17 A CDI is a meaningful group of compliance demonstration activities and data that can be considered, in isolation, for the purpose of performing the risk assessment that allows DASA to determine its LoI.

7.2.2.18 Applicants should follow AMC 21.A.15(b)(5) when proposing the CDIs, and the DASA MTC CPP template contains further guidance and tabular templates for presenting proposed CDIs.

7.2.2.19 **Proposed DASA LoI.** As outlined in AMC 21.A.15(b)(6), the Authority's LoI is a list of activities and data, in which the Authority retains the verification of compliance demonstration (e.g. review and acceptance of compliance data, witnessing of tests, etc.), as well as the depth of the verification. The depth of the verification for individual compliance reports, data, test witnessing, etc., may range

Superseded

from spot checks to extensive reviews. DASA will respond to those retained compliance demonstration activities and data with corresponding comments or a 'statement of no objection'. DASR 21.A.15(b)(6) requires that the CPP proposes the DASA LoI associated with compliance demonstration activities, noting that LoI should normally be proposed at the CDI level. As per DASR 21.A.15(b)(6), the DASA LoI must address the likelihood of an unidentified non-compliance with the TCB requirements and the potential impact of that non-compliance on safety (ie a risk-based determination). In practice, this is achieved through taking into consideration:

1. any novel or unusual features of the certification project, including operational, organisational and knowledge management aspects
2. the complexity of the design and/or demonstration of compliance
3. the criticality of the design or technology and the related safety risks, including those identified on similar designs
4. the performance and experience of the design organisation of the applicant in the domain concerned.

7.2.2.20 AMC 21.A.15(b)(6) contains a step-by-step process and extensive information that applicants should follow when determining the proposed DASA LoI. The DASA MTC CPP template also includes complementary guidance and tables. The three main steps that culminate in determining the DASA LoI are:

1. Step 1: Identification of the likelihood of an unidentified non-compliance. This includes taking into consideration novelty, complexity and the performance of the design organisation. Refer to Section 3.2 of AMC 21.A.15(b)(6) for details.
2. Step 2: Identification of the 'risk class'. This includes determining whether the potential impact of the non-compliance within a compliance demonstration activity (ie CDI) is critical or non-critical. This is then combined with the likelihood of an unidentified non-compliance (step 1) to determine the risk class. Refer to Sections 3.3-3.4 of AMC 21.A.15(b)(6) for details.
3. Step 3: Determination of the DASA LoI. Based on the qualitative risk class identified for each compliance demonstration activity (ie CDI), the applicant should propose a DASA LoI. Refer to Section 3.5 of AMC 21.A.15(b)(6) for details.

7.2.2.21 DASA will determine the depth and extent of its inspections for each CDI, based on the information provided in the certification programme and the applicant's proposal. DASA determination of LoI will be confirmed as part of DASA's acceptance of the CPP. Note that the depth and extent of DASA LoI may change throughout the project in order to account for changes that affect the basis of the initial LoI determination.

7.2.2.22 **Certification Programme Acceptance.** DASA acceptance of the certification programme is required for all MTC applications. Early engagement with DASA, and agreement on the key certification programme content, will reduce schedule and resource risks for the project. Delaying presentation of certification programmes to DASA until after compliance demonstration has commenced may result in delays, additional work, or additional resources, due to DASA:

1. determining that the proposed airworthiness requirements or means of compliance are unsuitable for the certification activity

Superseded

2. identifying a need for a LoI in compliance demonstration activities that have already been completed, therefore resulting in a need to repeat the compliance demonstration

3. identifying LoI that requires travel (eg for compliance demonstration being completed overseas) and insufficient time is available to organise funding and travel prior to the planned activity, resulting in a need to delay the activity

4. identifying a need for data access that was not accounted for prior to contracting or establishing government to government agreements for the activity, resulting in a need for contract changes or alternate workarounds.

7.2.2.23 DASA acceptance of a certification programme can be achieved incrementally, if some aspects are unknown at the beginning of the project or are expected to change throughout the project. A caveated acceptance may be possible to achieve agreement with DASA on specific aspects of the programme prior to full details being known. For an initial or caveated acceptance, the following is required:

1. identification of the applicant and any design organisations involved

2. broad detail on the design and aircraft intended use

3. an initial proposal for the TCB, including identification of the Primary Certification Code and identification of whether any TCB tailoring (including Military Certification Review Items (MCRIs)) will be required. Note: the TCB does not have to be fully defined at this point.

4. broad detail on the certification approach (i.e. whether there will be reliance on prior certification, or whether compliance demonstration evidence with be developed specifically for the DASA certification).

7.2.2.24 Where an incremental approach is taken to developing and achieving acceptance of the certification programme, the scope of acceptance intended by each version must be clearly understood and documented. A point at which the next update is required must be identified, this may be date based or linked to a specific project stage or milestone.

7.2.2.25 DASA acceptance of the certification programme will be agreed by formal communication, which will include confirmation of the DASA LoI for the activity, and any caveats on DASA acceptance.

7.2.2.26 **Certification Programme Updates.** In accordance with DASR 21.A.15(c), the certification programme is to be updated when there are changes to any of the content required under DASR 21.A.15(b). Key aspects that require the certification programme to be re-accepted by DASA are:

1. any changes that may impact on DASA LoI, such as:

   i. change to the design or intended use

   ii. change to compliance demonstration approach (including the means of compliance)

   iii. change to the CRE Assessment (CREA) or its outcomes for a program that is leveraging prior certification

   iv. change to design organisation resources or approvals

Superseded

2. any changes to the proposed TCB (except those achieving separate agreement via an MCRI)

3. significant changes to schedule that may impact on DASA LoI activities

7.2.2.27 Changes to the certification programme can be presented as an update to the original CPP, or via a supplement, depending on the scope of the changes.

7.2.2.28 Applicants should engage early with DASA (nominally DIA) staff and remain closely engaged with CPP development and subsequent amendment, heeding advice to prevent nugatory drafting and rewriting. The DASR Form 31 can be used to notify DASA of an upcoming certification project, to initiate discussions. A face-to-face session, before any CPP drafting occurs, is strongly recommended for for complex programs.

Type Certification Basis

7.2.2.29 **Contents of a TCB.** The TCB is an agreed set of airworthiness requirements that a product must be compliant with in order to obtain an MTC. The following DASR and concepts apply to the contents of a TCB:

1. DASR 21.A.16A (Airworthiness Codes). This regulation requires that DASA shall approve the use of Airworthiness Codes[8] and other detailed specifications that may be used to demonstrate compliance of products, parts and appliances. As noted in GM 21.A.16A, rather than define a Defence-unique Airworthiness Code, DASA has elected to recognise the Airworthiness Codes prescribed by several other CAAs and MAAs that have been demonstrated to achieve safe flight, and then prescribe supplementation as required. The Defence Aviation Safety Design Requirements Manual (DASDRM) identifies the Airworthiness Codes recognised by DASA.

2. DASR 21.A.16B (Special Conditions). This regulation requires that DASA shall approve any special detailed technical specification ('special conditions') if the related Airworthiness Code or specifications do not contain adequate or appropriate safety standards. As per 21.A.16B, the need for special conditions may arise due to:

   i. novel or unusual design features (relative to the design practices on which the applicable Airworthiness Code is based)

   ii. intended use of the product is unconventional

   iii. experience from other similar products in service or products having similar design features or newly identified hazards have shown that unsafe conditions may develop

   iv. applicable airworthiness codes do not exist for the concerned product class or do not address the requested kind of operations.

   In the Defence context, special conditions are required when the primary Airworthiness Code selected may contain deficiencies against contemporary airworthiness requirements and / or may not account for Defence's unique CRE. DASA uses the Defence Aviation Safety Design Requirements Manual (DASDRM) to define those 'essential' design requirements and standards that must be applied as special conditions to supplement Airworthiness Codes due to deficiencies in the Codes or to account for the Defence CRE. The DASDRM also defines a number of 'recommended'

Superseded

design requirements and standards for which compliance is not prescribed, but which should be applied where reasonably practicable.

3. DASR 21.A.17A (Type Certification Basis). This regulation defines the scope of the Defence TCB. The airworthiness requirements specified in the TCB include:

   i. the applicable requirements from the DASA recognised Airworthiness Code selected as a basis for the Defence aircraft certification (the Primary Certification Code (PCC))

   ii. the applicable 'essential' requirements prescribed in the Defence Aviation Safety Design Requirements Manual (DASDRM)

   iii. any supplementation or tailoring agreed to by DASA.

7.2.2.30 **Development of a Defence TCB.** Development of a Defence TCB is a joint activity between the applicant and DASA and is guided by the DASR listed above and the Defence Aviation Safety Design Requirements Manual (DASDRM). TCB agreement is obtained through acceptance of the certification programme in accordance with DASR 21.A.15(b).

7.2.2.31 The TCB for a new Defence aircraft type should be developed and agreed as early as practicable in the aircraft acquisition life-cycle. While a DASA-agreed TCB should be pursued prior to entering into an acquisition contract, this will not always be possible. In those cases, the acquisition project office may elect to present a draft TCB for DASA assessment as a cost and schedule risk reduction measure.

7.2.2.32 In most cases, DASR and the DASDRM allow the Defence TCB to be based on the recognised design standards used by the parent CAA/MAA under which the aircraft was initially designed and certified.

7.2.2.33 The TCB for a Defence aircraft must be consistent with Defence's intended role and operating environment for the aircraft. In the aircraft Type Certification domain, CRE is a pivotal concept. Where an ab-initio Type Certification programme is proposed for a Defence aircraft, defining the CRE is essential to ensure that the basis of certification is consistent with the intended Defence use of the aircraft.

7.2.2.34 Where the Defence Type Certification programme intends to leverage prior certification from a recognised CAA/MAA to any extent, a CRE Assessment (CREA) is required to confirm the applicability of that prior certification to the intended Defence use. Areas where the prior certification is not entirely applicable to the Defence CRE must be addressed through further compliance demonstration evidence, inclusion of additional requirements in the TCB, or tailoring of requirements for the TCB. Further guidance on leveraging prior certification is contained in Annex B to Section 7.2, and further guidance on the conduct of a CREA is contained in Annex C to Section 7.2.

7.2.2.35 **Tailoring the PCC.** During a certification program, there may be a need to tailor the PCC when seeking an MTC. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

7.2.2.36 Tailoring of the PCC may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.2.37 Tailoring of the PCC can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a Military Certification Review Item (MCRI).

Superseded

7.2.2.38 Annex A to Section 7.2 provides further guidance on tailoring the PCC, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support PCC tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Compliance Demonstration

7.2.2.39 **Overview.** Compliance demonstration evidence comprises of reports, engineering tool outputs, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the applicable TCB is demonstrated. The applicant shall demonstrate compliance with the type-certification basis either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.2.40 The agreed certification programme will include details of how compliance demonstration is being achieved for each project. Where difficulty arises in meeting the agreed certification programme activities or outcomes, engagement with DASA as early as practicable is recommended. This phase may identify issues in compliance demonstration evidence against the agreed Defence TCB that require equivalent safety finding arguments, processing of exceptions underpinned by an Airworthiness Issue Paper (AwIP) or equivalent, or introducing new interpretations or means of compliance. In these cases an MCRI, and an AwIP as required, should be raised and submitted by the applicant for DASA consideration.

7.2.2.41 **Leveraging Prior Certification.** Defence is rarely the prime customer for new aircraft, so most acquisitions will be based on an aircraft design that has or will be certified by another CAA/ MAA. DASR 21.A.20 enables an applicant for an MTC to leverage prior certification from a recognised CAA/MAA[9] to gain relief from developing compliance demonstration evidence.

7.2.2.42 The fundamental principle of leveraging prior certification is that any requisite Authority review of evidence; testing, or witnessing of testing; or inspections (refer DASR 21.A.33(b)) have already been performed by a competent Authority (ie a CAA/MAA recognised by DASA). Therefore, duplicate effort in terms of DASA also conducting inspections / analyses / tests is unnecessary. However, as per DASR AMC 21.A.20, in order to leverage the prior certification, the applicant for the MTC must ensure:

1. the certification is within the scope, conditions and caveats specific to DASA Recognition of the certifying CAA/MAA
2. the CAA/MAA is sufficiently experienced in certification of the particular design activity
3. the certification requirements employed by the CAA/MAA are understood and any deltas from the Defence TCB have been addressed
4. the CRE applied to the prior certification is understood and any deltas from the intended Defence CRE have been addressed
5. any safety risks associated with the CAA / MAA certification have been identified, and have been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) for the Defence CRE.

Superseded

7.2.2.43 Annex B to Section 7.2 provides additional guidance on the AMC 21.A.20 requirements for leveraging prior certification, and discusses common issues encountered with leveraging prior certification. Annex C to Section 7.2 provides further guidance on the conduct of a CREA to support relief from presenting CDE when leveraging prior recognition.

7.2.2.44 **Structures and Propulsion System Specific Guidance.** Guidance on the conduct of structures and propulsion system CREAs when leveraging prior certification can be found in GM1 21.A.20 and Chapter 6.6.2. Guidance to support AMC 21.A.41 (Structural and Propulsion System Critical Parts and Airworthiness Limitations (AUS)) can be found in Chapter 6.6.2.

MTC Application, Issuance and Type Certificate Data Sheet (TCDS)

7.2.2.45 **Application.** Upon completion of all activities identified within the CPP, including development of compliance demonstration evidence and completion of DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for issuance of an MTC. The exact format of the application for an MTC will differ depending upon each project, and should be agreed within the CPP.

7.2.2.46 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will issue the MTC.

7.2.2.47 For acquisitions of new aircraft types, the Defence Aviation Authority (Defence AA) will generally elect to convene an Airworthiness Board (AwB). Aircraft acquisition AwBs, including applicant and DASA submission of documents to support the AwB, are separate to the DASR type certification process outlined within this section. AwBs are discussed further in Section 6.1.2 and Section 13.

7.2.2.48 **Type Certificate Data Sheet (TCDS).** A TCDS will accompany each MTC. The TCDS contains all information (or reference thereto) about the type certification of the product including the TCB, the type design, operating limitations, the Aircraft Flight Manual (AFM), Instructions for Continuing Airworthiness (ICA), Airworthiness Limitations (AwLs), Certification Maintenance Requirements (CMRs), critical parts list (if applicable) and any other data necessary for the continued safe operation of the product.

7.2.2.49 DASA will develop and issue the TCDS concurrently with the MTC.

DASA Assurance

7.2.2.50 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining an MTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).
2. DASA agreement of the TCB, including tailoring (refer 'Type Certification Basis' section above).
3. DASA LoI in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme'

Superseded

section above). In all cases, DASA LoI activities should be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer below for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, and issue of the MTC and TCDS.

7.2.2.51 **DASA Assurance when Leveraging Prior Certification.** Where the certification programme indicates that an applicant is proposing to leverage prior certification from a recognised CAA/MAA, then DASA assurance activities will focus on the criteria outlined in AMC 21.A.20. The guidance outlined in Annex B to Section 7.2 provides an indication of the considerations that DASA will examine as part its assurance activities.

7.2.2.52 For certain aspects, the CPP will only be providing a proposal for how the applicant intends to address the criteria for leveraging prior certification outlined in AMC 21.A.20. For example, the applicant may need to conduct further activities to confirm that the CAA/MAA is sufficiently experienced in certification of the particular design activity, conduct further analysis to show that the design is compliant for the Defence CRE, and conduct sovereign assessments for safety risk decisions or risk retention made by an MAA. Therefore, DASA will typically request the applicant provide relevant documentation prior to, or as part of, the final application.

7.2.2.53 Note that while leveraging prior certification may provide relief from the need to develop new compliance demonstration evidence, it does not provide relief from the need to present compliance demonstration evidence to DASA. As such, DASA may request to review evidence that supported the prior certification where it is deemed necessary. Where it is not possible for the applicant to provide this evidence to DASA, for example due to limitations on access to OEM data, this will be negotiated between the applicant and DASA on a case-by-case basis.

MTC Holder Obligations

7.2.2.54 MTC holder obligations are outlined in DASR 21.A.44. Refer to Section 7.4.1 for detailed guidance on MTC holder obligations.

7.2.3 – Changes to Type Certificates and Military Supplemental Type Certificates (DASR 21 Subpart D and E)

Overview

7.2.3.1 **Scope of Section.** Section 7.2.3 primarily describes the DASR type certification process for major changes to the type certificate and obtaining a Military Supplemental Type Certificates (MSTC). Minor changes to the type certificate are only briefly addressed herein.

7.2.3.2 **Change to a Type Certificate.** As defined by DASR 21.A.41, the type certificate includes:

1. The Type Design, which includes[10]:

Superseded

i. The drawings and specifications, and a listing of those drawings and specifications, necessary to define the configuration and the design features of the product shown to comply with the applicable TCB;

ii. Information on materials and processes and on methods of manufacture and assembly of the product necessary to ensure the conformity of the product;

iii. An approved Airworthiness Limitations Section (ALS) of the ICA as defined by the applicable airworthiness codes; and

iv. Any other data allowing by comparison the determination of the airworthiness of later products of the same type.

2. Operating Limitations

3. The TCDS

4. The applicable TCB

5. Any other conditions or limitations prescribed for the product in the applicable airworthiness requirements.

7.2.3.3 A change to any aspect of the items listed above is considered a change to the type certificate, and must be undertaken in accordance with DASR 21 Subpart D or E.

7.2.3.4 Note that DASR M.A.304(d) allows for the Operator to directly consume data for minor changes that has been approved within the framework of Authorities recognised by DASA. Under this pathway, the requirements of DASR 21 are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. Data for major changes cannot be directly consumed via recognition, and must be processed in accordance with DASR 21 Subpart D or E. Refer to Section 8.2 for further information on the direct consumption of data via recognition. Consumption of data for minor changes via recognition is not discussed any further within this section.

Classification

7.2.3.5 In accordance with DASR 21.A.91, all changes to the type certificate must be classified as minor or major.

7.2.3.6 A minor change is defined as a change that has no appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product. All other changes are defined as major. Guidance on classification of changes to type certificates, including examples of changes that should be classified as major, can be found in DASR GM 21.A.91.

7.2.3.7 DASR 21J MDO approval holders will typically have the privilege to classify changes that are within the scope (e.g. technology or platform types) of their terms of approval. As noted in DASR GM 21.A.91, DASA should be consulted for clarification wherever there is doubt as to the classification of a change. Furthermore, when the strict application of the DASR GM 21.A.91 paragraph 3.4 criteria results in a major classification, the applicant may request reclassification, if justified, and DASA can take the responsibility in reclassifying the change.

Processing of Minor Changes

Superseded

7.2.3.8 Minor changes to the type certificate must be undertaken in accordance with DASR 21 Subpart D, and can be approved by DASA or a DASR 21J MDO approval holder with the necessary privilege and scope. DASA expects that in the Defence context, minor changes to type certificates undertaken in accordance with DASR 21 Subpart D will be developed and approved by a DASR 21J MDO[11].

Processing of Major Changes

7.2.3.9 Changes that are classified as major can be processed and approved as a:

1. major change to the existing MTC under DASR 21 Subpart D, or
2. a MSTC under DASR 21 Subpart E.

7.2.3.10 The decision to apply for a major change (DASR 21 Subpart D) versus a MSTC (DASR 21 Subpart E) will depend upon the specific context. Under the DASR construct, both these authorisations will be issued to the government MTC holder. The default approach is usually issue a major change to the existing MTC, however, as discussed in the following sub-section, there may be cases where an MSTC is more appropriate.

Use of Military Supplemental Type Certificates (MSTCs)

7.2.3.11 The reasons for using an MSTC are different in the Defence context from in the civilian context. This sub-section provides guidance on when an MSTC should be used under the DASR.

7.2.3.12 **Civil use of Supplemental Type Certificates (STCs).** In the civil context, STCs are generally used for commercial purposes. They are used where a designer (either the OEM or another designer) alters the aircraft to provide a new capability that they can sell separately to the original Type Certificate. Of note, designers who are not the holder of the original Type Certificate can only ever apply for STCs for design changes that are classified as major, as it is not possible to apply for a major change to a certificate you do not hold.

7.2.3.13 Major changes to the Type Certificate are limited to changes done by the Type Certificate Holder, and are mostly (though not always) mandatory Service Bulletins and Airworthiness Directives to address safety issues identified in service as part of the holder obligations (eg DASR 21.A.3A).

7.2.3.14 **Use of MSTCs Under DASR.** Under the DASR the reasons for using an MSTC are different to the civil context. The following are the reasons that an MSTC (as opposed to a major change to the MTC) would be used under the DASR:

1. Sub-fleet: An MSTC may be used to manage a sub-fleet. This would be where there is one or more aircraft in the fleet that are intended to be configured or operated in a significantly different manner to the remainder of the fleet. Note, sub-fleets can also be managed via major changes to the MTC, so an MSTC may be used but is not the only option for management of sub-fleets.
2. Significant Change to the TCB: An MSTC may be used to manage a change that involves a distinct change to the TCB. Generally this will be the result of reliance on prior certification which has adopted a different PCC than that used for the original MTC. While the change to the PCC may be able to be managed via MCRI(s), it may reduce the complexity of ongoing management of the authorisations by covering the change under an MSTC.

Superseded

3. Large and Complex Changes: An MSTC may be used for large and complex changes. While the process for review and approval of a major change or an MSTC is the same, use of an MSTC provides greater visibility, and as a result greater clarity, of the precise nature and scope of the change. MSTCs are often understood by Defence Operators as being a change of more significance, which warrants greater operational consideration.

4. Management Reasons: An MSTC may be used for ease of management from the perspective of the MTC holder. This may be required to provide alignment between the DASR authorisations and authorisations being leveraged via recognition. It may be simpler for an MTC holder to manage their obligations if the Defence authorisations are aligned with the OEM authorisations.

7.2.3.15 Note that when changes are applied to the MTC for a platform that also has MSTC(s), the compatibility of the change with the existing MSTC(s) must be explicitly addressed. Under the civil system, a change to the Type Certificate does not need to explicitly consider compatibility with potential STCs. It is the Operator's responsibility to consider the impact of change to the Type Certificate against any STCs applied to their aircraft, and to engage the STC holder as required. However, in the DASR context, the MTC and MSTCs are frequently more integrated and less able to be clearly separated from each other. In addition, the MTC and MSTCs are all held by the same organisation so separating consideration of the MTC and MSTCs is unnecessary and adds confusion for no benefit. As such, it is not appropriate to progress a major change to the MTC without considering the impact on existing MSTCs.

Eligibility

7.2.3.16 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the relevant authorisation.

7.2.3.17 **Major Change to the MTC.** In accordance with DASR 21.A.92, only the MTC holder can apply for a major change to the MTC. However, as noted by DASR GM 21.A.92(a), this includes any organisation acting on behalf of the MTC holder. DASA considers it appropriate for a design organisation to act as the applicant for a major change (on behalf of the MTC holder) where:

1. the agreement between the MTC holder and design organisation required by DASR 21.A.14(c) permits,

2. the TCAE reflects the agreement and arrangements under which such applications may occur, and

3. the proposed design change is within the scope of the design organisation's approval.

7.2.3.18 In all cases, the MTC holder must sign the final application for the major change (ie Form 31A) to confirm that they have been consulted on, and have no objection to, the major change, and will carry out holder responsibilities.

7.2.3.19 During sustainment, additional design organisations may be engaged by the MTC holder to support new modifications or reflect expanding design support agreements. In these cases, the MTC holder should inform DASA of the proposed support arrangements and define additional oversight requirements to support specific applications.

Superseded

7.2.3.20 **MSTC.** In accordance with DASR 21.A.112A, any organisation that has demonstrated, or is in the process of demonstrating, its capability under DASR 21.A.112B shall be eligible as an applicant for an MSTC. The DASR 21.A.112B demonstration of capability requirements are essentially the same as those of DASR 21.A.14 (refer to the 'Eligibility' guidance in Section 7.2.2, and relevant AMC and GM for further information).

7.2.3.21 However, as noted by DASR GM 21.A.115, DASA will issue all MSTCs to the relevant government MTC holder organisation. This means that, in effect, all applications for MSTC are being made on behalf of the MTC holder who will be the eventual holder of the MSTC. Applicants for MSTCs must be able to demonstrate that they are acting on behalf of the MTC holder.

7.2.3.22 **Major Change or MSTC Applications by CASG Project Offices.** In some cases, the CASG project office may act as the applicant for a major change or MSTC for larger or more complex modifications to an existing aircraft, such as for a mid-life upgrade program or significant capability upgrades.

7.2.3.23 Since only the MTC holder can apply for major changes to the existing MTC, the CASG project office would be considered to be applying for the approval on behalf of the MTC holder. For MSTC applications, the CASG project office could be considered the applicant under the DASR 21.A.112B(c) exception clause. In either case, the eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J.

7.2.3.24 Also refer to the 'MTC Applications by CASG SPOs (Project Offices)' guidance in Section 7.2.2 for further information, including guidance on applicant eligibility when CASG project offices wish to leverage recognition provisions.

7.2.3.25 CASG project offices seeking to apply for a major change or MSTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended program.

Certification Programme

7.2.3.26 **Overview.** Under DASR 21, a certification programme is required for all changes to type certificates and MSTCs. The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a CPP.

7.2.3.27 For MSTC and 'complex'[12] major change programs, the certification programme must be presented to DASA for formal acceptance prior to the final application and declaration of compliance, and it is recommended that it be presented as a CPP. For other certification activities, the certification programme may be documented through the design pack or final application, and does not require formal DASA acceptance. Table 7.1 summarises the certification programme requirements for different design activities.

Certification Activity	DASR Reference	Formal DASA Acceptance Required?	Comments
Application for an MSTC	21.A.113(b)	Yes	Certification programme should be presented as a

Superseded

	21.A.93(b)		CPP containing the information required by 21.A.93(b) and the supporting AMC. The DASA major change/MSTC CPP template will assist in meeting the required outcomes.
Application for a 'complex' major change	21.A.93(b)	Yes	
Application for a 'simple' major change	21.A.93(b)	Yes	Certification programme can be provided with the final application for approval of the change.
Minor change to type-certificate	21.A.93(b)[13]	No	

Table 1: Certification Programme Requirements for Design Change Activities

7.2.3.28 Two CPP templates are published on the DASA website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the major change/MSTC CPP template.

7.2.3.29 The organisation(s) involved in the development and submission of a certification program for a major change or an MSTC application will vary depending upon the platform support arrangements. As noted above, the design organisation that supports the MTC holder functions may act as the applicant on behalf of the MTC holder in certain circumstances. In these cases, the design organisation will usually develop the CPP and engage with DASA for formal acceptance when required.

7.2.3.30 **Simple Major Changes.** For 'simple'[14] major changes, the certification programme may be presented with the final application (ie with the Form 31a pack). This approach introduces a risk that if DASA identifies issues with the certification programme, or with the decision to treat the change as simple, there may be a requirement for rework of compliance demonstration activities, resulting in a delay to the program. As such, this approach should only be followed where the change is straightforward; for example, OEM Service Bulletins that have received CAA/MAA certification. If there is doubt as to whether a change would meet the definition of 'simple', DASA Type Certification section should be contacted for advice.

7.2.3.31 **Contents of a Certification Programme.** DASR 21.A.93(b) outlines the requirements for content of a certification programme for a major change or an MSTC.

7.2.3.32 Certification programmes must be tailored to meet the requirements of the certification activity. If a change has been assessed as 'simple', then there is no need to do a full breakdown of the programme into CDIs or to provide a detailed LoI proposal, as the LoI must be assessed as nil to meet the definition of a simple change. For changes that rely on prior certification, the breakdown of the programme into CDIs is only required for areas that are not able to fully leverage prior certification (ie where additional compliance demonstration evidence is being developed).

7.2.3.33 For 'complex' major changes and MSTC, the certification programme should be presented as a CPP containing the information required by DASR 21.A.93(b) and the supporting AMC and GM. The major change/MSTC CPP template published by DASA will assist in meeting the required outcomes.

Superseded

7.2.3.34 **Further Guidance.** Refer to the certification programme information in Section 7.2.2 for further guidance on proposal of CDIs and DASA LoI, as well as certification programme acceptance and updates.

Certification Basis

7.2.3.35 For all changes to a product, the design organisation must identify the areas affected by the change and the corresponding certification basis (airworthiness requirements) for those areas. The applicable airworthiness requirements will depend upon the nature of the change, and can be generalised as follows:

1. **Substantial changes.** Some changes are so extensive that a new type certificate is required (refer DASR 21.A.19), and therefore would require an entirely new TCB to be established. Substantial changes for an existing aircraft type are unlikely within the Defence context.

2. **Significant (major) changes.** For major changes that are categorised as significant[15] under DASR 21.A.101, then the latest amendment level of the airworthiness requirements referenced in the TCB should be used for the change.

3. **Non-significant (major) changes.** For major changes that are not categorised as significant, then the DASR 21.A.101(b) exception clause allows the existing airworthiness requirements in the TCB to be used for the change. DASR 21.A.101(b) also allows the existing airworthiness requirements to be used for a significant change in cases where use of the latest amendment of the airworthiness requirements referenced in the TCB would not contribute materially to the level of safety, or is impractical.

4. **Minor changes.** Minor changes, by definition, do not affect the airworthiness of the product. This means that it is appropriate to use the existing airworthiness requirements in the TCB for the change (refer DASR 21.A.95(b)(1) and DASR AMC 21.A.95).

7.2.3.36 As stated above, using the existing airworthiness requirements in the TCB is usually considered adequate for minor changes and non-significant major changes. However, as noted in DASR GM 21.A.93(b)(2), Australia's WHS Act levies additional obligations on designers, namely to exercise 'reasonable knowledge' when determining that any risk inherent in designs has been minimised SFARP. Updates (later amendments) to applicable standards may provide insight into hazards and potential controls that are not identified in the existing TCB. The requirements prescribed in the DASDRM also provide a source of requirements and standards that can assist engineers to satisfy their obligation to exercise reasonable knowledge of hazards and associated controls in aircraft design.

7.2.3.37 The certification programme for the change should identify the proposed certification basis (ie existing or latest amendment level, with justification as required) and any 'reinvestigations' required[16].

7.2.3.38 **Changed Product Rule.** DASR 21.A.101 is commonly referred to as the 'changed product rule' and is used by applicants and DASA to establish the certification basis for major changes and MSTCs. The primary decision under the changed product rule is whether the latest amendment of the airworthiness requirements referenced in the TCB must be used (ie significant major change), or whether the nature of the major change allows the existing airworthiness requirements to be used (ie non-significant major change). If an applicant elects to comply with the latest amendment for a major

Superseded

change that could otherwise be categorised as non-significant, then the change will be compliant with DASR 21.A.101(a) and no further justification would be required.

7.2.3.39 DASR GM 21.A.101 contains extensive guidance and a step-by-step process for applicants to follow in order to establish the proposed certification basis for the major change. A summary of the changed product rule criteria and outcomes is shown below in Table 7.2. Table 7.2 is taken from Appendix B to GM 21.A.101, and only provides a brief summary of the extensive guidance and step-by-step process contained in DASR GM 21.A.101. A number of the Appendices to GM 21.A.101 refer to the EASA GM 21.A.101, including Appendix A of EASA GM 21.A.101 which provides examples of changes that EASA, the FAA and other Authorities considered to be 'substantial', 'significant' and 'non-significant'.

<table>

<tr><td colspan="2">New certification basis using the latest airworthiness codes and standards, and special conditions if required.</td><td colspan="2">New certification basis using the airworthiness codes and standards at earlier approved amendments, and special conditions if required.</td><td>Existing certification basis.</td><td>Existing certification basis (if adequate); if not, first appropriate later amendment(s) and/or special conditions including 'elects to comply'.</td><td>Existing certification basis.</td></tr>
</table>

Table 2: Establishing Certification Basis for Changed Products

7.2.3.40 Significant major changes shall also comply with the relevant 'essential' design requirements defined in the DASDRM (refer DASR AMC 21.A.101).

7.2.3.41 Note that for major changes, DASR 21.A.101(e) is a further exception clause that allows applicants to propose an alternative to the airworthiness requirements in the TCB. DASA may agree to the use of an alternative set of airworthiness requirements provided the alternative provides at least an equivalent level of safety to the existing TCB.

7.2.3.42 The process and justification used to comply with DASR 21.A.101 should be included within the certification programme, and the DASA major change/MSTC CPP template contains specific headings to include this information.

7.2.3.43 When applicants believe that the major change under consideration may be significant, or have questions about application of DASR 21.A.101, then engagement with DASA as early as practicable is recommended.

7.2.3.44 **Tailoring the TCB.** During a certification program, there may be a need to tailor the TCB when seeking a major change approval. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

Superseded

7.2.3.45 Tailoring of the TCB may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.3.46 Tailoring of the TCB can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a MCRI.

7.2.3.47 Annex A to Section 7.2 provides further guidance on tailoring the TCB, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support TCB tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Reclassification of Changes Requiring TCB Tailoring

7.2.3.48 Occasionally, changes to type certificates that would otherwise be classified as minor, are required to be classified as major only because of the need to tailor the TCB. This section outlines an approach to enable these changes to be reclassified to minor, once the TCB tailoring has been agreed. This approach will allow greater use of DASR 21J MDO privileges, and reduce DASA assurance in areas where there is not a clear safety benefit.

7.2.3.49 **Reclassification Justification.** DASR GM 21.A.91 states that any changes that require an adjustment of the TCB, other than electing to comply with a later amendment of a requirement, must be classified as major. However, it also states that when the strict application of the classification criteria for a design change results in a major classification, the applicant may request re-classification, if justified, and DASA can take the responsibility in re-classifying the change.

7.2.3.50 DASA has identified that, for changes that are classified as major solely due to a need to tailor the TCB, continuing to process these as major changes once the tailoring of the TCB has been agreed imposes additional administrative burden without commensurate safety benefit, and can result in a delay to the introduction of safety improvements or capability upgrades. As such, DASA considers it appropriate for these changes to be re-classified to minor, as allowed by DASR GM 21.A.91, and either directly consumed (if subject to prior certification) or approved by a DASR 21J approved organisation holding appropriate privileges.

7.2.3.51 **Reclassification Process** (Figure1). Reclassification is only possible once the tailoring of the TCB has been agreed. An applicant may submit the requests for TCB tailoring and reclassification concurrently, allowing a single DASA response, or the reclassification request may be submitted after the tailoring has been agreed. Requests for reclassification are to be submitted via Letter or Minute to DASA via the DIA Type Certification mailbox (dasa.typecert@defence.gov.au). Requests must be submitted by an organisation that meets the eligibility requirements to apply for a major change under DASR 21 Subpart D (ie the MTC holder or a design organisation that provides MTC holder functions as part of establishing holder capability).[17]

7.2.3.52 The applicant must provide confirmation that the design would meet the requirements to be classified as minor if not for the tailoring of the TCB. This may be provided as an assessment from a DASR 21J approved organisation that has privileges to classify changes, or by providing evidence of approval as a minor change under the system of a recognised CAA/MAA with an equivalent classification system.

Superseded

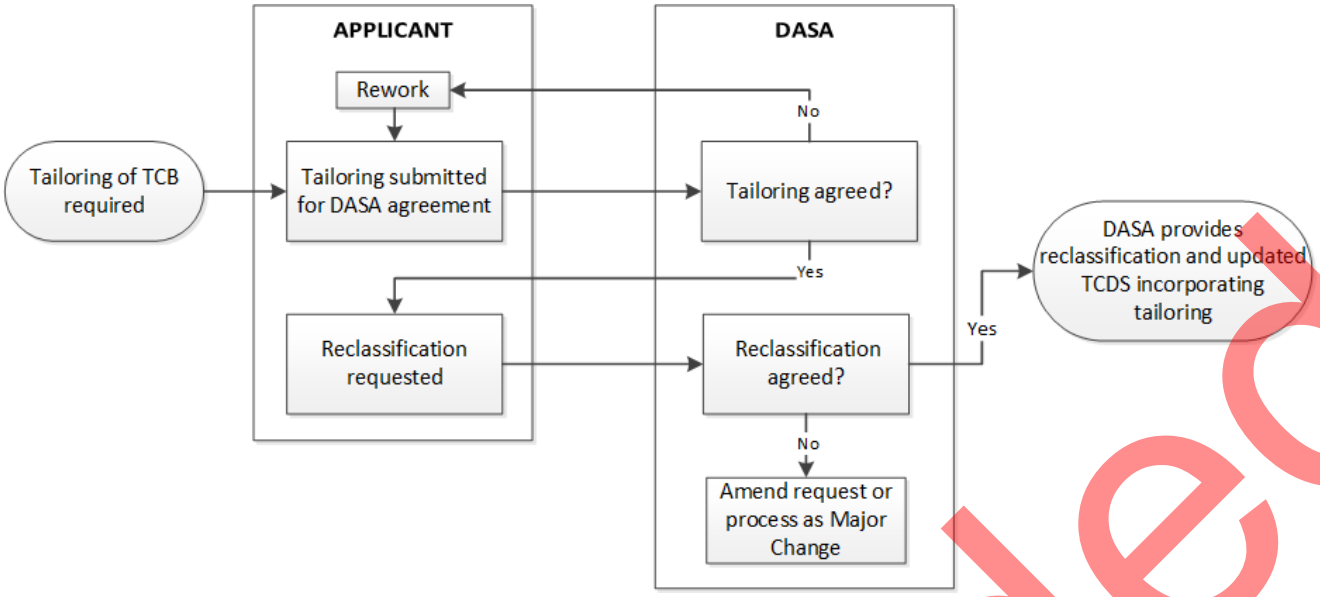

Figure 1: Process for reclassification when TCB tailoring is required

Compliance Demonstration

7.2.3.53 Compliance demonstration evidence comprises of reports, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the TCB requirements applicable to the change / MSTC is demonstrated. The applicant shall demonstrate compliance with the applicable TCB requirements either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.3.54 Refer to the 'Compliance Demonstration' evidence guidance in Section 7.2.2 for further information.

Application, Approval / Issue and TCDS Update

7.2.3.55 **Application.** Upon completion of all activities identified within the certification programme, including development of compliance demonstration evidence and DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for approval of a major change, or issuance of an MSTC, using the DASR Form 31A.

7.2.3.56 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will approve the major change or issue the MSTC.

7.2.3.57 **TCDS.** As required, DASA will develop and issue the TCDS update concurrently with the major change approval or MSTC issuance.

DASA Assurance

7.2.3.58 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining a major change or MSTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).

Superseded

2. DASA agreement of the TCB, including tailoring (refer 'Certification Basis' section above).

3. DASA Level of Involvement (LoI) in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme' section above). In all cases, DASA LoI activities must be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer to the 'DASA Assurance' guidance in Section 7.2.2 for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, approval of the major change or issue of the MTC, and update of the TCDS as required.

Holder Obligations

7.2.3.59 Given the DASR only allows the MTC holder to be the applicant for a major change to an existing MTC, there are no separate DASR holder obligations for major changes, and the MTC holder must undertake the obligations laid out in DASR 21.A.44 for the MTC, including and all major changes thereto.

7.2.3.60 Obligations for holders of an MSTC are laid out in DASR 21.A.118A . However, given DASA's policy of issuing all MSTCs to the government MTC holder organisation, and the fact that the DASR 21.A.118A obligations are essentially the same as those ofDASR 21.A.44, the MTC holder simply needs to continue to undertake all obligation laid out in DASR 21.A.44 for the MTC and all MSTCs they hold.

7.2.3.61 Refer to Section 7.4.1 for detailed guidance on the DASR 21.A.44 MTC holder obligations.

7.2.4 – Repair Designs (DASR 21 Subpart M)

Overview

7.2.4.1 Data that is used to accomplish repairs needs to be approved by a suitable and competent organisation. Data may be approved through a repair design approval process where DASA is the certifying authority, or through a process where recognition is used. These two broad pathways are covered by DASR M.A.304, which provides the requirements for data that is used to carry out repairs and modifications:

1. DASR M.A.304(a) and (b) allow data to be used that has been approved by DASA, and by a Design Organisation approved under DASR 21, respectively. In both cases DASA is the certifying authority and the requirements of DASR 21 Subpart M (Repairs) are applicable.

Superseded

2. DASR M.A.304(d) allows for the consumption of data that has been approved within the framework of Authorities recognised by DASA. In this instance the repair approval requirements of DASR 21 Subpart M (Repairs) are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate.

7.2.4.2 This section is relevant to data for repairs conforming to DASR M.A.304(a) and (b) and provides:

1. an overview of the repair approval process in accordance with DASR 21 Subpart M (Repairs)
2. guidance for design organisations and MTC holders regarding DASA's expectations for repair design development and approval
3. more detailed guidance in the form of a number of common repair scenarios.

7.2.4.3 Guidance regarding use of repair data in accordance with DASR M.A.304, including consumption of data using recognition provisions, is provided in the Section 8.2.

7.2.4.4 Note that additional general information about Repair Design authorisations is contained in Section 5.3 Annex R.

DASR 21 Repair Design Privileges

7.2.4.5 DASR 21 Subpart J privileges related to repair designs include the privilege to:

1. classify repairs (DASR 21.A.263(c)(1)),
2. approve minor repairs (DASR 21.A.263(c)(2)), and
3. approve certain[18] major repairs (DASR 21.A.263(c)(5)).

7.2.4.6 These privileges require the design organisation to have procedures agreed to by DASA, usually by issue of a Military Design Organisation Approval (MDOA). These procedures would normally be documented in a Design Organisation Handbook[19].

Repair Process

7.2.4.7 The overall process for development, approval and embodiment of repairs where DASA is the certifying authority is outlined in Table 7.3. Further guidance, in the form of specific scenarios are outlined in Annex D to Section 7.2 Repair Design Approval Scenarios. Note that the scenarios in Annex D are defined as an aid for explanation, rather than as a series of strict processes.

Stage	Description	Responsibility
Identify and Assess Damage	Damage identified for which there is no existing pre-approved solution.	CAMO
Develop Repair Design	Repair design data is developed.	Design organisation

Superseded

Repair Classification	Repair classified in accordance with the requirements of DASR 21.A.435a.	DASA or an appropriately approved design organisation under a procedure agreed with DASA
Repair Certification	Establish Certification Basis (CB). Demonstrate compliance with required CB elements, Compliance Verification, Declare Compliance. Submit application for approval if required.	Applicant that meets the eligibility criteria[20]
Repair Approval	Approval of Repair. The assignment of obligations to the repair approval holder (dependent on classification).	DASA or an appropriately approved design organisation under a procedure agreed with DASA.
Repair Configuration Management	Manage the accomplishment of repairs and maintain a record of aircraft configuration, which includes repairs.	CAMO
Production of Repair Parts	Produce repair parts.	Appropriately approved production organisation, under DASR 21 Subpart G or Subpart F, or an appropriately approved maintenance organisation under DASR 145
Repair Embodiment	Embody repair.	Appropriately approved maintenance organisation under DASR 145 or appropriately approved production organisation under DASR 21 Subpart G
Ongoing Holder Obligations		Repair design approval holder

Table 3: Repair Process where DASA is the Certifying Authority

Repair Design Classification

7.2.4.8 As per DASR 21.A.435a – Classification and approval of Repairs – a repair must be classified as either minor or major in accordance with the criteria laid out in DASR 21.A.435a. Classification of repairs guides DASA to apply appropriate assurance oversight and allows for the obligations of the holder of a repair design approval to be identified. Classification does not affect the certification basis, demonstration of compliance, independent checking or declaration of compliance and, as such, whether a repair is classified as major or minor does not affect the engineering rigour applied to the repair. Repair classification may be made by either DASA or by an appropriately privileged design organisation under a procedure agreed to with DASA[21].

7.2.4.9 DASR GM 21.A.435a states that a new repair – a repair that has not previously been approved for the application being considered on the individual aircraft in question – is classified as major if it has an appreciable effect on structural performance, weight, balance, systems, operational characteristics or other characteristics affecting airworthiness. This is elaborated on to highlight that repairs needing extensive static, fatigue or damage tolerance justification or testing, or requiring

Superseded

methods, techniques or practices that are unusual, are to be classified as major. This GM identifies repairs that require permanent changes to Airworthiness Limitations (AwLs) to be classified as major.

7.2.4.10 The paragraphs below give examples of what may need to be considered in developing a repair classification procedure. Each organisation must develop its own procedure which meets the requirements of DASR 21.A.435a, 21.A.239, 21.A.263 and 21.A.243 and is tailored to the organisations scope of work. However, the considerations below, based on the guidance provided in the GM 21.A.435a and GM 21.A.91, are provided to further clarify DASA's expectations of such a procedure.

7.2.4.11 For clarity, classification may consider the following three characteristics of the repair design:

1. Severity – the effect of the repair on airworthiness.
2. Complexity – the complexity of the design and the certification requirements.
3. Novelty – whether the design has been developed in accordance with established methods and practices for the repair application in question.

7.2.4.12 Generally repairs may be classified as major except when all of the following criteria are met:

1. Severity is low. Examples of the types of details that would be expected from repairs of low severity include:
    i. Structural performance, in terms of static strength, fatigue performance, damage tolerance performance, flutter and stiffness characteristics, is unaffected by the repair.
    ii. Load paths and load sharing in the vicinity of the repair are unaffected by the repair.
    iii. Weight and balance change is not greater than that allowed in the weight and balance manual or Original Equipment Manufacturer (OEM) repair guidance for weight and balance. This includes changes in centre of gravity and load distribution. Weight and balance of control surfaces can be particularly affected by even small changes.
    iv. Changes do not affect the operation or redundancy of a system, or an adjacent system.
    v. Changes do not affect operational characteristics.
    vi. Other characteristics related to airworthiness, or to environmental characteristics of the platform (such as noise, fuel venting and exhaust characteristics), are not affected including, but not limited to, fire protection, propulsion systems integrity and crashworthiness.
2. The repair design and the certification requirements are not complex. Examples of the types of details that would be expected from repairs of low complexity include:
    i. Repair requires no or minimal re-assessment or re-evaluation of original certification substantiation data
    ii. Repair design elements are straightforward.

Superseded

iii. Original type certification data is available, or if not available appropriate data can be established without complex engineering, and no assumptions are required in the definition of the certification requirements.

3. There are no new or novel features to the repair. Examples of the types of details that would be expected from a repair that does not have new or novel features include:

   i. Techniques, methods and practices are those employed in the regular management of the platform and type of defect.

   ii. Techniques, methods and practices are those accounted for in the platform Type Design.

7.2.4.13 It is recognised that in some cases not all data will be available at the time of initial repair classification, and so, judgement must be exercised. In the case where later data indicates that the initial classification is no longer valid, a repair may be reclassified. In this case, consultation with DASA and, where necessary, reconsideration of the Certification Programme (CP), is expected.

7.2.4.14 These classification considerations are outlined in Figure 2.

Superseded

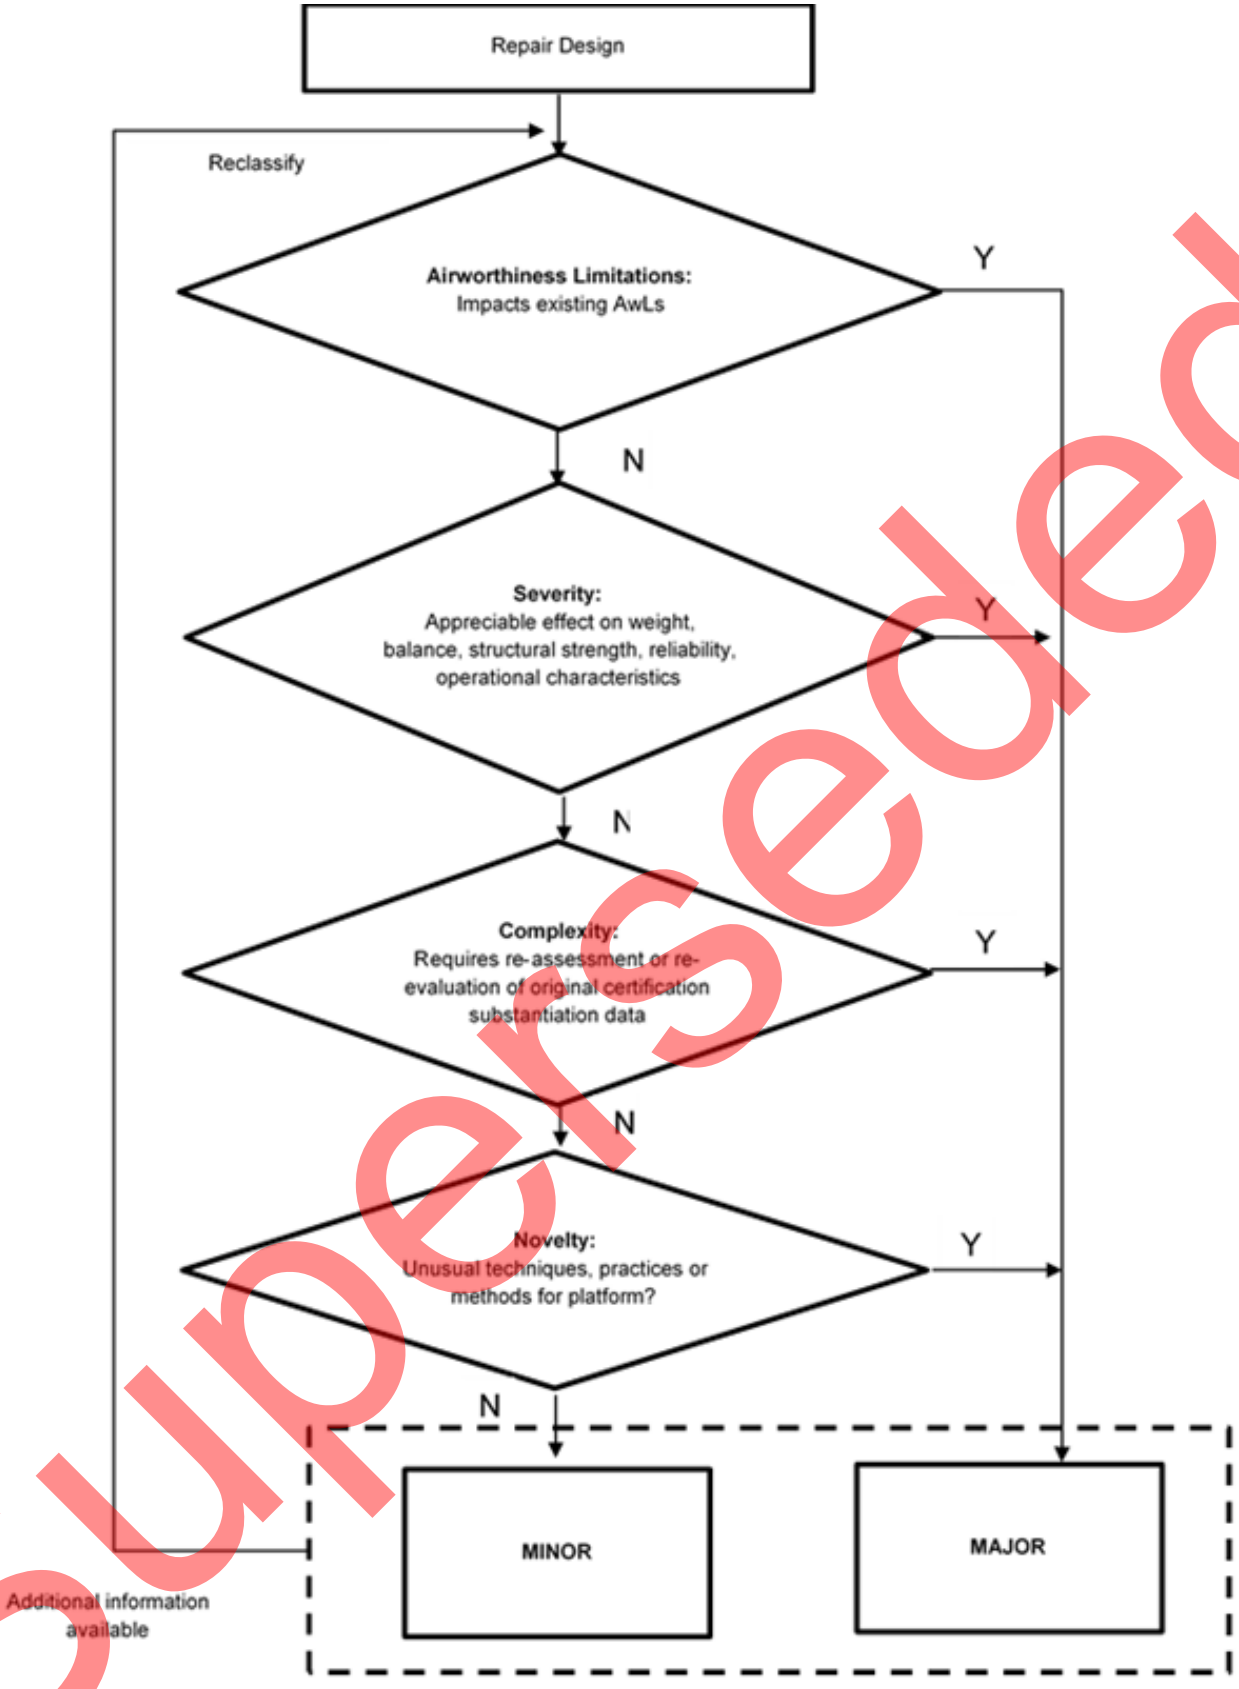

Figure 2 : Repair Classification Principles

Eligibility

7.2.4.15 Applicant eligibility requirements exist to control how designs are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance documents, artefacts

Superseded

and how the declaration of compliance is made. This provides DASA with confidence in the applicant's ability to fulfil the obligations of the repair approval holder where applicable. As such applicants for repairs must meet eligibility criteria as defined in DASR 21.A.432A.

7.2.4.16 To be eligible as an applicant for a major repair design approval, the applicant is to either hold an approval under DASR 21 Subpart J, or may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to demonstrate capability, or may be a government organisation which has agreements in place with a design organisation with access to the type design data.

7.2.4.17 Any organisation is eligible to apply for approval of a minor repair design. It is recommended that an organisation considering applying for DASA approval of a minor repair design seeks approval through an organisation holding a minor repair approval privilege under DASR 21 Subpart J, as DASA priorities will likely lead to delays in the approval of minor repairs.

Approval

7.2.4.18 Repair design approvals may be issued by DASA or an appropriately privileged design organisation, in accordance with DASR 21.A.435b.

7.2.4.19 In the case where DASA is issuing a major repair design approval, DASA receipt of a DASR Form 31B should signify the completion of a period of engagement between the applicant and DASA during which the certification activities agreed within the CP have been undertaken[22], including satisfactory DASA inspection of compliance documents. Upon receipt of the application, DASA assures itself that agreed CP activities have been completed, and if assured, DASA issues to the designated major repair design approval holder a signed DASR Form 31B for major repairs under DASR 21 Subpart M.

7.2.4.20 Design organisations approved under DASR 21 Subpart J can approve designs for minor repairs and certain major repairs, subject to the scope and privileges recorded in their terms of approval, and subject to their internal procedures agreed to by DASA. Further guidance based on repair classification is as follows:

1. **Minor Repairs.** Most MDOA holders approved by DASA will have the privilege to approve minor repairs that are within the scope of their terms of approval (privilege DASR 21.A.263(c)(2)).

2. **Major Repairs.** Some MDOA holders approved by DASA may also have the privilege to approve certain major repair designs that are within the scope of their terms of approval (privilege DASR AMC1 21.A.263(c)(5). The definition of 'certain major repairs' is provided in DASR AMC1 21.A.263(c)(5), (8) and (9), and depends upon whether or not the MDOA holder holds the relevant MTC, MSTC or Australian Military Technical Standard Order Authorisation (AUSMTSOA). In all cases, the ability to exercise the major repair approval privilege is subject to additional criteria and limits based on the characteristics of each individual repair design. For MDOA holders who do not hold the MTC, MSTC or AUSMTSOA, each new major repair design should be assessed against the 'List associated with the privilege' and the relevant 'Justification document' to determine whether the privilege can be exercised. Refer to AMC1 and AMC2 to DASR 21.A.263(c)(5), (8) and (9) for further information on award of, and exercising, the privilege to approve certain major changes.

Holder Obligations

Superseded

7.2.4.20 Following approval of the repair design, the obligations for the repair are assigned to the holder of the repair design approval in accordance with DASR 21.A.451. For both minor and major repairs these obligations include:

1. DASR 21.A.4 – Coordination between Design and Production.
2. DASR 21.A.447 – Record Keeping.
3. DASR 21.A.449 – Instructions for Continuing Airworthiness.
4. DASR 21.A.451(a)2 – Specify the markings in accordance within accordance with DASR 21.A.804(a).

7.2.4.21 For major repairs additional obligations of the holder of the repair design approval include:

1. DASR 21.A.3A – Failures, Malfunctions and Defects.
2. DASR 21.A.3B – Airworthiness Directives.
3. DASR 21.A.439 – Production of Repair Parts.
4. DASR 21.A.441 – Repair Embodiment.
5. DASR 21.A.443 – Limitations.
6. DASR 21.A.433(b) – Substantiation Data.

Superseded

7.2.5 – Instructions for Continuing Airworthiness (ICA)

Basic Principles of ICA

7.2.5.1 **ICA and maintenance data.** ICA is only a subset of all maintenance data that must be complied with in the conduct of maintenance[23]. Other sources of maintenance data include Airworthiness Directives (or other applicable requirements or operational directives issued by DASA), modification and repair implementation instructions and applicable maintenance standard practices. ICA should not be used as a collective term for all maintenance data as other sources of maintenance data are derived from different sources and subject to different regulation. This section deals only with ICA, not all forms of maintenance data.

7.2.5.2 **Airworthiness requirement.** The applicant for an MTC must develop ICA as required by the Type Certification Basis (TCB). Civil primary certification codes used for military products contain clauses (e.g. FAR/CS 23/25/27/29.1529 (aircraft), FAR 33.4 and CS-E 25 (engines), and FAR 35.4 and CS-P 40 (propellers)) that prescribe the content and format of ICA. Products with a military-derived TCB (e.g. from MIL-HDBK-516) have equivalent requirements for the development of maintenance instructions that achieve a similar intent to the civil airworthiness requirements above.

7.2.5.3 **Content and scope of ICA.** To meet the ICA requirements of a civil airworthiness code (or equivalent requirements of a military-derived TCB), the applicant for an MTC must provide:

1. Scheduling information for all recommended maintenance tasks. This information is normally contained in a Maintenance Review Board Report (MRBR) (or equivalent document).

2. Maintenance instructions including those required for servicing, troubleshooting, the methods of removing and replacing items, system testing, ground running, symmetry checks, weighing, towing, jacking, storage limitations etc. This will typically be provided in the form of an Aircraft Maintenance Manual(s), Structural Repair Manual, Fault Isolation Manual, Illustrated Parts Catalogue etc. This information can be amended by the MTC holder (broad scope to amend the master copy) or maintenance organisations approved under DASR 145 (very narrow scope to modify).

3. Mandatory maintenance requirements in a segregated and clearly distinguishable section of the ICA, typically called the Airworthiness Limitation Section (ALS). The ALS contains the mandatory maintenance tasks and intervals, identified in the type certification process. Specific terminology and requirements for the ALS content will vary depending upon the PCC, however, the ALS will generally include mandatory requirements such as:

   i. Airworthiness Limitations (AwLs). AwLs encompass mandatory retirement / replacement intervals and mandatory inspection requirements (including inspection interval(s) and the inspection method). The term AwLs is most often associated with structural life limits and structural inspections that result from FAR/CS 2x.571 or the equivalent fatigue/damage tolerance requirements in military certification standards. However, the term AwL may also be used for other aircraft systems, such as mandatory replacement times for Electrical Wiring and Interconnect System (EWIS) components. As noted within AMC 21.A.41, the definition of an AwL 'interval' includes the interval metric (e.g. flight hours, landings, Equivalent Flight Hours (EFH), Fatigue Index (FI) / Fatigue Life Expended Index (FLEI), engine cycles, etc), and any algorithm, equation, factor(s) or other engineering data which must be used to calculate life accrual against the interval.

   ii. Critical Design Configuration Control Limitations (CDCCLs). CDCCLs identify the critical design features such as proper wire separation, proper installation of a panel gasket, minimum bonding jumper resistance levels, etc., that must be maintained in exactly the same manner throughout the life of the aircraft in order to comply with the type certificate and maintain airworthiness. The purpose of CDCCLs is to provide instructions to ensure these critical features are present throughout the life of the aircraft and are inspected and verified when alterations, repairs, or maintenance actions occur in the area. Design features that are CDCCLs are defined and controlled by FAA Special Federal Aviation Regulation (SFAR) 88 and preserves critical features of the aircraft needed for the Flammability Reduction Means to perform their intended function and prevent the occurrence of an unsafe condition.

   iii. Certification Maintenance Requirements (CMRs)[24]. CMRs are required inspections or maintenance tasks, and associated intervals, developed to achieve compliance with safety analysis requirements (e.g. FAR/CS 25.1309/29.1309, other discrete safety analyses requirements such as FAR/CS 25.671, 25.783, 25.901, and 25.933, and FAR/CS 29 equivalents). A CMR is intended to detect safety-significant latent failures (failures not known to the flight or ground crew) that would, in combination with one or more other

Superseded

specific failures or events, result in a hazardous or catastrophic failure condition. A CMR can also be used to establish a required task to detect an impending wear-out of an item whose failure is associated with a hazardous or catastrophic failure condition.

7.2.5.4 **ICA and the MTC.** Even though a complete set of ICA is required to obtain an MTC, only the ALS of the ICA (or equivalent terminology including CDCCLs and CMRs) forms part of the type design[25] however, they do form part of the Type Certificate. Stand-alone amendments to ICA, other than the ALS, are allowed to be changed by the MTC holder using a procedure agreed with DASA. Note: when completing a stand-alone change to ICA other than the ALS, the MTC holder is not exercising a privilege, but is instead fulfilling their obligation to keep the ICA current[26]. Changes to the ALS of the ICA must be processed as a change to the MTC, and should be classified as a major change[27].

7.2.5.5 **Identification of ICA.** The complete set of ICA for any product should be identified on the TCDS. Other information or instructions required for continuing airworthiness or safe operation of the aircraft, e.g. the approved Aircraft Maintenance Programme (AMP) or a Minimum Equipment List (MEL), is not ICA and is not subject to regulation applicable to ICA.

7.2.5.6 **ICA supplements.** Some major changes to an MTC, MSTCs, minor changes or minor/major repair designs may require variations to the product's ICA[28]. Variations to ICA arising from these design changes or repairs stand-alone from the product's master ICA and are published as an ICA supplement[29]. This gives the aircraft operating organisation the flexibility in managing the ICA applicable to their aircraft, depending on which approved changes and repairs they have chosen to embody. The approval of ICA supplements (including any changed or additional mandatory maintenance requirements) are encapsulated in the approval of the design change or repair. ICA supplements should be identified on the Supplemental Type Certificate Data Sheet, or on the minor change or repair design approval.

7.2.5.7 **ICA and the AMP.** The approved AMP in and of itself is not ICA for the simple reason the ICA requirements of the TCB do not mandate an AMP to be developed by the applicant for an MTC. The recommended maintenance tasks and intervals in the MRBR and the mandatory maintenance requirements identified in the ALS, combined with other requirements unique to each operator's role and usage (including data from a reliability programme) forms the basis for approval of each operator's AMP.

7.2.5.8 The maintenance instructions provided by the MTC holder (or ICA supplements provided by other design approval holders) will provide detail on how to carry out the tasks and inspections in the AMP and should only be amended by the MTC holder (or other relevant design/repair approval holder for ICA supplements) – see paragraph 7.2.5.4 above. Mandatory maintenance requirements must be clearly identified as mandatory in the AMP and cannot be extended without a corresponding approval of a major change to the MTC, or issue of an MSTC. Other ICA must be changed by the MTC holder using DASA agreed procedures. Changes to other recommended task and inspection intervals in the AMP can be approved by a CAMO using a procedure agreed with DASA, without requiring approval of a change to the MTC[30].

Responsibilities for ICA

7.2.5.9 **MTC holders**. The MTC holder is Defence's custodian of the product's ICA regardless of its original author. The MTC holder is responsible for the ICA's content, amendment and distribution to all organisations that operate the aircraft. The MTC holder can amend the ICA (in accordance with

Superseded

approval processes) and must distribute amendments to those organisations affected. If a change to a mandatory maintenance requirement is required, the change must be approved by DASA before distribution of the amendment. The MTC holder's processes for discharging its responsibilities for ICA (even if exercised through external organisations) must be included in the MTC holder's Type Continued Airworthiness Exposition (TCAE). Regardless of a product's TCB, the MTC holder should be able to identify all ICA and have that documented in the TCDS.

7.2.5.10 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their ICA supplements as the MTC holder has for the product's master ICA.

7.2.5.11 **Aircraft operating organisations.** Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided.

7.2.5.12 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable ICA and relevant ICA supplements. Maintenance organisations may locally modify ICA or ICA supplements using an approved procedure specified in their Maintenance Organisation Exposition (MOE) only for the purposes of efficiency, achieving the intent of the ICA when the instructions are deficient, or for the use of alternative tools/equipment[31]. A maintenance organisation must notify the MTC holder (or relevant design approval holder in the case of ICA supplements) when it has locally modified ICA, so consideration can be given to amending the master copy for wider distribution. A maintenance organisation modifying ICA for the purposes stated above does not constitute approving an amendment to the ICA (i.e. the source document) held by the MTC holder (or ICA supplement held by another design approval holder). Only the MTC holder or holder of the ICA supplement can approve amendments to ICA, noting the need to also seek approval of a major change to the type certificate if the amendment alters any mandatory maintenance requirements.

Non-Destructive Testing (NDT) ICA

7.2.5.13 NDT ICA are applied to ensure the airworthiness of aircraft through the inspection of aircraft structure and components. NDT ICA is often used as part of damage tolerance inspection regimes to ensure structural integrity. Consequently, it is critical to ensure that NDT ICA is developed by competent staff and provides sufficient information to enable NDT staff to perform inspections effectively.

7.2.5.14 NDT ICA provided to a DASR 145 Maintenance Organisation should include the following minimum information:

1. the inspection procedure to be used
2. the inspection area
3. the material type of the inspection area
4. the type of discontinuities to be detected.

7.2.5.15 Those organisations responsible for developing NDT ICA (DASR 21J Design Organisations, MTC holder) should consider using NDT Level 3 staff (as defined in EN4179) to verify that inspections are achievable, repeatable and meet the expected detection requirements of the design or repair. This is especially important where NDT ICA is used to support an AwL.

Superseded

7.2.5.16 The procedure for approving or modifying NDT ICA should be documented in the relevant organisation exposition. DASA recommends that personnel certified to NDT Level 3 in the relevant method be employed to approve and/or modify existing NDT ICA for application in specific circumstances. This accords with the requirements of European Standard EN4179.

Master Minimum Equipment List (MMEL)

7.2.5.17 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable / inoperative under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL cannot, in itself, be regarded as providing operational permission. It, however, can be the basis for the development of an individual Operator's Minimum Equipment List (MEL).

7.2.5.18 An MMEL forms part of the MTC. Approval of new MMEL or an MMEL amendment should be undertaken in accordance with the relevant DASR 21 Subpart[32]. Further guidance on MMEL development and approval in contained in Chapter 8.2.2, including information on:

1. typical characteristics and contents of an MMEL
2. options for developing an MMEL
3. suitable certification specifications for an MMEL
4. classification (major/minor) for changes to an MMEL
5. the DASA MMEL approval process.

7.2.5.19 Note that DASA is currently evaluating EMAR 21 version 2.0 changes that introduce the Operational Suitability Data (OSD) concept and requirements. MMELs are considered a category of OSD, and therefore, this section will be updated in the future once the relevant DASR 21 updates have been incorporated.

7.2.6 – Manuals

Basic Principles for Manuals

7.2.6.1 T**ypes of Manuals.** As per DASR 21.A.57, the holder of a type-certificate shall produce, maintain and update master copies of all manuals required by the applicable TCB.

7.2.6.2 Manuals (for the purpose of DASR 21.A.57) will fall into one of two broad categories:

1. **Aircraft Flight Manual (AFM).** The AFM is an authoritative source of information necessary for the safe operation of an aircraft. It contains the aircraft's operating limitations, operating procedures, performance information and other information and instructions necessary to operate the aircraft safely. Note that this information may be contained in several documents that contain limitations, information and instructions to ensure safe aircraft operation. Examples of other documents/ publications (in addition to the AFM) may include a Flight Crew Operating Manual, Mission Crew Operating Manuals and Pilot Handling Notes.

Superseded

2. **Manuals Containing ICA.** Certification codes require that the ICA must be published in the form of a manual or manuals[33]. The relevant certification code requirements will dictate the specific ICA content that must be published. Due to the broad and varied type of information that must be published, ICA for a particular aircraft type will usually be distributed through a variety of manuals, such as Aircraft / Engine / Propeller Maintenance Manual, Structural Repair Manual, Engine / Propeller Installation Manual. As noted above at paragraph 7.2.5.5, the MTC holder should be able to identify the publications and manuals that meet the intent of ICA requirements.

7.2.6.3 **AFM Guidance.** DASA AC 008/2020 contains detailed information on AFM content and approval, amending AFM content and use of AFM supplements. Further information specific to changes to type certificates which affect AFMs include:

1. DASR GM 21.A.91 which contains guidance for the classification of changes to AFMs
2. DASR AMC3 21.A.263(c)(2) which contains information on approval of minor changes to the type certificate which affect the AFM.

7.2.6.4 **Approval of Manuals.** Even though particular manuals are required by the TCB and therefore required to obtain an MTC, only certain contents of manuals will form part of the enduring MTC and / or require DASA approval. Contents of manuals that requires DASA approval includes:

1. The ALS of the ICA[34] (i.e. as published within a maintenance manual). Refer Section 7.2.5 for further guidance.
2. Mandatory AFM content (Operating Limitations, Operating Procedures and Performance Information). Refer DASA AC 008/2020 for further guidance.

7.2.6.5 Consequently, amendments to other manual contents is not a change to the MTC and can be undertaken by the MTC holder using a procedure agreed with DASA. Furthermore, as noted by AMC1 21.A.57, the process to update a manual may be separate from the process to approve or authorise the content of the manual[35].

7.2.6.5 **Manuals in the Context of Defence Aviation Orders, Instructions and Procedures (OIP) Management.** Manuals (for the purpose DASR 21.A.57) are part of the Defence Aviation OIP for the platform type. Lifecycle management of Defence Aviation OIP is discussed further in Section 6.7. A key message of Section 6.7 is that in addition to accuracy and completeness of OIP (a well-established principle in DASR 21), the usability / readability of OIP can cause or contribute to aviation safety hazards. Therefore, aviation safety hazards related to Defence Aviation OIP should be managed through an organisation's SMS. Note that this principle is consistent with DASR GM1 21.A.239(a) paragraph 3.1.5 which states that design organisations should "establish a system to collect in-service experience to be used for the improvement of the [maintenance and operating] instructions".

Responsibilities for Manuals

7.2.6.6 **MTC Holder.** In order to meet their obligation under DASR 21.A.57, the MTC holder should establish a system to produce, maintain and update manuals. As per DASR AMC 21.A.57, this system should ensure:

1. manuals are complete, current, and uniquely identified;
2. manuals contain their authority for use, document name, date of issue, and document/amendment status details;

Superseded

3. manuals are provided in a medium compatible with user requirements;

4. new issues, re-issues and/or amendments are approved and/or endorsed by appropriate appointments prior to their release, noting that the process to update a manual may be separate from the process to approve or authorise the content of the manual, eg approve AwL in ICA;

5. manual management records are accurately maintained, controlled, traceable and are accessible; and

6. manuals can be reproduced to any previous amendment status.

7.2.6.7 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their manuals or manual supplements as the MTC holder has for the product's master set of manuals.

7.2.6.8 **Aircraft operating organisations.** The operating organisations must manage and distribute the AFM and all other relevant manuals as part of their OIP Management System[36]. Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to all relevant manuals to the extent necessary for the scope of maintenance services being provided. The operating organisation should manage any aviation OIP related hazards through their SMS, and coordinate with the MTC holder, or applicable design organisation, as required to effect any necessary updates or improvements to manuals.

7.2.6.9 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable manuals. Maintenance organisations shall establish procedures to ensure that if found, any inaccurate, incomplete or ambiguous procedure, practice, information or maintenance instruction contained in the maintenance data used by maintenance personnel is recorded and notified to the author of the maintenance data[37].

7.3 Production and Military Certificates of Airworthiness

7.3.1 Production Assurance in the Defence Aviation Safety Program

Aim

7.3.1.1 This chapter details how the production of aircraft components is assured in the Defence Aviation Safety Program (DASP). This includes what release documentation is acceptable under DASRs, and the means through which that documentation is obtained. This chapter only covers aircraft components and does not include whole aircraft. For whole aircraft see MCoA - Chapter 5.3 Annex O and MPO – Chapter 7.6.

Introduction

7.3.1.2 Production of Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured.

Superseded

Acceptable release documentation

7.3.1.3 The purpose of release documentation is to provide evidence that the manufactured component conforms to approved design data. Aircraft components to be installed on Defence registered aircraft must be accompanied by one of the following release documents:

a. DASR Form 1—Authorised Release Certificate.

b. A native or alternate component Certificate of Release to Service (CRS) issued within a recognised airworthiness framework (refer to Chapter 6.5 —Recognition of other Aviation Authorities for identification of a native and alternate component CRS).

c. For standard parts or items designated as specific equipment under DASR 21.A.303, a Certificate of Conformity from the item's manufacturer (refer AMC to DASR 145.A.42(a)(4)).

d. For components fabricated under DASR 145.A.42(c), certificates of conformity produced by the fabricating maintenance organisation that are acceptable to DASA.

7.3.1.4 Release documentation under (a), (b) or (c) above enables that component to cross organisational (and possibly national) boundaries between its manufacture and installation. Manufactured components that do not need to cross organisational boundaries can be installed with locally produced certificates of conformity that contain all of the technical information found on a DASR Form 1 per item (d) above.

DASA production assurance

7.3.1.5 DASA assures production of all Defence aircraft components using one of three mechanisms depending on the release documents required by continuing airworthiness regulations. This is depicted below in Figure 3.

Assurance through Recognition Frameworks

7.3.1.6 The majority of aircraft and aircraft component manufacture for Defence occurs outside Australia and is assured through DASA's recognition framework. To be installed on a Defence registered aircraft, these components must be accompanied by a recognised native (Form 1 equivalent) or alternate release certificate. Each DASA Recognition Certificate provides details on the unique conditions and caveats to be applied to validate the native or alternate release certificates. Production of components assured through recognition do not require a DASR Form 1 as it provides no additional safety assurance above what is inherent under the recognition framework.

Assurance through DASR 21 – production by Military Production Organisation Approval (MPOA) or letter of agreement holder

7.3.1.7 Components manufactured outside of a recognised airworthiness framework (other than standard parts, specific equipment or components fabricated under DASR 145.A.42(c)) require a DASR Form 1 for installation. To issue a DASR Form 1 an organisation must hold a Military Production Organisation Approval (MPOA) under DASR 21 Subpart G, or a letter of agreement to manufacture under DASR 21 Subpart F . In this instance, the award and oversight of MPOA is DASA's assurance mechanism for the production of such components.

7.3.1.8 The only organisations that DASA will consider for award of MPOA are those that do not hold a recognised approval that enables release of the manufactured components under a native or alternate artefact (see Chapter 6.5 —Recognition of other Aviation Authorities). That is, the

Superseded

requirements of DASR 21 Subparts G will be imposed on an organisation for the sole purpose of issuing a DASR Form 1 for the manufactured components.

Assurance through DASR 145 – fabrication by maintenance organisations

7.3.1.9 DASR Form 1 must not be used for components fabricated by maintenance organisations under their DASR 145 approval. A locally produced certificate of conformity must be used instead. DASA's assurance of this production is via the issue and oversight of the organisation's DASR 145 approval. A DASR 145 MO will only have this activity included in the scope of their DASR 145 approval if they can sufficiently demonstrate their capability to perform such fabrication. Note that unless otherwise approved by DASA, only the DASR 145 MO who fabricated the component can install this component.

Figure 3: Production Assurance and Release Documentation under DASP

Manufacture and release of test articles

Superseded

7.3.1.10 If a test article is manufactured to gather certification evidence, the responsibility to control the manufacture of that article and ensure it accurately reflects the proposed design data rests entirely with the organisation seeking certification of the design. For test article manufacture required to achieve certification of a major change, the Certification Programme should describe the production control processes that will be used by the applicant in producing the test articles. If DASR Form 1 is used to release a test article for trial installation in an aircraft, Block 12 of the DASR Form 1 must clearly state that the article is in conformity with non-approved design data. The manufacture of test articles for certification does not require MPOA under DASR 21 Subparts G or a letter of agreement under DASR 21 Subpart F. These principles also apply for minor changes being approved under MDOA privilege.

Manufacture of modification kits

7.3.1.11 Maintenance organisations approved under DASR 145 may fabricate modification kits and issue certificates of conformity provided (a) the scope of their DASR 145 approval allows it, and (b) the completed modification kit will be installed by the same maintenance organisation (and under the same DASR 145 approval) issuing the certificate of conformity. Modification kits meeting both criteria above must not be released using DASR Form 1, but must still be manufactured to the approved design data and have locally produced certificates of conformity attesting to that fact. Fabrication of modification kits for onward supply cannot be performed under a DASR 145 approval and constitutes series production that must be assured by either recognition or through DASR 21. Modification kits manufactured external to the installing maintenance organisation must be accompanied by a DASR Form 1, or release documentation acceptable to DASA through recognition.

7.3.1.15 AMC to DASR 145.A.42(c) – Acceptance of components

7.3.1.16 DASR 21 Subpart G – Military Production Organisation Approval

7.3.2 Military Certificate of Airworthiness (MCoA)

Introduction

7.3.2.1 This section supplements the DASP policy and provides guidance in support of DASR 21, Subpart H relating to MCoAs, their purpose, and their issue. The guidance included in this section discusses the MCoA concept and application from both an Australian Defence context, and where appropriate for the purposes of description, a civil aviation context.

7.3.2.2 Restricted MCoAs are also discussed where appropriate; however, such MCoAs are of limited utility in the Australian Defence context, and unlikely to be issued.

Purpose

7.3.2.3 A MCoA is an aircraft operating authorisation issued against an airframe tail that has the purpose to validate that the airframe conforms to the type design as specified on the Military Type

Superseded

Certificate (MTC). It serves as the final assurance artefact that the airframe is in a state of airworthiness per the inherent level of safety afforded by the type design and the underlying MTC basis. It is enabled by an organisation or operator, who has registered the airframe on the Australian Defence register, and has ensured conformity through meeting various requirements.

7.3.2.4 A restricted MCoA will follow the same rules albeit that the airframe shall conform to a restricted MTC and to specific airworthiness requirements ensuring adequate safety.

Application

7.3.2.5 MCoAs in the Australian Defence context can only be issued by the DASA or a Delegate of the Safety Authority (DoSA). The release document is via a DASR Form 25 Military Certificate Of Airworthiness and applies only to aircraft that are registered on the Defence register in Australia.

7.3.2.6 An application for a MCoA shall be made by an eligible organisation via DASR Form 25a - Application for Certificate Of Airworthiness. In the Australian Defence context, the MAO and/or their CAMO are eligible to be applicants for a MCoA as holders of a MAOC. Aircraft that are Non-Defence Registered (NDR) are not subject to Airworthiness DASRs, and are subject to a separate airworthiness requirements, typically under the applicable airworthiness Civil Aviation Safety Regulations. See further DASP Vol 3 guidance on NDR at Chapter 6.1.3.

7.3.2.7 A MCoA application shall be made in a form and manner established by the Authority (DASA in Australia) of the State of Registry[38], per DASR.21.A.174(a). When considering a MCoA application, the Authority will consider all documentation in support of the state of the airframe at application. This has particular significance for used aircraft, where records of usage, maintenance, modifications and repairs may not be to the standard normally required by Defence.

7.3.2.8 The MCoA application presents documentation that the aircraft conforms to the type design approved under the relevant MTC. The required documentation, artefacts, reports and historical evidence (if applicable) to support the application shall be in accordance with DASR.21.A.174(b). Any deviations from the certified type design must be approved by an appropriately authorised design organisation.

7.3.2.9 For used aircraft, DASA will require a Military Airworthiness Review Certificate (MARC) conducted in accordance with DASR Part M regulations before issuing an MCoA. The MARC review is a physical survey of the aircraft and supports issue of the MCoA to satisfy DASA that the submitted documentation is reflective of the physical aircraft. The MARC process is further discussed as part of paragraphs 7.3.2.15 and 7.3.2.16 of this section.

Issue of a MCoA

7.3.2.10 A MCoA can only be approved and issued if all modifications, repairs and/or production deviations implemented on the airframe are approved under DASR 21, or under a recognised national civil or military airworthiness framework.

7.3.2.11 For new civil or commercial derivative aircraft (CDA) delivered to Defence, the acquisition project should seek a civil export CoA from the Civil Aviation Authority (CAA), via the prime aircraft OEM, where a civil Type Certificate (TC) is in place. This export CoA needs to be obtained prior to transfer to the Defence register, and forms the foundation for the issue of an Australian MCoA. Failure to obtain an export CoA for a civil or CDA may limit DASA's ability to issue an evidence based MCoA.

7.3.2.12 For instances where a civil Type Certificate (TC) is not in force or Defence is leasing an aircraft that has been in civilian use, the requirement for a CAA CoA can be demonstrated if a CAA

Superseded

authorised delegate provides a document that attests the aircraft would be eligible for issue of a Standard or Export CoA, if the aircraft was to be registered by a Civil Aviation Authority. Defence will accept only a Standard CoA under DASR 21.A.172, DASR 21.A.173 and DASR 21.A.174. DASA-DIA staff should be consulted for specific advice.

Validity and Amendment

7.3.2.13 The MCoA Holder (typically the MAO) is responsible for the continuing validity of an MCoA. A MCoA may be amended or modified only by the Authority (DASA in Australia) of the State of registry[39]. A MCoA may be issued for an unlimited duration, and remains valid subject to the conditions described in DASR.21.A.181.

7.3.2.14 Additionally, the ongoing validity of a MCoA requires that damage be assessed, and all applicable modifications and repairs carried out, using as appropriate the data requirements of DASR.M.A.304.

7.3.2.15 The validity of a MCoA is periodically renewed via the MARC process, as per DASR.M.A.901. This involves an airworthiness review of the aircraft and its continuing airworthiness records. The initial airworthiness review is due within 12 months of the issue date of the aircraft's initial MCoA. The validity of MARCs issued by a CAMO may be extended twice for a period of one year each time if the aircraft has been in a controlled environment.

7.3.2.16 The MAO is accountable for the continuing airworthiness of an aircraft and shall ensure that no flight takes place unless the MCoA and the MARC remain valid, as per DASR.M.A.201. If a MCoA becomes invalid, the MAO must return the aircraft to an airworthy condition before operating the aircraft or seek an alternate flying authorisation. A new MCoA is only required if the aircraft is being returned to the Defence register after removal, or the certificate is revoked by the Authority (DASA in Australia) of the State of registry[40]

7.4.1 Military Type Certificate Holders

Introduction

7.4.1.1 A Military Type Certificate Holder within the DASR framework provides Defence a suitable entity to 'hold' the Type Certificate. Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed and that the inherent safety that the platform type certification basis affords is maintained.

7.4.1.2 Unlike civil TC obligations, Defence MTC obligations are not enforceable via national legislation, meaning there is no enduring obligation under law for foreign organisations to manage

Superseded

the basis of certification through the product's life cycle. Therefore, in the application of DASRs, the Defence MTCH is a government organisation, most likely the organisation that acquired the product under contract.

Application of DASR provisions for the MTCH

7.4.1.3 The following principles guide the application of the above regulatory provisions:

a. **Principle 1.** DASA issues an MTC for Defence registered aircraft types. Unlike the civil context, a separate TC for the aircraft power plant and/or propeller has not been issued thus far and is nominally included as part of the platform TC.

b. **Principle 2.** DASA shall only issue MTCs to suitable Commonwealth government organisations (the holding organisation) to hold the MTC. The holder is responsible for ensuring that holder functions/obligations are executed. In the Defence context, the MTCH is able to achieve the regulatory intent via a direct or indirect arrangement with the aircraft/engine OEM.

c. **Principle 3.** Military Supplemental Type Certificates (MSTCs) will also be held by the MTCH or holding organisation, with the MTCH responsible for carrying out all MSTC functions/obligations. An MSTC in the Defence context can supplement the MTC for managing sub-fleets, significant changes to the TCB, large and complex changes. They are not used to achieve a commercial outcome such as in the civil design domain.

MTCH Safety Objectives

7.4.1.4 The MTCH has two aviation safety objectives:

a. To support the safe operation of the aircraft type by command units. Achieving Defence strategic objectives requires continuous capability enhancement, and at times, the conduct of operations at markedly elevated levels of risk. In addition, operators of aircraft will require explanatory information, advice and data to operate the type safely. The MTCH must have access to type design data, or support arrangements with the aircraft/engine OEM for the provision of designs and advice to support safe operation of the type.

b. To continuously monitor the type in service and ensure the ongoing validity of the Type Certificate, by investigating issues and providing corrective actions where required. The initial certification of a type establishes the known and understood level of safety inherent in the standards against which it was certified. Through the life of the type, latent hazards within the certified design, not identified during initial certification, may emerge requiring some action to address. Similarly, the use of the aircraft may vary and new designs be incorporated. Regardless, the MTCH has the high level objective to maintain the level of safety intended during initial certification.

Australian Context

7.4.1.5 The MTCH must account for the unique Defence context where the MTCH is not the OEM of the type and noting that the DASR are an amplification of the broader Work Health and Safety[41] obligations for the Defence aviation environment. In this context, the MTCH is the steward of the Defence type in service. To fulfil this role:

1. The MTCH should be broadly aware of all historic and emerging hazards relevant to their type[42]. This awareness requires:

Superseded

i. The collection of relevant aviation safety information (occurrences etc.) from within the Defence aviation system;

ii. The collection of relevant aviation safety information (occurrences, service bulletins, airworthiness directives etc.) from operators and authorities of similar types; and

iii. Consideration and conduct of additional verification activities(such as test programs) to generate further data independently and as necessary.

2. The MTCH is to lead the risk management of the type for the life of type, from initial certification to withdrawal from service. This leadership includes:

i. Ensuring operators are made, and remain, aware of the hazards extant in their type;

ii. Ensuring that essential risk controls (both technical and operational) pertaining to the safety of the type are, and remain, effective;

iii. Leading local efforts to eliminate or further minimise known hazards;

iv. Influencing external organisations (such as OEMs, joint user groups, co-operative partnerships etc.) to eliminate or further minimise known hazards.

MTCH Structure

7.4.1.6 To support these safety objectives, the MTCH organisation is broadly structured around two key systems, as detailed in Figure 4. These systems are responsible for the interactions regulated by DASA and are required elements of the MTCH supporting organisation.[43] They are:

a. The Safety Management System (SMS). This system ensures that the MTCH will collect operational data, analyse that data, investigate potential safety concerns and provide corrective actions.

b. The Design Assurance System (DAS). This system provides products (for example Service Bulletins correcting deficiencies, publication updates etc.) to operators of the Type.

Superseded

Figure 4: Safety Structure pyramid

7.4.1.7 Note that the safety management and design assurance systems are generic and are broadly applicable to all MTCH structures and implementations noting their varying constructs. It is likely that in implementing the systems, each MTCH through their partner organisation will employ business processes specific to their context. For example, the MTCH may rely upon long standing Defence engineering processes such as Technical Information Review, System Safety Working Groups and Configuration Control Boards to achieve the SMS intent. Similarly, the DAS of a foreign design organisation may not be entirely aligned with the requirements described in DASR 21.A.239 invoking the need to utilise Authority recognition arrangements.

7.4.1.8 Each organisation that holds a Type Certificate will be different and the model outlined in Figure 4 will not be a one-size fits all construct. It is appropriate that each organisation will implement these functions with different size, scale, or complexity, dependent on their need. For example, a CDA

Superseded

may rely on a large portion of sub-contractor products from civil aircraft OEMs operating under legislated civil safety constructs, and thus will not require a large compliance verification element.

MTCH Responsibilities

7.4.1.9 In the Australian Defence context, the government organisation holding the MTC is usually relatively small and is supported by one or more other organisations (contractors, foreign Defence organisation, OEMs etc.). As a result, responsibility for the conduct of MTCH obligations is often vested with these support organisations. This has led to confusion regarding accountabilities. To clarify:

a. Regardless of the organisational construct, the government organisation is the MTCH, and is accountable for all activities undertaken by its partners with respect to the obligations of the MTCH.

b. As such, it is unlikely that a passive compliance assurance relationship between the government organisation and its partners will suffice. DASA needs to be assured that the MTCH is able to meet its obligations – this may require the government organisation to lead key MTCH activities and be active in resourcing, prioritising, and implementing MTCH activities to ensure continued airworthiness and supporting safe operation of the type by the operator.

Eligibility to hold an MTC

7.4.1.10 A government organisation can be eligible to hold an *MTCH* under one of three regulatory provisions when applying for an MTC:

a. DASR 21.A.14(a). This provision is applicable where the government organisation has demonstrated its capability by holding a Military Design Organisation Approval (MDOA), and thus meets the requirements of DASR Subpart J and is capable of performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources.

b. DASR 21.A.14(b). This provision is an exception to subpart (a) where the organisation has no demonstrated capability, but may be able to obtain an MDOA in the future, and thus alternative procedures can be used in the starting phase as an organisation moves toward an MDOA or where there are limited duration design activities that may be required (such as initial certification of a platform).

c. DASR 21.A.14(c). This provision is an exception to subparts (a) and (b) where the government organisation is not capable of meeting the requirements of Subpart J and/or performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources. In this instance, the government organisation is entirely reliant upon partners to meet the requirements of Subpart J.

Initial Assessment of MTCH capability

7.4.1.11 In the Defence context, assessment of the capability of the MTCH occurs in parallel to certification of the aircraft type, but must be completed before a Type Certificate can be awarded to the MTCH. DASA assessment of MTCH capability will include:

Superseded

a. An initial assessment of the organisation's personnel, processes, resources and support arrangements to establish that the MTCH will be able to perform/carry out the MTCH obligations outlined in DASR 21 and that the processes are present and suitable.

b. Supplementary on-site activities such as observing System Safety Working Groups, or reviewing Failure, Malfunction, and Defect data collected, in order to establish that the organisation is operating and effective.

c. An assessment of the MTCH Type Continued Airworthiness Exposition (TCAE). The TCAE describes all MTCH arrangements in order to execute the holder obligations and maintain the integrity of the type certificate. The broad content of the TCAE shall include, but is not limited to the description of the MTCH framework, design support arrangements, processes, procedures, governance, resources, and MAO/CAMO interfaces in place to meet the regulatory intent for the platform. In addition, the TCAE should include a detailed compliance matrix explicitly describing their arrangements in place to execute each MTCH obligation. The TCAE is the appropriate document where nuances particular to the platform and/or MTCH arrangements shall be described for Authority awareness and/or proposed alternative means of compliance.

MTCH Oversight & Enforcement

7.4.1.12 Oversight and Enforcement on the MTCH will be conducted by DASA as assurance activities in either a routine or a targeted format. The activities will have the objective to assess a MTCH organisation in their execution of MTCH obligations and functions. The scope of the assessment may involve any of the explicit and/or implicit obligations and may be a result of feedback received to warrant an assurance activity. Findings will be issued for non-compliances; however, the DASA team carrying out the assessment also looks to provide outcomes aiming to improve the overall effectiveness of the MTCH organisation. Oversight and enforcement on the MTCH arrangement will be based on the MTCH executing their obligations in accordance with the regulatory intent and their TCAE.

7.4.1.13 Further guidance on the DASA oversight and enforcement framework is provided in DASP Vol 3, section 4-1-5

MTCH Obligations

7.4.1.14 Within the DASRs the MTCH have the following obligations.

DASR 21.A.3A – Failures Malfunctions and Defects

7.4.1.15 This has three aspects which must be undertaken:

1. DASR 21.A.3A(a). Have a system for the collection, investigation and analysis of data relating to failures, malfunctions, defects or other occurrences, which cause or might cause adverse effects on the airworthiness of the product.

b. DASR 21.A.3A(b). Report to DASA occurrences, which may result in an unsafe condition.

c. DASR 21.A.3A(c). Investigate the root cause of occurrences and implement actions to eliminate or otherwise minimize any resulting hazards and their associated risks

Superseded

SFARP. If DASA finds action is required to correct the deficiency, the MTCH shall submit the relevant data to DASA.

7.4.1.16 **Reporting to DASA.** Where the MTCH assesses that an occurrence of a failure, malfunction or defect "may result in an unsafe condition[44]" that occurrence must be reported to DASA. Note this is a more limited and very specific subset of all occurrences that must be collected and considered by the MTCH. For these 'reportable occurrences' the MTCH must also report the results of MTCH investigations and any proposed action by the MTCH to DASA.

7.4.1.17 **Investigate and implement actions.** In the event that an unsafe condition may exist, the MTCH is obliged to take appropriate actions and be pro-active to eliminate and/or minimise the associated risks so far as reasonably practical. DASR 21.A.3A does not require the MTCH to consult DASA for review or approval prior to initiating any analysis, investigation and/or remediation actions. DASA provides additional, external and independent assurance of the actions of the MTCH but does not lead the MTCH in satisfying DASR 21.A.3A.

7.4.1.18 Further guidance on Occurrence reporting is provided in DASP Vol 3, section 7-4-2 and section 6-3

DASR 21.A.3B Airworthiness Directives

7.4.1.19 Where DASA determines an Airworthiness Directive (AD) is required for mandating actions for remediating an unsafe condition the MTCH must:

1. propose appropriate corrective actions and/or inspections

b. provide operators of the type all data required to comply with the AD

c. provide solutions/data to DASA to correct the deficiency and restore aircraft safety. This may include additional data to that provided under DASR 21.A.3A, specifically to support the release of an AD.

7.4.1.20 DASA's decision to release an AD may occur immediately following an occurrence or many weeks, months, or even years later. Per paragraph 7.4.1.17, the MTCH is to proceed with actions to eliminate the hazard or minimise the risks independently of DASA. This provision exists to support DASA mandating action proposed by the MTCH, not to direct the MTCH in the execution of their role.

7.4.1.21 Further guidance on Airworthiness Directives in the ADF context is provided in DASP Vol 3, section 7-4-3

DASR 21.A.4 Coordination between Design and production.

7.4.1.22 The MTCH shall coordinate between design and production organisations, to provide production data, as well as receive failure/malfunction/defect data from production organisations.

7.4.1.23 Where whole aircraft, parts and/or modification kits etc. are being produced, the MTCH arrangements are to ensure that the design and produced article align. For example, if the design is changing (materials/dimensions/finishing etc.) then that information will be provided to the organisation producing the item. Similarly, there cannot be changes to the item being produced without the knowledge of the MTCH and/or the responsible design organisation supporting the platform. Finally, this agreement must ensure the communication of occurrences, especially from the production organisation to the MTCH and/or their design organisation.

DASR 21.A.42 Integration

Superseded

7.4.1.24 The MTCH shall be responsible for the integration of Products, Weapons and other Systems onto the aircraft type.

7.4.1.25 This requirement places the obligation on the MTCH to consider the impact to airworthiness on integrating products, weapons or other systems, onto the aircraft. As the MTCH is also the only organisation eligible to apply for a major change to the type, the DAS of the MTCH (in cooperation with their partner organisations) must be sufficient to enable this. This obligation is not limited to aircraft components, but as expanded upon in Paragraph 7.4.1.49 for role equipment as well.

DASR 21.A.55 Record Keeping

7.4.1.26 The MTCH shall hold all relevant design information necessary to ensure the continued airworthiness of the type and make this available to DASA as required.

7.4.1.27 In the Defence context, the MTCH will not be the OEM, and the regulations cannot assume the MTCH created the type design data. Thus, this regulation ensures that the MTCH can access all data necessary to support the type design and ensure that major changes to the type continue to meet the appropriate airworthiness requirements.

DASR 21.A.57 Manuals

7.4.1.28 The MTCH shall produce, maintain and update master copies of all manuals required by the TCB and provide copies, on request, to DASA.

7.4.1.29 A manual under this regulation is part of the type design considered during type certification. It follows that any manual assessed during certification is therefore required by the TCB under this regulation. Such manuals contain content critical to keep the type airworthy or to operate the type safely within its designed limits. An example of a manual is the Aircraft flight manual, an engine manual[45] or a propeller manual[46].

7.4.1.30 For the purpose of initial certification, the MTCH is to provide manuals applicable to the ADF type. Thus, manuals produced for aircraft/products certified under other airworthiness authorities must be evaluated prior to releasing under the DASR. For the purpose of maintaining initial airworthiness in line with OEM issued updates, the MTCH must maintain and update master copies by enabling changes to be evaluated. Prior to promulgation, such change proposals will;

a. consider applicability to any unique ADF aspects or environment.

b. classify the content being considered.

7.4.1.31 The regulation implies that the MTCH will execute the obligation in a timely manner commensurate to the (safety) criticality of the update and any OEM advice.

7.4.1.32 Further guidance on the Aircraft Flight manual in the ADF context can be found in AC 008/2020

DASR 21.A.61 Instructions for Continuing Airworthiness

7.4.1.33 The MTCH shall provide the Instructions for Continuing Airworthiness (ICA) required by the TCB to operators. Changes to that ICA will also be provided to all operators.

7.4.1.34 ICA detail the methods, inspections, processes, and procedures necessary to maintain the aircraft and/or products in an airworthy condition and within the usage parameters of the aircraft

Superseded

design. ICA are an airworthiness requirement of the TCB and are prepared at initial certification by the appropriate manufacturer for each product, part or appliance. The regulation requires the MTCH to furnish the complete set of ICA to the Operator and to maintain the currency of the ICA for the ADF Type.

7.4.1.35 In the Defence context, this has particular relevance for the MTCH as often type design data will be produced under other regulatory systems and ICA will not be clearly identified. Part of the responsibility of the MTCH under this regulation is to identify and manage the ICA for a type where the OEM documentation has not explicitly referenced which instructions are ICA. This is usually where the aircraft is largely of military design, and in these cases, the MTCH will require an established relationship with the OEMs to enable clarification of maintenance documentation, when it cannot be determined from inspection what maintenance data is ICA.

DASR 21.A.44(b) - Identification of Products, parts and Appliances (DASR 21 Subpart Q)

7.4.1.36 Identification of products, parts and appliances. The MTCH shall:

a. specify how parts are to be identified.

b. specify how identification data (plates/etchings etc.) are to be handled.

c. identify critical parts.

7.4.1.37 In the context of EMAR, this obligation leverages a responsibility onto the MTCH to specify part marking schemes to their production organisations, who in the European context could be located in multiple countries. However in the Defence context the MTCH will in most cases rely on existing design organisation/production organisation arrangements in foreign countries with part identification already in place. To achieve the intent, the MTCH will appropriately leverage the OEMs part identification systems/schemes and only if applicable, specify the manner in which locally produced products, parts and appliances are identified.

7.4.1.38 Further guidance on Production in the ADF context is provided in DASP Vol 3, section 7-3-1.

DASR 21.A.44(c) - Continued Integrity of the Aircraft Structure and Propulsion System

7.4.1.39 DASR 21.A.44(c) requires that the MTCH shall ensure the continued integrity of the aircraft structure and propulsion system through ongoing monitoring and periodic assessment. Acceptable means of compliance for this regulation is provided in AMC 21.A.44(c). Chapter 6.6.3 provides extensive guidance to support application of AMC 21.A.44(c).

MTCH Obligations– Implicit Obligations

What is an implicit obligation?

7.4.1.40 In addition to the eligibility criteria listed at DASR 21.A.14(c) and the obligations listed at DASR 21.A.44(c), the regulations also include implicit obligations and expectations for the MTCH. That is, while an obligation has not been expressed, as “the MTCH must….” the operation of a regulation (or the AMC to that regulation) clearly depends upon the MTCH performing a function to ensure the continued airworthiness of the type or the safe operation of that type.

DASR 21.A.113 and 115

7.4.1.41 An applicant for a Supplemental Type Certificate (STC) shall prepare data to support the application independently or as part of an arrangement with the MTCH. In the defence context, the MTCH will hold all STCs and is therefore pivotal to enable an STC application through a ‘no technical

Superseded

objection' assessment and to provide the necessary design data. The advice provided by the MTCH shall enable for the safe integration by multiple design organisations of STCs onto the platform.

DASR 21.A.445 Subpart M Repairs

7.4.1.42 The MTCH is to support organisations performing major and minor repairs including unrepaired damage assessments by providing adequate information to enable their evaluation.

7.4.1.43 The MTCH may commission/initiate the activities through their supporting design organisation with appropriate approvals in place to design structural repairs. The MTCH will enable the provision of sufficient technical data where necessary.

AMC 21.A.709(b)(3) Approval of Flight Conditions

7.4.1.44 Flight Conditions underpin the issue of MPTFs as alternate authorisations assuring operations outside the strict requirements of the TCB and DASR M requirements and often at elevated levels of risk.

7.4.1.45 To make sure all reasonable knowledge is considered in the risk assessment supporting Flight Conditions and MPTF, the MTCH should be consulted to provide technical assessment inputs given access arrangements to type design data. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support/facilitate these assessments.

7.4.1.46 While not specifically identified, the reference to 'a design or engineering organisation suitably knowledgeable of the certified Type Design and with access to Type Design information' is usually read to mean the MTCH or OEM.

GM M.A.301(a)(2).2 Credible Data

7.4.1.47 Where operations are not at elevated levels of risk, but a defect remains preventing the release of the aircraft back to service, an operator may use 'credible data' for the deferral of defects in accordance with DASR M.A.301. Since the list of credible data includes type certification data, the MTCH would be a likely source of such information and be expected to provide it to operators as required. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support these assessments.

GM ORO.75 Use of Role Equipment

7.4.1.48 The MTCH is expected to support operators in the determination as to whether a piece of equipment is considered role equipment or a certified part.

7.4.1.49 Whilst the MAO has direct responsibility for integrating role equipment onto their aircraft, it is expected that they utilise technical assessments when appropriate. As the MTCH has access arrangements for assessments using type design data, the MTCH shall support the operator to ensure the part or equipment is integrated onto the type with appropriate consideration.

DASR AO.GEN.05(c) Management of Orders Instructions & Publications (OIP)

7.4.1.50 The MAO is required to have a documented agreement with the MTCH and seek MTCH support for control of air operational OIP and the use of Foreign Source Data (FSD).

7.4.1.51 This introduces an implicit requirement upon the MTCH to collaborate with the MAO via an agreement for review and appropriate approval of aviation operational OIP and FSD prior to use. This has particular relevance to the Aircraft Flight Manual (AFM). In the Defence context, the management of the AFM is complex with the one document having multiple uses and regulatory requirements. As

Superseded

a result, the MTCH shall be pivotal to ensure aviation operational OIP and FSD activities do not inadvertently alter content critical to compliance with the type certification basis.

7.4.1.52 Chapter 6.7 of the DASP Manual Volume 3 provides further guidance for OIP.

7.4.2 Continued Airworthiness Occurrence Reporting

Introduction

7.4.2.1 This section provides guidance to Occurrence reporting (OR) in the continued airworthiness domain (for design and production). This section is subordinate to the wider OR guidance provided as part of DASP Vol 3, chapter 6.3 which describes the wider OR framework.

7.4.2.2 Under DASR Part 21, organisations holding an approval have a requirement levied onto them to collect data on, conduct investigations of and provide analysis on any Failures, Malfunctions, Defects (FMD) or other occurrences, which creates or has the potential to create an unsafe condition. An unsafe condition is a state where an adverse effect on airworthiness exists being the result of a compromised or potentially compromised type design. Any occurrence that is assessed to have resulted in, or may result in, an unsafe condition[47],[48] must be reported to DASA and other organisations required by the implementing regulations.

7.4.2.3 Occurrence reporting by DASR 21 approval holder(s) is an essential continued airworthiness activity and enables risks and hazards associated with the type design to be identified and addressed in accordance with DASR 21.A.3A(a). All organisations that hold a DASR Part 21 approval including (but not limited to) the platform Military Type Certificate Holder (MTCH), Subpart J design organisations, Subpart F/G production organisations are obligated to have systems in place to achieve the regulatory intent of occurrence reporting.

Collecting FMD Data

7.4.2.4 The holder organisations operating under the DASR Part 21 regulations are expected to have arrangements in place that collects technical information from a spectrum of local and international sources/networks (civil and military) relevant to their platform. This has the primary purpose to access real time (critical) design related safety information for the product/part or appliance. The technical data may be directly applicable to types operated by the ADF or may require some applicability assessment before being considered for further consumption.

7.4.2.5 Collection of FMD data either directly from the ADF fleet or indirectly from other operators also has the purpose to provide the Holders with ongoing data that can be evaluated for patterns and/or reoccurrences. Such evaluation may identify failure issues that present as disparate, but may be linked. This level of analysis has the objective to identify latent design or manufacturing defects before they are realised during operation.

Occurrence Investigations in the DASR Part 21 Domain

7.4.2.6 In the Defence context, investigations involving FMD directly attributable to the type design and/or manufacturing are conducted by the platform MTCH under obligations in DASR 21.A.3A. Under this regulation, the MTCH must with all reasonable practicality initiate appropriate levels of investigation within their design support network to determine the root cause. This may take the form of reaching back into the OEM to evaluate the circumstances and determine the likely cause.

Superseded

Similarly, the production organisation or the part/component OEM may be consulted where a manufacturing issue needs analysis.

What constitutes a reportable Occurrence?

7.4.2.7 A FMD occurrence may originate from an issue identified on the ADF type or from a foreign fleet that is closely related to the ADF type. However, the immediate type design/airworthiness impacts from an FMD occurrence in the Part 21 domain are not always apparent and often requires detailed investigation to be completed. An occurrence may not be identifiable until investigation results are reported.

7.4.2.8 Similarly, there are instances where a failure, malfunction or defect, or analysis of failures, malfunctions or defects represents some level of shortfall to the type design but may not result in a reportable occurrence in accordance with DASR 21.A.3A(b) based on an assessment of the available information at that time. In these situations, the holder ought to make a judgement as to whether the shortfall constitutes a risk or not and what actions/advice is required to manage the risk (perceived or real). The Authority always encourages the community to be conservative in their judgements and provide an occurrence report - voluntary occurrence reports are an option.

7.4.2.9 In the Defence construct, the MTCH organisation is expected to receive relevant technical information (TI) from a range of sources including other operators (military or civilian, where relevant). In assessing the external TI, the MTCH must verify applicability to the ADF type and consider the ADF CRE. Once verified as applicable, a reportable occurrence is warranted satisfying any of the following conditions where the incoming technical information;

1. describes a design issue (real or potential) that leads to an unsafe condition; or
2. describes a safety concern that has a real or perceived airworthiness impact and requires some time compliance action; or
3. originates from the type OEM or Civil Aviation Authority (CAA) /Military Aviation Authority (MAA) regulator mandating an action with an accompanying risk assessment.

7.4.2.10 An occurrence on an ADF aircraft may require the outcome of an investigation before a determination can be made to report under DASR 21.A.3A. However, once the locally sourced TI is received, the same conditions of sub-paras 9a and 9b apply to determine if a reportable occurrence is warranted.

When and how to Report

7.4.2.11 Reporting occurrences to the Authority has the intent to make the Authority aware of an event that has caused or has potential to cause an unsafe condition in the current timeframe. This enables the Authority to begin their assurance function in real time and allow for intervention (where necessary) without undue delay. The reporting time period for the MTCH community is 72 hours for an occurrence once deemed reportable. It is acknowledged that the time between the actual occurrence and the MTCH being fully informed of an unsafe condition existing on their type can vary depending on many factors. Therefore, the 72 hour timeframe begins at the point where the MTCH organisation has enough information to make an informed determination of the airworthiness impact, based on the root cause (if known), type applicability, CRE considerations, etc.

7.4.2.12 The form and manner of which reportable occurrences are provided to the Authority from a MTCH organisation is via a DASR Form 44. The report shall contain (where practicable) all available information on the manufacturing or design deficiency, the results of any investigation to date, any

Superseded

actions they are taking or propose to take in order to correct the deficiency along with the submission of relevant data to support the actions.

MTCH Actions to address an unsafe condition resulting from FMD

7.4.2.13 The immediate actions that the MTCH organisation may take to eliminate and/or minimise the risks associated with the type design hazard will vary on a number of factors. However, the likelihood/consequence risk assessment will ultimately dictate the level of attention, timeliness, advice and resources that are attributed to the actions. Actions taken by the MTCH to address an unsafe condition should never rely on an Authority decision gate to implement.

7.4.2.14 The Authority will review the occurrence details and MTCH actions to gauge that the risk to aviation safety has been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) by the MTCH. This is not a one-off assessment; rather the unsafe condition determination by the MTCH organisation is an ongoing safety assurance activity conducted by DASA. It commences upon receipt of the occurrence and closes upon DASA's decision that the risk no longer warrants on-going monitoring by DASA.

7.4.2.15 Where the Authority does not have confidence that the design hazard has been eliminated or otherwise minimised SFARP, or if addressing the hazard requires development of a modification and subsequent fleetwide incorporation, then the DASA Airworthiness Directive (AD) process under DASR 21.A.3B may be invoked.

Structures and Propulsion Systems Guidance.

7.4.2.16 Structures and propulsion system specific considerations for the collection, investigation and analysis of failure, malfunctions, defects and other occurrences are addressed in AMC1 21.A.3A(a). Supporting guidance can be found in Chapter 6.6.3.

7.4.2.17 Specific guidance regarding risk analysis for propulsion systems (as could be used to develop the proposed corrective action(s) for a design- or manufacturing-related unsafe condition) is contained in Annex E to Chapter 7.2.

7.4.3 Airworthiness Directives (AD) in the DASP

Introduction

7.4.3.1 An Airworthiness Directive (AD) is *'a document issued (or adopted) by the Authority which mandates actions to be performed on an aircraft to restore an acceptable level of safety, when evidence shows that the safety level of this aircraft may otherwise be compromised'* [50]. Therefore, an AD is a key mechanism available to DASA to communicate mandatory action, in instances when an unsafe condition is determined to exist in an aircraft (and is likely to exist or develop in other aircraft) as a result of a deficiency in an aircraft's type design or conformance thereto.

7.4.3.2 This chapter sets out guidance for the use of ADs in the DASP. The guidance leverages civil practice, and expands on the regulatory criteria for the issue of an AD and key elements to execute the policy for the Defence aviation context.

Occurrence Reporting and Airworthiness Directives

Superseded

7.4.3.3 Whilst Defence-registered State aircraft are type-certified within the DASP (via the issue of a Military Type-Certificate (MTC)), and individual aircraft that conform to that type are awarded a Military Certificate of Airworthiness (MCoA), this is not a guarantee of enduring safety from a continued (and continuing) airworthiness perspective. This therefore necessitates that the potential for any unsafe condition (that may arise in-service) must be carefully monitored and managed.

7.4.3.4 Further to Chapter 7.4.2 (Continued Airworthiness Occurrence Reporting), respective Approval Holders[51] under the DASP have certain obligations[52] to DASA for the identification, communication and rectification of safety-related issues. DASA's role is to independently assure that the actions of the regulated community, in response to reportable/reported in-service occurrences affecting Defence-registered aircraft, are commensurate with the safety risk, and credible and defensible. This directly supports continued assessment of the validity of DASA-issued MTCs (/MSTCs) and/or MCoAs, and in certain instances, DASA's oversight of safety-related occurrences will need to consider if a DASA-issued AD is necessary to assure the safety of Defence aircraft (by explicitly approving and mandating the required corrective action to address an unsafe condition).

7.4.3.5 The nature of these occurrences, and the attendant severity and risk, vary considerably. In a practical sense, not every reported occurrence will (or should) result in an AD. In certain situations, it is entirely appropriate that lower-level safety-related issues reported to DASA by a sustainment enterprise (under DASR 21.A.3A) are just monitored (until defined closure criteria is met), if they do not actually constitute an unsafe condition *perse*.

Unsafe Condition Assessments (UCAs)

7.4.3.6 During the conduct of DASA's 'spectrum of assurance' for reported occurrences, the airworthiness impact to either the type, or individual aircraft of that type, must be considered. In every instance, what is unequivocally required is the determination of whether an unsafe condition exists (or not). Therefore, investigations and assessments conducted by Approval Holders within the regulated community must consider whether an unsafe condition exists; for this is not only DASA's function, but a shared responsibility. DASA's role is to be engaged with Approval Holders and determine/confirm[53] whether (or not) an unsafe condition exists (based on reports, investigations and assessments by, and engagement with, the regulated community[54]). DASA should generally not be conducting the UCA itself; for this is best-placed with respective Approval Holders[55] under DASRs (based upon type knowledge and understanding). That said, DASA always reserves the right to do so (if required).

Unsafe Conditions

7.4.3.7 Whilst DASR 21.A.3B(b) provides AMC and GM for what constitutes an unsafe condition, practical application is not always straight-forward in every instance, for discerning (and agreeing) which conditions are truly unsafe requires the exercise of professional judgement (by both Approval Holders and DASA). Moreover, the determination of what is truly an unsafe condition cannot be defined for every situation and scenario, for each platform (and DASA's assurance thereof). Generic aspects that will need to be considered are the:

1. nature of the deficiency/condition (and the associated consequence/likelihood of hazards)
2. elevated level of risk attributed to the deficiency (above that inherent in the type-certified design)
3. urgency for required mitigations, inspections and/or corrective action

Superseded

4. corresponding risk exposure period of (and any complexity within) required terminating action to resolve the deficiency.

7.4.3.8 It is important to understand that DASA (as the independent regulator) is not, and should never be, on the critical path to manage the day-to-day safety of aircraft. Under the DASRs (and the WHS Act 2011), regulated entities have obligations to ensure safety is not compromised and to alert DASA as the situations warrants. Therefore, regulated entities should not wait for DASA to provide a position before taking any appropriate action in response to an identified unsafe condition.

Criteria for issue of an AD

7.4.3.9 During the conduct of DASA's assurance of reported occurrences, and regardless of whether the actions of the Approval Holder are deemed to be credible and defensible, DASA will consider (on a case-by-case basis) the issue of an AD[56] when:

1. an unsafe condition has been determined by the Authority to exist in an aircraft, as a result of a deficiency in the aircraft, or an engine, propeller, part or appliance installed on this aircraft.

2. that condition is likely to exist or develop in other aircraft, including engine, propeller, part or appliance installed on those aircraft that may be affected by this unsafe condition.

7.4.3.10 In these instances, the 'safety benchmark' for the type or individual aircraft has (or potentially has) been compromised, and the continued validity of an aircraft's MCoA (and/or MTC) may be brought into question (via the presence of an unsafe condition). Therefore, DASA-approved inspection and/or remediation is necessary to restore an acceptable level of safety, via the issue of an AD.

7.4.3.11 Given an AD may be applicable to either all aircraft of a certified Defence type, or only certain individual aircraft of that type, ADs are by definition either type- or tail-related, issued to address identified in-service deficiencies pertaining to continued or continuing airworthiness (and potentially a hybrid thereof).

Purpose of an AD

7.4.3.12 The fundamental purpose of an AD is to:

1. approve corrective action and/or required inspections (proposed by the relevant Approval Holder under the DASRs)

2. communicate the presence of an unsafe condition affecting a Defence type and/or individual aircraft (that endangers flight safety) to the MAO/CAMO

3. mandate required action by the MAO/CAMO[57].

7.4.3.13 Regulated community compliance with DASA-issued ADs (to restore an acceptable level of safety) is mandatory within the DASP[58], which invokes the implementation of required action from a continuing airworthiness perspective under DASR Parts M and 145 (including military aircraft airworthiness review activities under DASR M Subpart I)[59].

Defence aviation context and considerations

Superseded

7.4.3.14 Since (EMAR-based) DASRs have a civil lineage – albeit adapted for the military context – fundamental aspects underpinning the intended application of DASR 21.A.3A and .3B are derived from ICAO-based concepts and civil regulations. That said, whilst DASA's assurance functions for reported unsafe conditions and the corresponding use of ADs within the DASP are *prima facie* the same, the combination of a number of inter-related features of the Defence aviation context requires additional policy considerations. In particular, how to pragmatically deal with the reality of:

1. sovereign government MTC Holder arrangements, that typically only coordinate the execution of holder obligations[60] and almost entirely leverage and recognise a much-broader (initial/) continued and continuing airworthiness management framework in place for a foreign type the same as, or similar to, the Defence type.
2. the general lack of centrality of the OEMs (as the original 'Approval Holders' for design and production that are not directly regulated under DASRs).
3. the nature of DASA as a relatively-small 'validating' Authority when issuing sovereign MTCs for Defence-registered aircraft (and most major changes to type-certificate (TC) thereafter).

7.4.3.15 Therefore, there is a strong reliance on the sustainment support arrangements established by CASG SPOs for the ongoing execution of sovereign MTC Holder functions required by DASR 21.A.3A and .3B [61], either with the actual OEM(s) and/or by leveraging the framework and actions of a foreign Civil/Military Aviation Authority (C/MAA), to support the identification and management of unsafe conditions applicable to Defence aircraft.

Sovereign MTC Holder support arrangements

7.4.3.16 The various in-service sustainment support arrangements implemented by CASG SPOs to support respective MTC Holder obligations, have differing degrees of OEM and/or foreign C/MAA involvement. Therefore, the extent to which sovereign MTC Holders leverage the initial, continued and continuing airworthiness management framework of a DASA-recognised foreign C/MAA, in direct support to the management of Defence types, will strongly influence the extent of sovereign decision-making required by MTC Holders (in the determination of required sovereign action to address an unsafe condition). In particular, those support arrangements that include a foreign C/MAA that acted as the primary certifying authority for an aircraft type similar to, or the same as, that operated by Defence.

7.4.3.17 Moreover, given the much-larger global fleets being oversighted and assured by respective foreign C/MAAs, the reality is that the vast majority of FMD/occurrences, assessments of any associated unsafe conditions, and the corresponding mandatory actions (to restore the safety benchmark) will be determined overseas (generally without sovereign MTC Holder and DASA involvement). However, FMD/occurrences for Defence aircraft do still arise, which may not be addressed by foreign type management arrangements. In particular, any design or part production deficiency that may be attributable to a military design or production organisation (MDO/MPO) approved by DASA under the DASP[62]. In these instances, the full intent of DASR 21.A.3A and .3B is required by respective Approval Holders and DASA.

7.4.3.18 Therefore, the degree of 'type management sovereignty' for Defence-registered aircraft – and therefore the extent to which sovereign decisions are required – will commensurately govern DASA's assurance of unsafe conditions affecting Defence-registered types (and the oversight of corresponding actions). That is, when more airworthiness-related 'type management' activity and

Superseded

decision-making is conducted in Australia, the greater DASA's involvement will be in the application of DASR 21.A.3A and .3B.

Sovereign Approval Holders propose required action to support the issue of an AD

7.4.3.19 When DASA decides that an AD needs to be issued within the DASP[63], the MTC Holder organisation (and/or other relevant Approval Holders under DASRs) should propose[64] appropriate corrective action and/or required inspections to DASA. Given sovereign MTC Holder organisations are primarily a coordinating (and not a design) organisation, OEM input should be considered mandatory, as well as C/MAA oversight and involvement (as appropriate)[65]. This therefore connects the original 'applicant' and the 'holder' of the design, as well as the primary certifying authority (that established the safety benchmark with the original 'OEM applicant' within their airworthiness management framework), which therefore executes the actual intent of DASR 21.A.3A and .3B.

7.4.3.20 Upon receipt, DASA's independent safety assurance function is to approve the holder's proposal, including required inspection(s) and/or rectification interval(s), and the associated risk exposure. DASA will engage with the Approval Holder and amend the proposal, if and as required. When satisfied that the AD's content (as proposed by the holder) provides appropriate terminating action to eliminate the unsafe condition (and to restore the 'safety benchmark'), and the associated risk during the exposure period will be otherwise minimised SFARP, DASA will issue an AD accordingly[66]. In doing so, DASA is explicitly approving the corrective action to address the unsafe condition and the corresponding exposure period.

Foreign ADs (or equivalent)

7.4.3.21 When sovereign MTC Holders receive relevant foreign ADs (or equivalent[67]) for assessment, and report this to DASA[68], the DASP is the beneficiary of relevant C/MAA assurance of the same/similar type to that operated by Defence. This broadly meets the intent of DASR 21.A.3A and .3B; for the 'problem' and the 'solution' is provided, that usually leverages the inputs of the actual OEM and recognises what the relevant C/MAA deemed mandatory. Therefore, a sovereign MTC Holder will need to consider the following:

1. the applicability of a foreign AD (or equivalent) to a Defence-registered type.
2. the availability and suitability of controls and corrective actions provided by a relevant foreign C/MAA that can be 'adopted' (including whether full (or partial) compliance and implementation is intended).
3. the extent to which a Defence type's Configuration, Role and Environment (CRE) considerations require necessary/appropriate variations to adapt the content of a foreign AD (or equivalent); and in particular, necessary/appropriate variations to risk controls, terminating action(s) and/or implementation timeframes/risk exposure periods.
4. the need to amplify other foreign-source safety advice for required actions and timeframes to rectify an unsafe condition[69].

7.4.3.22 Given the 'sovereignty' of DASA-issued MTCs (/MSTCs) and MCoAs for Defence-registered aircraft, the assessment of unsafe (or potentially unsafe) conditions identified for foreign aircraft that may affect Defence aircraft is fundamental to support the ongoing validity of these DASA-issued authorisations. However, it is important to note that these foreign ADs (or equivalent) are not automatically applicable and mandatory under the DASP, and despite the AD definition cited within

Superseded

DASR 21.A.3B(a), there is no regulatory mechanism within DASR 21 to 'adopt' foreign ADs (or equivalent)[70]. Therefore, whilst the regulated community may indeed decide to implement the required actions of a foreign AD (or equivalent) as a 'credible and defensible' means to address an unsafe condition for a Defence-registered aircraft, DASA nonetheless requires that applicable critical foreign safety-related information (and in particular, that issued by the primary certifying authority) is formally 'brought into the DASP' and actioned accordingly. The only way for this to occuris for DASA to issue an AD in the DASP[71], to mandate the same/similar action for Defence-registered aircraft.

Foreign ADs (or equivalent) issued by the primary certifying authority are mandatory when applicable to Defence-registered aircraft

7.4.3.23 DASA functions largely and almost exclusively as a 'validating authority', when issuing a sovereign MTC to establish the initial airworthiness of Defence types (and approving most major changes to TC thereafter), based upon recognition and leverage of the previous type-certification efforts of foreign C/MAAs. Similarly, the DASP should also recognise and leverage the type knowledge and understanding of the relevant C/MAA's management of continued and continuing airworthiness, for aircraft the same as/similar to Defence types.

7.4.3.24 Therefore, DASA's default policy position is that compliance with the technical content of foreign ADs (or equivalent) – issued by the primary certifying authority that DASA leveraged to underpin the award of a DASA MTC – is mandatory (when applicable to Defence-registered aircraft). If the primary certifying authority deemed a condition unsafe, then in near-all instances, their required mandatory action to address compromised airworthiness should be equally-applicable to Defence aircraft (notwithstanding any unique CRE considerations in certain situations).

7.4.3.25 The act of 'validating' the applicability and corresponding mandatory action within a foreign AD (or equivalent) for a Defence type is pragmatic and efficient. DASA issue of an AD when 'validating' a foreign AD (or equivalent) will in most instances be as simple as placing a DASA AD cover page on the foreign artefact(s) (if no changes are required), which may also include any minor adaption (that does not change the intent[72]), and promulgating this to the relevant MAO/CAMO for implementation.

7.4.3.26 Whilst this policy consideration would likely cater for many foreign ADs (or equivalent), DASA acknowledges there may be exceptions and complexities in certain situations, that require professional judgement. In particular, there may be compelling reasons why applicable foreign ADs are not intended for compliance (or only partial compliance), or there are substantial required and/or proposed variations on account of Defence CRE considerations (or otherwise) that will alter the intent and/or attendant risk. This will therefore require a much-greater degree of engagement between the relevant Approval Holder and DASA, to agree the content of the DASA AD (if issued).

Traceability with required mandatory action issued by the primary certifying authority

7.4.3.27 DASA's expectation is that sovereign MTC Holder arrangements implemented for each Defence type will monitor safety-related information from respective OEMs and C/MAAs (including other operators), to support required obligations under DASR 21.A.3A and .3B) (and DASR 21.A.44). In particular, this should include the documented methods and means to record the traceability of all actions mandated by the primary certifying authority[73], and the alignment with that implemented within the DASP.

7.4.3.28 For civil-derivative military aircraft, certified by a foreign MAA yet underpinned substantially by a foreign CAA's certification of the 'green aircraft', the applicability of foreign civil ADs would ideally be assessed and actioned by the relevant foreign MAA (that oversights the overseas

Superseded

fleet the same as/similar to a Defence type), but this may not always occur as expected. Therefore, due consideration should also be given to record the traceability (or otherwise) to Emergency or Alert Service Bulletins (issued by civil OEMs) and ADs (issued by the relevant CAA) that may not be mandated by the relevant MAA.

Platform DoSAs may issue ADs (for validated foreign ADs (or equivalent))

7.4.3.29 When a DASA AD needs to be issued within the DASP, and in instances where the relevant Platform Delegate of the Safety Authority (DoSA) is not developing the technical content therein – but rather only validating that a foreign AD (or equivalent) is applicable to, and should be mandatory for, Defence-registered aircraft – the Platform DoSA is the most-appropriate release authority (for, and on behalf of, DASA[74]). This is pragmatic and efficient, and is the most-responsive and agile arrangement (particularly for exigent circumstances), which is also aligned with a Platform DoSA's safety-related role and functions.

7.4.3.30 Moreover, this also fully aligns with the distributed model established for each Defence type to monitor, review and assess foreign safety-related data that may impact Defence aircraft, and should be invoked to the greatest extent possible[75]. The only caveat is that if the risk exposure is DHRM MEDIUM (or higher) until terminating action is accomplished, this should default to DASA (yet supported and staffed by the Platform DoSA).

AD issue in the absence of a foreign AD (or equivalent)

7.4.3.31 For the Defence aviation context, and in addition to the aforementioned, DASA will also consider (on a case-by-case basis) the issue of an AD in the DASP, in advance of a primary certifying authority's release of a foreign AD (or equivalent). DASA's expectation is that whenever continued operations are intended with protracted exposure to a (post-mitigation) residual risk to airworthiness – on account of an unsafe condition associated with catastrophic and hazardous consequences that cannot be eliminated or fully-controlled immediately by design – an AD in the DASP should be issued. This will usually manifest in situations where foreign MAAs have conducted a risk assessment and recommended initial treatment/controls for continued operations (due to the presence of an unsafe condition), yet the design solution and the attendant foreign AD (or equivalent) does not (and will not) exist for a significant period of time (to detail required terminating action and compliance timeframe to restore an acceptable level of safety).

7.4.3.32 This therefore sets a default position for compromised airworthiness associated with long-standing exposure to an elevated level of residual risk (whilst design solutions are being devised). In this instance, a DASA-issued AD therefore provides a means to formally communicate instances of elevated levels of risk within the DASP (bounded by a date for terminating action and compliance to be implemented), which will also provide improved Command awareness, visibility and traceability of required actions.

DASA-issued ADs associated with elevated risk should be underpinned by 7-Step Risk Management

7.4.3.33 By definition, continued (post-mitigation) operations with an unsafe condition that cannot be eliminated immediately constitutes an elevated level of risk to airworthiness during the exposure period, until terminating action detailed within an AD restores an acceptable level of safety.

7.4.3.34 Therefore, consistent with a MAO's DASR and WHS obligations, the elevated level of risk attributed to a deficiency (above that inherent in the certified design) and the corresponding residual risk exposure period should be underpinned by a MAO's Risk-Decision Brief (RDB). In particular, for instances that:

Superseded

1. deviate significantly from compliance requirements with 'validated and adopted' foreign ADs (or equivalent).

2. where there is markedly-elevated risk being retained, and the corresponding design solution required to address the deficiency will not be available for an extended period of time[76].

7.4.3.35 This policy position will primarily affect military aircraft (and likely not affect Defence-registered aircraft that are ostensibly civil). The need for an RDB for lower-level risks should be considered on a case-by-case basis (aligned with a MAO's Safety Management System (SMS)), and may not be required at all – particularly for instances where DASA leverages and 'adopts' foreign CAA ADs with no variations to risk controls and exposure periods.

7.4.3.36 MAO RDBs (that underpin DASA-issued ADs) will need to consider and disposition all available and suitable technical and operational risk controls, to support appropriate operating conditions and/or limitations. This therefore ensures and requires that MAO Hazard Tracking Authorities (HTAs) and Risk Management Authorities (RMAs) are suitably-engaged for airworthiness issues, and the corresponding DASA AD is a mechanism to communicate and document DASA's independent safety assurance for an agreed risk management strategy.

7.4.4 Other Design Approval Holders

7.4.4.1 This section addresses other design approval holders under the DASR framework. This primarily covers any Australian Military Technical Standard Order Authorisations (AUSMTSO) under DASR 21 Subpart O. AUSMTSO Authorisations are not expected to be widely used in the Defence regulatory framework and will only be issued by exception. The Authorisation is common in the civil domain under the term Technical Standard Order (TSO) and TSO Authorisations and encourages competition across the industry through novel design which does readily translate across into the military domain.

7.4.4.2 An AUSMTSO under DASR is considered equal in concept to the civil use where a TSO is defined as a minimum performance standard for specified materials, parts, and appliances used on civil aircraft. An AUSMTSO Authorisation enables the holder to manufacture a material, part, or appliances to a TSO standard. Receiving an AUSMTSO Authorisation is both a design and production approval, but importantly does not extend to installing and using the article in the aircraft.

7.4.4.3 In the civil domain, a TSO Authorisation enables the manufacture of articles that may be installed on an aircraft only after showing that the article meets the specific airworthiness requirements (certification basis) of a particular aircraft model. Receiving a TSO Authorisation verifies that an article meets a minimum performance requirement independent of the article's intended installation on an aircraft. Under the DASR, using the AUSMTSO Authorisation will be more nuanced and will not be issued on a competitive basis.

7.4.4.4 Common articles on modern day aircraft including Military aircraft that have their genesis through the civil TSO provisions include Embedded GPS and INS Units (EGIs), Auxiliary Power Units, Tires, seat belts, crew oxygen masks, seat assemblies, brake assemblies, antennae, various instrumentation, cargo containers along with many more. Under the DASR framework, the use of AUSMTSO has been very limited.

Superseded

7.4.4.5 Under DASR 21, Subpart O, the holder of an AUSMTSO has obligations to ensure that the article continually conforms to its design and is manufactured accordingly per regulations detailed under production (Subpart G). The holder is also subject to a number of other initial airworthiness regulations such as occurrence reporting and part marking with respect to their article. Although the Defence MTC construct results in a nuanced use, the AUSMTSO holder is required to engage with the aircraft Type certificate holder to integrate their article into the aircraft type or where design changes impact the integration.

7.5.1 Introduction

7.5.1.1 A Military Permit to Fly (MPTF) is a 'product authorisation' issued by DASA to aircraft that do not meet, or have not been shown to meet, the requirements of the Type-Certification Basis (TCB) and/or Military Air Operator Certificate (MAOC), but are nonetheless capable of safe flight under defined conditions and for specified purposes. An MPTF is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application.

7.5.1.2 An MPTF is a risk-based authorisation, within the suite of Defence aviation flexibility provisions provided under DASR GR.80, to facilitate military flexibility in support of a capability imperative, which is valid for a defined period of time, underpinned by a seven-step risk assessment with both technical and operational input.

7.5.1.3 Further to the overview of the Flight Conditions and MPTF authorisations provided at Chapter 5.3 Annex N, this chapter details DASR implementation of applications for, and approval of, Flight Conditions and MPTF (and the associated risk management aspects).

Audience

7.5.1.4 This chapter applies to DASR-regulated entities exercising roles or responsibilities when applying for an MPTF under DASR 21 Subpart P Military Permit To Fly. Whilst this will primarily be Military Air Operators (MAOs) – including Continuing Airworthiness Management Organisations (CAMOs) and service providers – it also extends to any organisation engaged to assist with the preparation of the application, such as: Military Type-Certificate (MTC) holders; design organisations (DASR Military Design Organisations (MDOs) and equivalents) and organisations involved in managing the configuration of Defence aircraft (CASG Systems Program Offices (SPOs) and Through-Life Support (TLS) contractors).

7.5.1.5 While cognisant of the above, the application for (and holding of) an MPTF within the DASR environment will almost exclusively be a MAO requirement for the subject aircraft defined within the MAOC Operations Specification (OpSpec)[77]. The MAO should therefore establish in-service procedures to implement attendant MPTF regulation and Acceptable Means of Compliance (AMC) that reflects the central role of the MAO Accountable Manager (AM) and authorised staff within the MPTF process.

Purpose

7.5.1.6 This chapter provides guidance in relation to Initial Airworthiness requirements under DASR 21 Subpart P, for developing MPTF applications, inclusive of: collating substantiation documentation; gaining operational endorsement; signing the declaration of safety; engaging with the Authority

Superseded

(inclusive of the Delegate of the Safety Authority (DoSA)) for approval and issue of the MPTF; and meeting MPTF holder obligations. Moreover, this chapter explains how applications for approval of flight conditions and an MPTF should follow the seven-step risk management process detailed in DASA AC 003-2018—Risk Management in the Defence Aviation Safety Program, and describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the Work Health and Safety Act 2011 (WHS Act).

Background

7.5.1.7 Within civilian aviation regulations, a permit to fly is predominately used to support development, certification, production and delivery of new aircraft and major modifications, and to support in-service operation outside the bounds of the Certificate of Airworthiness (CoA); such as ferry flights to a suitable maintenance venue for defect rectification or the conduct of an overdue scheduled servicing.

7.5.1.8 The use of MPTFs within the DASR context is subtly different. Design, certification and production of a new aircraft solely within a DASR MDO/MPO has not yet occurred, and flight test for development of major modifications will likely occur for Defence-registered aircraft operated by a MAO (rather than a DASR MDO/MPO at this stage). Furthermore, as recognised and afforded by DASR GR.80 Flexibility Provisions, Defence aviation requires flexibility to support capability imperatives for certain operational circumstances that would not be allowed within the civilian aviation domain.

7.5.1.9 Under normal circumstances, all Defence-registered aircraft should only be operated with a valid Military CoA (MCoA) issued by DASA. An MCoA is issued when the aircraft was shown, at the time of issue, to conform to its MTC awarded post-certification. Whilst in-service, the validity of the aircraft's MCoA is maintained by meeting the continuing airworthiness requirements of DASR M[78]. A valid MCoA represents a baseline level of airworthiness, aligning to both civil and military global conventions. Importantly, in the Defence context, an MPTF authorisation supplements, rather than replaces, the MCoA.

7.5.1.10 However, as stated, military aviation requires flexibility for Commanders to operate aircraft in certain circumstances without having met all the prescribed initial, continued or continuing airworthiness or aviation safety requirements, but are nonetheless capable of safe flight under defined conditions. In these circumstances, and without the necessary flexibility provisions in DASRs, the MAO would be unable to operate under the regulations. To accommodate Defence aviation flexibility, DASRs include provisions for issue of either of the following, to facilitate operation when the prescribed airworthiness or aviation safety requirements are not met:

1. MPTF under DASR 21 Subpart P Military Permit To Fly, which is augmented with AUS-unique AMC and Guidance Material (GM), which stipulate specific application requirements and include additional expectations for the holders of an MPTF, or
2. Command Clearance (CC) under DASR Specific Purpose Approval – SPA.10 *Command Clearance* [79].

7.5.2 Difference between MPTF and CC

7.5.2.1 The DASR SPA.10 CC provides for a similar outcome to that of an MPTF, in so far as the CC may also be used to authorise flight(s) where the MCoA's Instructions for Continuing Airworthiness (ICA) conditions are unable to be met. However, the key difference between the MPTF and CC is that the MPTF is an initial airworthiness authorisation subject to DASA approval and issue, whereas a CC is

Superseded

an operational authorisation via the command chain. In ideal circumstances, conditions that require an MPTF would be managed via an MPTF; however, in the event of compelling time-critical capability imperatives or emergencies, and where there is insufficient time to process an MPTF application, a DASR SPA.10 CC may be exercised.

7.5.2.2 Regardless of whether MPTF or CC provisions are used, the operating organisation remains responsible for meeting WHS obligations to eliminate or otherwise minimise risk to aviation safety, so far as reasonably practicable (SFARP). Therefore, both the MPTF application process and issue of a CC require the MAO to exercise the seven-step risk management process detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. However, an MPTF provides the MAO with independent assurance over the discharge of their obligations and should be sought whenever reasonably practicable. Should the requirement for operation of an aircraft under DASR SPA.10 be for an extended period, an MPTF or other appropriate authorisation must replace the CC.

7.5.3 Defence use of MPTFs

7.5.3.1 Whilst DASR 21.A.701(a) provides a non-exhaustive list of examples illustrating situations when an MPTF should be used, the majority of those examples are EASA/EMAR-based, and focused more on development of aircraft design, production, delivery and initial training within an OEM organisation (operating under privilege), as opposed to in-service scenarios that are typical for Defence aviation. For the Defence context, and as outlined within GM to DASR GR.80(c), aircraft operation in the following circumstances potentially entails flight at an elevated level of risk that may require an MPTF:

1. **Prior to initial issue of an MTC and MCoA.** DASR 21 precludes the issue of an MCoA if an MTC has not yet been issued. This will typically be due to the requirement to operate new aircraft prior to completion of the type-certification programme.

2. **Aircraft operation while continuing airworthiness requirements are not satisfied.** The aircraft has been issued an MCoA and is required for operational tasking; however, any of the following continuing airworthiness requirements have not been met:

   i. a defect that cannot be deferred as it has been assessed to endanger flight safety

   ii. scheduled maintenance in the Aircraft Maintenance Programme (AMP) has not been carried out

   iii. an Airworthiness Limitation (AwL) or Certification Maintenance Requirement (CMR) has been reached

   iv. an Airworthiness Directive (AD) has not been incorporated.

3. **Aircraft not conforming to an approved design configuration for the purpose of flight test.** Installation of a yet-to-be-approved modification for flight test, in order to gather compliance demonstration evidence to support approval of a change to type-certificate (or subsequent flights prior to the design change approval being issued).

4. **Aircraft operation outside approved limitations.** The aircraft has been issued an MCoA but is intended to be flown beyond the approved operating limitations in the Aircraft Flight Manual (AFM), or outside the approved role and/or environment detailed within the MAOC OpSpec. These circumstances can arise from either

Superseded

operational tasking or for the purpose of flight test (to support role expansion activities).

7.5.4 Overview of Organisational Responsibilities

7.5.4.1 The following organisations have specific responsibilities with respect to the application for, and issue of, MPTFs:

1. MAOs. MAOs are responsible for applying to DASA for the approval of flight conditions and the issue of an MPTF. They must fulfil the responsibilities of the applicant, including the conduct of a risk assessment that fully integrates all technical and operational considerations. MAOs should engage relevant external organisations in the course of preparing the application in order to effectively conduct an integrated risk assessment. These organisations may include the product's MTC holder, design organisations, CAMOs (and service providers), flight test organisations, and/or relevant maintenance organisations. All MPTFs are issued to MAOs who are then responsible for discharging the obligations of the holder of a MPTF.

2. DASA. Upon receipt of an application(s), DASA will provide independent assurance that there is evidence that the MAO met their obligations and has eliminated or otherwise minimised all risks SFARP. DASA assurance will focus on credible and defensible risk management, which provides advice to Commanders if the capability imperative has been sufficiently described and would support a decision-to-proceed with the identified Elevated Level of Risk (ELOR); however the decision-to-proceed always remains with the applicant.

7.5.5 Overview of MPTF Process and DASR Forms

7.5.5.1 The application process to obtain an MPTF is relatively straightforward, but does require clear identification of the participants and an understanding of the associated responsibilities. Whilst two separate applications are required, DASRs do not prohibit both being submitted to DASA concurrently. Relevant DASR Forms are as follows:

1. DASR Form 18b. Application for, and approval of, flight conditions that enable the aircraft to operate safely. This form is raised and submitted by an applicant to DASA. DASA approves the application and returns the approved form to the applicant.

2. DASR Form 21. Application for issue of an MPTF. Raised by the applicant and submitted to DASA. This may reference pre-existing and approved flight conditions within DASR Form 18b.

3. DASR Form 20a. Issue of an MPTF in response to a DASR Form 21 application. Raised by DASA and issued to the applicant; that is, the organisation responsible for conducting the associated flight(s) and ensuring the flight conditions are adhered to.

7.5.5.2 Further to GM to DASR 21 Subpart P, Annex A provides a 'swim-lane' flowchart illustrating the application process within organisational responsibilities. Reiterating, the approval of flight conditions is separate from the issue of an MPTF to give the applicant flexibility. Reasons include:

1. One set of flight conditions may underpin a number of MPTFs.

Superseded

2. The approval of flight conditions and the issue of an MPTF may be separated in time.

3. The issue of an MPTF by a local DoSA, in instances where DASA has previously approved flight conditions that are beyond the DoSA's delegation, may improve flexibility and timeliness.

4. The approval of flight conditions and issue of an MPTF represent different steps in the seven-step risk management process, and therefore address different WHS Act requirements.

7.5.6 Summary of the Seven-Step Risk Management Process

7.5.6.1 GM to DASR SMS.A.25(b)(2)(2.2) outlines Defence's seven-step risk management process (depicted in Figure 5), with further aviation-specific guidance detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. AC 003/2018 describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the WHS Act.

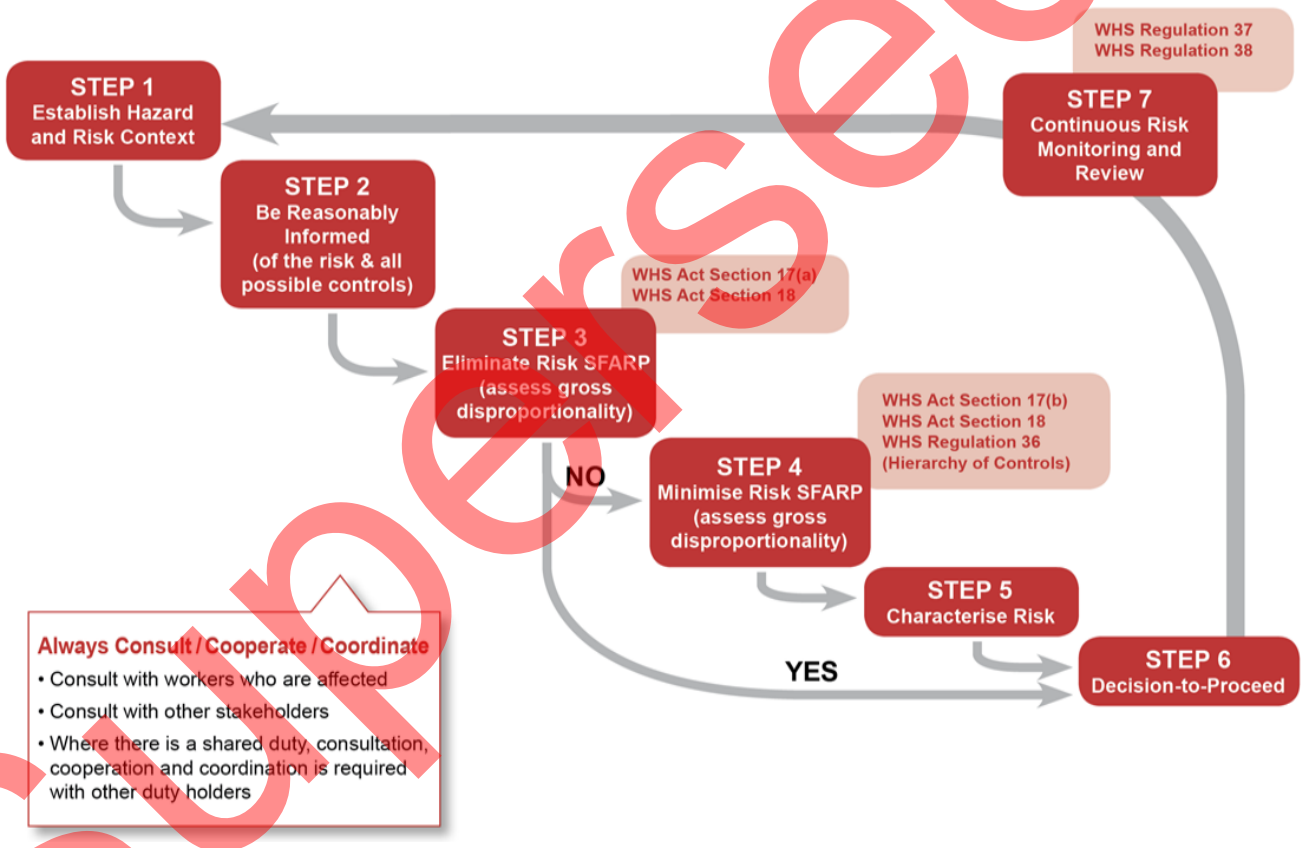

Figure 5: Safety Risk Management Process

7.5.6.1.2 DASR application forms for the approval of flight conditions and the issue of an MPTF collectively cover all of the required steps in the safety risk management process. DASR Forms 18b and 21 should summarise key information arising from the seven-step risk management process. Additional detail may be included in separate documents.

Superseded

7.5.7 Application for Approval of Flight Conditions

7.5.7.1 An approved set of flight conditions underpins every MPTF, which are the risk controls required to eliminate or otherwise minimise the risk SFARP. In applying for the approval of flight conditions, the applicant should execute and document Steps 1–5 of the seven-step risk management process. A single set of approved flight conditions may be applied to several MPTFs.

7.5.7.2 The specific application of these steps in applying for the approval of flight conditions are as follows:

1. **Step 1 – Establishing the risk context.** The applicant must define the task objective(s) including a clear strategic, operational or tactical imperative for the task and why it is necessary to fly with an ELOR. In defining task objective(s), the applicant should consider whether the task is new or existing, the discretionary/non-discretionary nature of the task and its urgency. The applicant should also identify and engage relevant stakeholders to ensure the risk assessment fully integrates all technical and operational factors. The risk context establishes the depth of risk assessment required and informs all reasonably practicable judgements. Establishing the context, also includes the duration of the activity. Retention of ELOR must be for the minimum possible duration to remain defensible within the WHS obligations and DASRs. As such, long-term MPTFs are unlikely to be defensible[80].

2. **Step 2.a – Being reasonably informed of the risks.** The applicant must proactively take steps to gain reasonable knowledge of the exact nature of all hazards and risks (both technical and operational). This may include use of existing OIP, the AFM, ICA or the provision of specialist advice from appropriate support organisations. This could include design organisations, technology or operational specialists, flight test specialists or the aircraft's OEM. There is no fixed list of who must be consulted for each application; instead, the applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context.

3. **Step 2.b – Being reasonably informed of all possible controls.** The applicant must take steps to gain reasonable knowledge of all possible controls (both technical and operational) in order to identify which ones are available and potentially suitable. Per Step 2.a, the applicant must seek relevant specialist advice where appropriate. Again, there is no fixed list of who must be consulted for each application. The applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context. The applicant must not discard any controls at this stage, as all identified controls should be used as inputs to Steps 3 and 4 in the risk management process.

4. **Steps 3 and 4 – Eliminate or otherwise minimise risk SFARP.** There is an explicit requirement to eliminate risk SFARP in the first instance and only if not reasonably practicable to do so (informed by the risk context established at Step 1), implement risk controls to minimise the risk SFARP. The applicant should systematically work through every control identified in Step 2 to determine if they are reasonably practicable to implement. The applicant must also address any additional hazards introduced by the risk controls. The integrated set of technical and operational risk controls that are reasonably practicable to implement, form the proposed flight conditions that will underpin the MPTF.

Superseded

5. **Step 5 – Characterising and communicating residual risk.** The applicant must characterise the residual risk using their safety risk management system (Note: DASA anticipates the residual risk will be characterised using the Defence Harmonised Risk Matrix (DHRM) in the Defence Aviation Safety Manual (DASM), but does not mandate its use). This step must include a declaration from the applicant that the flight conditions are a set of risk controls, integrated from a technical and operational perspective, which eliminates or otherwise minimises the risk SFARP.

7.5.7.3 Specific detail of the information and supporting documentation required to complete DASR Form 18b- *Application for Approval of Flight Conditions* is provided in the instruction sheets covering the form. See also DASR 21.A.708 and 21.A.709.

7.5.7.4 Flight Test. When an MPTF relates to flight test activity, DASRs require that flight conditions and operational endorsement must be provided by a competent MAO staff member, as determined by a DoSA-Flight Test (DoSA-FT)[81]. MAOs may apply to a DoSA-FT for a determination of competence for nominated MAO staff.

7.5.8 Approval of Flight Conditions

7.5.8.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can approve flight conditions. DASA will approve flight conditions if it has sufficient confidence that:

1. The applicant has given due consideration to the risk context, including the objectives and significance of the flying activity.
2. Elimination of the risk by restoring the aircraft to an airworthy condition IAW existing approved data, or deferring a defect, is not reasonably practicable.
3. Proposed flight conditions represent a set of risk controls that provide a credible and defensible level of safety for the flights/duration requested.
4. The applicant has appropriately characterised and communicated the residual risk.
5. The applicant has made an explicit declaration that the flight conditions, when implemented effectively, will eliminate or otherwise minimise the risk SFARP. The risk context of the application must support the depth of risk assessment undertaken and reasonably practicable judgements made by the applicant.

7.5.8.2 In assessing the application, DASA reviews the information supplied by the applicant and independently assures that it demonstrates the risk has been eliminated or minimised SFARP, and has been characterised accurately. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

Superseded

7.5.9 Application for an MPTF

7.5.9.1 Applications to DASA for the issue of an MPTF are made for specific aircraft and tasking using DASR Form 21 - *Application for a Military Permit to Fly*. All applications must reference an approved set of flight conditions, or an accompanying application for their approval. DASR Form 21 supports and records the applicant's 'decision-to-proceed' at Step 6 in the seven-step risk management process.

7.5.9.2 Note, in submitting an application for an MPTF and making the decision-to-proceed, the applicant also revisits Step 1 – Establishing the Risk Context, for that application. The test of SFARP is contextual and temporal; so this return to the risk context for the MPTF application is necessary to ensure that the applicant has made the decision-to-proceed based on the characterisation of risk in the flight conditions and in the context defined by the MPTF application, at the time of that application.

7.5.9.3 For example, the risk context of the flight conditions may be broad and enduring, covering activities such as 'deployed or directed operations'. However, the context of an application for an MPTF referencing those flight conditions must justify proceeding with the risk characterised in those flight conditions in its own right. As a result, an MPTF for a flight which itself is discretionary with little or no military capability imperative, relying upon flight conditions with a broad context such as 'deployed operations', may not be credible or defensible with the risk characterised in the referenced flight conditions, despite occurring while 'deployed'.

7.5.9.4 The key information required to support this step in the risk management process is the applicant's justification that:

1. The purpose of flight for this application is within the risk context of the referenced flight conditions and the specific task in this application warrants proceeding with the residual risk at the time of application.
2. The specific aircraft to be tasked meet(s) the configuration required by the approved flight conditions.
3. The conditions and restrictions (risk controls) in the approved flight conditions will be implemented on the subject aircraft for the subject flight(s).

7.5.9.5 The applicant must identify a suitable delegate within their organisation who has capacity to make the decision-to-proceed with the flight(s) (i.e. retain the risk). In making the decision-to-proceed, the applicant must act within their safety risk management system. Specific details of the information and supporting documentation required to complete DASR Form 21 - *Application for a Military Permit to Fly* is provided in the instruction sheets covering the form. See also DASR 21.A.707.

7.5.9.6 Flight Test. Within specialist Service Flight Test Organisations (FTOs), procedures exist to streamline MPTF applications and approvals for a range of flight test activities, such as:

1. Flight test activities on any Defence aircraft type to be conducted by, or under the direct supervision of, a Defence Aviation Authority (DAA)-approved FTO (all CAT 1 and 2 flight test and some CAT 4 tests)
2. Where Flight Test Instrumentation (FTI) or modifications are to be used, or
3. Where flight test operational substantiation and/or endorsement is required.

Superseded

7.5.9.7 MAOs considering flight test activities are encouraged to engage their respective Service FTO or a DoSA-FT, who will advise on the process to use. See also DASR FT–Flight Test.

7.5.10 Issue of a MPTF

7.5.10.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can issue an MPTF. DASA will issue an MPTF (via DASR Form 20a) if it has sufficient confidence that:

1. The decision-to-proceed has been made by an appropriate person within the applicant's organisation, given the characterisation of the residual risk (Note: DASA does not prescribe what this level is, nor what organisational authorisations they must hold).

2. The assignment of the responsibilities to implement and monitor risk controls (i.e. adherence to the approved flight conditions) is clear.

3. If applicable, there has been consideration that the flight conditions are compatible with any other MPTFs currently in effect for that aircraft (Note: The applicant is responsible for managing the implementation of multiple or concurrent MPTFs).

4. The risk context of the MPTF application is within that of the referenced flight conditions and supports the decision-to-proceed with the risk characterised by those flight conditions.

7.5.10.2 In assessing the application for an MPTF, DASA reviews the information supplied by the applicant and independently assures that it supports flying with an aircraft that does not meet the prescribed airworthiness or aviation safety requirements and may be operating at an ELOR. This will include whether the period of risk retention (the context) is defensible. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

7.5.10.3 Flight Test. When the MPTF relates to a flight test activity categorised IAW DASR.FT.05, flight conditions must be endorsed by competent staff of a MAO (as per para 22), and for a CAT 1 or 2 activity, Authority approval of flight conditions and issuing of the MPTF must be conducted by a DoSA-FT.

7.5.11 Obligations of the holder of an MPTF

7.5.11.1 As the holder of an MPTF, the MAO is responsible for ensuring the flight conditions are implemented and remain effective for the duration of the MPTF. This satisfies Step 7 of the seven-step risk management process and includes ensuring the risk context supporting the approved flight conditions remains applicable for the duration of the MPTF. See also DASR 21.A.727 and DASR 21.A.708.

7.5.11.2 Configuration management. An MPTF may introduce specific aircraft configuration management requirements, especially if an MPTF covers a yet-to-be-approved modification for operational use or flight test activity. MPTF conditions may include information such as: incorporation and maintenance instructions for new modifications; periodic inspections for non-standard damage;

Superseded

or increased usage data recording requirements. The CAMO must be aware of MPTFs that are applicable to a given aircraft to ensure overlapping continuing airworthiness requirements are resolved or coordinated, to ensure no loss of configuration management and the appropriate aircraft technical log and maintenance documentation remains accurate.

7.5.11.3 Operation by another MAO. The holder of an MPTF is responsible for ensuring the DASR 21.A.708 flight conditions are met. However, in instances where aircraft may be transferred between MAOs, this situation requires the holder to establish suitable arrangements for the transfer of holder obligations for an aircraft (that is subject to one or more MPTFs) when operated by another MAO.

7.5.12 MPTF Examples within DASR Context

7.5.12.1 Annex B provides a non-exhaustive list of examples intended to illustrate the conduct of the MPTF process within the DASR environment. Where uncertainty exists, contact a DASA Desk Officer (DIA-TC or DAVENG), the platform DoSA, or a DoSA-FT (for MPTFs related to flight test). In addition, Annex C provides a comprehensive guide to good practice and common issues pertaining to applications for flight conditions and MPTFs.

7.6.1 Military Design Organisations

Aim

7.6.1.1 This chapter details the approval and ongoing oversight of a Military Design Organisation (MDO). A MDO is approved under DASR Part21J and can only undertake design work related to the privileges granted under that approval and within the scope of that approval. Often the scope restricts what platforms a design can be applied to and can impose further limitations to aspects of their design work if required.

Introduction

7.6.1.2 Design organisation means an organisation responsible for the design of aircraft, aircraft engines, propellers, auxiliary power units, or related parts and appliances, and holding, or applying for, type-certificates, supplemental type-certificates, changes or repair design approvals. These design organisations that design aircraft, make changes to aircraft or design repairs of aircraft, and parts and appliances, need to fulfil the requirements as defined in DASR Part 21. Such organisations need to demonstrate that they have the right organisation, procedures, competencies and resources to effectively produce the design.

Obligations

7.6.1.3 DASA impose regulatory obligations on Design Organisations as part of the approval to ensure the airworthiness of aircraft and aviation products being designed within Defence. These obligations are intended to maintain high standards of design, engineering, and manufacturing processes throughout the defence aviation industry.

7.6.4 By placing obligations on design organisations, DASA aims to assure that the design, modification, and production of aircraft, components, and systems meet appropriate airworthiness standards.

Privileges

7.6.1.5 Under the DASR construct, the authority is the controlling signatory for all product released related to the type certificate. To reduce the burden on DASA, approved organisations are typically awarded privileges that allow work to be approved on behalf of the authority. For example, a design organisation may be privileged to approve minor changes to type design as well as minor and major repairs.

7.6.1.6 Granted privileges are documented on a Form 83. The Form 83 outlines the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

Superseded

7.6.1.7 An organisation attains a DASR 21 MDO Approval by submitting a Form 80 Application for Military Design Organisation Approval (MDOA) for DASA consideration, or a Form 82 Application for Significant Changes to Design Organisation Approval where a MDOA is already held but scope change is needed. Along with the application, the organisation must furnish a handbook (formerly an exposition) whereby all the processes utilised under the established Design Assurance System (DAS) are detailed. The Design Organisation Handbook Requirements are outlined in Appendix 1 of Chapter 5.3 of DASP Manual Volume 3.

DASA Design organisation assurance

7.6.1.8 Once a design organisation has gained an approval to conduct design activity, DASA will schedule oversight activities in order to assure that the MDO has maintained / is maintaining their approval to the standard as governed by the DASR Pt21 regulations. For organisations maintaining a Part21 approval, DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, and Resources as detailed in the approved Design organisation handbook, as well as consideration of the quality of design products.

7.6.1.9 The DAS is effectively the Quality Management System (QMS) specific to the output of designs against the scope issued under the Form 83. The DAS can utilise elements of the organisation QMS to satisfy requirements of the DAS. The DAS and the QMS are not the same and oversight of the DAS will be conducted specifically to design products produced.

Further information

1. DASP Manual Vol 3 Chapter 5.3 Annex E
2. DASR 21 Subpart J – Military Design Organisation Approval

7.6.2 Military Production Organisations

Aim

7.6.2.1 This chapter details the approval and ongoing oversight of a Military Production Organisation (MPO). A MPO is approved under DASR Part21 G and can only undertake production work related to the privileges granted under that approval. This includes what release documentation is acceptable under DASRs.

Introduction

7.6.2.2 Production for Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured. Acceptable release documentation is outlined at Chapter 7.3.2.

Obligations

7.6.2.3 With a Production Organisation Approval, DASA impose a set of obligations as part of the approval and as part of its regulatory framework to ensure the safety and airworthiness of aircraft and aviation products being utilised within Defence. By placing obligations on production organisations, DASA aims to assure that the production of aircraft, components, and systems meet rigorous safety and airworthiness standards.

Superseded

Privileges

7.6.2.4 Under the DASR construct, an approved MPO will be granted privileges to conduct design work to support changes to the type certificate for which the MTCH manages. Granted privileges are documented on a Form 55. The Form 55 is the certificate outlining the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

7.6.2.5 An organisation attains a DASR 21 MPO Approval by submitting a Form 55 Application for Military Production Organisation Approval (MDOA) for DASA consideration, or a Form 51 Application for Significant Changes to Production Organisation Approval where an MPOA is already held but scope change is needed. Along with the application, the organisation must furnish an exposition, whereby all the processes utilised to produce the category items under the ToA are documented.

7.6.2.6 Currently, DASA will not accept applications for production without a Military Production Organisation Approval as the authority is not resourced adequately to oversight this type of approval.

DASA production organisation assurance

7.6.2.7 Once a production organisation has gained an approval to produce category items, DASA will schedule oversight activities in order to assure the MPO has maintained/is maintaining their approval to the standard as governed by the DASR 21 regulations. DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, Resources which is detailed in the approved Production Organisation Exposition.

7.6.5 Guidance for Organisations Developing and Producing Aviation Software

Introduction

Superseded

7.6.5.1 This section provides guidance for the design and production of aviation software under DASR 21. This guidance does not apply to software designed or produced under recognition as defined in DASP Vol 3 Chapter 7.3.1 Production

7.6.5.2 Aviation software is classified as a 'part or appliance' and subject to the same rules applicable to all 'tangible' parts and appliances.

7.6.5.3 Aviation software refers only to software installed in an aircraft used for operating and controlling the aircraft and does not include mission system software, condition monitoring software, aeronautical information or ground-based aircraft diagnostic systems.

7.6.5.4 For the context of aviation software, the following definitions apply:

1. **Manufacturing** – is the development of aviation software, including compiling of source code into executable object code.
2. **Production** – is the process of preparing aviation software for distribution, including packaging the executable object code and associated engineering and technical data on distribution media.
3. **Replication** – is the process of copying aviation software (executable object code) that has been authorised through a production process.

Certification of Aviation Software

7.6.5.5 Organisations manufacturing software for installation on Defence registered aircraft must hold a Military Design Organisation Approval (MDOA) under DASR 21 Subpart J. The development of new (or the modification of existing) aviation software is a change to a product's type design and must be approved under DASR 21 Subpart D or E. For changes to aviation software classified as minor, a minor change approval can be issued by an organisation holding an MDOA in accordance with its Terms of Approval. For changes to aviation software classified as major, the approval must be issued by DASA as either an amended Military Type Certificate (MTC) or a Military Supplemental Type Certificate (MSTC).

Production of Aviation Software

7.6.5.6 The production of software is the responsibility of an organisation holding an appropriate Military Production Organisation Approval (MPOA) and the release of aviation software for installation on a Defence registered aircraft is via a DASR Form 1. The software's 'part' number (version) should be marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

7.6.5.7 DASR 21 does not allow the production of aviation software under an organisation's MDOA Terms of Approval. Organisations producing aviation software for installation in Defence registered aircraft must meet the requirements of DASR 21 Subpart G—Military Production Organisation Approval in order to obtain privileges to release the software for installation.

Replication of Aviation Software

7.6.5.8 Software authorised for installation on a Defence registered aircraft via a DASR Form 1 and provided to the Continuing Airworthiness Maintenance Organisation (CAMO) may be replicated by an Approved Maintenance Organisation (AMO) in accordance with OEM or DASR 21 MDO approved procedures. It is the responsibility of the CAMO or AMO to ensure that their quality systems have processes in place to manage and verify the integrity of the replicated software. This is typically done

Superseded

using a checksum value that is generated during production of software and provided to the CAMO or AMO alongside the produced software.

7.6.5.9 Any software replication process should also include a step to ensure the software's 'part' number (version) is marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

Organisation Approval Requirements

7.6.5.10 Development and production of software are often done by the same organisation. In this case, the organisation must hold both a MDOA under DASR 21 Subpart J and a MPOA under DASR 21 Subpart G in order to obtain the necessary privileges to approve the development and production of aviation software. Typically, there are no organisations with an MPOA with software scope without a corresponding MDOA with software scope.

7.6.5.11 Underpinning these organisation approvals and privileges are a Design Assurance System documented in a Handbook (Design Organisation Exposition/DOE), and a Production Quality System documented in a Production Organisation Exposition (POE). For a software development and production organisation, it is not necessary to have discrete and dedicated stand-alone procedures manuals entitled 'DOE' or 'POE' to meet both sets of organisation approval requirements. A single manual, document (irrespective of its title) or set of procedures that covers the development and production of software may simultaneously meet the requirements of both a DOE and POE.

7.6.5.12 The regulatory requirements of a DOE (DASR 21.A.243) and a POE (DASR 21.A.143) are the minimum required of such a manual or document to be awarded the relevant organisation approval and privileges. Any manual or document(s) identified as a DOE/POE (or both simultaneously) should be a working level document(s) published for use by personnel working in the organisation. The DOE/POE should not be written purely to satisfy regulatory requirements, although this aspect will be assessed by DASA when reviewing the working level documentation and the organisation's staff's understanding of it.

7.6.6 GUIDANCE ON CONSIDERING EXPLOSIVES IN AVIATION DESIGNS

Introduction

7.6.6.1 This DASPMAN section explains what Military Design Organisations (MDO) and Military Type Certification Holders (MTCH) must consider when performing design activities on aircraft systems containing explosives and integrating air-launched stores containing explosives onto aircraft[82]. Such design activities include physical design changes to systems and equipment containing explosives, assessments that unrelated design changes do not adversely impact explosive safety, changes to Airworthiness Limitations (AwL), changes to explosives-related Instructions for Continuing Airworthiness (ICA), monitoring for new explosive-related hazards within safety management systems (SMS), and aircraft stores compatibility engineering activities.

Superseded

What is an explosive?

7.6.6.2 An explosive is '… a substance manufactured with a view to producing an explosion or pyrotechnic effect[83].'Many Defence aircraft contain explosives, either forming part of an aircraft system (such as ejection seats) and within air-launched stores such as bombs, missiles and gun ammunition[84].

Explosives requirements within Type Certification Basis

7.6.6.3 In deciding what type of explosive requirements should be included in an aircraft's Type Certification Basis (TCB) the key document is the *European Military Airworthiness Certification Criteria* (EMACC) published by the European Defence Agency. The EMACC indicates that all explosives forming part of an aircraft system should be considered when developing TCB requirements. Accordingly, the TCB should include explosive-related requirements during initial certification and when MDOs develop major or minor changes to the type design.

7.6.6.4 For aircraft stores containing explosives the EMACC implies that the TCB should only consider requirements relevant to the installation, integration and interface of the aircraft and stores. That is, the TCB should only include explosive-related design requirements to the extent they affect the store's installation, integration and interface. Any subsequent major or minor changes to the type design should also only consider the installation, integration and interface of the store.

Legislative requirements

7.6.6.5 The legislation relevant to the safe design, maintenance and operation of Defence aircraft containing explosives is the Work Health and Safety Act (Cth) 2011 (the WHS Act), the Explosives Act (Cth) 1961, and their subordinate regulations.

Explosive Safety Regulatory Framework

7.6.6.6 To comply with their explosive-related obligations under all this legislation, MDOs and MTCHs must understand Defence's *Explosive Safety Regulatory Framework* (ESRF), which amplifies this legislation for the explosives context. The ESRF purpose is to provide a Defence-wide explosive safety risk management framework which ensures explosives safety risks are effectively managed. Explosives safety aims to '… prevent premature, unintentional, or unauthorised initiation of explosives and devices containing explosives; and with minimising the effects of explosions, combustion, toxicity, and any other deleterious effects'[85].Within the ESRF, Director General Explosive Ordnance (DGEO) is the Explosive Ordnance Safety Regulator (EOSR), supported by the Director of Ordnance Safety (DOS).

7.6.6.7 Under the ESRF, the safe conduct of activities involving explosives (including design) requires adherence to the following three fundamental concepts:

1. Explosives must be designed and manufactured to design requirements so as to eliminate or minimise explosives safety hazards so far as is reasonably practicable. This concept is referred to as 'safety and suitability for service' (S3).

2. Activities involving explosives must be conducted at locations where the consequence of an explosives safety mishap is understood, and risks are minimised (referred to as a 'safe location').

Superseded

3. Activities involving explosives must be conducted through safe work practices, conducted by trained and competent personnel, which will minimise both the likelihood and consequences of an explosives safety mishap (referred to as 'safe work practices').

7.6.6.8 In applying these three concepts, the ESRF provides requirements (12 principles and 28 regulations) and guidance relevant to the design, production, operation, maintenance, handling, storage and transport of explosives throughout its lifecycle.

7.6.6.9 The ESRF is documented within the following Defence Explosive Ordnance Publications (DEOP):

1. DEOP 100 comprises three volumes of which only Volume 2 Defence Explosives Safety Regulatory Framework has been issued. Volume 2 describes the 12 mandatory principles of the ESRF, not all of which are relevant to aviation design activities. For each principle, information is provided on its rationale, the expected outcome, the constraints, obligations, external requirements and controls. DEOP 100 Volume 2 also describes the ESRF risk management and assurance processes. The ESRF relies on organisational compliance with its mandatory requirements but does not provide organisational certifications.

2. DEOP 101 provides the 28 ESRF regulations with not all applying to aviation design activities. The regulations are not in a standard format, but most comprise a general overview, the requirements, responsibilities and any accompanying procedures. Each of the 28 regulations contain some mandatory requirements.

3. DEOP 102 provides information relevant to assessing the 'Safety and Suitability for Service of Defence Explosive Ordnance'. The publication mentions the 12 principles and the 28 regulations, while providing no further requirements relevant to aviation design activities. This DEOP also discusses several explosive-related hazards[86].

7.6.6.10 Within the ESRF, the EOSR releases Defence Explosives Safety Advisory Circulars (ESAC) to promulgate important safety information. ESACs do not mandate any actions, but provide informed, well-considered safety advice and guidance. ESACs can be accessed at: drnet/JCG/JLC/ExplosiveOrdnance/DOS/Pages/ESRF.aspx (Available on DPN Only)

Relationship between the DASF and ESRF

7.6.6.11 The ESRF is specifically intended to integrate with and support other Defence regulatory frameworks that aim to achieve safety outcomes, including aviation safety. Comparison of the DASF and ESRF demonstrates that regulated organisations within the DASF can comply with both the Defence Aviation Safety Regulations (DASR) and relevant ESRF requirements, with no inconsistencies between the two safety frameworks. Importantly, both safety frameworks are subject to the WHS Act's concept of shared duty holders (s16), who must consult, co-operate and co-ordinate their activities (s46) to ensure explosive-related risks are eliminated or otherwise minimised so far as is reasonably practicable (s17).

7.6.6.12 DASA regulates the design of aircraft systems and the integration of all air-launched stores onto a type. Complementing these regulations, DGEO provides mandatory explosive-related requirements (both principles and regulations) for the design of aircraft systems containing explosives and air-launched stores containing explosives.

Superseded

7.6.6.13 The S3 construct within the ESRF requires consideration of the hazards posed to explosives safety by carriage environments. Accordingly, the ESRF requires designers to consider whether the failure or partial performance of the non-explosive components of aircraft stores adversely affects the safety of the explosives within the store. Forms of component failure or partial performance that do not affect explosive safety are outside the ESRF scope, but are considered by Guided Weapons and Explosive Ordnance Group (GWEO) as part of its broader safety responsibilities.

ESRF applicability to DASR 21 scope

7.6.6.14 Several ESRF principles and regulations fall within the scope of DASR 21. Specifically:

1. ten of the 12 ESRF principles (Principles 1-10) impose obligations on aircraft designers within MDOs and MTCH organisations
2. all of these ten principles fall within the scope of DASR 21
3. compliance with DASR 21 provides total compliance with one principle (Principle 1), partial compliance with eight principles (Principles 2, 3, 5, 6, 7, 8, 9 and 10) and no compliance with one principle (Principle 4)
4. only four of the 28 ESRF regulations (1.1, 1.2, 1.5 and 2.5) within DEOP 101 impose obligations on aviation designers within MDOs and MTCH organisations
5. of these four regulations, three fall within the scope of DASR 21 (1.1, 1.5 and 2.5)
6. compliance with DASR 21 provides only partial compliance with these three regulations.

7.6.6.15 These principles and regulations within the scope of DASR 21 provide no limits or constraints on which individuals or organisations within Defence may perform design activities for aircraft systems and aircraft stores containing explosives.

Satisfying applicable ESRF requirements

7.6.6.16 Compliance with DASR 21 provides total or partial compliance with several mandatory ESRF principles and regulations. To achieve full compliance, MDOs and MTCHs must:

1. obtain explosives safety hazard and risk management advice from personnel and organisations competent in explosives safety management (refer paragraph 7.6.6.18)
2. when complying with DASR SMS, ensure that consideration is given to explosive-specific hazards and risks
3. ensure that explosives safety hazards and residual risks of explosives are identified and communicated to affected Services, Groups and others (including non-Defence entities)
4. aim to reduce the consequences of on-aircraft explosive hazards through careful design of where explosives are located in the aircraft and the quantity of explosives used
5. ensure that personnel performing design activities on aircraft systems and air-launched stores containing explosives receive explosive-related training compliant with ESRF Regulation 1.1 (eDEOP 101)[87]

Superseded

6. when creating Instructions for Continuing Airworthiness (ICA) for aircraft systems and air-launched stores containing explosives, be aware of the inspection requirements in ESRF Regulation 1.5 (eDEOP 101)

7. when engaged in the process for the initial certification of explosives installed in aircraft systems and amendments to their life limits, comply with the process described in Annex B.

7.6.6.17 While outside the scope of DASR 21, where MDOs handle explosives as part of the design process, they should ensure their sites, platforms and facilities have the necessary facility certifications, and that the minimum number of people are exposed and are aware of the risks.

Explosives safety hazard and risk management advice

7.6.6.18 MDOs and MTCHs can obtain explosives safety hazard and risk management advice from the following organisations competent in explosives safety management:

1. the Directorate of Ordnance Safety within Joint Logistics Command

2. Joint Proof and Experimental Unit within Joint Logistics Command

3. Aerospace Explosive Ordnance Systems Program Office within GWEO

4. Directorate of Engineering and Technical within GWEO's Systems Division.

7.6.6.19 MDOs and MTCHs should have confidence in the explosives safety hazard and risk management advice provided by these organisations because they:

1. have roles (either regulatory or in-practice) that require them to comprehensively understand explosive safety hazards and risks

2. are subject to the requirements of the well-established ESRF and will provide advice compliant with all relevant ESRF principles and regulations

3. have an extensive demonstrated history of providing safe explosives advice across Defence, including to the aviation community

4. work within well-developed engineering frameworks that have evolved over several years.

7.6.6.20 MDOs and MTCHs can consume explosives safety hazard and risk management advice from these specified organisations, without the need to invoke DASR 21.A.239. That is, they do not need to consider these organisations as a '… partner or subcontractor' and are not obliged to specify the manner in which the MDO/MTCH design assurance system accounts for the acceptability of the advice provided by these external organisations or specialist personnel within them.

7.6.6.21 Some forms of advice may not need be obtained case-by-case but could be obtained as a 'standing' advice relevant to a particular type of design change whenever it occurred (for example a proposed change to a component throwaway life or maintenance interval). The relevance of specific 'standing' advice to a new circumstance would depend on the aircraft type, the form of explosives, the aircraft's operating environment and its specific sustainment arrangements.

7.6.6.22 The relationships that MDOs establish with specialist explosives organisations should be documented in the Handbook (Design Organisation Exposition), required by DASR 21.A.243. Similarly,

Superseded

MTCHs should documents their relationships in the Type Continued Airworthiness Exposition required by GM 21.A.14(c) and discussed at DASPMAN Chapter 5.3 Annex J Appendix 1.

Other guidance

7.6.6.23 A variety of other Defence stakeholders can contribute to the safe design of aircraft systems containing explosives and the safe integration of air-launched stores containing explosives. Such organisations include:

1. **Maintenance organisations** - to understand the maintenance implications of design decisions and the utility of proposed ICA relating to explosives
2. **CAMOs** - to understand the continuing airworthiness implications of explosive-related design decisions, such as the potential need for pre-flight inspections and the effect of explosive-related component lives on the aircraft maintenance program
3. **MAOs** - to understand the operational implications of explosives-related design decisions, such as preferred aircrew actions for stores release
4. **DASA** - to understand the scope of the ability to approve minor explosives-related design changes
5. **Organisations who transport and store explosives.** Organisations within various Defence Groups and Services, whose primary roles is transporting and storing explosives, would not usually be a source of explosives design safety advice. Nevertheless, there may be occasions when MDOs should seek information from them that provides necessary context for design activities.

Design activities for aircraft systems containing explosives

7.6.6.24 An aircraft system may contain explosives, usually to separate an air-launched store from the aircraft, but sometimes to separate parts of the aircraft such as ejection seats and cockpit canopies. Specific guidance on the design activities for aircraft systems containing explosives is provided in Annex A.

Design activities for ALSE/role equipment containing explosives but not part of the aircraft's type design

7.6.6.25 ALSE/Role equipment containing explosives, but not part of the aircraft type design, are outside the scope of this chapter. Nevertheless, the ESRF requirements at 7.6.6.16 a/c/d/e still apply to organisations performing relevant design activities.

Design activities for air-launched stores containing explosives

7.6.6.26 An air-launched store is an aircraft store that is intended to be separated from an aircraft in flight. Some air-launched stores contain explosives:

1. to separate the store from the aircraft (such as some chaff, some flares, some sonobuoys and gun ammunition)[88]
2. to create an explosive effect post separation (such as bombs, missiles and flares)
3. for both purposes.

Superseded

7.6.6.27 Design activities on the explosives within air-launched stores are outside an MDO's scope, performed within the scope of GWEO organisations.

7.6.6.28 Specific guidance on the integration of air-launched stores containing explosives, which is within the MDO/MTCH scopes, is provided in Annex B.

Superseded

Annexes

Annex A – Tailoring a Type Certification Basis and Military Certification Review Items

Introduction

(a) During a certification program, there may be a need to tailor[1] either:

1. the Primary Certification Code (PCC), when seeking an initial certification approval,
2. the existing Type Certification Basis (TCB), when seeking a major change approval.

(b) Throughout this Annex, the term 'tailoring of the TCB' is used to cover both tailoring of the PCC in order to develop a TCB for an initial certification approval, and tailoring of an established TCB.

(c) Tailoring may be required to provide supplementary requirements for a specific technology area, to specify later amendments of requirements, or to otherwise account for the Defence Configuration, Role and Environment (CRE). This tailoring may occur during initial certification of the platform or during changes to the type certificate. The Defence Aviation Safety Design Requirements Manual (DASDRM) prescribes essential and recommended design requirements for a range of technologies and these are incorporated into TCBs through tailoring when required.

(d) Tailoring of the TCB can be achieved by directly including additional requirements or standards in the TCB and Type Certificate Data Sheet (TCDS), or through use of a Military Certification Review Item (MCRI).

(e) This Annex supports Section 7.2.2 and Section 7.2.3 in terms of providing further guidance on tailoring of the TCB, including:

1. when an MCRI is required and the MCRI categories adopted and employed by DASA
2. when Operator agreement is required to support tailoring of the TCB and how that agreement should be achieved
3. illustration of the process for obtaining DASA agreement on tailoring of the TCB.

Tailoring of the TCB Without an MCRI

(f) **Supplementation of the PCC.** Where tailoring is required to supplement the PCC with additional requirements, this can be done directly (without an MCRI) where the supplementation does not require discussion or explanation, and where the supplementation does not rely on reference to internal Defence documents[2]. For example MIL-STD-464C for Electromagnetic Environmental Effects can be listed directly in the TCB and TCDS, because it is a recognised standard from an C/MAA which is widely available for use by future designers, and requires no further discussion or explanation.

(g) **Use of later amendments of airworthiness requirements.** Where a change proposes to use later amendments of airworthiness requirements than the current platform TCB, this can be recorded directly in the TCDS without the use of an MCRI. DASA will review and provide

Superseded

agreement to the proposed use of later amendments via the applicable Certification Program Plan (CPP). Elect to Comply MCRIs will be used to record the use of later amendments only when further justification needs to be recorded, such as when there is a need to record justification that the change to the later standard does not have a negative impact on safety, or where there is a need to place limits or conditions on the use of the later amendment.

(h) **TCDS Update.** Where tailoring is incorporated into the TCDS directly, without an MCRI, it will be made clear whether the tailoring applies to the entire platform or only to certain systems or modifications. For example, if a new requirement is introduced for Electromagnetic Environmental Effects for a specific modification, but the remainder of the aircraft is not certified to that requirement, the TCDS will clearly state that the requirement is only applicable to the modification.

MCRI Categories

(i) An MCRI is an agreement between DASA and an applicant and provides formal documentation of the TCB tailoring. DASA employs the five categories of MCRIs outlined below. These categories and their descriptions/definitions have been adapted for Defence's context from European Military Airworthiness Certification Criteria (EMACC) and European Aviation Safety Agency (EASA) descriptions.

1. **Exception MCRI.** An Exception MCRI details agreed tailoring to an Airworthiness Code or design standard that reduces the level of safety inherent in the native requirement, on the basis that requiring compliance would adversely affect Defence capability. Exception MCRIs are used where it is not practicable to achieve or demonstrate compliance to a requirement in the PCC or TCB due to the impact on capability, and an equivalent level of safety cannot be demonstrated. Exception MCRIs require Operator agreement based on appropriate understanding of the risk and potential controls[3].
2. **Special Condition MCRI.** A Special Condition MCRI details those elements of the design for which a bespoke certification specification has been developed[4].
3. **Elect to Comply MCRI.** An Elect to Comply MCRI details those elements where the use of a later version of the PCC or alternative standard has been agreed[5].
4. **Equivalent Safety Finding MCRI.** An Equivalent Safety Finding (ESF) MCRI details where an airworthiness requirements or standard cannot be met through direct compliance, and agreement has been reached to provide a safety argument to demonstrate that an equivalent level of safety has been achieved. ESF MCRIs that rely on the implementation of operational controls to achieve an equivalent level of safety require Operator agreement[6].
5. **Interpretive Material/Means of Compliance/Acceptable Means of Compliance (IM/MOC/AMC) MCRI.** An IM/MOC/AMC MCRI is used where the applicant proposes to use an extant IM/MOC/AMC, but only in parts or with some changes to the content, or if there was a discussion about the application of such documents, which needs to be recorded.

(j) MCRIs cannot be assigned multiple categories. In certain cases, a Special Condition or Exception MCRI may include content from a different MCRI type, for example for technology areas where the determination of the certification requirement/standard is based on a risk

Superseded

decision, such a Defence Long Range Operations (DLRO). These MCRIs will be assigned a single category based on the primary type of tailoring, in the case of DLRO this would be a Special Condition MCRI. However, ordinarily where different types of tailoring is required (such as a partial ESF and partial Exception), it is expected that these will be included in separate MCRIs to cover each type of tailoring.

(k) A template for an MCRI is available on the DASR Templates website.

Grouping Issues into a Single MCRI

(l) Tailoring to multiple elements of the TCB can be 'grouped' into a single MCRI, where the tailoring is associated with a common issue or relates to the same technology area. Any MCRIs that 'group' issues should be able to be given a meaningful title that encompasses all of the tailoring inside. If a meaningful title cannot be developed due to the MCRI containing disparate topics, then they should be separated into multiple MCRIs. The decision on appropriate grouping of issues into a single MCRI ultimately rests with the Military Type Certificate Holder (MTCH), who will be responsible for managing the MCRI through the life of the platform. A key aspect of DASA agreement will be the assurance that decisions around MCRI grouping are suitable for long-term management of the TCB.

Operational Controls and Risk Management Associated with Tailoring the TCB

Overview

(m) In some cases, tailoring of the TCB requires agreement from the relevant Operator. Operator agreement is required where operational controls are introduced to overcome design shortfalls or where there is a need to manage a level of risk above that represented by compliance with Authority prescribed design requirements and standards.

(n) This sub-section outlines when Operator agreement is required to support tailoring of the TCB, and how that agreement should be achieved.

Operator Agreement for Tailoring of the TCB

(o) An MCRI should be used for any tailoring of the TCB that requires Operator agreement. The following situations and types of MCRIs must be underpinned by Operator agreement:

1. MCRIs that result in a level of risk above that represented by compliance with the Authority prescribed design requirements and standards (ie Exception MCRIs and some Special Condition MCRIs)

2. MCRIs that rely on the implementation of operational controls to achieve an equivalent level of safety to a TCB requirement or standard (ie some Equivalent Safety Finding MCRIs).

(p) MCRIs that require Operator agreement must include a reference to where that agreement was achieved on the front page of the MCRI.

(q) Operator agreement must be provided prior to requesting DASA agreement.

Superseded

(r) Operator Agreement. Tailoring of the TCB that results in an 'elevated level of risk'[7] must be underpinned by Operator agreement. This Operator agreement must be based on appropriate understanding of the risk and potential controls, through the completion of a WHS compliant (7-step) risk management process (refer DASR GM SMS.A.25(b)(2)(2.2) and DASA AC 003/2018 Risk Management in the DASP).

(s) Risk management and Operator agreement underpinning an MCRI can be documented in an Airworthiness Issue Paper (AwIP)[8]. For non-complex issues with minor safety impact this risk management and Operator agreement can alternatively be documented in an equivalent risk management document, such as the webform AE628 'Risk Decision Brief' (RDB). The RDB does not include a step for DASA input[9] and, therefore, DASA can only retrospectively review the risk management process. This is suitable for low-level and non-complex risks, where the risk management is a simple process for the Operator to complete. However, this approach is rarely suitable for more significant or complex risks where DASA input may be required to confirm the understanding of the risk associated with the non-compliance, or to confirm that potential controls have been identified and evaluated appropriately. The AwIP process includes a section for a DASA position, enabling DASA to review the risk evaluation and provide advice to the RMA prior to decisions being made, and therefore is appropriate for more complex or higher level risks.

(t) A key consideration in the acceptability of any risk management process used to justify an MCRI that has an elevated level of risk, is that it must meet the same outcomes as the AwIP, ie it must:

1. clearly document the full 7-step risk management process based on an accurate understanding of the hazards and risks associated with the TCB non-compliance
2. demonstrate that co-ordinated technical and operational input have been provided
3. show that the risk has been appropriately retained.

(u) Risk management cannot be achieved directly through the MCRI as this is an agreement between the applicant (ie project office or MTCH) and DASA, documenting tailoring of the TCB, and does not include the entity responsible for the risk management (ie the Operator).

(v) Any document used to demonstrate Operator agreement for an MCRI must be clearly referenced in the MCRI and traceable in the future. A 'live' document that undergoes frequent update (such as a Hazard Log) does not provide a suitable enduring reference for the risk management decision (though it may be used for continuous monitoring and review of a risk that has been assessed and retained elsewhere).

(w) **Documentation.** The responsibility for the management of a TCB and the responsibility for the management of risk associated with TCB shortfalls belong to two different entities. The applicant is responsible for developing / managing the TCB and ensuring that the type design complies with the TCB, and that the risk associated with any design shortfalls is identified and communicated to the Operator. The Military Air Operator (MAO) is responsible for the management of risk associated with their platform(s). As such, the documentation of the TCB tailoring is separated from the documentation on the management of the associated risk, allowing the applicant (ie project office or MTCH) to manage the former while the MAO manages the latter. While the MCRI must include a reference to the relevant Operator

Superseded

agreement, it cannot not include discussion on the risk, especially the risk characterisation, for the following reasons:

1. Duplicating the risk management information over two documents (eg the AwIP and MCRI) can lead to conflicts if they are updated separately. Noting that open AwIPs can undergo regular updates as part of an effective continuous monitoring and review system, including the risk detail in the MCRI could drive unnecessary updates to the TCB (via updating the MCRI). Updates to the MCRI should only be required when there is a change to the TCB tailoring that has been agreed.

2. The MCRI is used to document what standard/benchmark has been accepted for a design, and is underpinned by sound risk management. The risk associated with the MCRI can change as controls (particularly operational controls) are implemented or removed, but this does not necessarily change the type design/certificate and therefore should not automatically require the MCRI to be updated. Changes to controls which impact on the type design/certificate, or which impact on the level of compliance/tailoring in the MCRI, will require the MCRI to be updated.

3. Continuous monitoring and review of the hazards and risks on the platform is the MAO's responsibility. The MTCH and supporting design organisation(s) will provide considerable input to the risk management process for hazards and risks associated with the type design however, it should remain clear that the ultimate responsibility for the risk management is with the MAO.

(x) The MCRI must clearly outline how the design does not meet the TCB, what (if any) standard/ requirement the design does meet instead, and any relevant controls which have been agreed in lieu of the original requirement (ie risk controls which have been agreed to enable the tailoring to occur)[10]. It is not sufficient to reference out to the AwIP (or other risk management document) to provide the understanding of how the TCB is being tailored, as those documents are not part of the certification of the platform and may not be accessible to future designers.

Risk Controls and Operator Agreement for Equivalent Safety Finding MCRIs

(y) Equivalent Safety Finding (ESF) MCRIs may be agreed by DASA if the risk associated with a non-compliance to the TCB can be eliminated[11] through the implementation of controls. An ESF MCRI that is based on the implementation of risk controls can only be agreed if those controls are implemented in a DASA approved document, such as the TCDS, Military Air Operator – Operations Specification (MAO OpSpec), or the DASA-approved areas of the Aircraft Flight Manual (AFM). Controls implemented solely through Flying Orders or Standing Instructions are not sufficient to enable an ESF MCRI to be approved, as they could be removed without DASA or MTCH knowledge, thus invalidating the ESF justification[12].

(z) 26. Operator agreement is required where an MCRI justification relies on the implementation of 'operational' controls, to demonstrate that the controls are acceptable from an operational perspective and able to be implemented safely. This Operator agreement may be documented in an AwIP (especially if there are a number of Exceptions related to the same design change that are already being covered by an AwIP), but can equally be documented in a suitable alternative format. Operator agreement cannot be achieved through the MCRI itself, as the MCRI is an agreement between the applicant (ie project office or MTCH) and DASA, and the Operator is not a signatory. Where an AwIP or alternative risk

Superseded

management documentation is used to support an ESF MCRI, it can only be utilised to demonstrate Operator agreement to the implementation of controls, it cannot be used to imply 'agreement' to the ESF claim (by DASA or the Operator). The ESF claim must be entirely established and agreed within the MCRI, without reliance on other documents.

TCB Tailoring Process

(aa) TCB tailoring (either with an MCRI or without) must be agreed prior to submitting a declaration of compliance for the relevant certification approval. A declaration of compliance must be made against the approved TCB, therefore if there is outstanding tailoring that has not yet been agreed, compliance cannot be declared. The following flowcharts show the process for gaining agreement to TCB tailoring either with or without an MCRI.

Superseded

Annex B - Leveraging Prior Certification

Introduction

DASR 21.A.20 enables an applicant for a certification authorisation[1] to leverage prior certification from a recognised Civilian Aviation Authority (CAA) / Military Aviation Authority (MAA) to gain relief from developing compliance demonstration evidence. This Annex provides guidance on the requirements associated with leveraging prior certification, and what to do if the prior certification can only be partially leveraged.

Outcomes of Leveraging Prior Certification

(b) Leveraging prior certification provides relief from the requirement to develop compliance demonstration evidence. It does not provide relief from any other requirements for certification prescribed in the DASRs.

(c) As such, applicants seeking to leverage prior certification must still do the following:

1. Develop a certification programme that provides the information required in the relevant DASR.

   Note: for certain major changes, this certification programme may be provided in conjunction with the Form 31a, as outlined in Section 7.2.3.

2. Provide a proposed TCB. For a major change this will include identifying the specific airworthiness requirements (termed re-investigations under DASR 21.A.93)[2] impacted by the change.

3. Provide a declaration of compliance.

(d) While use of prior certification may provide relief from the need to develop new compliance demonstration evidence, it does not provide relief from the need to present compliance demonstration evidence to DASA. As such, DASA may request to review evidence that supported the prior certification where it is deemed necessary. Where it is not possible for the applicant to provide this evidence to DASA, for example due to limitations on access to Original Equipment Manufacturer (OEM) data, this will be negotiated between the Applicant and DASA on a case-by-case basis.

Requirements for Leveraging Prior Certification

(e) In order to leverage prior certification, the following is required:

1. Evidence of certification from a recognised CAA/MAA[3] (e.g. an authorisation issued by the CAA/MAA).

2. Confirmation that the certification is within the scope, conditions and caveats of the relevant CAA/MAA recognition certificate. This will commonly require the following:

   i. Scope: Whether the evidence of certification matches the recognised authorisations on the recognition certificate.

Superseded

ii. Caveats: That evidence exists that the CAA/MAA applied a level of oversight to the design commensurate with the consequences of system failure.

- This is particularly relevant in situations where the CAA/MAA is certifying a design solely for Defence use. In this case there needs to be confirmation that the level of oversight is the same as would normally be used for their own certification activities. Investigation into this aspect should commence as soon as the intent to leverage an CAA/MAA approval that is unique to Defence is known, to avoid any potential delays to progressing the DASA certification.
- If the certification from the other CAA/MAA is a standard certification which has been provided for use in their regulatory system as well as Defence's, stating that in the application is a sufficient response to this caveat.

3. Confirmation that the CAA/MAA is sufficiently experienced in certification of the particular design activity. For example, certification from a civil CAA that relates to safe separation of weapons on a military aircraft is unlikely to be within the experience of the CAA.

4. Identification and management of any deltas between the certification requirements employed by the CAA / MAA and the Defence TCB.

i. **Step 1 – Identification of TCB Deltas.** This requires knowledge of the requirements employed by the other CAA/MAA, and comparison against the Defence TCB. Deltas may include:

- Use of a different airworthiness code.
- Use of later amendments of requirements than the current Defence TCB.
- Not covering requirements that exist in the Defence TCB. This is particularly common for requirements added to the TCB during initial certification as a result of 'Essential' requirements in the Defence Aviation Safety Design Requirements Manual (DASDRM), such as Crash Protection, Oxygen, and Defence Long Range Operations (DLRO) requirements.

ii. **Step 2 – Management of TCB Deltas.** Deltas in the certification requirements employed by the prior certifying CAA/MAA and the Defence TCB can be addressed in the following ways:

- Modification of the design to meet additional Defence TCB requirements.
- Development of additional compliance demonstration evidence to demonstrate compliance to the Defence TCB.
- Tailoring the TCB to match the requirements used by the other CAA/MAA. Depending on the types of deltas in requirements this may require assessment/management of risks associated with use of the different requirements. See Annex A to Section 7 for more information on TCB tailoring.

Superseded

5. Identification and management of any deltas between the Configuration, Role and Environment (CRE) of the prior certification and the intended Defence CRE. Also refer to Annex C to Section 7 for more detailed guidance on the conduct of a CREA Assessment (CREA) in support of leveraging prior certification.

i. **Step 1 – Identification of CRE Deltas.** This step requires the following:

- An understanding of the CRE underpinning the other CAA/MAA certification.
- An understanding of the intended Defence CRE once the authorisation is approved.
- Comparison of the two CREs to identify any deltas. For platforms that regularly rely on prior certification from a specific CAA/MAA, a platform level CREA may be developed (often during initial certification) which documents all known deltas at that time. This can be used as a starting point for future certification activities, where the known deltas in the 'platform' CRE are considered for their impact on the current certification activity. However, the application must still address whether any additional CRE deltas are introduced as a result of the current certification activity.

Note: The CREA is not comparing pre-modification Defence CRE against post-modification Defence CRE. A comparison of pre and post-modification CRE is useful in order to identify impacted areas of the type design, identify required re-investigations and develop a proposed Type Certification Basis (TCB) but does not assist in leveraging prior certification.

ii. **Step 2 – Management of CRE Deltas.** In order to manage any CRE deltas, the requirements of the Type Certification Basis that are impacted by the CRE delta must be identified. Once the impacted requirements are identified, the following options are available:

- Re-design to make the product suitable for the Defence CRE. This will require additional compliance demonstration evidence to demonstrate that the changed design is compliant with the TCB.
- Develop additional compliance demonstration evidence to show that the design is compliant for the Defence CRE.
- Change the Defence CRE to match the CRE from the original CAA/MAA. This may involve modifying the proposed roles or operating environment to remain within the certified role and environments, or choosing not to make Defence unique modifications to the configuration.
- Tailor the requirements of the TCB to account for CRE deltas. This may result in Exception MCRIs, where it is not possible to demonstrate that the design is fully compliant to the TCB for the Defence CRE. See Annex A to Section 7 for more information on TCB tailoring.

Note: It is possible to have a CRE delta that does not impact on the ability to leverage the prior certification. This may be because the CRE delta does not impact on a certification requirement, or because it does not impact on the applicability of the compliance demonstration evidence. If the applicant is

Superseded

claiming that the CRE delta does not impact on the ability to leverage prior certification, the justification for this claim must be clearly provided in the certification programme or final application.

6. Identification and management of any safety risks associated with the CAA / MAA certification.

i. **Step 1 – Identifying Safety Risks**

– Safety risk decisions or risk retention is generally associated with MAA approvals. Civil CAA approvals are not issued on the basis of risk retention, as civil regulators require either that requirements are met directly or that an equivalent level of safety to the requirements has been demonstrated.

– Access to the original authorisation issued by the CAA/MAA may provide insight into risk decisions associated with the approval, but access to System Safety documentation, the Compliance Checklist, or other risk artefacts will likely be required. When engaging in a program that will rely on prior certification from a Military Aviation Authority, it is important to ensure that there is sufficient insight into the supporting documentation to be able to identify any risk underpinning the certification.

Note: Equivalent Level of Safety (ELOS) justifications associated with another CAA/MAA certification may only be true for the certification context in which they were considered. As such, any CRE deltas between the original certified CRE and the Defence CRE may invalidate the ELOS finding and therefore result in an additional safety risk in the Defence context. Careful consideration of the CREA to identify deltas will assist in identifying any additional safety risks introduced due to CRE differences.

ii. **Step 2 – Management of Safety Risks**

– Once risks have been identified, they must be managed through a 7-step risk management process to ensure that they have been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) for the Defence CRE[4]. Claims that the risks were managed and accepted by another MAA is not sufficient, as most MAA do not use the 'SFARP' methodology required by Defence, and the risk management will not be contextualised for the Defence CRE.

– Any safety risks which are the result of non-compliance with the TCB will require an Exception MCRI to be raised, after the risk management has been completed. See Annex A to Section 7 for more information.

Note: Any risk management must be finalised and MCRIs approved prior to completing a declaration of compliance and seeking an authorisation from DASA.

Superseded

(f) Applicants may encounter a range of issues when intending to leverage prior certification that mean that the above requirements cannot be met. This does not necessarily mean that the prior certification cannot be leveraged, but further justification will be required to support the use of that prior certification. Where issues are encountered, the issue and proposed solutions should be outlined in the Certification Programme, and presented to DASA at the earliest opportunity to enable agreement on the proposed approach and reduce risks to the program.

(g) Common issues encountered:

1. **Lack of insight into TCB/re-investigations used by other CAA/MAA.** This is common for aircraft leveraging civil certification, particularly service bulletins, where the design detail is not available.

i. Insight into the TCB/re-investigations is required for the following reasons:

– To confirm that the certification matches the Defence TCB. ie to confirm that no risk is introduced as a result of using older requirements or due to requirements in the Defence TCB not being addressed.

To establish the current TCB of the design, as a starting point for future design activities, to ensure that the level of safety does not diminish with future designs.

Alternate way of addressing this requirement:

– Confirming the known certification basis underpinning the other CAA/MAA certificate. ie it may not be possible to confirm the specific requirements used for the current design, but the baseline certification basis, which would serve as a starting point for the certification activity, will be available on the original Type Certificate.

Identifying any deltas between the baseline CAA/MAA certification basis and the Defence TCB. If the two are largely common (ie airworthiness code and amendment level is common), with any deltas clearly in an area not impacted by the change, this may support proceeding with limited insight into the requirements used by the CAA/MAA for the change. If the baseline TCBs are not common (ie differing airworthiness codes or amendment levels are used) then further insight into the CAA/MAA basis for the change must be obtained.

Confirming the process used by the CAA/MAA in managing the certification basis for changes. In most cases the CAA/MAA will not change the airworthiness code, or add new Special Condition requirements without amendment the original certificate, and in such cases the potential changes to the certification basis would usually be limited to the use of later amendments of requirements, or equivalent level of safety arguments.

Confirming that there is no intent for future design changes to be implemented without reliance on the CAA/MAA in question. If all future changes are intended to leverage prior certification from the CAA/MAA in question, then confidence can be gained that any changes to the TCB related to this certification (eg decisions to comply with later amendments of requirements) will be carried over to any future design changes. However, if it is likely that Defence will undertake Defence unique modifications, or will rely on modification with prior certification from a different CAA/MAA, then

Superseded

detailed insight into the requirements for the change will likely be required in order to establish the basis for future changes.

Note: This alternate approach will generally only be suitable for simple civil certified changes such as major changes released under a Service Bulletin, where the Defence type has minimal CRE deltas from the civil type. Due to the potential for Military certifications to include risk retention, as discussed above, lack of insight into the requirements and level of compliance against those requirements is unlikely to be able to be justified.

2. **Prior certification is against different airworthiness code/requirements than the Defence TCB.** This may happen when Defence relies on certification from a single CAA/MAA and they have decided that due to issues in the original certification basis, or safety benefits available in a new airworthiness code, to alter their certification basis. This may also happen when Defence relies on prior certification from different Authorities for different activities, and those Authorities use different airworthiness codes. This may be addressed in the following ways:

   i. Use of a Military Supplemental Type Certificate (MSTC) to cover the specific design activity that uses a different certification basis. This approach is suitable where there is single stand-alone activity which will use the new certification basis, and other future activities are expected to continue to use the original certification basis. Use of an MSTC enables a TCB to be defined separately to the MTC TCB, though the certification programme will need to address the congruence between the two TCBs to ensure there are no safety risks introduced due to the use of the alternate TCB.

   ii. Modifying the Defence TCB to match the prior certification. This could involve modifying only some elements of the TCB, or could involve a change to the whole TCB. See Annex A to Section 7 for more information.

   iii. Mapping the evidence from the other CAA/MAA across to the Defence TCB without modifying the TCB. This will require a good understanding of differences between the airworthiness codes or requirements and insight into the specific elements of the code impacted by the change. Where there are shortfalls in the ability to map the evidence to the Defence TCB this will require management via additional evidence, limitations or TCB tailoring.

3. **Direct evidence of CAA/MAA approval is not available.** This may occur where Defence receives the output from the OEM (for example a Service Bulletin or updated Aircraft Flight Manual (AFM)) but does not have access to the underpinning CAA/MAA approval.

   i. Direct evidence of approval is required for the following reasons:

      – To confirm that the recognised CAA/MAA has provided an approval.

      – To confirm that the type of approval from the CAA/MAA matches the products on the DASA recognition certificate.

      – To confirm that there were no caveats, conditions or limitations associated with the approval.

   ii. Alternate way of addressing this requirement:

Superseded

- Providing evidence that shows a product has been released under privilege based on an approval from the CAA/MAA. This will often be stated on the product (for example a service bulletin issued under the EASA system will often reference the underpinning EASA approval).
- Confirming that this is a standard type of product under the CAA/MAA system, and therefore would have been approved using a standard authorisation covered under our recognition certificate. The type of approval may actually be referenced on the product (eg Service Bulletin or AFM update) that has been released, therefore addressing this requirement.
- Addressing the potential for conditions, caveats or limitations associated with the product. This may require engaging with the organisation that has released the product (eg OEM) to confirm whether any conditions, caveats or limitations were associated with the approval. Normally conditions or limitations associated with an approval would be released to Operators, and therefore be available even if the underpinning design approval is not available.

Note: This alternate approach will generally only be suitable for simple civil certified changes. Due to the potential for Military certifications to include risk retention, as discussed above, lack of direct evidence of MAA approval to enable assessment of potential risk treatment decisions is unlikely to be able to be justified.

4. **Evidence of CAA/MAA approval does not match the recognition certificate.** This may occur where the CAA/MAA uses a different system for approval of certain artefacts that is not covered under the recognition certificate. For example, the Federal Aviation Authority (FAA) approval of changes to a Master Minimum Equipment List (MMEL) is managed through the Flight Operations Evaluation Board process and may not receive a major change approval as listed on the recognition certificate.

   i. Alternate way of addressing this requirement:

   - Provide information on the type of approval that was provided, the area of the CAA/MAA that provided it (especially if it is a separate element of the CAA/MAA than normally completes certification activities), and why this approval was not provided under one of the standard/recognised authorisations.
   - Provide justification (based on the above factors) for why this available authorisation should be considered equivalent to other recognised authorisations. For example, it is the standard process used for this technology area, it has undergone the same level of oversight from an appropriate area of the Authority, it has been approved as a 'major' change which is equivalent to the classification under DASRs.

5. **Prior certification is from a CAA/MAA that DASA does not recognise or is not covered by the DASA recognition.** This could be due to three reasons – the certification is from a historical CAA/MAA that no longer exists, the certification is from a current CAA/MAA that DASA has not assessed, or the certification is from a recognised CAA/MAA but not covered by the current recognition. In any of these cases, early engagement with DASA to discuss the potential for leveraging a

Superseded

certification from an unrecognised CAA/MAA is essential. For current CAA/MAAs, DASA may be able to undertake the recognition activities to support the use of prior certification, but this will require sufficient notice.

i. Historical CAA/MAA.

- Recognition of current CAA/MAAs does not cover any previous variations of the Authority. As such, additional work will be required to establish confidence that the historical CAA/MAA processes provided an equivalent safety outcome to the DASRs, before the certification can be leveraged. In order to do this, the applicant must gain as much insight as possible into the authorisation that they are intending to leverage and the system under which it was issued, and engage with DASA early to determine possible approaches to recognition.
- Use of a certification from a historical CAA/MAA is also likely to be provided against older airworthiness requirements than would be currently required under the DASRs. As such, assessment and treatment of any risks relating to the deltas between the older requirements and the contemporary requirements will likely be required in order to leverage the prior certification.

ii. Current CAA/MAA (unrecognised or not covered by the current recognition)

- DASA should be engaged as early as possible if there is an intent to leverage certification from a current CAA/MAA that is not recognised. In order to be able to leverage that certification, DASA would need to undertake a recognition activity which will require significant notice and planning. If DASA is unable to conduct a recognition activity of the CAA/MAA, prior certification will not be able to be leveraged and a standard certification approach must be followed, including presentation of all compliance demonstration evidence to DASA.

6. **Insufficient insight into the level of oversight provided by the other CAA/MAA**

i. As mentioned above, if the design is being certified for use within the other CAA/MAA's system then that is normally sufficient to confirm an appropriate level of oversight has been provided. If the design is being certified solely for Defence use, then insight into the CAA/MAA oversight is required, and applicants should establish a plan for gaining this insight as early as possible.

ii. If the applicant has exhausted all options available to them for gaining this insight, then DASA may be able to engage on an Authority-to-Authority level to address this requirement. Note that this is not a standard practice, and will only be done in exceptional circumstances. The Authority-to-Authority engagement may not be able to occur on applicant timelines and, as such, if an applicant is reliant on this approach then it may result in delays to certification.

Superseded

Annex C - CRE Assessments in Support of Aircraft Certification Programs

Introduction

(a) DASR 21.A.20 requires the applicant for a Military Type Certificate (MTC) to demonstrate compliance with the applicable Type Certification Basis (TCB), and to provide the Authority with the means by which such compliance has been demonstrated. The Acceptable Means of Compliance (AMC) accompanying this regulation requires the applicant to demonstrate compliance through either:

1. Compliance Demonstration Evidence (CDE) developed by a Military Design Organisation Approval (MDOA) holder (or alternative as agreed by the Authority); or

2. appropriate evidence of prior certification provided by a recognised Civilian Aviation Authority (CAA) or Military Aviation Authority (MAA) - collectively C/MAAs.

(b) The latter of these two demonstration methods recognises that most Defence aircraft and design changes have previously been assessed as suitably safe ('certified[1]') by another C/MAA. It therefore makes sense for Defence to leverage that effort to the maximum practicable extent. Apart from the obvious direct benefits to Defence (eg savings in time, cost and effort through not producing or assessing CDE), it also presents opportunities for Defence to benefit from international C/MAA expertise and privileged access to design data.

(c) However, the certification issued by an C/MAA is normally specific to their local operational context. Defence has long described this context in terms of the aircraft's 'CRE', that is, its:

1. Configuration - the physical and functional attributes of the aircraft

2. Role - the way the aircraft is flown and employed

3. Environment - the physical and functional conditions in which the aircraft is operated.

(d) Defence has historically found that its operational context can differ markedly to other civil and military operators, and therefore C/MAA certifications may be only partly relevant to Defence aircraft. This may affect the extent to which an applicant can rely on prior certification - and instead must develop CDE to demonstrate compliance with the TCB.

(e) **Purpose of Annex.** The aim of this Annex is to assist applicants for MTCs and Major design change approvals in identifying opportunities to leverage prior certification, thereby obtaining partial or full relief from developing CDE. This Annex supports the guidance contained in Section 7.2 *Type Certification*, and is complemented by Annex B to Section 7 *Leveraging Prior Certification*.

(f) While not the direct audience for this Annex, the content may also assist organisations managing the acquisition of, and design changes to, Defence aircraft in meeting their Smart Buyer and other obligations.

(g) **Overview of Annex.** This Annex briefly summarises the concept of prior certification and its applicability to Defence aircraft acquisitions and Major design changes. It will then provide guidance on completing a CRE Assessment (CREA) to justify an application to leverage prior certification.

Superseded

(h) Finally, it will briefly explain how some minor adaptions to the CREA process can assist Defence in its Smart Buyer and other endeavours.

Prior Certification

(i) This Annex assumes the reader has a reasonable knowledge of prior certification, as provided through Annex B to Section 7 *Leveraging Prior Certification*, the DASR Type Certification Course, and AMC/GM to DASR 21.A.20. However, to ensure readers share a common context for the next section on CREA, a brief overview is provided below.

(j) To promote efficiency and flexibility in the DASP, DASA may acknowledge that products and services from other Aviation Authorities and their respective systems are acceptable. This concept, known as Recognition, is provided for by the Defence Aviation Safety Regulation and is explored in Section 6 *Recognition of other Aviation Authorities*. Recognition is contingent on a DASA assessment of, amongst other things, the C/MAA's staffing (including qualifications and training), airworthiness regulations, policies applied by the Authority, and the airworthiness authorisations issued by the Authority.

(k) In the context of aircraft design, prior certification of a product - whether a whole aircraft, a system, an item of equipment or even a software load - by a recognised C/MAA can provide Defence with equivalent confidence in the safety of design as if we had conducted the product certification ourselves. This presents the applicant for an airworthiness authorisation with the opportunity to reduce, or perhaps even eliminate, the need to develop CDE to demonstrate that the design meets the agreed TCB.

(l) Prior certification can only be applied to the extent that the following prerequisites are met:

1. the certification is within the scope, conditions and caveats specific to DASA's recognition of the certifying C/MAA
2. the C/MAA is sufficiently experienced in certification of the particular design activity
3. the certification requirements employed by the C/MAA (primarily related to disclosure of the TCB) are understood
4. any safety risks associated with the C/MAA certification have been identified, and Defence has ensured those risks have been eliminated or otherwise minimised so far as is reasonably practicable
5. the Configuration, Role and Environment (CRE) applied to the C/MAA's certification is understood and any deltas from the intended Defence CRE have been addressed.

(m) The first four of these prerequisites, while sometimes challenging to verify, are largely self-explanatory. However, the fifth prerequisite, namely identifying and managing CRE deltas, is often a complex undertaking and is the subject of the remainder of this Annex.

Configuration, Role and Environment

(n) This section introduces the concept of 'CRE', and then explores the differences between the as-designed CRE, the as-certified CRE, and Defence's required CRE.

What is CRE ?

Superseded

(o) An aircraft operator, whether civil or military, will have a particular operational context in mind when procuring an aircraft. An aircraft design organisation will similarly have a particular operational context in mind when designing an aircraft. Alignment between these two contexts is unsurprisingly pivotal to airworthiness.

(p) Since there is no internationally-accepted terminology for this operational context, Defence has historically defined it in terms of an aircraft's Configuration, Role and Environment. The following paragraphs provide an overview of the factors that constitute an aircraft's CRE:

1. **Configuration.** An aircraft's Configuration comprises all its physical and functional attributes. It includes, amongst other things, the attributes of aircraft systems (eg avionics, fuel, oxygen, flight controls), structures (eg wings, doors, nacelle), powerplant (eg fuel, engine, exhaust), and propellers and rotors[2].

2. **Role.** An aircraft's Role encompasses how it is flown and employed. It includes flight profiles, external stores carriage, possible cargo configurations, operating weights, speed/altitude ranges, and so on. The desired Role for an aircraft often influences its Configuration and Environment.

3. **Environment.** An aircraft's operating Environment encompasses the physical and functional conditions in which the aircraft is operated. It includes:

   i. the physical airborne environment (for example the electromagnetic environment, the corrosive environment, moisture and gust loads)

   ii. the physical ground environment (for example landing loads, taxi loads, tie-down loads and so on)

   iii. the functional environment (for example national airspace equipage and navigation performance requirements)

   iv. Australian and Defence policies, procedures and equipment requirements (for example Australia has legislated requirements for safety risk management, Defence has specific policy requirements for aircraft crash protection).

(q) The Role and Environment for a particular aircraft will usually remain fairly constant throughout its life. Changes to Configuration, on the other hand, are commonplace - usually to introduce new functionality or to remedy latent design/construction deficiencies.

(r) While the vernacular of 'CRE' is probably unique to Defence, the underlying principles are common across civil and military aviation.

The 'as designed' CRE

(s) As noted previously, aircraft designers will have a particular operational context in mind when designing a new aircraft or a change to an aircraft. For military aircraft, this is usually defined by the lead military customer, as documented in their procurement specification. For civil aircraft, this is often defined by the design company itself, after identifying the likely needs of prospective customers.

(t) In both cases the final design will often exceed the customers' requirements. This might be in anticipation of future customer needs, or because off-the-shelf components exceed requirements, or to incorporate generous safety margins for design/production inaccuracies.

Superseded

(u) From a customer's perspective, identifying an aircraft's Configuration is usually straightforward. However, identifying the Role and Environment assumed by the designer can be particularly difficult. In DASA's experience, this is partly because designers do not explicitly employ this terminology or construct, and partly due to commercial/security considerations. Avenues to overcome these hurdles are presented later in this Annex.

The 'as certified' CRE

(v) CAAs will normally certify a new aircraft against their promulgated airworthiness codes[6]. These airworthiness codes, inclusive of their referenced standards, implicitly include bounds on the aircraft's Role and Environment. These bounds are reflective of the common operational context that the authors had in mind when they drafted those airworthiness codes and standards.

(w) The concept of a unique and explicit Role and Environment is therefore irrelevant to most CAA certifications[4]. Consequently, if Defence wishes to identify the certified Role and Environment, it is usually sufficient to explore the relevant airworthiness code and its referenced standards. This may sometimes be straightforward (eg identifying the certification limits for electromagnetic immunity), but more often it requires deep domain knowledge (eg limits for repeated engine dust ingestion).

(x) MAAs, on the other hand, will normally certify an aircraft against its intended operational context. They may use a standards-based approach, or a specification-based approach, or more commonly a combination of both. Because of the often unique and challenging operational context for military aircraft, MAAs will ultimately certify to the intended Role and Environment, albeit that terminology is rarely used outside Defence.

(y) If Defence wishes to identify the MAA-certified Role and Environment, much of the information should be available in the original aircraft procurement specification . The remaining information can normally be sought directly from the MAA, through targeted requests for certification data. Where the MAA is unable to release that information, an alternate approach may be to seek MAA confirmation that the certified design does indeed meet a particular Defence Role or Environment requirement. A final approach, albeit much less-preferred, is to explore whether the MAA's indigenous aircraft operate to a similar extreme of Role or Environment .

(z) Importantly, neither a CAA nor MAA certification will precisely match the as-designed Role and Environment. Rather, the latter will invariably exceed the former. The C/MAA merely confirms that their requirements are met, whereas the designer may elect to exceed those requirements for their own reasons. The significance of this delta will become clear later in this Annex.

Defence's required CRE

(aa) Defence procures aircraft to meet its operational needs. However, with a few rare exceptions, Defence's intended CRE for a new aircraft will be different to other major operators of the same aircraft type. This is due to Australia's unique location and environment, the need to multi-role our aircraft fleet, and so on.

(ab) DASR ARO.50 requires all Defence-registered aircraft to be issued with a Statement of Operating Intent and Usage (SOIU). Ideally, the SOIU should form a cornerstone of the aircraft Type Certification process, since it should contain all the Roles and Environments in which the aircraft type is intended to operate[7]. Practically, however, there is still variability across

Superseded

aircraft SOIUs, so Defence acquisition and design staff may also need to glean additional information from other sources[8].

(ac) The next section explores how Defence certification programs may still be able to leverage prior certification, despite apparent differences between Defence's required CRE and the as-certified CRE, through a CRE Assessment.

CRE Assessment - New Defence Aircraft

(ad) The applicant for a MTC for a new Defence aircraft is required to develop a certification programme (which should be presented as a stand-alone Certification Programme Plan (CPP)) for Authority acceptance. A central element of the CPP is the TCB for the aircraft and the proposed means of demonstrating compliance with the TCB. Both are commonly combined into a Compliance Checklist (CCL).

(ae) Unsurprisingly, applicants endeavour to leverage prior certification to the maximum practicable extent, rather than develop additional CDE. The onus is on the applicant to compare Defence's CRE with the prior certified CRE, and draw one of three conclusions for every TCB line item:

1. There is no CRE delta, so prior certification can be fully claimed for that TCB line item
2. There is a CRE delta, but it only affects certain elements of the TCB line item, so CDE will be developed to supplement the prior certification.
3. There is a marked CRE delta, so CDE will be developed to fully demonstrate compliance (ie prior certification will not be used)

Note: *Before starting to develop CDE, some CASG Project offices attempt to eliminate or minimise CRE deltas through various means, for example negotiating role/ environment changes with aircraft operators. However, this is not a certification activity - rather it is a CASG Smart Buyer activity that endeavours to reduce certification costs and schedule. See Section 7 for further information.*

(af) Most applicants elect to produce a CRE Assessment report to summarise and justify their findings. However, this is not a regulatory requirement. Rather, the applicant must ultimately find a way to satisfy the Authority that each instance of leveraging 'prior certification' is justified before the Authority will agree to the CPP. The applicant will also need to define the additional CDE that will be developed, where full reliance on 'prior certification' cannot be supported.

CRE Assessment process

(ag) A template for conducting a CRE Assessment is provided at Appendix 1 to this Annex. At its core is a list of items where Defence has historically encountered CRE deltas to certified designs. Each line provides space for the applicant to decide whether the item is relevant to their situation, and if so to list potentially affected TCB elements.

(ah) The common CRE Assessment process is presented in steps 1 to 4 of the figure below. Steps 5 to 8 are normal design actions that are beyond the scope of this Annex, but are included for completeness.

Superseded

Figure 1: Common CRE Assessment Process

Note: *While the TCB is first mentioned at Step 4, the TCB would preferably be developed well before this, to help inform each step in the CRE assessment.*

(ai) Guidance in completing Steps 1 to 4 is presented in the following paragraphs. Guidance on completing the green Smart Buyer step is included later in this Annex.

Step 1: Document the Defence CRE

(aj) Paragraph 28 noted that the SOIU should contain a comprehensive description of Defence's Role and Environment, but did not provide guidance on what might be considered 'comprehensive'. While the determination of comprehensiveness is guided by AMC to DASR 21.A.15(b), and also the SOIU, CREA and CPP templates, it ultimately is a judgement made by competent engineers.

(ak) Importantly, this step must identify any areas where Defence's Role and Environment for the aircraft could conceivably be unusual, and then document Defence's requirements for those areas. Conversely, as a matter of pragmatism, other areas may be omitted simply because

Superseded

Defence's intended use for the aircraft is so obviously unremarkable[9]. The ideal balance is where we do not drown in detail, but we also do not miss any potential deltas.

(al) The two preceding paragraphs have focused on Role and Environment, but not Configuration. This is because Configuration differences are usually identified directly in Step 3.

Step 2: Determine the CRE that was employed by the certifying C/MAA

(am) Refer to the 'as-certified' CRE information earlier in this Annex for guidance on identifying and exploring the CRE employed by the certifying C/MAA.

Step 3: Compare the CREs and identify deltas

(an) **Role and Environment.** While identifying Role and Environment deltas is conceptually straightforward, it can often be complex in practice. In DASA's experience it takes professional engineering effort, and there are few if any shortcuts.

(ao) DASA offers the following guidance:

1. The CRE assessment is usually most effective when conducted in two phases. The first phase evaluates each line item in the Appendix 1 template, with the sole aim of identifying issues that might present a CRE delta. The second phase methodically explores each item to confirm that status.

2. In DASA's experience the first phase is best conducted as a workshop, comprising experienced representatives from the Military Air Operator (MAO), Air Warfare Centre, DASA, CASG, and other relevant domain experts. The second phase is normally a project office activity.

3. The second phase should avoid delving too deeply into issues that may only have a trivial safety effect. Defence has limited resources, and must focus its effort on identifying and managing sources of elevated safety risk.

4. It can be tempting during this step to source additional evidence from the aircraft designer to confirm the as-designed aircraft does in fact encompass Defence's Role and Environment, even though the as-certified aircraft does not. However, this approach can muddy the application of prior certification. Rather, the additional evidence is best identified and sourced in Step 5 of the CRE assessment process.

5. This step is complete only when Defence has certainty over CRE deltas. If Defence only suspects there is a CRE delta, then further authoritative data should be sought. Proceeding to Step 4 prior to this certainty can lead to Defence wasting resources by implementing unnecessary modifications or generating superfluous CDE.

(ap) Conversely, based on previous DASA experience, DASA offers the following cautions:

1. The CRE comparison activity should not be levied onto a foreign C/MAA or foreign program office or aircraft designer, because it will almost certainly be unsuccessful[10]. At most, Defence should present targeted questions to the C/MAA on elements of CRE.

2. The activity should not be completed in isolation by engineers. Some CRE deltas can be obscure, and are only revealed after deeper exploration by operational and other stakeholders.

Superseded

3. The methodical CRE exploration should not be relegated to an inexperienced project engineer or contractor. Identifying and managing CRE deltas can be a substantial contributor to safety, and needs to be tackled with commensurate skill and diligence.

(aq) **Configuration.** Identifying Configuration deltas is usually straightforward. Configuration deltas commonly result from either a unique Defence capability requirement, or are a security pre-requisite of the originating customer[11].

Step 4: Explore the effect a CRE delta will have on TCB line items

(ar) As described in paragraph 31, prior certification can only be leveraged for a particular TCB item to the extent that the certification is relevant to Defence's particular CRE. Otherwise, the applicant would normally need to develop CDE to cover the gap[12].

(as) **Role and Environment.** This step methodically identifies every TCB line item that will be affected by a particular Role and Environment delta. For example, if Step 3 concludes that Defence will conduct higher sink rate landings than the C/MAA certification currently covers, the analyst must identify every affected TCB item. These will range from the obvious (eg TCB items covering undercarriage strength) to the obscure (eg TCB items covering ICA for crash-rated seats).

(at) The engineers completing this process must have a deep understanding not only of each TCB item, but also the standards that underpin each TCB item. Most often, this depth of knowledge will only be resident in a DASA-approved Military Design Organisation (MDO), although there is no regulatory requirement for an MDO to complete this step.

(au) Completion of this step will ideally result in two artefacts, although only the latter is a prerequisite for proceeding to Step 5:

1. A CREA report, usually based on the template at Appendix 1, which documents the affected TCB line items for every identified CRE delta. This can be a particularly useful artefact for through-life support, as will become evident in Section 6.

2. A Compliance Checklist (CCL) which lists every TCB line item and identifies where 'prior certification' will contribute partly or fully to demonstrating compliance.

(av) **Configuration.** Where a Configuration delta exists, the outcome is usually unambiguous. That is, relief through prior certification usually cannot be applied, so new CDE must be developed to support Type Certification of those systems or equipment. This activity will be performed by a MDO or other organisation accepted by the Authority. The template at Appendix 1 is not normally used for Configuration deltas; rather they are addressed directly in the CPP.

(aw) DASR 21.A.97 states that the approval of a Major design change requires compliance to be demonstrated with the Authority-approved TCB. Since Defence mostly procures off-the-shelf designs that have been certified by a recognised C/MAA, leveraging 'prior certification' has the potential to markedly reduce the CDE to be developed by design organisations.

(ax) This section examines the role of CRE assessments in certifying design changes, and separately covers:

Superseded

1. Major design changes[13] to Defence aircraft that possess a quality CREA that has been well documented and iteratively improved over time

2. Major design changes to Defence aircraft that do not possess a quality CREA

3. Minor design changes to Defence aircraft

Major design changes - for aircraft with a quality CREA

(ay) An existing CREA is primarily useful where the C/MAA certification basis for the Major design change is largely equivalent to the Defence TCB, and the change does not introduce a marked change to the Defence SOIU (and, therefore, the CRE which underpinned the original CREA). Where these assumptions do not hold, a new CREA will probably be needed (see paragraph 55).

(az) Extant CREAs are usually used in one of two ways. The most common is for straightforward design changes where 'prior certification' is reasonably expected to entirely support Defence's own certification (ie no new CDE should be required). In this case, a two-step approach is normally applied by the applicant:

1. **Step 1:** Use the CREA to confirm the particular aircraft systems/functions relevant to the change are not affected by Defence's unique Role and Environment.

2. **Step 2:** Confirm the design change does not introduce any new Role and Environment deltas[14].

3. Provided both steps are positively confirmed, and Defence's aircraft configuration matches the C/MAA-certified configuration, then the applicant should be justified in claiming full relief from developing CDE.

(ba) A variation on the above approach is where the CREA is used to identify where partial 'prior certification' might be applied. For example, the design organisation might create the CCL for a design change, and then use the CREA to identify CCL line items that were noted as being affected by Defence's unique Role and Environment. The CREA would then help the applicant determine whether the particular Role and operating Environment attribute was relevant to this particular design change.

(bb) **CREA maintenance.** For a CREA to be used per paragraphs 51 to 53, the CREA must be maintained throughout the aircraft's lifecycle. This includes not only adding CREA items as new deltas are identified, but also amending items where the CRE delta is reduced or no longer exists (eg if a design change eliminates a CRE delta, or the C/MAA changes what they are certifying to).

Major design changes - for aircraft lacking a quality CREA

(bc) Where a quality CREA does not yet exist for the aircraft, an applicant wishing to leverage 'prior certification' will need to apply the process in Section 5, covering the scope of the particular design change.

Minor design changes

(bd) DASA issues Recognition certificates for recognised C/MAAs, which are available on the DASA recognition web page. These certificates, and DASR M.A.304(d), allow Continuing Airworthiness Management Organisations (CAMOs) to directly consume certain Minor design changes, provided the resulting design change is compatible with Defence's CRE. AMC to

Superseded

DASR M.A.304(d) requires the CAMO to establish procedures to assess and process data intended for consumption. A starting point for these procedures would be the guidance presented above at paragraphs 51 to 53.

(be) For Minor design changes that cannot be consumed under M.A.304(d), for reasons including CRE deltas, an approval under DASR 21 is required. The Initial Airworthiness DASRs do not specifically mention prior certification in relation to 'Minor' design changes. However, a MDO's Design Organisation Handbook must describe how their design assurance system accounts for the acceptability of the parts or appliances designed by partners or subcontractors. Where these parties are not MDOs, the application of 'prior certification' (including CRE assessments per paragraph 55) may contribute to a pragmatic solution.

CRE Assessments - Contribution to Smart Buyer

(bf) This Annex has naturally focused on the direct contributions that CREAs make to aircraft type certification. This last section is presented as a service to CASG, exploring some ways that CRE assessments can contribute to CASG's cost, schedule and capability aims.

Minimising CRE deltas

(bg) DASA has long advised aircraft acquisition project offices to conduct CRE assessments early in the project lifecycle, well before acquisition contracts are signed. By identifying potential CRE deltas early, CASG can explore a wider array of options for minimising the deltas, resulting in potential cost, schedule and capability benefits. For example, upon identifying a potential CRE delta, CASG might:

1. expand the acquisition contract to modify the aircraft so it fully meets Defence's required Role and Environment
2. include requirements in the contract for the aircraft designer or C/MAA to develop or disclose CDE that shows the design already encompasses Defence's needs
3. allocate project funding to develop additional evidence to confirm the aircraft exceeds designer or C/MAA expectations (eg fund structural fatigue tests or targeted EMI testing)
4. seek MAO concurrence with operational limitations or changes to the SOIU, to eliminate or minimise CRE deltas
5. make provision for expanded Instructions for Continuing Airworthiness (eg add inspections or maintenance) so the design remains safe for the proposed Defence use.

(bh) While each of these avenues can be pursued after contract signature, they can become markedly more difficult and expensive. If left too late, opportunities to eliminate a CRE delta might become impractical, potentially obliging a MAO to accept a capability reduction or to retain an elevated level of risk.

Other uses for CRE assessments

(bi) CASG projects have previously found CRE assessments to be useful for issues beyond type certification. One such use is to identify areas where a new aircraft and its support systems

Superseded

may not be entirely compatible with Defence's systems and legal obligations. Once identified, the project can work through resolving the incompatibilities. Candidates might include:

1. aeronautical data
2. electronic flight bags
3. mission planning systems
4. compatibility of aircraft operating and maintenance procedures and publications with Defence's standard training and doctrine
5. compatibility with night vision lighting systems, on the ground or on other aircraft
6. long-term health effects due to RADHAZ, HAZCHEM, etc
7. airfield limitations
8. compatibility with Defence's common ground support equipment
9. extended operation of aircraft systems on the ground.

Superseded

(a) This Appendix presents a template for methodically identifying and exploring deltas between the as-certified CRE and Defence's required CRE, to justify relief from presenting Compliance Demonstration Evidence due to a prior certification from another C/MAA. The list has been compiled through DASA and CASG experience with many previous aircraft acquisitions.

(b) A link to the current CRE Assessment Template can be found on the DASA website.

(c) When employing the above template, it can be useful to understand the common causes of Role and Environment deltas.

(d) **Role.** Role deltas may be caused, or exacerbated, due to:

1. increased frequency of particular types of missions or the missions may be carried out substantially differently, leading to accelerated fatigue and lifing issues
2. a system was intended for primarily training roles, but will now be used for an operational role
3. a system was not designed for the increased frequency of particular training serials (e.g. landings, stalls, etc.)
4. some aerobatic or other aggressive manoeuvres may not have formed part of the design basis or operating intent when considered by the original certification authority
5. systems which were designed to be advisory only, or to support a mission outcome, are now to be relied upon as a safety critical system.

(e) Table 1 presents a tool for broadly identifying role deltas, which may assist in completing the attached template.

Superseded

Table 1: Comparison of SOIU and Original Certified Roles

(f) Operating Environment deltas may be caused, or exacerbated, due to:

1. harsh extremes of the Australian environment
2. unique Australian legislated or Defence policy requirements specified within DASR, the Defence Aviation Safety Design Requirements Manual (DASDRM) and other Defence Policies
3. unique Defence crewing or crew skill requirements
4. differences between communication and navigation system requirements of nations
5. unique Defence roles for the aircraft, beyond those considered by the certifying authority.

Superseded

Annex D - Repair Design Approval Scenarios

Introduction

(a) This Annex provides examples of approval processes for repairs IAW DASR 21 Subpart M, with a focus on major repairs. Within the Defence context there are a number of scenarios that are applicable for different repair development circumstances. These scenarios are defined herein as an aid for explanation, rather than as a series of strict application processes. This Annex contains detailed guidance, and highlights how processes vary, for the following scenarios:

1. Scenario 1 – Major Repair developed by an organisation holding an approval under DASR 21 Subpart J, and approved by DASA. An application for DASA approval of a major repair processed by an organisation holding an approval under DASR 21 Subpart J.

2. Scenario 2 – Major Repair approved by an organisation holding an approval under DASR 21 Subpart J with major repair privileges. The process by which an organisation holding an approval under DASR 21 Subpart J, and holding the privilege to approve certain major repairs, may approve a major repair design.

3. Scenario 3 – Major Repair which has not been approved by a CAA/MAA and which has been developed by an organisation which does not hold an organisational design approval issued by a DASA recognised CAA/MAA. The process by which a major repair developed by an organisation such as OEM, which has not been approved by a recognised CAA/MAA, may be approved.

4. Scenario 4 – Approval of unrepaired damage utilising major repair provisions where compliance can be shown with the Type Certification Basis (TCB). The process by which unrepaired damage[1], which can be shown to be in compliance with the TCB with specific maintenance action (for example with an additional inspection program), is subject to approval via the major repair arrangements of DASR 21.A.435(b). These arrangements are also applicable where an individual aircraft is to be flown beyond an AwL item and where compliance with the risk level inherent in the TCB can be demonstrated. In cases where compliance with the TCB cannot be shown a major repair approval is not an appropriate authorisation[2].

5. Scenario 5 – Staged approval of damage tolerant repairs. The process by which approval of repairs which include fatigue and damage tolerance evaluation, may be staged to allow an operator to return its aircraft to service before all the fatigue and damage tolerance data have been developed and approved. The staged process is not applicable to propulsion systems and dynamic systems for helicopters.

6. Scenario 6 – Approval of new repairs based on pre-approved repairs contained in the type data set. The process by which new repairs are developed based on those contained in the aircraft type repair manual, or based on repairs previously developed for the aircraft type, but outside of the limitations of the existing repair approval, are approved.

7. Scenario 7 – Approval of changes to the approved type design repair data. The process by which changes to approved data for repairs for the platform are approved (typically changes to the aircraft type Structural Repair Manual).

Superseded

(b) As a reminder, CAMOs may be able to directly consume repair data approved by a CAA/MAA recognised by DASA as competent for the approval of major repairs or approved by an organisation privileged by such a CAA/MAA. Refer to the Section 8.2 for further information.

Scenario 1 – Major Repair developed by an organisation holding an approval under DASR 21 Subpart J, and approved by DASA

(c) The process for major repair design development and approval for the case of a major repair developed by an organisation holding an approval under DASR 21 Subpart J and approved by DASA is outlined in Table D.1.

Stage	Description	Responsibility
Identify and Assess Damage	Damage identified for which there is no existing pre-approved solution. A repair is required to eliminate damage and/or restore the aircraft to an airworthy condition. There is no existing solution available and approved that is applicable to the damage in question, and therefore a new repair design is required. Repairs for similar damage that have not been approved for the application or specific aircraft in question are to be treated as a new repair design.	CAMO
Develop Repair Design	A new repair design is developed by a design organisation. DASA may be notified of an upcoming major repair design. This can be accomplished via an optional DASR Form 31 directed to the DASA Type Certification Group mailbox. The requirement for a detailed CP is determined in consultation with DASA. In the case of major repairs, if long and complex compliance demonstration activities are deemed to not be required, the CP can be submitted in simplified form as part of the application (see AMC 21.A.432C(a)). Minimum requirements for a CP are outlined in DASR 21.A.432C(b) and include the purpose and description of the change/repair, applicability, applicable airworthiness requirements, description of the compliance demonstration process (including means of compliance and reference to compliance documents), and where relevant, the schedule for delivery of compliance documents.	Design organisation

Superseded

Repair Classification	Classification of the repair as either major or minor[3] (see DASR 21.A.435a). The classification of repairs is to meet the requirements of DASR 21.A.91 for changes to type certificates. Guidance regarding the classification of repairs is contained in Section 7.2.4. Classification is conducted by DASA or by an organisation holding an approval under DASR 21 Subpart J with a classification privilege under a procedure agreed with DASA[4].	DASA or appropriately approved design organisation under a procedure agreed with DASA
Repair Certification	The applicant shall establish the relevant CB for the repair, demonstrate compliance with the required CB elements, verify compliance and declare compliance. The applicant shall apply for a major repair approval by way of submittal of a DASR Form 31B and declaration of compliance to the DASA Type Certification Group mailbox. The Form 31B contains the MTCH declaration, confirming the organisation holding the MTC will carry out holder obligations related to the major repair. As per DASR 21.A.433(b) the applicant shall allow DASA to review any report, make any inspection and perform or witness any test necessary to check the validity of the submitted compliance statements.	Applicant that meets the eligibility criteria[5]
Repair Approval	Once a repair has been shown to meet the CB and applicable environmental protection requirements, and has been declared as such, DASA will issue a major repair design approval. The approval will be issued to the organisation holding the MTC who gains the obligations of the major repair approval holder IAW DASR 21.A.451.	DASA
Repair Configuration Management	Once the major repair design has been approved by DASA, the data can be used to accomplish the repair on the applicable aircraft (per DASR M.A.304(a)). The CAMO is responsible for managing the accomplishment of modifications and repairs (DASR M.A.708(b)(3)), and maintaining a record of aircraft configuration, which includes the status of modifications and repairs (DASR M.A.305(d)(2)).	CAMO
Production of Repair Parts	Produce repair parts	Appropriately approved production

		organisation, under DASR 21 Subpart G or Subpart F, or an appropriately approved maintenance organisation under DASR 145.
Repair Embodiment	Embody repair	Appropriately approved maintenance organisation under DASR 145 or appropriately approved production organisation under DASR 21 Subpart G.
Ongoing Holder Obligations	The organisation holding the MTC gains the obligations of the major repair approval holder IAW DASR 21.A.451	MTC holder

Table D.1: Detailed process for Scenario 1

Scenario 2 – Major Repair approved by an organisation holding an approval under DASR 21 Subpart J with major repair privileges

In Scenario 2 the organisation holding an approval under DASR 21 Subpart J has the privilege to approve certain major repairs IAW AMC2 21.A.263(c)(5). As part of this privilege, major repair approvals will be conducted under a procedure approved by DASA, which will include steps to ensure the privilege is only exercised when valid (refer Section 7.2.4 for further guidance). In cases where the MDOA cannot approve the specific major repair design under their current privilege they must either seek expansion of their privilege (refer AMC2 21.A.263(c)(5), (8) and (9)), or submit an application for DASA to approve the major repair (as per Scenario 1). The MDOA should also consider a means to provide a list of approved major repairs to DASA during surveillance activities (see AMC2 21.A.263(c)(5), (8) and (9) and GM 21.A.435(b)). The process for major repair approval for scenario 2 is outlined in Table D.2.

Stage	Description	Responsibility

Superseded

Identify and Assess Damage	As per Scenario 1	CAMO
Develop Repair Design	As per Scenario 1	Design organisation
Repair Classification	Classification IAW DASR 21.A.435a conducted by the privileged organisation holding an approval under DASR 21 Subpart J under a procedure agreed with DASA (see DASR 21.A.435(b)2). A procedure agreed by DASA is to be documented in the Handbook.	Appropriately approved design organisation under a procedure agreed with DASA
Repair Certification	Establish if the privilege to approve certain major repairs can be exercised for the specific repair design. If not, apply to DASA to extend the privilege, or follow Scenario 1. If the privilege to approve certain major repair designs can be exercised then the MDOA shall establish the CB, demonstrate compliance with the required CB elements, verify compliance and declare compliance.	Appropriately approved design organisation under a procedure agreed with DASA
Repair Approval	IAW DASR 21.A.435(b)2, once a repair has been shown and declared to meet the CB and applicable environmental requirements, a major repair shall be approved by the privileged organisation holding an approval under DASR 21 Subpart J. The approval procedures are to have been agreed by DASA and documented in the Handbook. In the case where compliance is found with a standard other than that in the TCB, this assessment is considered as interpretation of standards. DASA is the only organisation able to interpret standards[5] and as such approve the repair. In this case Scenario 1 is applicable.	Appropriately approved design organisation under a procedure agreed with DASA
Repair Configuration Management	Once the major repair design has been approved by the design organisation, the data can be used to accomplish the repair on the applicable aircraft (per DASR M.A.304(b)). The CAMO is responsible for	CAMO

Superseded

	managing the accomplishment of modifications and repairs (DASR M.A.708(b)(3)), and maintaining a record of aircraft configuration, which includes the status of modifications and repairs (DASR M.A.305(d)(2)).	
Production of Repair Parts	Produce repair parts	As per Scenario 1
Repair Embodiment	Embody repair	As per Scenario 1
Ongoing Holder Obligations	As per Scenario 1	MTC holder
DASA Review of Approved Repairs	If following the GM 21.A.435(b), consideration should be given to maintaining a summary list of major repair approvals conducted by the privileged organisation holding an approval underDASR 21 Subpart J for review by DASA during surveillance activities. The periodicity of the provision of this summary list is to be as agreed with DASA and documented in the Handbook. This list should provide summary details of the repair approvals including: • title and purpose of design • applicable product and system • amendments to ICA • damage description • damaged part numbers • affected areas • reference to the reporting source • reference to the substantiating data • reference to the assessment of Configuration, Role and Environment (CRE) compatibility • repair description	Appropriately approved design organisation under a procedure agreed with DASA

Table D.2: Detailed process for Scenario 2

Scenario 3 – Major Repair which has not been approved by a CAA/MAA and which has been developed by an organisation which does not hold an organisational design approval issued by a DASA recognised CAA/MAA

(e) This scenario documents the process by which major repair data developed by an organisation from outside of an airworthiness framework for which recognition is applicable,

Superseded

or from within an airworthiness framework for which the recognition scope, conditions and caveats do not allow for direct consumption of major repairs. In this scenario there is no scope to leverage a recognition framework for direct consumption; however, the data may be used to support an application for approval by DASA or by an appropriately privileged organisation holding an approval under DASR 21 Subpart J. The detailed process is shown at Table D.3.

Stage	Description	Responsibility
Identify and Assess Damage	As per scenario 1	CAMO
Develop Repair Design	Repair data has been produced by an organisation outside of the DASA approval framework, from an airworthiness system that has not been recognised by DASA for direct consumption of major repairs.	Design organisation
Repair Classification	As per scenario 1 or scenario 2 depending on privileges.	As per scenario 1 or scenario 2 depending on privileges
Repair Certification	As per scenario 1 or scenario 2 depending on privileges. Note: the data developed by the design organisation may be used by the applicant to seek relief from developing compliance documents themselves, to support an application for approval to DASA.	As per scenario 1 or scenario 2 depending on privileges
Repair Approval	As per scenario 1 or scenario 2 depending on privileges.	As per scenario 1 or scenario 2 depending on privileges
Repair Configuration Management	As per scenario 1 or scenario 2 depending on privileges.	CAMO
Production of Repair Parts	Produce repair parts	As per scenario 1

Superseded

Repair Embodiment	Embody repair	As per scenario 1
Ongoing Holder Obligations	As per scenario 1	MTC holder

Table D.3: Detailed Process for Scenario 3

Scenario 4 – Approval of unrepaired damage utilising major repair provisions where compliance can be shown with the TCB

(f) This scenario documents the process by which unrepaired damage can be shown to be in compliance with the TCB. This process may also be applied to the case when an individual aircraft without damage is to be flown beyond an existing AwL.

(g) This scenario may be used for managing the demonstration of compliance with the TCB of unrepaired damage for which a repair is required, and for which implementation of additional maintenance inspections or limitations would allow demonstration of compliance with the TCB. In this case, the CAMO seeks an approved design from an organisation holding an approval under DASR 21 Subpart J with access to appropriate type design data.

(h) The limitations may be related to the limit of duration of the approval; however, operational limitations such as flight restrictions are not managed within this scenario. Flight restrictions are to be managed via the Military Permit To Fly (MPTF) process.

(i) Where an individual aircraft without damage is to be flown beyond an AwL item and where compliance with the risk level inherent in the TCB can be demonstrated, and is approved via a major repair approval for unrepaired damage, the arrangements described in this scenario are also applicable. In this case, it constitutes a major repair[8] and follows the approval process outlined herein. Where compliance with the TCB cannot be shown, a major repair approval is not an appropriate authorisation. In this case a MPTF should be considered[9].

Stage	Description	Responsibility
Identify and Assess Damage	As per scenario 1	CAMO
Develop Repair Design	A design is developed which shows that compliance with the TCB can still be demonstrated.	Design organisation
Repair Classification	As per scenario 1 or scenario 2 depending on privileges.	As per scenario 1 or scenario 2 depending on privileges

Superseded

Repair Certification	As per scenario 1 or scenario 2 depending on privileges.	As per scenario 1 or scenario 2 depending on privileges
Repair Approval	As per scenario 1 or scenario 2 depending on privileges. Note: where the design organisation is not the organisation holding the MTC or supporting this organisation, the design organisation must justify that the information on which the evaluation is based is adequate as per DASR 21.A.445(b).	As per scenario 1 or scenario 2 depending on privileges
Repair Configuration Management	As per scenario 1 or scenario 2 depending on privileges.	CAMO
Production of Repair Parts	Produce repair parts	As per scenario 1
Repair Embodiment	Embody repair	As per scenario 1
Ongoing Holder Obligations	As per scenario 1	MTC holder

Table D.4: Detailed Process for Scenario 4

Scenario 5 – Staged approval of damage tolerant repairs

(j) The process by which approval of repairs that include fatigue and damage tolerance evaluation may be staged, to allow an operator to return an individual aircraft to service before all of the fatigue or damage tolerance data has been developed and approved. Note that such repairs are considered major repairs and a staged approach for repairs which include fatigue and damage tolerance evaluation may only be applied for aircraft types for which the basis for fatigue or damage tolerance evaluation is part of the TCB[11]. Note, propulsion systems, and dynamic systems for helicopters, are not eligible for the staged approval process. The general approach outlined below follows the 3-stage approach documented in FAA Advisory Circular 120-93 Appendix 5: Approval Process for New Repairs; however, it is noted that the implementation of the stages is to be outlined as part of the CP, and the combination of stages into a one or two-staged delivery may be appropriate depending on the repair requirements. The stages are described below:

Superseded

1. The first stage is approval of the static strength data and the schedule for submittal of the fatigue or damage tolerance data. This approval is required prior to returning an aircraft to service. For a staged approach to be considered acceptable, good damage-tolerant design practices are required. Prior to a staged approach being invoked, an assessment of the suitability of a damage-tolerant approach with staged approval is to be considered and documented in the CP.

2. The second stage is approval of the fatigue or damage tolerance data. The fatigue or damage tolerance data should be submitted no later than agreed as part of the stage 1 approval . Damage tolerance data might only contain the threshold where inspections are required to begin as long as a process is in place to develop the required inspection method and recurring intervals before the threshold is reached. In this case, the submittal and approval of the remaining damage tolerance data may be deferred to the third stage.

3. The third stage is approval of the damage tolerance data not submitted and approved in the second stage. This would typically involve the inspection method and the recurring intervals. This data would need to be submitted and approved prior to the inspection threshold being reached. Operation beyond the threshold would not be allowed unless the data are submitted to and approved by DASA.

(k) Organisations with major repair approval privileges who wish to approve damage tolerant repairs in a staged process, are to have documented the process via which these approvals will be conducted in the Handbook as per DASR 21.A.435(b)2.

Stage	Description	Responsibility
Identify and Assess Damage	As per scenario 1	CAMO
Develop Repair Design	As per Scenario 1; however, the repair design development may be staged as per paragraph 10.	Design organisation
Repair Classification	As per scenario 1; however, due to the nature of a repair requiring Damage Tolerance Evaluation it is expected that the repair is classified as major[12]	DASA or appropriately approved design organisation under a procedure agreed with DASA
Repair Certification	As the compliance demonstration process is to be staged, a CP is to be established as per the Major Design Changes, see DASR 21.A.93(b), related AMC and GM and Section 7.2.3.	Applicant that meets the eligibility criteria.[13]

Superseded

	DASA may be notified of an upcoming major repair design via a DASR Form 31 directed to the DASA Type Certification Group mailbox. The applicant shall apply for a major repair design approval by way of submittal of a DASR Form 31B and declaration of compliance. The Form 31B is to be submitted to the DASA Type Certification Group mailbox. As the approval process is to be staged, separate applications for approval will be made at each stage of the process as planned in the CP. Each application is made via a DASR Form 31B which clearly documents the extent of the approval applied for.	
Repair Approval	As per scenario 1 or scenario 2 depending on privileges; however, in this case approval is staged with clear limitations to the extent of the approval documented.	As per scenario 1 or scenario 2 depending on privileges
Repair Configuration Management	As per scenario 1 or scenario 2 depending on privileges; however it is critical that when a staged approval process is implemented that the CAMO identifies the staged limits in the maintenance documentation to ensure that the limits are not overflown prior to the approval of the relevant next stage.	CAMO
Production of Repair Parts	Produce repair parts	As per Scenario 1
Repair Embodiment	Embody repair	As per Scenario 1
Ongoing Holder Obligations	As per Scenario 1	MTC holder

Table D.5: Detailed Process for Scenario 5

Scenario 6 – Approval of new repairs based on pre-approved repairs contained in the type data set

(l) This scenario documents the process by which new repairs developed based on those contained in the aircraft repair manual, or based on repairs previously developed for the aircraft, but outside of the limitations of the existing repair approval, are approved. When

Superseded

repairs are developed that are outside of the limitations (for example effectivity and location) of the previously-approved repair scheme they are treated as new repairs, and follow the processes documented in Scenarios 1 and 2. This scenario may leverage compliance demonstration documents developed for previously approved repairs, where applicable, as part of the demonstration of compliance. This may make the repair certification and approval steps more straightforward, but these steps are still required to be conducted.

Stage	Description	Responsibility
Identify and Assess Damage	As per scenario 1	CAMO
Develop Repair Design	A design, based on a pre-approved repair, but not within the pre-approved limitations of that repair, is developed.	Design organisation
Repair Classification	As per scenario 1 or scenario 2 depending on privileges.	As per scenario 1 or scenario 2 depending on privileges
Repair Certification	As per scenario 1 or scenario 2 depending on privileges. Note: compliance demonstration documents developed for previously approved repairs, where applicable, may be leveraged as part of the demonstration of compliance.	As per scenario 1 or scenario 2 depending on privileges
Repair Approval	As per scenario 1 or scenario 2 depending on privileges.	As per scenario 1 or scenario 2 depending on privileges
Repair Configuration Management	As per scenario 1 or scenario 2 depending on privileges.	CAMO
Production of Repair Parts	Produce repair parts	As per scenario 1
Repair Embodiment	Embody repair	As per scenario 1

Superseded

Ongoing Holder Obligations	As per scenario 1	MTC holder

Table D.6: Detailed Process for Scenario 6

Scenario 7 – Approval of changes to the approved type design repair data

(m) Manuals and other Instructions for Continuing Airworthiness (ICA) (such as the Manufacturer's Structural Repair Manual (SRM), Maintenance Manuals and Engine Manuals provided by the holder of the type-certificate, supplemental type-certificate, design approval or Auxiliary Power Unit (APU) AUSMTSO authorisation as applicable) for operators, contain useful information for the development and approval of repairs. When these data are explicitly identified as approved, they may be used by operators without further approval to respond to anticipated in-service problems arising from normal usage, provided that they are used strictly for the purpose for which they have been developed.

(n) The process by which changes to any pre-approved repairs, as documented in the aircraft ICA (such as the SRM), are approved is considered a change to the type certificate (i.e. DASR 21 Subpart D).

(o) Changes to the approved repair schemes provided for the platform are to be treated as changes to type and classified / managed IAW DASR 21 Subpart D[14]. When developing standard repairs as changes to the type certificate, the developer should also take into account GM 21.A.435(a) and AMC 21.A.433(a) respectively for classifying and substantiating the design. In the case of changes to the previously-approved data being developed by the aircraft OEM, a CRE assessment is required to be included as part of the application for approval of the change to the type certificate. Note that, once the change to the type certificate for the repair is approved, updates to the ICA (such as SRM), which promulgates that repair data, is managed by the organisation holding the MTC, under a procedure agreed with DASA IAW DASR 21.A.61 and DASR 21.A.57 by the organisation holding the MTC.

Superseded

Annex E - Propulsion System Related Risk Analysis

Aim

(a) This Annex provides a generic overview of the process that may be followed when assessing the risk to an Australian Defence Force (ADF) aircraft fleet when a notable propulsion system related hazard is identified. This Annex ostensibly supports the broader risk management process that would underpin the response to an unsafe condition associated with a propulsion system design or manufacturing deficiency, or a certification shortfall.

(b) This Annex provides guidance to understand a Risk Analysis (RA) generated by a propulsion system Original Equipment Manufacturer (OEM) and identifies the key steps the operator should consider when characterising technical risk as part their 7-step risk management process. This Annex does not provide tools or equations to conduct a RA[1].

Introduction

(c) In the event of a propulsion system related component failure, in particular one that would lead to an unsafe condition[2], it is imperative to understand the failure mechanism and the risk that additional failures may pose to ongoing and future ADF operations.

(d) Due to typically high production, repair, and replacement costs, and potential logistics constraints for propulsion system components, the operator may be required to operate an aircraft fleet at a higher risk for a period of time. In order to continue operations, the risk must be eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) and retained at the appropriate level. In order to characterise the risk to the ADF fleet and conduct a robust RA, adequate information on the failure mechanism, understanding the population at risk, failure rate data, propulsion system usage, maintenance history and propulsion system component life distributions are required. Generally, type design data access limitations will mean that the engine OEM conducts the RA for the ADF; however this may not always be the case.

DASA Recommended Propulsion Risk Analysis Approach

(e) When attempting to characterise the risk of a propulsion system related hazard that may lead to a hazardous propulsion system effect[3], DASA recommends using an approach aligned with *FAA AC39–8 - Continuing Airworthiness Assessment Methodology*, in combination with appropriate engineering judgement and consideration of individual operator context, to identify and assesses strategies to eliminate or otherwise minimise the hazard SFARP[4]. The approach outlined in AC39-8 is well understood by industry and is used by engine OEMs globally to manage propulsion system related hazards and communicate risk to the relevant regulators and operators. Further guidance on understanding the conduct of risk analysis for propulsion systems can be found within the *FAA Risk Analysis Correspondence Course*.

(f) The Defence Harmonised Risk Matrix (DHRM) and aircraft System Safety Programs (SSP) are focused on the instantaneous or average risk to the fleet at the point in time the risk was calculated. They usually do not fully account for the future utilisation of the fleet or the risk associated with any mitigation strategies that may be utilised to minimise the risk across an

Superseded

extended campaign. As propulsion system related hazards may take a relatively long time to remediate and often involve complex interim risk controls, DHRM or the SSP should not be used as the sole mechanism to characterise the risk.

Generic RA Mathodology Post Fleet Identification

(g) There is no 'one size fits all' approach to risk management and not every identified hazard requires the conduct of a detailed risk analysis as outlined in the following steps. The following approach provides guidance on the process that should be followed in order to conduct a more detailed RA for a hazard that has been identified as complex, or requires risk to be retained for an extended period. RAs are only approximations based on the information available at the time. As such, good engineering judgement and a pragmatic approach should be used when an RA is performed.

(h) Typical propulsion system failure investigations can often take months to identify root cause and contributing factors. As such, in order to support Commanders in the short-term, a simple RA should be conducted in order to determine the immediate risk to the ADF fleet. It would require ADF, and if applicable, global fleet life usage data of the affected component (i.e. Time Since New, Time Since Overhaul, engine cycles, number of global failures). The RA should be conducted at the aircraft level using a method consistent with the platform SSP, in order to quantify the immediate risk to the fleet where the likelihood value would be defined as failures 'per AFHR' or 'per ENHR'. The likelihood value and the consequence of the failure are then applied to the platform SSP to generate a system safety Hazard Risk Index (HRI). The calculated HRI and any other applicable technical data related to the failure should be provided to the operator to support the operator's risk management process.

(i) To support an initial decision regarding the risk to continuing ADF operations, the operator should use the risk management process applicable to their platform (usually DHRM) to make an initial determination whether to continue operation. This is expected to be informed by knowledge of the event, the initial HRI, available technical data, and available technical and operational risk controls. It is likely that technical data, such as root cause or identification of an 'at risk' population will not be known at this time and therefore specialist judgement will be required.

(j) Once more information on the failure mode is available, and it is identified that the hazard is likely to manifest in other aircraft, a detailed RA should be conducted to enable a more accurate estimation of the likelihood of a similar failure occurring in the future. This is generally developed once more data is gathered by the organisation conducting the RA on the global fleet and individual fleet usage statistics. OEMs will usually be heavily engaged in developing detailed RAs for propulsion systems, and therefore are the usual, but not only, source of RA data[5].

(k) A detailed RA for propulsion system issues usually involves the following steps:

1. **Inputs to detailed RA.** When conducting an RA, a representative dataset of the affected component should be compiled. It would include the current fleet life distribution of the suspect pool of components, life accrual details of the failed components and any data associated with the failure mechanism of the component.

2. **Developing a Representative Statistical Distribution.** Utilising the dataset from step 11.a, a statistical distribution (i.e. Weibull, lognormal, etc., depending on the failure characteristics and dataset) should be generated. A Weibull plot (see Figure 1) is

Superseded

commonly used in industry to model failure data, although other statistical methods may be used by the OEM (or organisation conducting the RA) depending on their processes or the failure mechanism. The Weibull plot typically represents time to failure or another similar usage parameter on the x-axis versus cumulative failure probability for the component population on the y-axis. The Weibull distribution is typically defined by two parameters: the shape parameter, called the 'slope' or β, and the scale parameter, also called the 'characteristic life', θ or η (note these symbols may vary). These parameters define the specific component failure distribution and corresponding plot.

Figure 1 - Example Weibull Chart

3. **Develop the Cumulative Density Function (CDF).** Based on the statistical distribution generated in step 11.b, a failure probability curve (also referred to as the CDF curve or per part probability of failure curve) should be produced for the affected part. The cumulative probability of failure from time zero until a given time is displayed by this curve and is used to estimate the proportion of components that will fail over a period of time. The y-axis of the CDF curve ranges from 0-1 (or 0%-100%) and is a probability

Superseded

value. Generally, the OEM may only provide an excerpt of the CDF to align with the current life limit of the affected component as shown in Figure 2 below.

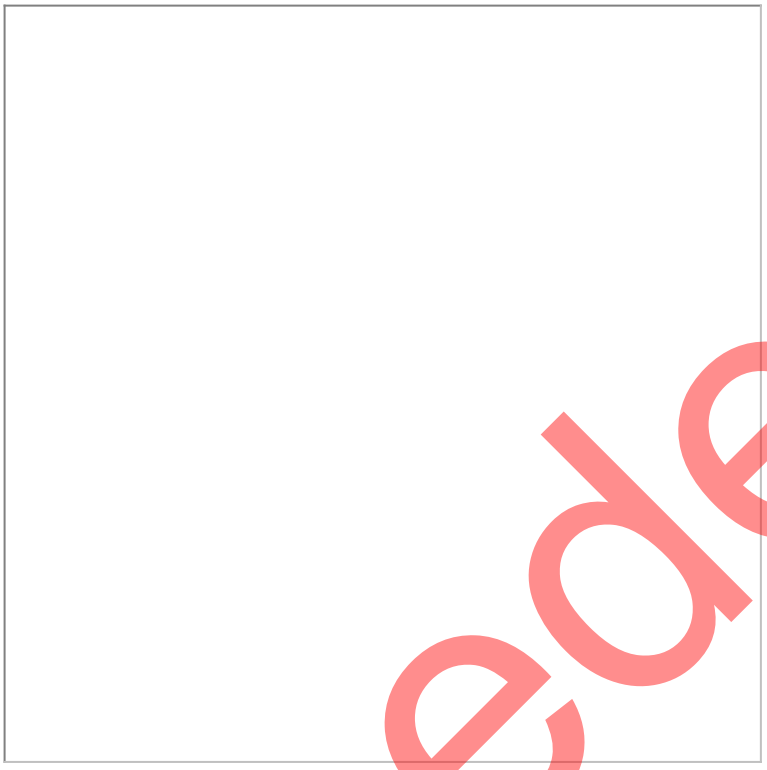
Figure 2 - Weibull CDF Curve

4. **Validate Weibull & CDF Curve.** Having produced a statistical model, it is important that the model be validated against the real world understanding of the problem. This is often achieved by calculating the historical predicted number of events (PNE) and comparing that to the actual number of events experienced to date. The PNE for the fleet is calculated by summing all the individual component probabilities of failure calculated from the CDF curve. Where there is significant difference between the statistical model and actual fleet experience, the assumptions, data and model type may need to be revised. When using PNE as part of the risk assessment process, it is important to understand the following:

   i. The PNE cannot be translated directly to a probability of failure (%). Using the PNE (ϕ) for the ADF fleet at any point in time, the probability that a discrete

Superseded

number of failures (x) will have occurred in the fleet can be calculated using the Poisson distribution as follows



For example, if the PNE for affected components to-date was calculated to be 0.33, the probability of having an 'X' event up until the point of calculation is detailed within Table 1 below:

Table 1 - Historical PNE depicting the probability of events occurred to-date

Superseded

5. **Develop a Fleet Management Strategy.** As previously identified, elimination of a propulsion fleet hazard can take years to implement, especially if a change to type design is required or there are considerable logistics constraints. As such, the operator supported by the relevant engineering, logistics and maintenance organisations will need to develop a fleet management strategy to eliminate or minimise the risk SFARP. Fleet management strategies usually include requirements for minimum aircraft availability, expected rate of effort (ROE), maintenance capacity and turnaround times, interim or final airworthiness / inspection limit reductions, and any other relevant logistics or operational constraints. When developing a fleet management strategy, it is common for multiple scenarios to be developed to examine the corresponding risk, cost and operational impact. The time period where the ADF fleet is exposed to an elevated level of risk, as predicted by the fleet management strategy, is defined as the campaign period.

6. **Determine Future PNE.** Utilising the CDF curve for the failure, the life usage distribution of the affected components and the assumed future utilisation rate(s) for the fleet, the future PNE can be calculated for the campaign period. A PNE estimate should be produced for every fleet management strategy scenario, including a 'baseline' scenario where no action is taken to mitigate the risk. This method has significant advantages over traditional average probability of failure based methods, as it enables the operator to understand how variations in operational requirements, logistics constraints, and engineering risk controls influence risk over the campaign period. Figure 3 provides an example of how the cumulative PNE for an example fleet varies based on different fleet management scenarios. This type of model can further inform the Risk Management Authority (RMA) when selecting a fleet management strategy that is SFARP, when balanced against contextual considerations (i.e. logistics, cost, time-to-implement, capability requirements).

Superseded

Figure 3 - PNE Comparison

7. As per the example in Table 2 below, Poisson distribution must be used to convert the final PNE for each scenario into a probability of a discrete event (i.e. 0, 1, 2 … n events). This should be applied to each fleet management scenario to determine the likelihood of zero and non-zero events occurring over the campaign period.

Superseded

Table 2 - Probability of 'X' Events Occurring During Campaign Period

(l) Once this analysis is complete, each fleet management strategy scenario and the subsequent risk can be used to inform the risk characterisation step in the 7-step risk management process. This allows the RMA to understand the long-term risk for each scenario, and to allow for the adoption of a fleet management strategy that balances operational impact, cost and risk. Importantly, this approach does not replace an operator's DHRM or SSP, but rather supplements those approaches with a method that provides increased visibility and understanding of risk drivers.

(m) **Monitoring Risk.** Once a risk fleet management strategy has been implemented it is possible to track progress against that plan to support risk monitoring. Should there be notable deviations from the plan, further information relating to root cause, or changes to underlying assumptions identified, the RA should be revised. This includes changes to assumptions made when developing the fleet management strategy.

Superseded

(a) Risk management activities that warrant the use of this approach to characterise the risk of a propulsion system hazard would usually require retention of an elevated level of risk to aviation safety for a period of time. In these circumstances, the operator would normally seek independent safety assurance from DASA via the Military Permit to Fly (MPTF) process (refer DASR 21 Subpart P and DASP Manual Volume 3 Section 7.5 for further information). Alternatively, the risk analysis process outlined herein may support the proposed corrective actions for DASA to issue Airworthiness Directive (AD) (refer to DASR 21.A.3B and DASP Manual Volume 3 Section 7.4.3 for further information).

Further Assistance

15. The Propulsion System Integrity (PSI) Section in DAVENG acts as the aerospace propulsion system integrity Centre of Expertise for Defence[6], and can provide additional information and training on the RA methodology outlined within this Annex. PSI Section and DSTG can also assist with reviewing, interpreting and validating OEM RAs to determine if the methodology, assumptions and data used in generating the RA is appropriate.

Risk Analysis Terms and Definitions

Component (or part) risk. Risk from operating one of the parts of a particular type in the fleet; risk from operating a single component or part.

Cumulative Density Function, CDF – F(t). The cumulative probability of failure from time zero until time t. CDF is used to estimate the proportion of components that will fail over a period of time. It is also referred to as Per Part Probability of failure

Cumulative. Cumulative refers to failures or risk accumulated from a beginning time point to a later point; stated as total expected failures, etc.

Current risk. Today's risk based on current in-service management practices.

Engine risk. Rollup of risk from all critical parts in one single engine, or rollup of risk from all modules in one engine.

Expected failures. The expected number of failures over an extended time (part life or age, calendar time, etc.); usually stated as failures or fractions of failures (0.0, 0.2, 0.4, 1.05, 2.0, etc.).

Failure rate. The expected failures or events over a specified time period, stated as expected failures per X hours, X cycles, etc.

Fleet risk. Rollup of risk from the total population of that critical part, or module or engine in the fleet.

Future risk. Risk projected at a later date based on current or alternate in-service management practices.

Hazard Rate. This is the instantaneous probability of failure per unit time. Instantaneous failure rate or we say instantaneous hazard rate

Superseded

PoF. Probability of Failure

Predicted Number of Events, PNE. The estimated number of times an engine/component failure will occur in a given fleet expressed over a given campaign period. Also referred to as Expected Number of Events, ENE

Probability of occurrence or failure. The probability of 1 event (or more) occurring; stated as 0.0 to 1.0, or zero to 100%.

Risk analysis. A probabilistic method used to estimate, among other things, the expected number of 'events' (e.g. cracking, failure) in a given period of time and to estimate the probability of one 'event' or more occurring in that time period

Risk methodology. Statistical methods used to conduct the risk analysis. Typically, a Monte Carlo computer simulation model manipulates inputs such as part life distribution, part age histogram, and fleet operational data such as life limits, cycles or hours/month, maintenance scenarios, etc., to produce the above defined outputs. The statistical distribution of failures can be assumed as normal, log normal, Weibull, etc.

Weibull Parameters. For wear-out problems, the Weibull distribution will have a slope greater than 1, and values typically are in the range of 3 to 5, but may vary. A Weibull distribution with a slope equal or close to 1 reflects a random failure mode, and a slope of less than 1 is indicative of infant mortality

7.1 Introduction

7.1.1 Background

7.1.1.1 While there is no internationally-accepted definition for Initial Airworthiness, common definitions for 'initial' (happening at the beginning) and 'airworthiness' (the fact of an aircraft being safe to fly) are helpful. After all, Initial Airworthiness does indeed focus extensively on whether a new aircraft is initially safe to fly - that is, whether it has been suitably designed and manufactured.

7.1.1.2 However, by convention, Initial Airworthiness also encompasses any design changes subsequently made to the new aircraft (including the certification of those changes) and the design of repairs. Furthermore, it includes the activities needed to ensure the design remains safe throughout its lifecycle, although this activity is often termed 'continued' airworthiness (not to be confused with 'continuing' airworthiness, per chapter 8).

7.1.1.3 This chapter presents an overview of the DASR approach to aircraft design, production and certification, which are the activities commonly associated with initial and continued airworthiness. The subsequent chapters will then explore several of these concepts in more detail.

7.1.1.4 Note this chapter is relevant only to Defence Registered aircraft; for non-Defence Registered aircraft, all initial and continued airworthiness functions are conducted per the requirements of the relevant Civil or military Aviation Authority (normally CASA).

7.1.2 DASR 21 – Aircraft Design, Production and Certification

7.1.2.1 From an Initial and Continued Airworthiness (INCA) perspective, an aircraft's lifecycle might follow a progression something like this:

a. To start, an engineering organisation demonstrates its professional ability to produce an aircraft design ('design organisation approval').

b. Next, the organisation produces a new aircraft design, and an Aviation Authority certifies that the design is suitably safe ('aircraft design and certification').

c. Individual aircraft are then produced, and an Aviation Authority certifies each as conforming to the certified design ('aircraft production and certification').

d. Over the following decades of fleet operation, numerous Minor and Major design changes and repairs will be made to the aircraft ('aircraft design changes and repairs').

e. Occasionally, there may be a need for limited flying of a possibly unairworthy aircraft, either to demonstrate a new capability or to avoid grounding an important asset ('permit to fly').

Superseded

f. Critically, throughout this complex lifecycle, an engineering organisation will need to monitor for defects in the design, facilitate risk management of the design, and so on ('type certificate holder').

g. Finally, an Aviation Authority might occasionally mandate certain remediation actions in the interests of fleet safety ('airworthiness directives').

7.1.2.2 Each of these seven functions, and several others, is regulated under DASR Pt 21– *Aircraft Design, Production and Certification.* The remainder of this chapter provides a brief summary of these functions.

7.1.2.3 **Design organisation approval.** Deficiencies in an aircraft's design can range from those with immediate catastrophic consequences (eg inadequate structural strength), to an erosion of safety margins (eg misleading navigation information), to an annoyance (eg a Minor human-machine interface flaw). Designing an aircraft where risks have been eliminated or otherwise minimised so far as is reasonably practicable (SFARP) is a particularly complex endeavour.

7.1.2.4 Consequently, the initial design of Defence aircraft should only be undertaken by skilled individuals within professional aircraft design organisations. DASRs make provision for DASA to issue Military Design Organisation Approval (MDOA) status to organisations who have demonstrated that they are able to maintain a design assurance system for the control and supervision of the design, and of design changes, of aircraft products, parts and appliances.

7.1.2.5 DASA's default expectation is that a new Defence aircraft will be designed by a MDOA of suitable scope. As a matter of pragmatism, however, DASR also make provision for Defence to accept designs that have been certified by a DASA-recognised civil or military Aviation Authority (CAA/MAA), without the need for the design organisation to be a DASA-approved MDOA, within certain bounds. This approach, often called 'prior acceptance' is explored in Chapter 7.2, *Product Certification*. These same provisions apply for design changes to an extant aircraft.

7.1.2.6 MDOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.7 **Initial aircraft design and certification.** Defence periodically acquires aircraft to meet a capability need. In practice, Defence usually acquires its new aircraft as off-the-shelf designs, and then incorporates design changes to cater for Defence's unique roles and operating environment. The entire design will meet a set of airworthiness requirements - commonly called a Type Certification Basis (TCB) - and the designer(s) will produce extensive evidence (via analysis, test and other means) to demonstrate that their design meets the TCB.

7.1.2.8 As noted in paragraph 7.1.2.5, these designs will be produced by a DASA-approved MDOA, or a design organisation whose design is certified by a DASA-recognised CAA/MAA, or sometimes both. Regardless, the final design will always be certified by DASA, signified by the issue of a Military Type Certificate (MTC)[1] for the aircraft.

7.1.2.9 In the absence of a pertinent CAA/MAA certification, DASA's certification for a new aircraft would be an immense undertaking for both DASA and the Defence acquisition organisation. More commonly, however, there will be a pertinent CAA/MAA certification, and leveraging off this certification can substantially reduce the impost on both organisations. In that case, much of the effort focuses on whether the certified design is compatible with Defence's intended Configuration, Role and Environment (CRE). Chapter 7.2, Product Certification, explores the certification process in detail.

Superseded

7.1.2.10 **Aircraft production and certification.** An expertly designed and certified aircraft provides the basis for safe aircraft operation. However, just as importantly, that design must be accurately implemented on the Defence aircraft.

7.1.2.11 DASR make provision for DASA to issue a Military Production Organisation Approval (MPOA) to an organisation when assured they have the ability to manufacture aircraft parts and appliances in conformity with approved data. DASR also make provision for Defence to accept an aircraft produced under the systems of a DASA-recognised CAA/MAA. This latter approach is used for most new Defence aircraft.

7.1.2.112 Following production of an individual aircraft, DASA must certify that the aircraft is in a state of airworthiness per the inherent level of safety specified on the MTC. This certification is signified by the DASA issue of a Military Certificate of Airworthiness (MCoA)[2] for each individual Defence aircraft.

7.1.2.13 Aircraft production and MCoAs are explored in Chapter 7.3, Production. MPOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.14 **Aircraft design changes and repairs.** Defence aircraft will usually be in service for several decades. During this time, numerous design changes will inevitably be implemented, either to enhance military capability or to address design or obsolescence problems. These design changes are classified under DASR as either Minor of Major, differentiated by the degree of airworthiness effect of the design change.

7.1.2.15 The DASR approach for Minor and Major design changes is very similar. They will both be performed by a DASA-approved MDOA or another design organisation whose design is certified by a recognised CAA/MAA, and both should preserve the level of airworthiness of the aircraft. For Major design changes, however, DASA will usually provide a proportionate level of independent assurance, and DASA itself will usually certify the design as safe. This certification is usually via an amendment to the MTC, although occasionally a Military Supplemental Type Certificate (MSTC) may be issued. Chapter 7.2, Product Certification, explores the certification process in detail.

7.1.2.16 Throughout an aircraft's life, degradation (damage) of the systems/structures integrity supporting safe flight may be compromised through direct (accidental impact and battle damage) overload, or insidious (fatigue, corrosion, moisture ingress, dis-bond, ultraviolet light etc) environmental sources. Repairs are those actions developed and implemented to restore damaged products to a suitably airworthy state. Similar to aircraft design changes, aircraft repairs are classified under DASR as Minor or Major, must be designed by a MDOA or other organisation agreed by DASA, and may be subjected to a proportionate level of DASA independent assurance.

7.1.2.17 **Permit to fly.** A Military Permit to Fly (MPTF) may be issued by DASA for an aircraft that does not meet, or has not been shown to meet, the requirements of its TCB, but is nonetheless capable of safe flight under defined conditions and for specified purposes. MPTFs are most commonly used for flight test (for aircraft development or role expansion activities), for flights where the design has not yet been certified, or for flights where the aircraft temporarily does not conform to the Type Design (eg due to unrepaired damaged, overdue maintenance, etc).

7.1.2.18 An MPTF may or may not entail an elevated level of risk, and is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application. Chapter 7.5, Flight Conditions and Military Permits to Fly, explores this in more detail.

Superseded

7.1.2.19 **Type certificate holder.** As noted earlier in this chapter, DASA issues an MTC for Defence Registered aircraft types. This MTC is issued to a suitable Commonwealth government organisation (usually the relevant Defence Systems Program Office), who are then charged with 'holding' the MTC.

7.1.2.20 Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed, and the level of safety inherent in the TCB is maintained. This includes, for a particular aircraft type, collecting aviation safety information (both locally and from external sources), ensuring operators are aware of extant hazards, ensuring that essential risk controls remain effective, leading local efforts to eliminate or further minimise known risks, and many other important roles.

7.1.2.21 These expansive holding responsibilities are often beyond the capacity and capability of the government organisation holding the MTC. Consequently, responsibility for the conduct of MTCH obligations is often vested with various support organisations, for example contractors, foreign project offices and other military operators. The government organisation remains accountable for all activities undertaken by those organisations.

7.1.2.22 Chapter 7.4, Continued Airworthiness, explores the MTCH role in more detail.

7.1.2.23 **Airworthiness directives.** In the Australian Defence context, the WHS Act and DASR place responsibility and obligation solely on the regulated community for managing the day-to-day safety of their aircraft, and for ensuring risks are eliminated or otherwise minimised so far as is reasonably practicable. DASR do, however, still make provision for DASA to mandate actions and/or impose conditions on aircraft operation in certain circumstances. This is achieved through the issue of an Airworthiness Directive (AD).

7.1.2.24 Like its civil counterpart, ADs under DASR provide a means to mandate an action in order to restore an aircraft to an acceptable level of safety, where that safety level may be otherwise compromised. However, due to Defence's unique context, DASA issues ADs infrequently, particularly in comparison to civil aviation.

7.1.2.25 Chapter 7.4, Continued Airworthiness, explores DASR ADs in more detail.

7.1.2.26 **Other.** In addition to the seven common INCA functions mentioned above, DASR 21 also makes provision for a number of niche functions. Since this chapter aims to provide an overview of INCA that is consumable to a wide audience, these niche functions will not be explored here. They include: Australian Military Technical Standard Order (AUSMTSO) authorisations, restricted type certificates, restricted certificates of airworthiness, approval of parts and appliances, and the identification of parts and appliances.

Structure of these chapters

7.1.2.27 This chapter has provided a brief overview of the functions encompassed within Initial and Continued Airworthiness. The subsequent chapters explore several of these functions in greater detail, as follows:

a. Chapter 7.2: Product certification

b. Chapter 7.3: Production and military certificates of airworthiness

c. Chapter 7.4: Continued airworthiness (including military type certificate holders, occurrence reporting, airworthiness directives and other organisational approvals)

d. Chapter 7.5: Flight conditions and military permits to fly

Superseded

e. Chapter 7.6: Design and production organisations.

7.2 Product Certification

7.2.1 – Introduction

7.2.1.1. Product certification authorisations represent DASA's assurance that an individual product complies with the applicable airworthiness[3] requirements. These are issued following review of compliance evidence presented by the applicant seeking product certification. Product certification authorisations covered under this chapter are MTCs, Changes to MTCs, MSTCs, and Repair Designs.

7.2.1.2. Product certification authorisations are built around four pillars of safety assurance; Organisational Capability, Compliance demonstration, Compliance Verification, and Obligations of the holder

7.2.1.3. **Organisational Capability.** Before an organisation can apply for a product certification, they need to be eligible. Eligibility is based on an assessment of whether the organisation is equipped/ resourced to achieve a successful authorisation.

7.2.1.4. **Compliance Demonstration.** The applicant for a product certification authorisation must show that their product complies with the applicable airworthiness requirements.

7.2.1.5. **Compliance Verification.** The authority must independently verify that compliance has been achieved to the applicable airworthiness requirements. As compliance demonstration and compliance verification are intrinsically linked, a certification programme is put in place to document the means by which the applicant will demonstrate compliance and the authority will verify compliance.

7.2.1.6. **Obligations of the Holder.** Following issue of a certification approval, the certificate holder must continue to carry out obligations outlined under the DASRs to ensure the product certification remains safe.

7.2.1.7. The following sections expand upon these safety assurance areas for each product certification authorisation.

7.2.2 – Type Certification – Military Type Certificates (DASR 21 Subpart B)

Overview

7.2.2.1 **Scope of Section.** Section 7.2.2 describes the DASR type certification process for obtaining a Military Type Certificate (MTC). Military Restricted Type Certificates (MRTCs) are not yet employed by DASA, and are not addressed herein.

7.2.2.2 **Military Type Certificate.** An MTC is issued by DASA to certify that a product's type design complies with the applicable Type Certification Basis (TCB) when operated within specified conditions and limitations. Further description of the MTC authorisation can be found in Section 5.3 Annex K.

Eligibility

Superseded

7.2.2.3 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the MTC.

7.2.2.4 DASR 21.A.13 (Eligibility), and by extension DASR 21.A.14 (Demonstration of Capability), define which organisations can apply for an MTC under DASR 21. As per DASR 21.A.14, applicants for an MTC can be:

1. A DASR 21 Subpart J approved Military Design Organisation (MDO) (21.A.14(a)). Holding a DASR 21J approval provides an organisation with the eligibility to apply directly to DASA for an MTC. However, given the scope of the Australian aviation industry, development and certification of a new aircraft wholly under a DASR 21J MDO will be a rare occurrence.

2. An organisation demonstrating its capability through alternative procedures (21.A.14(b)). An applicant may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to comply with this DASR. This eligibility provision is ostensibly aimed at products with simple or limited scope of design, or organisations starting toward a MDO approval or limited duration of design activities. Use of this provision to demonstrate capability to apply for an MTC would only be considered by DASA by exception.

3. A government organisation who has an agreement in place with a design organisation that has access to the type design data (21.A.14(c)). Any government organisation applying for an MTC may demonstrate its capability by having an agreement in place, accepted by DASA, with a design organisation that has access to the necessary type design data. This is the normal provision through which DASA expects government organisations (usually the relevant CASG System Program Office (SPO)) to demonstrate their capability to apply for an MTC. The agreement with the relevant design organisation shall include detailed statements how the actions and obligations are delegated to enable the government organisation, in cooperation with the contracted organisation, to comply with the requirements of Subpart J and DASR 21.A.44 (holder obligations). AMC and GM to 21.A.14(c) provide further information on demonstration of capability under this provision.

7.2.2.5 **MTC Applications by CASG SPOs (Project Offices).** To be issued an MTC by DASA, a CASG project office develops a Type Continued-Airworthiness Exposition (TCAE) for DASA review. The TCAE details the CASG arrangements with the design organisation(s) that has access to the type-design data and through which the provision of holder obligation functions occur. Further guidance on holder obligations and arrangements can be found in Section 7.4.1.

7.2.2.6 CASG project offices seeking issue of an MTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended acquisition program.

7.2.2.7 The eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J. Since a CASG project office scope of responsibility is usually limited to a single application, and does not include the through-life holder responsibilities, the CASG project office eligibility information is not required to be delivered as a single document and can instead be contained within

Superseded

Project or Acquisition documentation. The documentation requires review by DASA prior to the project office becoming eligible to act as an applicant. However, the CASG project office must include a transition plan to manage delivery of the Type Design to the MTC holder, and where the MTC holder organisation is being created, include plans for assessment of eligibility of the MTC holder, by DASA.

7.2.2.8 Additional guidance with respect to MTC applicant eligibility when CASG project offices wish to leverage recognition provisions is as follows:

1. Application will be exclusively based upon an aircraft type-design that has been certified by a recognised CAA/MAA. In this situation, the project office, in conjunction with any associated design organisation(s), can gain eligibility by demonstrating its ability to conduct the required certification programme activities (develop CPP, conduct applicability assessment against Defence context, develop the Defence TCB, and provide a declaration of compliance), rather than demonstrate full adherence to the DASR 21 Subpart J requirements.

2. Application will be based on a design that has not been certified, but was developed using a design system (organisation, people, processes, data, and tools) external to the DASR, and where that system is used to produce designs for certification by a recognised CAA/MAA. In this situation, the DASA recognition framework[4] must be leveraged by the project office to assist in demonstrating to DASA that the arrangements with the external DO provides an acceptable equivalence to the DASR 21 Subpart J requirements. Activities to meet the eligibility requirements should be completed prior to initial engagement with DASA and throughout certification programme activities. The project office is to address the following expectations in their respective eligibility submission:

   i. Confirm that the external design organisation is normally oversighted by a CAA/MAA recognised by DASA[5].

   ii. Confirm that the external design organisation has appropriate technical scope and expertise for the intended design(s).

   iii. Confirm that the systems, processes and personnel used in developing other designs for certification by the parent CAA/MAA will be used in the design development or holder activities associated with the ADF design.

   iv. Confirm that the design organisation is able to provide an attestation of compliance against the Defence TCB for any provided design product.

   Note: In some circumstances, the PO or MTC holder may wish to allow the external design organisation to engage directly with DASA for Defence TCB agreement, development and conduct of the CCP, and provision of a declaration of compliance to the Defence TCB. In this case, the eligibility documentation shall demonstrate that the external design organisation systems and process are sufficiently similar to the DASR 21J requirements to support such delegation.

   v. Confirm any expected oversight by the DO's parent CAA/MAA is appropriate.

   vi. Confirm where applicable, arrangements for DASA oversight are in place.

Superseded

vii. Articulate how the recognition arrangements as per paragraphs 7.2.2.8.(b)(iii), (iv) and (v) will be monitored and ensured during the design development and submission process[6].

Certification Programme

7.2.2.9 **Overview.** Under DASR 21, a certification programme is required for all applications for an MTC, and the certification programme requires formal acceptance by DASA.

7.2.2.10 The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a Certification Program Plan (CPP).

7.2.2.11 Two CPP templates are published on the DASA Website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the MTC CPP template.

7.2.2.12 The organisation(s) involved in the development and submission of a certification program for an MTC application will vary depending upon the acquisition arrangements. GM1 21.A.15(b) provides further guidance based on some common acquisition scenarios.

7.2.2.13 **Contents of a Certification Programme.** DASR 21.A.15(b) outlines the requirements for content of a certification programme for an MTC. Certification programmes must be tailored to meet the requirements of the certification activity.

7.2.2.14 The certification programme should be presented as a CPP containing the information required by DASR 21.A.15(b) and the supporting AMC. The MTC CPP template published by DASA will assist in meeting the required outcomes.

7.2.2.15 Two key outcomes are achieved through the development and DASA acceptance of the certification programme:

1. Applicant development and DASA agreement of the Defence TCB for the MTC[7].
2. Formalising and agreement on the approach to be taken for demonstrating compliance against the Defence TCB, and the DASA Level of Involvement (LoI) in compliance demonstration activities.

7.2.2.16 **Proposed Compliance Demonstration Items (CDIs)**. DASR 21.A.15(b)(5) requires that the CPP proposes a breakdown of the certification programme into meaningful groups of compliance demonstration activities and data, and a proposal for the means of compliance and related compliance documents.

7.2.2.17 A CDI is a meaningful group of compliance demonstration activities and data that can be considered, in isolation, for the purpose of performing the risk assessment that allows DASA to determine its LoI.

7.2.2.18 Applicants should follow AMC 21.A.15(b)(5) when proposing the CDIs, and the DASA MTC CPP template contains further guidance and tabular templates for presenting proposed CDIs.

7.2.2.19 **Proposed DASA LoI.** As outlined in AMC 21.A.15(b)(6), the Authority's LoI is a list of activities and data, in which the Authority retains the verification of compliance demonstration (e.g. review and acceptance of compliance data, witnessing of tests, etc.), as well as the depth of the verification. The depth of the verification for individual compliance reports, data, test witnessing, etc., may range

Superseded

from spot checks to extensive reviews. DASA will respond to those retained compliance demonstration activities and data with corresponding comments or a 'statement of no objection'. DASR 21.A.15(b)(6) requires that the CPP proposes the DASA LoI associated with compliance demonstration activities, noting that LoI should normally be proposed at the CDI level. As per DASR 21.A.15(b)(6), the DASA LoI must address the likelihood of an unidentified non-compliance with the TCB requirements and the potential impact of that non-compliance on safety (ie a risk-based determination). In practice, this is achieved through taking into consideration:

1. any novel or unusual features of the certification project, including operational, organisational and knowledge management aspects
2. the complexity of the design and/or demonstration of compliance
3. the criticality of the design or technology and the related safety risks, including those identified on similar designs
4. the performance and experience of the design organisation of the applicant in the domain concerned.

7.2.2.20 AMC 21.A.15(b)(6) contains a step-by-step process and extensive information that applicants should follow when determining the proposed DASA LoI. The DASA MTC CPP template also includes complementary guidance and tables. The three main steps that culminate in determining the DASA LoI are:

1. Step 1: Identification of the likelihood of an unidentified non-compliance. This includes taking into consideration novelty, complexity and the performance of the design organisation. Refer to Section 3.2 of AMC 21.A.15(b)(6) for details.
2. Step 2: Identification of the 'risk class'. This includes determining whether the potential impact of the non-compliance within a compliance demonstration activity (ie CDI) is critical or non-critical. This is then combined with the likelihood of an unidentified non-compliance (step 1) to determine the risk class. Refer to Sections 3.3-3.4 of AMC 21.A.15(b)(6) for details.
3. Step 3: Determination of the DASA LoI. Based on the qualitative risk class identified for each compliance demonstration activity (ie CDI), the applicant should propose a DASA LoI. Refer to Section 3.5 of AMC 21.A.15(b)(6) for details.

7.2.2.21 DASA will determine the depth and extent of its inspections for each CDI, based on the information provided in the certification programme and the applicant's proposal. DASA determination of LoI will be confirmed as part of DASA's acceptance of the CPP. Note that the depth and extent of DASA LoI may change throughout the project in order to account for changes that affect the basis of the initial LoI determination.

7.2.2.22 **Certification Programme Acceptance.** DASA acceptance of the certification programme is required for all MTC applications. Early engagement with DASA, and agreement on the key certification programme content, will reduce schedule and resource risks for the project. Delaying presentation of certification programmes to DASA until after compliance demonstration has commenced may result in delays, additional work, or additional resources, due to DASA:

1. determining that the proposed airworthiness requirements or means of compliance are unsuitable for the certification activity

Superseded

2. identifying a need for a LoI in compliance demonstration activities that have already been completed, therefore resulting in a need to repeat the compliance demonstration

3. identifying LoI that requires travel (eg for compliance demonstration being completed overseas) and insufficient time is available to organise funding and travel prior to the planned activity, resulting in a need to delay the activity

4. identifying a need for data access that was not accounted for prior to contracting or establishing government to government agreements for the activity, resulting in a need for contract changes or alternate workarounds.

7.2.2.23 DASA acceptance of a certification programme can be achieved incrementally, if some aspects are unknown at the beginning of the project or are expected to change throughout the project. A caveated acceptance may be possible to achieve agreement with DASA on specific aspects of the programme prior to full details being known. For an initial or caveated acceptance, the following is required:

1. identification of the applicant and any design organisations involved

2. broad detail on the design and aircraft intended use

3. an initial proposal for the TCB, including identification of the Primary Certification Code and identification of whether any TCB tailoring (including Military Certification Review Items (MCRIs)) will be required. Note: the TCB does not have to be fully defined at this point.

4. broad detail on the certification approach (i.e. whether there will be reliance on prior certification, or whether compliance demonstration evidence with be developed specifically for the DASA certification).

7.2.2.24 Where an incremental approach is taken to developing and achieving acceptance of the certification programme, the scope of acceptance intended by each version must be clearly understood and documented. A point at which the next update is required must be identified, this may be date based or linked to a specific project stage or milestone.

7.2.2.25 DASA acceptance of the certification programme will be agreed by formal communication, which will include confirmation of the DASA LoI for the activity, and any caveats on DASA acceptance.

7.2.2.26 **Certification Programme Updates.** In accordance with DASR 21.A.15(c), the certification programme is to be updated when there are changes to any of the content required under DASR 21.A.15(b). Key aspects that require the certification programme to be re-accepted by DASA are:

1. any changes that may impact on DASA LoI, such as:

   i. change to the design or intended use

   ii. change to compliance demonstration approach (including the means of compliance)

   iii. change to the CRE Assessment (CREA) or its outcomes for a program that is leveraging prior certification

   iv. change to design organisation resources or approvals

Superseded

2. any changes to the proposed TCB (except those achieving separate agreement via an MCRI)

3. significant changes to schedule that may impact on DASA LoI activities

7.2.2.27 Changes to the certification programme can be presented as an update to the original CPP, or via a supplement, depending on the scope of the changes.

7.2.2.28 Applicants should engage early with DASA (nominally DIA) staff and remain closely engaged with CPP development and subsequent amendment, heeding advice to prevent nugatory drafting and rewriting. The DASR Form 31 can be used to notify DASA of an upcoming certification project, to initiate discussions. A face-to-face session, before any CPP drafting occurs, is strongly recommended for for complex programs.

Type Certification Basis

7.2.2.29 **Contents of a TCB.** The TCB is an agreed set of airworthiness requirements that a product must be compliant with in order to obtain an MTC. The following DASR and concepts apply to the contents of a TCB:

1. DASR 21.A.16A (Airworthiness Codes). This regulation requires that DASA shall approve the use of Airworthiness Codes[8] and other detailed specifications that may be used to demonstrate compliance of products, parts and appliances. As noted in GM 21.A.16A, rather than define a Defence-unique Airworthiness Code, DASA has elected to recognise the Airworthiness Codes prescribed by several other CAAs and MAAs that have been demonstrated to achieve safe flight, and then prescribe supplementation as required. The Defence Aviation Safety Design Requirements Manual (DASDRM) identifies the Airworthiness Codes recognised by DASA.

2. DASR 21.A.16B (Special Conditions). This regulation requires that DASA shall approve any special detailed technical specification ('special conditions') if the related Airworthiness Code or specifications do not contain adequate or appropriate safety standards. As per 21.A.16B, the need for special conditions may arise due to:

   i. novel or unusual design features (relative to the design practices on which the applicable Airworthiness Code is based)

   ii. intended use of the product is unconventional

   iii. experience from other similar products in service or products having similar design features or newly identified hazards have shown that unsafe conditions may develop

   iv. applicable airworthiness codes do not exist for the concerned product class or do not address the requested kind of operations.

   In the Defence context, special conditions are required when the primary Airworthiness Code selected may contain deficiencies against contemporary airworthiness requirements and / or may not account for Defence's unique CRE. DASA uses the Defence Aviation Safety Design Requirements Manual (DASDRM) to define those 'essential' design requirements and standards that must be applied as special conditions to supplement Airworthiness Codes due to deficiencies in the Codes or to account for the Defence CRE. The DASDRM also defines a number of 'recommended'

Superseded

design requirements and standards for which compliance is not prescribed, but which should be applied where reasonably practicable.

3. DASR 21.A.17A (Type Certification Basis). This regulation defines the scope of the Defence TCB. The airworthiness requirements specified in the TCB include:

   i. the applicable requirements from the DASA recognised Airworthiness Code selected as a basis for the Defence aircraft certification (the Primary Certification Code (PCC))

   ii. the applicable 'essential' requirements prescribed in the Defence Aviation Safety Design Requirements Manual (DASDRM)

   iii. any supplementation or tailoring agreed to by DASA.

7.2.2.30 **Development of a Defence TCB.** Development of a Defence TCB is a joint activity between the applicant and DASA and is guided by the DASR listed above and the Defence Aviation Safety Design Requirements Manual (DASDRM). TCB agreement is obtained through acceptance of the certification programme in accordance with DASR 21.A.15(b).

7.2.2.31 The TCB for a new Defence aircraft type should be developed and agreed as early as practicable in the aircraft acquisition life-cycle. While a DASA-agreed TCB should be pursued prior to entering into an acquisition contract, this will not always be possible. In those cases, the acquisition project office may elect to present a draft TCB for DASA assessment as a cost and schedule risk reduction measure.

7.2.2.32 In most cases, DASR and the DASDRM allow the Defence TCB to be based on the recognised design standards used by the parent CAA/MAA under which the aircraft was initially designed and certified.

7.2.2.33 The TCB for a Defence aircraft must be consistent with Defence's intended role and operating environment for the aircraft. In the aircraft Type Certification domain, CRE is a pivotal concept. Where an ab-initio Type Certification programme is proposed for a Defence aircraft, defining the CRE is essential to ensure that the basis of certification is consistent with the intended Defence use of the aircraft.

7.2.2.34 Where the Defence Type Certification programme intends to leverage prior certification from a recognised CAA/MAA to any extent, a CRE Assessment (CREA) is required to confirm the applicability of that prior certification to the intended Defence use. Areas where the prior certification is not entirely applicable to the Defence CRE must be addressed through further compliance demonstration evidence, inclusion of additional requirements in the TCB, or tailoring of requirements for the TCB. Further guidance on leveraging prior certification is contained in Annex B to Section 7.2, and further guidance on the conduct of a CREA is contained in Annex C to Section 7.2.

7.2.2.35 **Tailoring the PCC.** During a certification program, there may be a need to tailor the PCC when seeking an MTC. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

7.2.2.36 Tailoring of the PCC may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.2.37 Tailoring of the PCC can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a Military Certification Review Item (MCRI).

Superseded

7.2.2.38 Annex A to Section 7.2 provides further guidance on tailoring the PCC, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support PCC tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Compliance Demonstration

7.2.2.39 **Overview.** Compliance demonstration evidence comprises of reports, engineering tool outputs, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the applicable TCB is demonstrated. The applicant shall demonstrate compliance with the type-certification basis either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.2.40 The agreed certification programme will include details of how compliance demonstration is being achieved for each project. Where difficulty arises in meeting the agreed certification programme activities or outcomes, engagement with DASA as early as practicable is recommended. This phase may identify issues in compliance demonstration evidence against the agreed Defence TCB that require equivalent safety finding arguments, processing of exceptions underpinned by an Airworthiness Issue Paper (AwIP) or equivalent, or introducing new interpretations or means of compliance. In these cases an MCRI, and an AwIP as required, should be raised and submitted by the applicant for DASA consideration.

7.2.2.41 **Leveraging Prior Certification.** Defence is rarely the prime customer for new aircraft, so most acquisitions will be based on an aircraft design that has or will be certified by another CAA/ MAA. DASR 21.A.20 enables an applicant for an MTC to leverage prior certification from a recognised CAA/MAA[9] to gain relief from developing compliance demonstration evidence.

7.2.2.42 The fundamental principle of leveraging prior certification is that any requisite Authority review of evidence; testing, or witnessing of testing; or inspections (refer DASR 21.A.33(b)) have already been performed by a competent Authority (ie a CAA/MAA recognised by DASA). Therefore, duplicate effort in terms of DASA also conducting inspections / analyses / tests is unnecessary. However, as per DASR AMC 21.A.20, in order to leverage the prior certification, the applicant for the MTC must ensure:

1. the certification is within the scope, conditions and caveats specific to DASA Recognition of the certifying CAA/MAA
2. the CAA/MAA is sufficiently experienced in certification of the particular design activity
3. the certification requirements employed by the CAA/MAA are understood and any deltas from the Defence TCB have been addressed
4. the CRE applied to the prior certification is understood and any deltas from the intended Defence CRE have been addressed
5. any safety risks associated with the CAA / MAA certification have been identified, and have been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) for the Defence CRE.

Superseded

7.2.2.43 Annex B to Section 7.2 provides additional guidance on the AMC 21.A.20 requirements for leveraging prior certification, and discusses common issues encountered with leveraging prior certification. Annex C to Section 7.2 provides further guidance on the conduct of a CREA to support relief from presenting CDE when leveraging prior recognition.

7.2.2.44 **Structures and Propulsion System Specific Guidance.** Guidance on the conduct of structures and propulsion system CREAs when leveraging prior certification can be found in GM1 21.A.20 and Chapter 6.6.2. Guidance to support AMC 21.A.41 (Structural and Propulsion System Critical Parts and Airworthiness Limitations (AUS)) can be found in Chapter 6.6.2.

MTC Application, Issuance and Type Certificate Data Sheet (TCDS)

7.2.2.45 **Application.** Upon completion of all activities identified within the CPP, including development of compliance demonstration evidence and completion of DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for issuance of an MTC. The exact format of the application for an MTC will differ depending upon each project, and should be agreed within the CPP.

7.2.2.46 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will issue the MTC.

7.2.2.47 For acquisitions of new aircraft types, the Defence Aviation Authority (Defence AA) will generally elect to convene an Airworthiness Board (AwB). Aircraft acquisition AwBs, including applicant and DASA submission of documents to support the AwB, are separate to the DASR type certification process outlined within this section. AwBs are discussed further in Section 6.1.2 and Section 13.

7.2.2.48 **Type Certificate Data Sheet (TCDS).** A TCDS will accompany each MTC. The TCDS contains all information (or reference thereto) about the type certification of the product including the TCB, the type design, operating limitations, the Aircraft Flight Manual (AFM), Instructions for Continuing Airworthiness (ICA), Airworthiness Limitations (AwLs), Certification Maintenance Requirements (CMRs), critical parts list (if applicable) and any other data necessary for the continued safe operation of the product.

7.2.2.49 DASA will develop and issue the TCDS concurrently with the MTC.

DASA Assurance

7.2.2.50 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining an MTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).
2. DASA agreement of the TCB, including tailoring (refer 'Type Certification Basis' section above).
3. DASA LoI in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme'

Superseded

section above). In all cases, DASA LoI activities should be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer below for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, and issue of the MTC and TCDS.

7.2.2.51 **DASA Assurance when Leveraging Prior Certification.** Where the certification programme indicates that an applicant is proposing to leverage prior certification from a recognised CAA/MAA, then DASA assurance activities will focus on the criteria outlined in AMC 21.A.20. The guidance outlined in Annex B to Section 7.2 provides an indication of the considerations that DASA will examine as part its assurance activities.

7.2.2.52 For certain aspects, the CPP will only be providing a proposal for how the applicant intends to address the criteria for leveraging prior certification outlined in AMC 21.A.20. For example, the applicant may need to conduct further activities to confirm that the CAA/MAA is sufficiently experienced in certification of the particular design activity, conduct further analysis to show that the design is compliant for the Defence CRE, and conduct sovereign assessments for safety risk decisions or risk retention made by an MAA. Therefore, DASA will typically request the applicant provide relevant documentation prior to, or as part of, the final application.

7.2.2.53 Note that while leveraging prior certification may provide relief from the need to develop new compliance demonstration evidence, it does not provide relief from the need to present compliance demonstration evidence to DASA. As such, DASA may request to review evidence that supported the prior certification where it is deemed necessary. Where it is not possible for the applicant to provide this evidence to DASA, for example due to limitations on access to OEM data, this will be negotiated between the applicant and DASA on a case-by-case basis.

MTC Holder Obligations

7.2.2.54 MTC holder obligations are outlined in DASR 21.A.44. Refer to Section 7.4.1 for detailed guidance on MTC holder obligations.

7.2.3 – Changes to Type Certificates and Military Supplemental Type Certificates (DASR 21 Subpart D and E)

Overview

7.2.3.1 **Scope of Section.** Section 7.2.3 primarily describes the DASR type certification process for major changes to the type certificate and obtaining a Military Supplemental Type Certificates (MSTC). Minor changes to the type certificate are only briefly addressed herein.

7.2.3.2 **Change to a Type Certificate.** As defined by DASR 21.A.41, the type certificate includes:

1. The Type Design, which includes[10]:

Superseded

i. The drawings and specifications, and a listing of those drawings and specifications, necessary to define the configuration and the design features of the product shown to comply with the applicable TCB;

ii. Information on materials and processes and on methods of manufacture and assembly of the product necessary to ensure the conformity of the product;

iii. An approved Airworthiness Limitations Section (ALS) of the ICA as defined by the applicable airworthiness codes; and

iv. Any other data allowing by comparison the determination of the airworthiness of later products of the same type.

2. Operating Limitations

3. The TCDS

4. The applicable TCB

5. Any other conditions or limitations prescribed for the product in the applicable airworthiness requirements.

7.2.3.3 A change to any aspect of the items listed above is considered a change to the type certificate, and must be undertaken in accordance with DASR 21 Subpart D or E.

7.2.3.4 Note that DASR M.A.304(d) allows for the Operator to directly consume data for minor changes that has been approved within the framework of Authorities recognised by DASA. Under this pathway, the requirements of DASR 21 are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. Data for major changes cannot be directly consumed via recognition, and must be processed in accordance with DASR 21 Subpart D or E. Refer to Section 8.2 for further information on the direct consumption of data via recognition. Consumption of data for minor changes via recognition is not discussed any further within this section.

Classification

7.2.3.5 In accordance with DASR 21.A.91, all changes to the type certificate must be classified as minor or major.

7.2.3.6 A minor change is defined as a change that has no appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product. All other changes are defined as major. Guidance on classification of changes to type certificates, including examples of changes that should be classified as major, can be found in DASR GM 21.A.91.

7.2.3.7 DASR 21J MDO approval holders will typically have the privilege to classify changes that are within the scope (e.g. technology or platform types) of their terms of approval. As noted in DASR GM 21.A.91, DASA should be consulted for clarification wherever there is doubt as to the classification of a change. Furthermore, when the strict application of the DASR GM 21.A.91 paragraph 3.4 criteria results in a major classification, the applicant may request reclassification, if justified, and DASA can take the responsibility in reclassifying the change.

Processing of Minor Changes

Superseded

7.2.3.8 Minor changes to the type certificate must be undertaken in accordance with DASR 21 Subpart D, and can be approved by DASA or a DASR 21J MDO approval holder with the necessary privilege and scope. DASA expects that in the Defence context, minor changes to type certificates undertaken in accordance with DASR 21 Subpart D will be developed and approved by a DASR 21J MDO[11].

Processing of Major Changes

7.2.3.9 Changes that are classified as major can be processed and approved as a:

1. major change to the existing MTC under DASR 21 Subpart D, or
2. a MSTC under DASR 21 Subpart E.

7.2.3.10 The decision to apply for a major change (DASR 21 Subpart D) versus a MSTC (DASR 21 Subpart E) will depend upon the specific context. Under the DASR construct, both these authorisations will be issued to the government MTC holder. The default approach is usually issue a major change to the existing MTC, however, as discussed in the following sub-section, there may be cases where an MSTC is more appropriate.

Use of Military Supplemental Type Certificates (MSTCs)

7.2.3.11 The reasons for using an MSTC are different in the Defence context from in the civilian context. This sub-section provides guidance on when an MSTC should be used under the DASR.

7.2.3.12 **Civil use of Supplemental Type Certificates (STCs).** In the civil context, STCs are generally used for commercial purposes. They are used where a designer (either the OEM or another designer) alters the aircraft to provide a new capability that they can sell separately to the original Type Certificate. Of note, designers who are not the holder of the original Type Certificate can only ever apply for STCs for design changes that are classified as major, as it is not possible to apply for a major change to a certificate you do not hold.

7.2.3.13 Major changes to the Type Certificate are limited to changes done by the Type Certificate Holder, and are mostly (though not always) mandatory Service Bulletins and Airworthiness Directives to address safety issues identified in service as part of the holder obligations (eg DASR 21.A.3A).

7.2.3.14 **Use of MSTCs Under DASR.** Under the DASR the reasons for using an MSTC are different to the civil context. The following are the reasons that an MSTC (as opposed to a major change to the MTC) would be used under the DASR:

1. Sub-fleet: An MSTC may be used to manage a sub-fleet. This would be where there is one or more aircraft in the fleet that are intended to be configured or operated in a significantly different manner to the remainder of the fleet. Note, sub-fleets can also be managed via major changes to the MTC, so an MSTC may be used but is not the only option for management of sub-fleets.
2. Significant Change to the TCB: An MSTC may be used to manage a change that involves a distinct change to the TCB. Generally this will be the result of reliance on prior certification which has adopted a different PCC than that used for the original MTC. While the change to the PCC may be able to be managed via MCRI(s), it may reduce the complexity of ongoing management of the authorisations by covering the change under an MSTC.

Superseded

3. Large and Complex Changes: An MSTC may be used for large and complex changes. While the process for review and approval of a major change or an MSTC is the same, use of an MSTC provides greater visibility, and as a result greater clarity, of the precise nature and scope of the change. MSTCs are often understood by Defence Operators as being a change of more significance, which warrants greater operational consideration.

4. Management Reasons: An MSTC may be used for ease of management from the perspective of the MTC holder. This may be required to provide alignment between the DASR authorisations and authorisations being leveraged via recognition. It may be simpler for an MTC holder to manage their obligations if the Defence authorisations are aligned with the OEM authorisations.

7.2.3.15 Note that when changes are applied to the MTC for a platform that also has MSTC(s), the compatibility of the change with the existing MSTC(s) must be explicitly addressed. Under the civil system, a change to the Type Certificate does not need to explicitly consider compatibility with potential STCs. It is the Operator's responsibility to consider the impact of change to the Type Certificate against any STCs applied to their aircraft, and to engage the STC holder as required. However, in the DASR context, the MTC and MSTCs are frequently more integrated and less able to be clearly separated from each other. In addition, the MTC and MSTCs are all held by the same organisation so separating consideration of the MTC and MSTCs is unnecessary and adds confusion for no benefit. As such, it is not appropriate to progress a major change to the MTC without considering the impact on existing MSTCs.

Eligibility

7.2.3.16 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the relevant authorisation.

7.2.3.17 **Major Change to the MTC.** In accordance with DASR 21.A.92, only the MTC holder can apply for a major change to the MTC. However, as noted by DASR GM 21.A.92(a), this includes any organisation acting on behalf of the MTC holder. DASA considers it appropriate for a design organisation to act as the applicant for a major change (on behalf of the MTC holder) where:

1. the agreement between the MTC holder and design organisation required by DASR 21.A.14(c) permits,

2. the TCAE reflects the agreement and arrangements under which such applications may occur, and

3. the proposed design change is within the scope of the design organisation's approval.

7.2.3.18 In all cases, the MTC holder must sign the final application for the major change (ie Form 31A) to confirm that they have been consulted on, and have no objection to, the major change, and will carry out holder responsibilities.

7.2.3.19 During sustainment, additional design organisations may be engaged by the MTC holder to support new modifications or reflect expanding design support agreements. In these cases, the MTC holder should inform DASA of the proposed support arrangements and define additional oversight requirements to support specific applications.

Superseded

7.2.3.20 **MSTC.** In accordance with DASR 21.A.112A, any organisation that has demonstrated, or is in the process of demonstrating, its capability under DASR 21.A.112B shall be eligible as an applicant for an MSTC. The DASR 21.A.112B demonstration of capability requirements are essentially the same as those of DASR 21.A.14 (refer to the 'Eligibility' guidance in Section 7.2.2, and relevant AMC and GM for further information).

7.2.3.21 However, as noted by DASR GM 21.A.115, DASA will issue all MSTCs to the relevant government MTC holder organisation. This means that, in effect, all applications for MSTC are being made on behalf of the MTC holder who will be the eventual holder of the MSTC. Applicants for MSTCs must be able to demonstrate that they are acting on behalf of the MTC holder.

7.2.3.22 **Major Change or MSTC Applications by CASG Project Offices.** In some cases, the CASG project office may act as the applicant for a major change or MSTC for larger or more complex modifications to an existing aircraft, such as for a mid-life upgrade program or significant capability upgrades.

7.2.3.23 Since only the MTC holder can apply for major changes to the existing MTC, the CASG project office would be considered to be applying for the approval on behalf of the MTC holder. For MSTC applications, the CASG project office could be considered the applicant under the DASR 21.A.112B(c) exception clause. In either case, the eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J.

7.2.3.24 Also refer to the 'MTC Applications by CASG SPOs (Project Offices)' guidance in Section 7.2.2 for further information, including guidance on applicant eligibility when CASG project offices wish to leverage recognition provisions.

7.2.3.25 CASG project offices seeking to apply for a major change or MSTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended program.

Certification Programme

7.2.3.26 **Overview.** Under DASR 21, a certification programme is required for all changes to type certificates and MSTCs. The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a CPP.

7.2.3.27 For MSTC and 'complex'[12] major change programs, the certification programme must be presented to DASA for formal acceptance prior to the final application and declaration of compliance, and it is recommended that it be presented as a CPP. For other certification activities, the certification programme may be documented through the design pack or final application, and does not require formal DASA acceptance. Table 7.1 summarises the certification programme requirements for different design activities.

Certification Activity	DASR Reference	Formal DASA Acceptance Required?	Comments
Application for an MSTC	21.A.113(b)	Yes	Certification programme should be presented as a

Superseded

	21.A.93(b)		CPP containing the information required by 21.A.93(b) and the supporting AMC. The DASA major change/MSTC CPP template will assist in meeting the required outcomes.
Application for a 'complex' major change	21.A.93(b)	Yes	
Application for a 'simple' major change	21.A.93(b)	Yes	Certification programme can be provided with the final application for approval of the change.
Minor change to type-certificate	21.A.93(b)[13]	No	

Table 1: Certification Programme Requirements for Design Change Activities

7.2.3.28 Two CPP templates are published on the DASA website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the major change/MSTC CPP template.

7.2.3.29 The organisation(s) involved in the development and submission of a certification program for a major change or an MSTC application will vary depending upon the platform support arrangements. As noted above, the design organisation that supports the MTC holder functions may act as the applicant on behalf of the MTC holder in certain circumstances. In these cases, the design organisation will usually develop the CPP and engage with DASA for formal acceptance when required.

7.2.3.30 **Simple Major Changes.** For 'simple'[14] major changes, the certification programme may be presented with the final application (ie with the Form 31a pack). This approach introduces a risk that if DASA identifies issues with the certification programme, or with the decision to treat the change as simple, there may be a requirement for rework of compliance demonstration activities, resulting in a delay to the program. As such, this approach should only be followed where the change is straightforward; for example, OEM Service Bulletins that have received CAA/MAA certification. If there is doubt as to whether a change would meet the definition of 'simple', DASA Type Certification section should be contacted for advice.

7.2.3.31 **Contents of a Certification Programme.** DASR 21.A.93(b) outlines the requirements for content of a certification programme for a major change or an MSTC.

7.2.3.32 Certification programmes must be tailored to meet the requirements of the certification activity. If a change has been assessed as 'simple', then there is no need to do a full breakdown of the programme into CDIs or to provide a detailed LoI proposal, as the LoI must be assessed as nil to meet the definition of a simple change. For changes that rely on prior certification, the breakdown of the programme into CDIs is only required for areas that are not able to fully leverage prior certification (ie where additional compliance demonstration evidence is being developed).

7.2.3.33 For 'complex' major changes and MSTC, the certification programme should be presented as a CPP containing the information required by DASR 21.A.93(b) and the supporting AMC and GM. The major change/MSTC CPP template published by DASA will assist in meeting the required outcomes.

Superseded

7.2.3.34 **Further Guidance.** Refer to the certification programme information in Section 7.2.2 for further guidance on proposal of CDIs and DASA LoI, as well as certification programme acceptance and updates.

Certification Basis

7.2.3.35 For all changes to a product, the design organisation must identify the areas affected by the change and the corresponding certification basis (airworthiness requirements) for those areas. The applicable airworthiness requirements will depend upon the nature of the change, and can be generalised as follows:

1. **Substantial changes.** Some changes are so extensive that a new type certificate is required (refer DASR 21.A.19), and therefore would require an entirely new TCB to be established. Substantial changes for an existing aircraft type are unlikely within the Defence context.

2. **Significant (major) changes.** For major changes that are categorised as significant[15] under DASR 21.A.101, then the latest amendment level of the airworthiness requirements referenced in the TCB should be used for the change.

3. **Non-significant (major) changes.** For major changes that are not categorised as significant, then the DASR 21.A.101(b) exception clause allows the existing airworthiness requirements in the TCB to be used for the change. DASR 21.A.101(b) also allows the existing airworthiness requirements to be used for a significant change in cases where use of the latest amendment of the airworthiness requirements referenced in the TCB would not contribute materially to the level of safety, or is impractical.

4. **Minor changes.** Minor changes, by definition, do not affect the airworthiness of the product. This means that it is appropriate to use the existing airworthiness requirements in the TCB for the change (refer DASR 21.A.95(b)(1) and DASR AMC 21.A.95).

7.2.3.36 As stated above, using the existing airworthiness requirements in the TCB is usually considered adequate for minor changes and non-significant major changes. However, as noted in DASR GM 21.A.93(b)(2), Australia's WHS Act levies additional obligations on designers, namely to exercise 'reasonable knowledge' when determining that any risk inherent in designs has been minimised SFARP. Updates (later amendments) to applicable standards may provide insight into hazards and potential controls that are not identified in the existing TCB. The requirements prescribed in the DASDRM also provide a source of requirements and standards that can assist engineers to satisfy their obligation to exercise reasonable knowledge of hazards and associated controls in aircraft design.

7.2.3.37 The certification programme for the change should identify the proposed certification basis (ie existing or latest amendment level, with justification as required) and any 'reinvestigations' required[16].

7.2.3.38 **Changed Product Rule.** DASR 21.A.101 is commonly referred to as the 'changed product rule' and is used by applicants and DASA to establish the certification basis for major changes and MSTCs. The primary decision under the changed product rule is whether the latest amendment of the airworthiness requirements referenced in the TCB must be used (ie significant major change), or whether the nature of the major change allows the existing airworthiness requirements to be used (ie non-significant major change). If an applicant elects to comply with the latest amendment for a major

Superseded

change that could otherwise be categorised as non-significant, then the change will be compliant with DASR 21.A.101(a) and no further justification would be required.

7.2.3.39 DASR GM 21.A.101 contains extensive guidance and a step-by-step process for applicants to follow in order to establish the proposed certification basis for the major change. A summary of the changed product rule criteria and outcomes is shown below in Table 7.2. Table 7.2 is taken from Appendix B to GM 21.A.101, and only provides a brief summary of the extensive guidance and step-by-step process contained in DASR GM 21.A.101. A number of the Appendices to GM 21.A.101 refer to the EASA GM 21.A.101, including Appendix A of EASA GM 21.A.101 which provides examples of changes that EASA, the FAA and other Authorities considered to be 'substantial', 'significant' and 'non-significant'.

<table>

</table>

Table 2: Establishing Certification Basis for Changed Products

7.2.3.40 Significant major changes shall also comply with the relevant 'essential' design requirements defined in the DASDRM (refer DASR AMC 21.A.101).

7.2.3.41 Note that for major changes, DASR 21.A.101(e) is a further exception clause that allows applicants to propose an alternative to the airworthiness requirements in the TCB. DASA may agree to the use of an alternative set of airworthiness requirements provided the alternative provides at least an equivalent level of safety to the existing TCB.

7.2.3.42 The process and justification used to comply with DASR 21.A.101 should be included within the certification programme, and the DASA major change/MSTC CPP template contains specific headings to include this information.

7.2.3.43 When applicants believe that the major change under consideration may be significant, or have questions about application of DASR 21.A.101, then engagement with DASA as early as practicable is recommended.

7.2.3.44 **Tailoring the TCB.** During a certification program, there may be a need to tailor the TCB when seeking a major change approval. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

Superseded

7.2.3.45 Tailoring of the TCB may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.3.46 Tailoring of the TCB can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a MCRI.

7.2.3.47 Annex A to Section 7.2 provides further guidance on tailoring the TCB, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support TCB tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Reclassification of Changes Requiring TCB Tailoring

7.2.3.48 Occasionally, changes to type certificates that would otherwise be classified as minor, are required to be classified as major only because of the need to tailor the TCB. This section outlines an approach to enable these changes to be reclassified to minor, once the TCB tailoring has been agreed. This approach will allow greater use of DASR 21J MDO privileges, and reduce DASA assurance in areas where there is not a clear safety benefit.

7.2.3.49 **Reclassification Justification.** DASR GM 21.A.91 states that any changes that require an adjustment of the TCB, other than electing to comply with a later amendment of a requirement, must be classified as major. However, it also states that when the strict application of the classification criteria for a design change results in a major classification, the applicant may request re-classification, if justified, and DASA can take the responsibility in re-classifying the change.

7.2.3.50 DASA has identified that, for changes that are classified as major solely due to a need to tailor the TCB, continuing to process these as major changes once the tailoring of the TCB has been agreed imposes additional administrative burden without commensurate safety benefit, and can result in a delay to the introduction of safety improvements or capability upgrades. As such, DASA considers it appropriate for these changes to be re-classified to minor, as allowed by DASR GM 21.A.91, and either directly consumed (if subject to prior certification) or approved by a DASR 21J approved organisation holding appropriate privileges.

7.2.3.51 **Reclassification Process** (Figure1). Reclassification is only possible once the tailoring of the TCB has been agreed. An applicant may submit the requests for TCB tailoring and reclassification concurrently, allowing a single DASA response, or the reclassification request may be submitted after the tailoring has been agreed. Requests for reclassification are to be submitted via Letter or Minute to DASA via the DIA Type Certification mailbox (dasa.typecert@defence.gov.au). Requests must be submitted by an organisation that meets the eligibility requirements to apply for a major change under DASR 21 Subpart D (ie the MTC holder or a design organisation that provides MTC holder functions as part of establishing holder capability).[17]

7.2.3.52 The applicant must provide confirmation that the design would meet the requirements to be classified as minor if not for the tailoring of the TCB. This may be provided as an assessment from a DASR 21J approved organisation that has privileges to classify changes, or by providing evidence of approval as a minor change under the system of a recognised CAA/MAA with an equivalent classification system.

Superseded

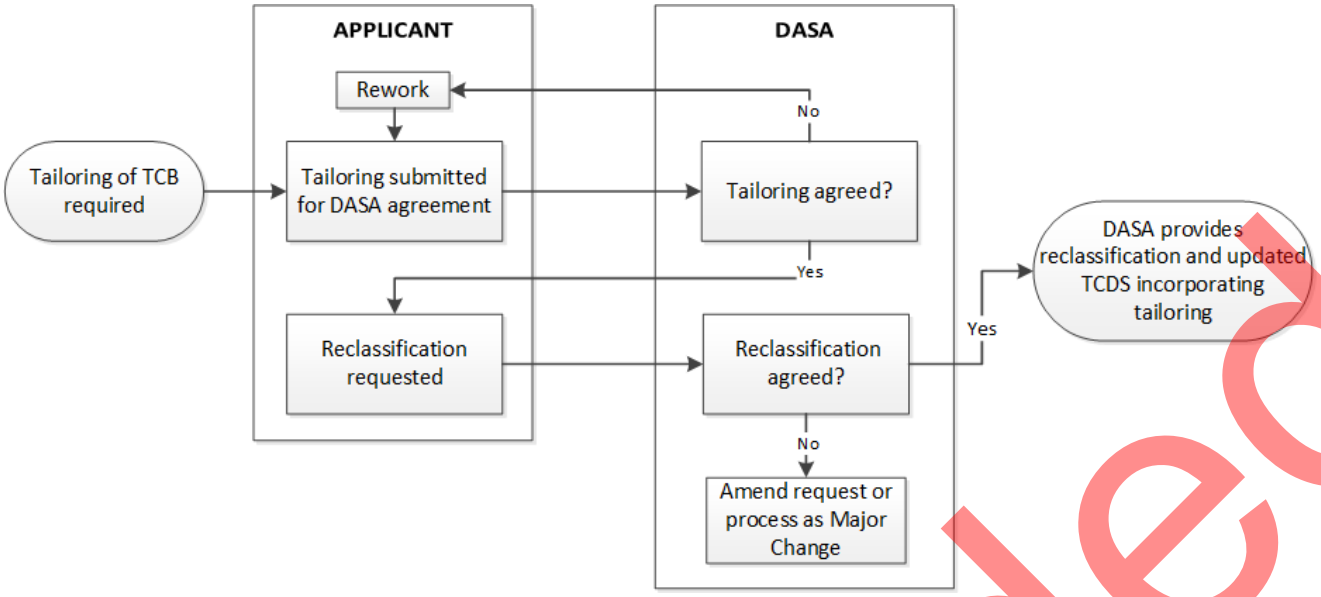

Figure 1: Process for reclassification when TCB tailoring is required

Compliance Demonstration

7.2.3.53 Compliance demonstration evidence comprises of reports, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the TCB requirements applicable to the change / MSTC is demonstrated. The applicant shall demonstrate compliance with the applicable TCB requirements either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.3.54 Refer to the 'Compliance Demonstration' evidence guidance in Section 7.2.2 for further information.

Application, Approval / Issue and TCDS Update

7.2.3.55 **Application.** Upon completion of all activities identified within the certification programme, including development of compliance demonstration evidence and DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for approval of a major change, or issuance of an MSTC, using the DASR Form 31A.

7.2.3.56 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will approve the major change or issue the MSTC.

7.2.3.57 **TCDS.** As required, DASA will develop and issue the TCDS update concurrently with the major change approval or MSTC issuance.

DASA Assurance

7.2.3.58 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining a major change or MSTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).

Superseded

2. DASA agreement of the TCB, including tailoring (refer 'Certification Basis' section above).

3. DASA Level of Involvement (LoI) in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme' section above). In all cases, DASA LoI activities must be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer to the 'DASA Assurance' guidance in Section 7.2.2 for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, approval of the major change or issue of the MTC, and update of the TCDS as required.

Holder Obligations

7.2.3.59 Given the DASR only allows the MTC holder to be the applicant for a major change to an existing MTC, there are no separate DASR holder obligations for major changes, and the MTC holder must undertake the obligations laid out in DASR 21.A.44 for the MTC, including and all major changes thereto.

7.2.3.60 Obligations for holders of an MSTC are laid out in DASR 21.A.118A . However, given DASA's policy of issuing all MSTCs to the government MTC holder organisation, and the fact that the DASR 21.A.118A obligations are essentially the same as those ofDASR 21.A.44, the MTC holder simply needs to continue to undertake all obligation laid out in DASR 21.A.44 for the MTC and all MSTCs they hold.

7.2.3.61 Refer to Section 7.4.1 for detailed guidance on the DASR 21.A.44 MTC holder obligations.

7.2.4 – Repair Designs (DASR 21 Subpart M)

Overview

7.2.4.1 Data that is used to accomplish repairs needs to be approved by a suitable and competent organisation. Data may be approved through a repair design approval process where DASA is the certifying authority, or through a process where recognition is used. These two broad pathways are covered by DASR M.A.304, which provides the requirements for data that is used to carry out repairs and modifications:

1. DASR M.A.304(a) and (b) allow data to be used that has been approved by DASA, and by a Design Organisation approved under DASR 21, respectively. In both cases DASA is the certifying authority and the requirements of DASR 21 Subpart M (Repairs) are applicable.

Superseded

2. DASR M.A.304(d) allows for the consumption of data that has been approved within the framework of Authorities recognised by DASA. In this instance the repair approval requirements of DASR 21 Subpart M (Repairs) are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate.

7.2.4.2 This section is relevant to data for repairs conforming to DASR M.A.304(a) and (b) and provides:

1. an overview of the repair approval process in accordance with DASR 21 Subpart M (Repairs)
2. guidance for design organisations and MTC holders regarding DASA's expectations for repair design development and approval
3. more detailed guidance in the form of a number of common repair scenarios.

7.2.4.3 Guidance regarding use of repair data in accordance with DASR M.A.304, including consumption of data using recognition provisions, is provided in the Section 8.2.

7.2.4.4 Note that additional general information about Repair Design authorisations is contained in Section 5.3 Annex R.

DASR 21 Repair Design Privileges

7.2.4.5 DASR 21 Subpart J privileges related to repair designs include the privilege to:

1. classify repairs (DASR 21.A.263(c)(1)),
2. approve minor repairs (DASR 21.A.263(c)(2)), and
3. approve certain[18] major repairs (DASR 21.A.263(c)(5)).

7.2.4.6 These privileges require the design organisation to have procedures agreed to by DASA, usually by issue of a Military Design Organisation Approval (MDOA). These procedures would normally be documented in a Design Organisation Handbook[19].

Repair Process

7.2.4.7 The overall process for development, approval and embodiment of repairs where DASA is the certifying authority is outlined in Table 7.3. Further guidance, in the form of specific scenarios are outlined in Annex D to Section 7.2 Repair Design Approval Scenarios. Note that the scenarios in Annex D are defined as an aid for explanation, rather than as a series of strict processes.

Stage	Description	Responsibility
Identify and Assess Damage	Damage identified for which there is no existing pre-approved solution.	CAMO
Develop Repair Design	Repair design data is developed.	Design organisation

Superseded

Repair Classification	Repair classified in accordance with the requirements of DASR 21.A.435a.	DASA or an appropriately approved design organisation under a procedure agreed with DASA
Repair Certification	Establish Certification Basis (CB). Demonstrate compliance with required CB elements, Compliance Verification, Declare Compliance. Submit application for approval if required.	Applicant that meets the eligibility criteria[20]
Repair Approval	Approval of Repair. The assignment of obligations to the repair approval holder (dependent on classification).	DASA or an appropriately approved design organisation under a procedure agreed with DASA.
Repair Configuration Management	Manage the accomplishment of repairs and maintain a record of aircraft configuration, which includes repairs.	CAMO
Production of Repair Parts	Produce repair parts.	Appropriately approved production organisation, under DASR 21 Subpart G or Subpart F, or an appropriately approved maintenance organisation under DASR 145
Repair Embodiment	Embody repair.	Appropriately approved maintenance organisation under DASR 145 or appropriately approved production organisation under DASR 21 Subpart G
Ongoing Holder Obligations		Repair design approval holder

Table 3: Repair Process where DASA is the Certifying Authority

Repair Design Classification

7.2.4.8 As per DASR 21.A.435a – Classification and approval of Repairs – a repair must be classified as either minor or major in accordance with the criteria laid out in DASR 21.A.435a. Classification of repairs guides DASA to apply appropriate assurance oversight and allows for the obligations of the holder of a repair design approval to be identified. Classification does not affect the certification basis, demonstration of compliance, independent checking or declaration of compliance and, as such, whether a repair is classified as major or minor does not affect the engineering rigour applied to the repair. Repair classification may be made by either DASA or by an appropriately privileged design organisation under a procedure agreed to with DASA[21].

7.2.4.9 DASR GM 21.A.435a states that a new repair – a repair that has not previously been approved for the application being considered on the individual aircraft in question – is classified as major if it has an appreciable effect on structural performance, weight, balance, systems, operational characteristics or other characteristics affecting airworthiness. This is elaborated on to highlight that repairs needing extensive static, fatigue or damage tolerance justification or testing, or requiring

Superseded

methods, techniques or practices that are unusual, are to be classified as major. This GM identifies repairs that require permanent changes to Airworthiness Limitations (AwLs) to be classified as major.

7.2.4.10 The paragraphs below give examples of what may need to be considered in developing a repair classification procedure. Each organisation must develop its own procedure which meets the requirements of DASR 21.A.435a, 21.A.239, 21.A.263 and 21.A.243 and is tailored to the organisations scope of work. However, the considerations below, based on the guidance provided in the GM 21.A.435a and GM 21.A.91, are provided to further clarify DASA's expectations of such a procedure.

7.2.4.11 For clarity, classification may consider the following three characteristics of the repair design:

1. Severity – the effect of the repair on airworthiness.
2. Complexity – the complexity of the design and the certification requirements.
3. Novelty – whether the design has been developed in accordance with established methods and practices for the repair application in question.

7.2.4.12 Generally repairs may be classified as major except when all of the following criteria are met:

1. Severity is low. Examples of the types of details that would be expected from repairs of low severity include:
    i. Structural performance, in terms of static strength, fatigue performance, damage tolerance performance, flutter and stiffness characteristics, is unaffected by the repair.
    ii. Load paths and load sharing in the vicinity of the repair are unaffected by the repair.
    iii. Weight and balance change is not greater than that allowed in the weight and balance manual or Original Equipment Manufacturer (OEM) repair guidance for weight and balance. This includes changes in centre of gravity and load distribution. Weight and balance of control surfaces can be particularly affected by even small changes.
    iv. Changes do not affect the operation or redundancy of a system, or an adjacent system.
    v. Changes do not affect operational characteristics.
    vi. Other characteristics related to airworthiness, or to environmental characteristics of the platform (such as noise, fuel venting and exhaust characteristics), are not affected including, but not limited to, fire protection, propulsion systems integrity and crashworthiness.
2. The repair design and the certification requirements are not complex. Examples of the types of details that would be expected from repairs of low complexity include:
    i. Repair requires no or minimal re-assessment or re-evaluation of original certification substantiation data
    ii. Repair design elements are straightforward.

Superseded

iii. Original type certification data is available, or if not available appropriate data can be established without complex engineering, and no assumptions are required in the definition of the certification requirements.

3. There are no new or novel features to the repair. Examples of the types of details that would be expected from a repair that does not have new or novel features include:

   i. Techniques, methods and practices are those employed in the regular management of the platform and type of defect.

   ii. Techniques, methods and practices are those accounted for in the platform Type Design.

7.2.4.13 It is recognised that in some cases not all data will be available at the time of initial repair classification, and so, judgement must be exercised. In the case where later data indicates that the initial classification is no longer valid, a repair may be reclassified. In this case, consultation with DASA and, where necessary, reconsideration of the Certification Programme (CP), is expected.

7.2.4.14 These classification considerations are outlined in Figure 2.

Superseded

Superseded

Figure 2 : Repair Classification Principles

Eligibility

7.2.4.15 Applicant eligibility requirements exist to control how designs are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance documents, artefacts

and how the declaration of compliance is made. This provides DASA with confidence in the applicant's ability to fulfil the obligations of the repair approval holder where applicable. As such applicants for repairs must meet eligibility criteria as defined in DASR 21.A.432A.

7.2.4.16 To be eligible as an applicant for a major repair design approval, the applicant is to either hold an approval under DASR 21 Subpart J, or may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to demonstrate capability, or may be a government organisation which has agreements in place with a design organisation with access to the type design data.

7.2.4.17 Any organisation is eligible to apply for approval of a minor repair design. It is recommended that an organisation considering applying for DASA approval of a minor repair design seeks approval through an organisation holding a minor repair approval privilege under DASR 21 Subpart J, as DASA priorities will likely lead to delays in the approval of minor repairs.

Approval

7.2.4.18 Repair design approvals may be issued by DASA or an appropriately privileged design organisation, in accordance with DASR 21.A.435b.

7.2.4.19 In the case where DASA is issuing a major repair design approval, DASA receipt of a DASR Form 31B should signify the completion of a period of engagement between the applicant and DASA during which the certification activities agreed within the CP have been undertaken[22], including satisfactory DASA inspection of compliance documents. Upon receipt of the application, DASA assures itself that agreed CP activities have been completed, and if assured, DASA issues to the designated major repair design approval holder a signed DASR Form 31B for major repairs under DASR 21 Subpart M.

7.2.4.20 Design organisations approved under DASR 21 Subpart J can approve designs for minor repairs and certain major repairs, subject to the scope and privileges recorded in their terms of approval, and subject to their internal procedures agreed to by DASA. Further guidance based on repair classification is as follows:

1. **Minor Repairs.** Most MDOA holders approved by DASA will have the privilege to approve minor repairs that are within the scope of their terms of approval (privilege DASR 21.A.263(c)(2)).

2. **Major Repairs.** Some MDOA holders approved by DASA may also have the privilege to approve certain major repair designs that are within the scope of their terms of approval (privilege DASR AMC1 21.A.263(c)(5). The definition of 'certain major repairs' is provided in DASR AMC1 21.A.263(c)(5), (8) and (9), and depends upon whether or not the MDOA holder holds the relevant MTC, MSTC or Australian Military Technical Standard Order Authorisation (AUSMTSOA). In all cases, the ability to exercise the major repair approval privilege is subject to additional criteria and limits based on the characteristics of each individual repair design. For MDOA holders who do not hold the MTC, MSTC or AUSMTSOA, each new major repair design should be assessed against the 'List associated with the privilege' and the relevant 'Justification document' to determine whether the privilege can be exercised. Refer to AMC1 and AMC2 to DASR 21.A.263(c)(5), (8) and (9) for further information on award of, and exercising, the privilege to approve certain major changes.

Holder Obligations

Superseded

7.2.4.20 Following approval of the repair design, the obligations for the repair are assigned to the holder of the repair design approval in accordance with DASR 21.A.451. For both minor and major repairs these obligations include:

1. DASR 21.A.4 – Coordination between Design and Production.
2. DASR 21.A.447 – Record Keeping.
3. DASR 21.A.449 – Instructions for Continuing Airworthiness.
4. DASR 21.A.451(a)2 – Specify the markings in accordance within accordance with DASR 21.A.804(a).

7.2.4.21 For major repairs additional obligations of the holder of the repair design approval include:

1. DASR 21.A.3A – Failures, Malfunctions and Defects.
2. DASR 21.A.3B – Airworthiness Directives.
3. DASR 21.A.439 – Production of Repair Parts.
4. DASR 21.A.441 – Repair Embodiment.
5. DASR 21.A.443 – Limitations.
6. DASR 21.A.433(b) – Substantiation Data.

Superseded

7.2.5 – Instructions for Continuing Airworthiness (ICA)

Basic Principles of ICA

7.2.5.1 **ICA and maintenance data.** ICA is only a subset of all maintenance data that must be complied with in the conduct of maintenance[23]. Other sources of maintenance data include Airworthiness Directives (or other applicable requirements or operational directives issued by DASA), modification and repair implementation instructions and applicable maintenance standard practices. ICA should not be used as a collective term for all maintenance data as other sources of maintenance data are derived from different sources and subject to different regulation. This section deals only with ICA, not all forms of maintenance data.

7.2.5.2 **Airworthiness requirement.** The applicant for an MTC must develop ICA as required by the Type Certification Basis (TCB). Civil primary certification codes used for military products contain clauses (e.g. FAR/CS 23/25/27/29.1529 (aircraft), FAR 33.4 and CS-E 25 (engines), and FAR 35.4 and CS-P 40 (propellers)) that prescribe the content and format of ICA. Products with a military-derived TCB (e.g. from MIL-HDBK-516) have equivalent requirements for the development of maintenance instructions that achieve a similar intent to the civil airworthiness requirements above.

7.2.5.3 **Content and scope of ICA.** To meet the ICA requirements of a civil airworthiness code (or equivalent requirements of a military-derived TCB), the applicant for an MTC must provide:

1. Scheduling information for all recommended maintenance tasks. This information is normally contained in a Maintenance Review Board Report (MRBR) (or equivalent document).

2. Maintenance instructions including those required for servicing, troubleshooting, the methods of removing and replacing items, system testing, ground running, symmetry checks, weighing, towing, jacking, storage limitations etc. This will typically be provided in the form of an Aircraft Maintenance Manual(s), Structural Repair Manual, Fault Isolation Manual, Illustrated Parts Catalogue etc. This information can be amended by the MTC holder (broad scope to amend the master copy) or maintenance organisations approved under DASR 145 (very narrow scope to modify).

3. Mandatory maintenance requirements in a segregated and clearly distinguishable section of the ICA, typically called the Airworthiness Limitation Section (ALS). The ALS contains the mandatory maintenance tasks and intervals, identified in the type certification process. Specific terminology and requirements for the ALS content will vary depending upon the PCC, however, the ALS will generally include mandatory requirements such as:

   i. Airworthiness Limitations (AwLs). AwLs encompass mandatory retirement / replacement intervals and mandatory inspection requirements (including inspection interval(s) and the inspection method). The term AwLs is most often associated with structural life limits and structural inspections that result from FAR/CS 2x.571 or the equivalent fatigue/damage tolerance requirements in military certification standards. However, the term AwL may also be used for other aircraft systems, such as mandatory replacement times for Electrical Wiring and Interconnect System (EWIS) components. As noted within AMC 21.A.41, the definition of an AwL 'interval' includes the interval metric (e.g. flight hours, landings, Equivalent Flight Hours (EFH), Fatigue Index (FI) / Fatigue Life Expended Index (FLEI), engine cycles, etc), and any algorithm, equation, factor(s) or other engineering data which must be used to calculate life accrual against the interval.

   ii. Critical Design Configuration Control Limitations (CDCCLs). CDCCLs identify the critical design features such as proper wire separation, proper installation of a panel gasket, minimum bonding jumper resistance levels, etc., that must be maintained in exactly the same manner throughout the life of the aircraft in order to comply with the type certificate and maintain airworthiness. The purpose of CDCCLs is to provide instructions to ensure these critical features are present throughout the life of the aircraft and are inspected and verified when alterations, repairs, or maintenance actions occur in the area. Design features that are CDCCLs are defined and controlled by FAA Special Federal Aviation Regulation (SFAR) 88 and preserves critical features of the aircraft needed for the Flammability Reduction Means to perform their intended function and prevent the occurrence of an unsafe condition.

   iii. Certification Maintenance Requirements (CMRs)[24]. CMRs are required inspections or maintenance tasks, and associated intervals, developed to achieve compliance with safety analysis requirements (e.g. FAR/CS 25.1309/29.1309, other discrete safety analyses requirements such as FAR/CS 25.671, 25.783, 25.901, and 25.933, and FAR/CS 29 equivalents). A CMR is intended to detect safety-significant latent failures (failures not known to the flight or ground crew) that would, in combination with one or more other

Superseded

specific failures or events, result in a hazardous or catastrophic failure condition. A CMR can also be used to establish a required task to detect an impending wear-out of an item whose failure is associated with a hazardous or catastrophic failure condition.

7.2.5.4 **ICA and the MTC.** Even though a complete set of ICA is required to obtain an MTC, only the ALS of the ICA (or equivalent terminology including CDCCLs and CMRs) forms part of the type design[25] however, they do form part of the Type Certificate. Stand-alone amendments to ICA, other than the ALS, are allowed to be changed by the MTC holder using a procedure agreed with DASA. Note: when completing a stand-alone change to ICA other than the ALS, the MTC holder is not exercising a privilege, but is instead fulfilling their obligation to keep the ICA current[26]. Changes to the ALS of the ICA must be processed as a change to the MTC, and should be classified as a major change[27].

7.2.5.5 **Identification of ICA.** The complete set of ICA for any product should be identified on the TCDS. Other information or instructions required for continuing airworthiness or safe operation of the aircraft, e.g. the approved Aircraft Maintenance Programme (AMP) or a Minimum Equipment List (MEL), is not ICA and is not subject to regulation applicable to ICA.

7.2.5.6 **ICA supplements.** Some major changes to an MTC, MSTCs, minor changes or minor/major repair designs may require variations to the product's ICA[28]. Variations to ICA arising from these design changes or repairs stand-alone from the product's master ICA and are published as an ICA supplement[29]. This gives the aircraft operating organisation the flexibility in managing the ICA applicable to their aircraft, depending on which approved changes and repairs they have chosen to embody. The approval of ICA supplements (including any changed or additional mandatory maintenance requirements) are encapsulated in the approval of the design change or repair. ICA supplements should be identified on the Supplemental Type Certificate Data Sheet, or on the minor change or repair design approval.

7.2.5.7 **ICA and the AMP.** The approved AMP in and of itself is not ICA for the simple reason the ICA requirements of the TCB do not mandate an AMP to be developed by the applicant for an MTC. The recommended maintenance tasks and intervals in the MRBR and the mandatory maintenance requirements identified in the ALS, combined with other requirements unique to each operator's role and usage (including data from a reliability programme) forms the basis for approval of each operator's AMP.

7.2.5.8 The maintenance instructions provided by the MTC holder (or ICA supplements provided by other design approval holders) will provide detail on how to carry out the tasks and inspections in the AMP and should only be amended by the MTC holder (or other relevant design/repair approval holder for ICA supplements) – see paragraph 7.2.5.4 above. Mandatory maintenance requirements must be clearly identified as mandatory in the AMP and cannot be extended without a corresponding approval of a major change to the MTC, or issue of an MSTC. Other ICA must be changed by the MTC holder using DASA agreed procedures. Changes to other recommended task and inspection intervals in the AMP can be approved by a CAMO using a procedure agreed with DASA, without requiring approval of a change to the MTC[30].

Responsibilities for ICA

7.2.5.9 **MTC holders**. The MTC holder is Defence's custodian of the product's ICA regardless of its original author. The MTC holder is responsible for the ICA's content, amendment and distribution to all organisations that operate the aircraft. The MTC holder can amend the ICA (in accordance with

Superseded

approval processes) and must distribute amendments to those organisations affected. If a change to a mandatory maintenance requirement is required, the change must be approved by DASA before distribution of the amendment. The MTC holder's processes for discharging its responsibilities for ICA (even if exercised through external organisations) must be included in the MTC holder's Type Continued Airworthiness Exposition (TCAE). Regardless of a product's TCB, the MTC holder should be able to identify all ICA and have that documented in the TCDS.

7.2.5.10 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their ICA supplements as the MTC holder has for the product's master ICA.

7.2.5.11 **Aircraft operating organisations.** Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided.

7.2.5.12 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable ICA and relevant ICA supplements. Maintenance organisations may locally modify ICA or ICA supplements using an approved procedure specified in their Maintenance Organisation Exposition (MOE) only for the purposes of efficiency, achieving the intent of the ICA when the instructions are deficient, or for the use of alternative tools/equipment[31]. A maintenance organisation must notify the MTC holder (or relevant design approval holder in the case of ICA supplements) when it has locally modified ICA, so consideration can be given to amending the master copy for wider distribution. A maintenance organisation modifying ICA for the purposes stated above does not constitute approving an amendment to the ICA (i.e. the source document) held by the MTC holder (or ICA supplement held by another design approval holder). Only the MTC holder or holder of the ICA supplement can approve amendments to ICA, noting the need to also seek approval of a major change to the type certificate if the amendment alters any mandatory maintenance requirements.

Non-Destructive Testing (NDT) ICA

7.2.5.13 NDT ICA are applied to ensure the airworthiness of aircraft through the inspection of aircraft structure and components. NDT ICA is often used as part of damage tolerance inspection regimes to ensure structural integrity. Consequently, it is critical to ensure that NDT ICA is developed by competent staff and provides sufficient information to enable NDT staff to perform inspections effectively.

7.2.5.14 NDT ICA provided to a DASR 145 Maintenance Organisation should include the following minimum information:

1. the inspection procedure to be used
2. the inspection area
3. the material type of the inspection area
4. the type of discontinuities to be detected.

7.2.5.15 Those organisations responsible for developing NDT ICA (DASR 21J Design Organisations, MTC holder) should consider using NDT Level 3 staff (as defined in EN4179) to verify that inspections are achievable, repeatable and meet the expected detection requirements of the design or repair. This is especially important where NDT ICA is used to support an AwL.

Superseded

7.2.5.16 The procedure for approving or modifying NDT ICA should be documented in the relevant organisation exposition. DASA recommends that personnel certified to NDT Level 3 in the relevant method be employed to approve and/or modify existing NDT ICA for application in specific circumstances. This accords with the requirements of European Standard EN4179.

Master Minimum Equipment List (MMEL)

7.2.5.17 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable / inoperative under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL cannot, in itself, be regarded as providing operational permission. It, however, can be the basis for the development of an individual Operator's Minimum Equipment List (MEL).

7.2.5.18 An MMEL forms part of the MTC. Approval of new MMEL or an MMEL amendment should be undertaken in accordance with the relevant DASR 21 Subpart[32]. Further guidance on MMEL development and approval in contained in Chapter 8.2.2, including information on:

1. typical characteristics and contents of an MMEL
2. options for developing an MMEL
3. suitable certification specifications for an MMEL
4. classification (major/minor) for changes to an MMEL
5. the DASA MMEL approval process.

7.2.5.19 Note that DASA is currently evaluating EMAR 21 version 2.0 changes that introduce the Operational Suitability Data (OSD) concept and requirements. MMELs are considered a category of OSD, and therefore, this section will be updated in the future once the relevant DASR 21 updates have been incorporated.

7.2.6 – Manuals

Basic Principles for Manuals

7.2.6.1 T**ypes of Manuals.** As per DASR 21.A.57, the holder of a type-certificate shall produce, maintain and update master copies of all manuals required by the applicable TCB.

7.2.6.2 Manuals (for the purpose of DASR 21.A.57) will fall into one of two broad categories:

1. **Aircraft Flight Manual (AFM).** The AFM is an authoritative source of information necessary for the safe operation of an aircraft. It contains the aircraft's operating limitations, operating procedures, performance information and other information and instructions necessary to operate the aircraft safely. Note that this information may be contained in several documents that contain limitations, information and instructions to ensure safe aircraft operation. Examples of other documents/ publications (in addition to the AFM) may include a Flight Crew Operating Manual, Mission Crew Operating Manuals and Pilot Handling Notes.

Superseded

2. **Manuals Containing ICA.** Certification codes require that the ICA must be published in the form of a manual or manuals[33]. The relevant certification code requirements will dictate the specific ICA content that must be published. Due to the broad and varied type of information that must be published, ICA for a particular aircraft type will usually be distributed through a variety of manuals, such as Aircraft / Engine / Propeller Maintenance Manual, Structural Repair Manual, Engine / Propeller Installation Manual. As noted above at paragraph 7.2.5.5, the MTC holder should be able to identify the publications and manuals that meet the intent of ICA requirements.

7.2.6.3 **AFM Guidance.** DASA AC 008/2020 contains detailed information on AFM content and approval, amending AFM content and use of AFM supplements. Further information specific to changes to type certificates which affect AFMs include:

1. DASR GM 21.A.91 which contains guidance for the classification of changes to AFMs
2. DASR AMC3 21.A.263(c)(2) which contains information on approval of minor changes to the type certificate which affect the AFM.

7.2.6.4 **Approval of Manuals.** Even though particular manuals are required by the TCB and therefore required to obtain an MTC, only certain contents of manuals will form part of the enduring MTC and / or require DASA approval. Contents of manuals that requires DASA approval includes:

1. The ALS of the ICA[34] (i.e. as published within a maintenance manual). Refer Section 7.2.5 for further guidance.
2. Mandatory AFM content (Operating Limitations, Operating Procedures and Performance Information). Refer DASA AC 008/2020 for further guidance.

7.2.6.5 Consequently, amendments to other manual contents is not a change to the MTC and can be undertaken by the MTC holder using a procedure agreed with DASA. Furthermore, as noted by AMC1 21.A.57, the process to update a manual may be separate from the process to approve or authorise the content of the manual[35].

7.2.6.5 **Manuals in the Context of Defence Aviation Orders, Instructions and Procedures (OIP) Management.** Manuals (for the purpose DASR 21.A.57) are part of the Defence Aviation OIP for the platform type. Lifecycle management of Defence Aviation OIP is discussed further in Section 6.7. A key message of Section 6.7 is that in addition to accuracy and completeness of OIP (a well-established principle in DASR 21), the usability / readability of OIP can cause or contribute to aviation safety hazards. Therefore, aviation safety hazards related to Defence Aviation OIP should be managed through an organisation's SMS. Note that this principle is consistent with DASR GM1 21.A.239(a) paragraph 3.1.5 which states that design organisations should "establish a system to collect in-service experience to be used for the improvement of the [maintenance and operating] instructions".

Responsibilities for Manuals

7.2.6.6 **MTC Holder.** In order to meet their obligation under DASR 21.A.57, the MTC holder should establish a system to produce, maintain and update manuals. As per DASR AMC 21.A.57, this system should ensure:

1. manuals are complete, current, and uniquely identified;
2. manuals contain their authority for use, document name, date of issue, and document/amendment status details;

Superseded

3. manuals are provided in a medium compatible with user requirements;

4. new issues, re-issues and/or amendments are approved and/or endorsed by appropriate appointments prior to their release, noting that the process to update a manual may be separate from the process to approve or authorise the content of the manual, eg approve AwL in ICA;

5. manual management records are accurately maintained, controlled, traceable and are accessible; and

6. manuals can be reproduced to any previous amendment status.

7.2.6.7 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their manuals or manual supplements as the MTC holder has for the product's master set of manuals.

7.2.6.8 **Aircraft operating organisations.** The operating organisations must manage and distribute the AFM and all other relevant manuals as part of their OIP Management System[36]. Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to all relevant manuals to the extent necessary for the scope of maintenance services being provided. The operating organisation should manage any aviation OIP related hazards through their SMS, and coordinate with the MTC holder, or applicable design organisation, as required to effect any necessary updates or improvements to manuals.

7.2.6.9 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable manuals. Maintenance organisations shall establish procedures to ensure that if found, any inaccurate, incomplete or ambiguous procedure, practice, information or maintenance instruction contained in the maintenance data used by maintenance personnel is recorded and notified to the author of the maintenance data[37].

7.3 Production and Military Certificates of Airworthiness

7.3.1 Production Assurance in the Defence Aviation Safety Program

Aim

7.3.1.1 This chapter details how the production of aircraft components is assured in the Defence Aviation Safety Program (DASP). This includes what release documentation is acceptable under DASRs, and the means through which that documentation is obtained. This chapter only covers aircraft components and does not include whole aircraft. For whole aircraft see MCoA - Chapter 5.3 Annex O and MPO – Chapter 7.6.

Introduction

7.3.1.2 Production of Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured.

Superseded

Acceptable release documentation

7.3.1.3 The purpose of release documentation is to provide evidence that the manufactured component conforms to approved design data. Aircraft components to be installed on Defence registered aircraft must be accompanied by one of the following release documents:

a. DASR Form 1—Authorised Release Certificate.

b. A native or alternate component Certificate of Release to Service (CRS) issued within a recognised airworthiness framework (refer to Chapter 6.5 —Recognition of other Aviation Authorities for identification of a native and alternate component CRS).

c. For standard parts or items designated as specific equipment under DASR 21.A.303, a Certificate of Conformity from the item's manufacturer (refer AMC to DASR 145.A.42(a)(4)).

d. For components fabricated under DASR 145.A.42(c), certificates of conformity produced by the fabricating maintenance organisation that are acceptable to DASA.

7.3.1.4 Release documentation under (a), (b) or (c) above enables that component to cross organisational (and possibly national) boundaries between its manufacture and installation. Manufactured components that do not need to cross organisational boundaries can be installed with locally produced certificates of conformity that contain all of the technical information found on a DASR Form 1 per item (d) above.

DASA production assurance

7.3.1.5 DASA assures production of all Defence aircraft components using one of three mechanisms depending on the release documents required by continuing airworthiness regulations. This is depicted below in Figure 3.

Assurance through Recognition Frameworks

7.3.1.6 The majority of aircraft and aircraft component manufacture for Defence occurs outside Australia and is assured through DASA's recognition framework. To be installed on a Defence registered aircraft, these components must be accompanied by a recognised native (Form 1 equivalent) or alternate release certificate. Each DASA Recognition Certificate provides details on the unique conditions and caveats to be applied to validate the native or alternate release certificates. Production of components assured through recognition do not require a DASR Form 1 as it provides no additional safety assurance above what is inherent under the recognition framework.

Assurance through DASR 21 – production by Military Production Organisation Approval (MPOA) or letter of agreement holder

7.3.1.7 Components manufactured outside of a recognised airworthiness framework (other than standard parts, specific equipment or components fabricated under DASR 145.A.42(c)) require a DASR Form 1 for installation. To issue a DASR Form 1 an organisation must hold a Military Production Organisation Approval (MPOA) under DASR 21 Subpart G, or a letter of agreement to manufacture under DASR 21 Subpart F . In this instance, the award and oversight of MPOA is DASA's assurance mechanism for the production of such components.

7.3.1.8 The only organisations that DASA will consider for award of MPOA are those that do not hold a recognised approval that enables release of the manufactured components under a native or alternate artefact (see Chapter 6.5 —Recognition of other Aviation Authorities). That is, the

Superseded

requirements of DASR 21 Subparts G will be imposed on an organisation for the sole purpose of issuing a DASR Form 1 for the manufactured components.

Assurance through DASR 145 – fabrication by maintenance organisations

7.3.1.9 DASR Form 1 must not be used for components fabricated by maintenance organisations under their DASR 145 approval. A locally produced certificate of conformity must be used instead. DASA's assurance of this production is via the issue and oversight of the organisation's DASR 145 approval. A DASR 145 MO will only have this activity included in the scope of their DASR 145 approval if they can sufficiently demonstrate their capability to perform such fabrication. Note that unless otherwise approved by DASA, only the DASR 145 MO who fabricated the component can install this component.

Figure 3: Production Assurance and Release Documentation under DASP

Manufacture and release of test articles

Superseded

7.3.1.10 If a test article is manufactured to gather certification evidence, the responsibility to control the manufacture of that article and ensure it accurately reflects the proposed design data rests entirely with the organisation seeking certification of the design. For test article manufacture required to achieve certification of a major change, the Certification Programme should describe the production control processes that will be used by the applicant in producing the test articles. If DASR Form 1 is used to release a test article for trial installation in an aircraft, Block 12 of the DASR Form 1 must clearly state that the article is in conformity with non-approved design data. The manufacture of test articles for certification does not require MPOA under DASR 21 Subparts G or a letter of agreement under DASR 21 Subpart F. These principles also apply for minor changes being approved under MDOA privilege.

Manufacture of modification kits

7.3.1.11 Maintenance organisations approved under DASR 145 may fabricate modification kits and issue certificates of conformity provided (a) the scope of their DASR 145 approval allows it, and (b) the completed modification kit will be installed by the same maintenance organisation (and under the same DASR 145 approval) issuing the certificate of conformity. Modification kits meeting both criteria above must not be released using DASR Form 1, but must still be manufactured to the approved design data and have locally produced certificates of conformity attesting to that fact. Fabrication of modification kits for onward supply cannot be performed under a DASR 145 approval and constitutes series production that must be assured by either recognition or through DASR 21. Modification kits manufactured external to the installing maintenance organisation must be accompanied by a DASR Form 1, or release documentation acceptable to DASA through recognition.

7.3.1.16 DASR 21 Subpart G – Military Production Organisation Approval

7.3.2 Military Certificate of Airworthiness (MCoA)

Introduction

7.3.2.1 This section supplements the DASP policy and provides guidance in support of DASR 21, Subpart H relating to MCoAs, their purpose, and their issue. The guidance included in this section discusses the MCoA concept and application from both an Australian Defence context, and where appropriate for the purposes of description, a civil aviation context.

7.3.2.2 Restricted MCoAs are also discussed where appropriate; however, such MCoAs are of limited utility in the Australian Defence context, and unlikely to be issued.

Purpose

7.3.2.3 A MCoA is an aircraft operating authorisation issued against an airframe tail that has the purpose to validate that the airframe conforms to the type design as specified on the Military Type

Superseded

Certificate (MTC). It serves as the final assurance artefact that the airframe is in a state of airworthiness per the inherent level of safety afforded by the type design and the underlying MTC basis. It is enabled by an organisation or operator, who has registered the airframe on the Australian Defence register, and has ensured conformity through meeting various requirements.

7.3.2.4 A restricted MCoA will follow the same rules albeit that the airframe shall conform to a restricted MTC and to specific airworthiness requirements ensuring adequate safety.

Application

7.3.2.5 MCoAs in the Australian Defence context can only be issued by the DASA or a Delegate of the Safety Authority (DoSA). The release document is via a DASR Form 25 Military Certificate Of Airworthiness and applies only to aircraft that are registered on the Defence register in Australia.

7.3.2.6 An application for a MCoA shall be made by an eligible organisation via DASR Form 25a - Application for Certificate Of Airworthiness. In the Australian Defence context, the MAO and/or their CAMO are eligible to be applicants for a MCoA as holders of a MAOC. Aircraft that are Non-Defence Registered (NDR) are not subject to Airworthiness DASRs, and are subject to a separate airworthiness requirements, typically under the applicable airworthiness Civil Aviation Safety Regulations. See further DASP Vol 3 guidance on NDR at Chapter 6.1.3.

7.3.2.7 A MCoA application shall be made in a form and manner established by the Authority (DASA in Australia) of the State of Registry[38], per DASR.21.A.174(a). When considering a MCoA application, the Authority will consider all documentation in support of the state of the airframe at application. This has particular significance for used aircraft, where records of usage, maintenance, modifications and repairs may not be to the standard normally required by Defence.

7.3.2.8 The MCoA application presents documentation that the aircraft conforms to the type design approved under the relevant MTC. The required documentation, artefacts, reports and historical evidence (if applicable) to support the application shall be in accordance with DASR.21.A.174(b). Any deviations from the certified type design must be approved by an appropriately authorised design organisation.

7.3.2.9 For used aircraft, DASA will require a Military Airworthiness Review Certificate (MARC) conducted in accordance with DASR Part M regulations before issuing an MCoA. The MARC review is a physical survey of the aircraft and supports issue of the MCoA to satisfy DASA that the submitted documentation is reflective of the physical aircraft. The MARC process is further discussed as part of paragraphs 7.3.2.15 and 7.3.2.16 of this section.

Issue of a MCoA

7.3.2.10 A MCoA can only be approved and issued if all modifications, repairs and/or production deviations implemented on the airframe are approved under DASR 21, or under a recognised national civil or military airworthiness framework.

7.3.2.11 For new civil or commercial derivative aircraft (CDA) delivered to Defence, the acquisition project should seek a civil export CoA from the Civil Aviation Authority (CAA), via the prime aircraft OEM, where a civil Type Certificate (TC) is in place. This export CoA needs to be obtained prior to transfer to the Defence register, and forms the foundation for the issue of an Australian MCoA. Failure to obtain an export CoA for a civil or CDA may limit DASA's ability to issue an evidence based MCoA.

7.3.2.12 For instances where a civil Type Certificate (TC) is not in force or Defence is leasing an aircraft that has been in civilian use, the requirement for a CAA CoA can be demonstrated if a CAA

Superseded

authorised delegate provides a document that attests the aircraft would be eligible for issue of a Standard or Export CoA, if the aircraft was to be registered by a Civil Aviation Authority. Defence will accept only a Standard CoA under DASR 21.A.172, DASR 21.A.173 and DASR 21.A.174. DASA-DIA staff should be consulted for specific advice.

Validity and Amendment

7.3.2.13 The MCoA Holder (typically the MAO) is responsible for the continuing validity of an MCoA. A MCoA may be amended or modified only by the Authority (DASA in Australia) of the State of registry[39]. A MCoA may be issued for an unlimited duration, and remains valid subject to the conditions described in DASR.21.A.181.

7.3.2.14 Additionally, the ongoing validity of a MCoA requires that damage be assessed, and all applicable modifications and repairs carried out, using as appropriate the data requirements of DASR.M.A.304.

7.3.2.15 The validity of a MCoA is periodically renewed via the MARC process, as per DASR.M.A.901. This involves an airworthiness review of the aircraft and its continuing airworthiness records. The initial airworthiness review is due within 12 months of the issue date of the aircraft's initial MCoA. The validity of MARCs issued by a CAMO may be extended twice for a period of one year each time if the aircraft has been in a controlled environment.

7.3.2.16 The MAO is accountable for the continuing airworthiness of an aircraft and shall ensure that no flight takes place unless the MCoA and the MARC remain valid, as per DASR.M.A.201. If a MCoA becomes invalid, the MAO must return the aircraft to an airworthy condition before operating the aircraft or seek an alternate flying authorisation. A new MCoA is only required if the aircraft is being returned to the Defence register after removal, or the certificate is revoked by the Authority (DASA in Australia) of the State of registry[40]

7.4.1 Military Type Certificate Holders

Introduction

7.4.1.1 A Military Type Certificate Holder within the DASR framework provides Defence a suitable entity to 'hold' the Type Certificate. Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed and that the inherent safety that the platform type certification basis affords is maintained.

7.4.1.2 Unlike civil TC obligations, Defence MTC obligations are not enforceable via national legislation, meaning there is no enduring obligation under law for foreign organisations to manage

Superseded

the basis of certification through the product's life cycle. Therefore, in the application of DASRs, the Defence MTCH is a government organisation, most likely the organisation that acquired the product under contract.

Application of DASR provisions for the MTCH

7.4.1.3 The following principles guide the application of the above regulatory provisions:

a. **Principle 1.** DASA issues an MTC for Defence registered aircraft types. Unlike the civil context, a separate TC for the aircraft power plant and/or propeller has not been issued thus far and is nominally included as part of the platform TC.

b. **Principle 2.** DASA shall only issue MTCs to suitable Commonwealth government organisations (the holding organisation) to hold the MTC. The holder is responsible for ensuring that holder functions/obligations are executed. In the Defence context, the MTCH is able to achieve the regulatory intent via a direct or indirect arrangement with the aircraft/engine OEM.

c. **Principle 3.** Military Supplemental Type Certificates (MSTCs) will also be held by the MTCH or holding organisation, with the MTCH responsible for carrying out all MSTC functions/obligations. An MSTC in the Defence context can supplement the MTC for managing sub-fleets, significant changes to the TCB, large and complex changes. They are not used to achieve a commercial outcome such as in the civil design domain.

MTCH Safety Objectives

7.4.1.4 The MTCH has two aviation safety objectives:

a. To support the safe operation of the aircraft type by command units. Achieving Defence strategic objectives requires continuous capability enhancement, and at times, the conduct of operations at markedly elevated levels of risk. In addition, operators of aircraft will require explanatory information, advice and data to operate the type safely. The MTCH must have access to type design data, or support arrangements with the aircraft/engine OEM for the provision of designs and advice to support safe operation of the type.

b. To continuously monitor the type in service and ensure the ongoing validity of the Type Certificate, by investigating issues and providing corrective actions where required. The initial certification of a type establishes the known and understood level of safety inherent in the standards against which it was certified. Through the life of the type, latent hazards within the certified design, not identified during initial certification, may emerge requiring some action to address. Similarly, the use of the aircraft may vary and new designs be incorporated. Regardless, the MTCH has the high level objective to maintain the level of safety intended during initial certification.

Australian Context

7.4.1.5 The MTCH must account for the unique Defence context where the MTCH is not the OEM of the type and noting that the DASR are an amplification of the broader Work Health and Safety[41] obligations for the Defence aviation environment. In this context, the MTCH is the steward of the Defence type in service. To fulfil this role:

1. The MTCH should be broadly aware of all historic and emerging hazards relevant to their type[42]. This awareness requires:

Superseded

i. The collection of relevant aviation safety information (occurrences etc.) from within the Defence aviation system;

ii. The collection of relevant aviation safety information (occurrences, service bulletins, airworthiness directives etc.) from operators and authorities of similar types; and

iii. Consideration and conduct of additional verification activities(such as test programs) to generate further data independently and as necessary.

2. The MTCH is to lead the risk management of the type for the life of type, from initial certification to withdrawal from service. This leadership includes:

i. Ensuring operators are made, and remain, aware of the hazards extant in their type;

ii. Ensuring that essential risk controls (both technical and operational) pertaining to the safety of the type are, and remain, effective;

iii. Leading local efforts to eliminate or further minimise known hazards;

iv. Influencing external organisations (such as OEMs, joint user groups, co-operative partnerships etc.) to eliminate or further minimise known hazards.

MTCH Structure

7.4.1.6 To support these safety objectives, the MTCH organisation is broadly structured around two key systems, as detailed in Figure 4. These systems are responsible for the interactions regulated by DASA and are required elements of the MTCH supporting organisation.[43] They are:

a. The Safety Management System (SMS). This system ensures that the MTCH will collect operational data, analyse that data, investigate potential safety concerns and provide corrective actions.

b. The Design Assurance System (DAS). This system provides products (for example Service Bulletins correcting deficiencies, publication updates etc.) to operators of the Type.

Superseded

Figure 4: Safety Structure pyramid

7.4.1.7 Note that the safety management and design assurance systems are generic and are broadly applicable to all MTCH structures and implementations noting their varying constructs. It is likely that in implementing the systems, each MTCH through their partner organisation will employ business processes specific to their context. For example, the MTCH may rely upon long standing Defence engineering processes such as Technical Information Review, System Safety Working Groups and Configuration Control Boards to achieve the SMS intent. Similarly, the DAS of a foreign design organisation may not be entirely aligned with the requirements described in DASR 21.A.239 invoking the need to utilise Authority recognition arrangements.

7.4.1.8 Each organisation that holds a Type Certificate will be different and the model outlined in Figure 4 will not be a one-size fits all construct. It is appropriate that each organisation will implement these functions with different size, scale, or complexity, dependent on their need. For example, a CDA

Superseded

may rely on a large portion of sub-contractor products from civil aircraft OEMs operating under legislated civil safety constructs, and thus will not require a large compliance verification element.

MTCH Responsibilities

7.4.1.9 In the Australian Defence context, the government organisation holding the MTC is usually relatively small and is supported by one or more other organisations (contractors, foreign Defence organisation, OEMs etc.). As a result, responsibility for the conduct of MTCH obligations is often vested with these support organisations. This has led to confusion regarding accountabilities. To clarify:

a. Regardless of the organisational construct, the government organisation is the MTCH, and is accountable for all activities undertaken by its partners with respect to the obligations of the MTCH.

b. As such, it is unlikely that a passive compliance assurance relationship between the government organisation and its partners will suffice. DASA needs to be assured that the MTCH is able to meet its obligations – this may require the government organisation to lead key MTCH activities and be active in resourcing, prioritising, and implementing MTCH activities to ensure continued airworthiness and supporting safe operation of the type by the operator.

Eligibility to hold an MTC

7.4.1.10 A government organisation can be eligible to hold an *MTCH* under one of three regulatory provisions when applying for an MTC:

a. DASR 21.A.14(a). This provision is applicable where the government organisation has demonstrated its capability by holding a Military Design Organisation Approval (MDOA), and thus meets the requirements of DASR Subpart J and is capable of performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources.

b. DASR 21.A.14(b). This provision is an exception to subpart (a) where the organisation has no demonstrated capability, but may be able to obtain an MDOA in the future, and thus alternative procedures can be used in the starting phase as an organisation moves toward an MDOA or where there are limited duration design activities that may be required (such as initial certification of a platform).

c. DASR 21.A.14(c). This provision is an exception to subparts (a) and (b) where the government organisation is not capable of meeting the requirements of Subpart J and/or performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources. In this instance, the government organisation is entirely reliant upon partners to meet the requirements of Subpart J.

Initial Assessment of MTCH capability

7.4.1.11 In the Defence context, assessment of the capability of the MTCH occurs in parallel to certification of the aircraft type, but must be completed before a Type Certificate can be awarded to the MTCH. DASA assessment of MTCH capability will include:

Superseded

a. An initial assessment of the organisation's personnel, processes, resources and support arrangements to establish that the MTCH will be able to perform/carry out the MTCH obligations outlined in DASR 21 and that the processes are present and suitable.

b. Supplementary on-site activities such as observing System Safety Working Groups, or reviewing Failure, Malfunction, and Defect data collected, in order to establish that the organisation is operating and effective.

c. An assessment of the MTCH Type Continued Airworthiness Exposition (TCAE). The TCAE describes all MTCH arrangements in order to execute the holder obligations and maintain the integrity of the type certificate. The broad content of the TCAE shall include, but is not limited to the description of the MTCH framework, design support arrangements, processes, procedures, governance, resources, and MAO/CAMO interfaces in place to meet the regulatory intent for the platform. In addition, the TCAE should include a detailed compliance matrix explicitly describing their arrangements in place to execute each MTCH obligation. The TCAE is the appropriate document where nuances particular to the platform and/or MTCH arrangements shall be described for Authority awareness and/or proposed alternative means of compliance.

MTCH Oversight & Enforcement

7.4.1.12 Oversight and Enforcement on the MTCH will be conducted by DASA as assurance activities in either a routine or a targeted format. The activities will have the objective to assess a MTCH organisation in their execution of MTCH obligations and functions. The scope of the assessment may involve any of the explicit and/or implicit obligations and may be a result of feedback received to warrant an assurance activity. Findings will be issued for non-compliances; however, the DASA team carrying out the assessment also looks to provide outcomes aiming to improve the overall effectiveness of the MTCH organisation. Oversight and enforcement on the MTCH arrangement will be based on the MTCH executing their obligations in accordance with the regulatory intent and their TCAE.

7.4.1.13 Further guidance on the DASA oversight and enforcement framework is provided in DASP Vol 3, section 4-1-5

MTCH Obligations

7.4.1.14 Within the DASRs the MTCH have the following obligations.

DASR 21.A.3A – Failures Malfunctions and Defects

7.4.1.15 This has three aspects which must be undertaken:

1. DASR 21.A.3A(a). Have a system for the collection, investigation and analysis of data relating to failures, malfunctions, defects or other occurrences, which cause or might cause adverse effects on the airworthiness of the product.

b. DASR 21.A.3A(b). Report to DASA occurrences, which may result in an unsafe condition.

c. DASR 21.A.3A(c). Investigate the root cause of occurrences and implement actions to eliminate or otherwise minimize any resulting hazards and their associated risks

Superseded

SFARP. If DASA finds action is required to correct the deficiency, the MTCH shall submit the relevant data to DASA.

7.4.1.16 **Reporting to DASA.** Where the MTCH assesses that an occurrence of a failure, malfunction or defect "may result in an unsafe condition[44]" that occurrence must be reported to DASA. Note this is a more limited and very specific subset of all occurrences that must be collected and considered by the MTCH. For these 'reportable occurrences' the MTCH must also report the results of MTCH investigations and any proposed action by the MTCH to DASA.

7.4.1.17 **Investigate and implement actions.** In the event that an unsafe condition may exist, the MTCH is obliged to take appropriate actions and be pro-active to eliminate and/or minimise the associated risks so far as reasonably practical. DASR 21.A.3A does not require the MTCH to consult DASA for review or approval prior to initiating any analysis, investigation and/or remediation actions. DASA provides additional, external and independent assurance of the actions of the MTCH but does not lead the MTCH in satisfying DASR 21.A.3A.

7.4.1.18 Further guidance on Occurrence reporting is provided in DASP Vol 3, section 7-4-2 and section 6-3

DASR 21.A.3B Airworthiness Directives

7.4.1.19 Where DASA determines an Airworthiness Directive (AD) is required for mandating actions for remediating an unsafe condition the MTCH must:

1. propose appropriate corrective actions and/or inspections

b. provide operators of the type all data required to comply with the AD

c. provide solutions/data to DASA to correct the deficiency and restore aircraft safety. This may include additional data to that provided under DASR 21.A.3A, specifically to support the release of an AD.

7.4.1.20 DASA's decision to release an AD may occur immediately following an occurrence or many weeks, months, or even years later. Per paragraph 7.4.1.17, the MTCH is to proceed with actions to eliminate the hazard or minimise the risks independently of DASA. This provision exists to support DASA mandating action proposed by the MTCH, not to direct the MTCH in the execution of their role.

7.4.1.21 Further guidance on Airworthiness Directives in the ADF context is provided in DASP Vol 3, section 7-4-3

DASR 21.A.4 Coordination between Design and production.

7.4.1.22 The MTCH shall coordinate between design and production organisations, to provide production data, as well as receive failure/malfunction/defect data from production organisations.

7.4.1.23 Where whole aircraft, parts and/or modification kits etc. are being produced, the MTCH arrangements are to ensure that the design and produced article align. For example, if the design is changing (materials/dimensions/finishing etc.) then that information will be provided to the organisation producing the item. Similarly, there cannot be changes to the item being produced without the knowledge of the MTCH and/or the responsible design organisation supporting the platform. Finally, this agreement must ensure the communication of occurrences, especially from the production organisation to the MTCH and/or their design organisation.

DASR 21.A.42 Integration

Superseded

7.4.1.24 The MTCH shall be responsible for the integration of Products, Weapons and other Systems onto the aircraft type.

7.4.1.25 This requirement places the obligation on the MTCH to consider the impact to airworthiness on integrating products, weapons or other systems, onto the aircraft. As the MTCH is also the only organisation eligible to apply for a major change to the type, the DAS of the MTCH (in cooperation with their partner organisations) must be sufficient to enable this. This obligation is not limited to aircraft components, but as expanded upon in Paragraph 7.4.1.49 for role equipment as well.

DASR 21.A.55 Record Keeping

7.4.1.26 The MTCH shall hold all relevant design information necessary to ensure the continued airworthiness of the type and make this available to DASA as required.

7.4.1.27 In the Defence context, the MTCH will not be the OEM, and the regulations cannot assume the MTCH created the type design data. Thus, this regulation ensures that the MTCH can access all data necessary to support the type design and ensure that major changes to the type continue to meet the appropriate airworthiness requirements.

DASR 21.A.57 Manuals

7.4.1.28 The MTCH shall produce, maintain and update master copies of all manuals required by the TCB and provide copies, on request, to DASA.

7.4.1.29 A manual under this regulation is part of the type design considered during type certification. It follows that any manual assessed during certification is therefore required by the TCB under this regulation. Such manuals contain content critical to keep the type airworthy or to operate the type safely within its designed limits. An example of a manual is the Aircraft flight manual, an engine manual[45] or a propeller manual[46].

7.4.1.30 For the purpose of initial certification, the MTCH is to provide manuals applicable to the ADF type. Thus, manuals produced for aircraft/products certified under other airworthiness authorities must be evaluated prior to releasing under the DASR. For the purpose of maintaining initial airworthiness in line with OEM issued updates, the MTCH must maintain and update master copies by enabling changes to be evaluated. Prior to promulgation, such change proposals will;

a. consider applicability to any unique ADF aspects or environment.

b. classify the content being considered.

7.4.1.31 The regulation implies that the MTCH will execute the obligation in a timely manner commensurate to the (safety) criticality of the update and any OEM advice.

7.4.1.32 Further guidance on the Aircraft Flight manual in the ADF context can be found in AC 008/2020

DASR 21.A.61 Instructions for Continuing Airworthiness

7.4.1.33 The MTCH shall provide the Instructions for Continuing Airworthiness (ICA) required by the TCB to operators. Changes to that ICA will also be provided to all operators.

7.4.1.34 ICA detail the methods, inspections, processes, and procedures necessary to maintain the aircraft and/or products in an airworthy condition and within the usage parameters of the aircraft

Superseded

design. ICA are an airworthiness requirement of the TCB and are prepared at initial certification by the appropriate manufacturer for each product, part or appliance. The regulation requires the MTCH to furnish the complete set of ICA to the Operator and to maintain the currency of the ICA for the ADF Type.

7.4.1.35 In the Defence context, this has particular relevance for the MTCH as often type design data will be produced under other regulatory systems and ICA will not be clearly identified. Part of the responsibility of the MTCH under this regulation is to identify and manage the ICA for a type where the OEM documentation has not explicitly referenced which instructions are ICA. This is usually where the aircraft is largely of military design, and in these cases, the MTCH will require an established relationship with the OEMs to enable clarification of maintenance documentation, when it cannot be determined from inspection what maintenance data is ICA.

DASR 21.A.44(b) - Identification of Products, parts and Appliances (DASR 21 Subpart Q)

7.4.1.36 Identification of products, parts and appliances. The MTCH shall:

a. specify how parts are to be identified.

b. specify how identification data (plates/etchings etc.) are to be handled.

c. identify critical parts.

7.4.1.37 In the context of EMAR, this obligation leverages a responsibility onto the MTCH to specify part marking schemes to their production organisations, who in the European context could be located in multiple countries. However in the Defence context the MTCH will in most cases rely on existing design organisation/production organisation arrangements in foreign countries with part identification already in place. To achieve the intent, the MTCH will appropriately leverage the OEMs part identification systems/schemes and only if applicable, specify the manner in which locally produced products, parts and appliances are identified.

7.4.1.38 Further guidance on Production in the ADF context is provided in DASP Vol 3, section 7-3-1.

DASR 21.A.44(c) - Continued Integrity of the Aircraft Structure and Propulsion System

7.4.1.39 DASR 21.A.44(c) requires that the MTCH shall ensure the continued integrity of the aircraft structure and propulsion system through ongoing monitoring and periodic assessment. Acceptable means of compliance for this regulation is provided in AMC 21.A.44(c). Chapter 6.6.3 provides extensive guidance to support application of AMC 21.A.44(c).

MTCH Obligations– Implicit Obligations

What is an implicit obligation?

7.4.1.40 In addition to the eligibility criteria listed at DASR 21.A.14(c) and the obligations listed at DASR 21.A.44(c), the regulations also include implicit obligations and expectations for the MTCH. That is, while an obligation has not been expressed, as “the MTCH must….” the operation of a regulation (or the AMC to that regulation) clearly depends upon the MTCH performing a function to ensure the continued airworthiness of the type or the safe operation of that type.

DASR 21.A.113 and 115

7.4.1.41 An applicant for a Supplemental Type Certificate (STC) shall prepare data to support the application independently or as part of an arrangement with the MTCH. In the defence context, the MTCH will hold all STCs and is therefore pivotal to enable an STC application through a ‘no technical

Superseded

objection' assessment and to provide the necessary design data. The advice provided by the MTCH shall enable for the safe integration by multiple design organisations of STCs onto the platform.

DASR 21.A.445 Subpart M Repairs

7.4.1.42 The MTCH is to support organisations performing major and minor repairs including unrepaired damage assessments by providing adequate information to enable their evaluation.

7.4.1.43 The MTCH may commission/initiate the activities through their supporting design organisation with appropriate approvals in place to design structural repairs. The MTCH will enable the provision of sufficient technical data where necessary.

AMC 21.A.709(b)(3) Approval of Flight Conditions

7.4.1.44 Flight Conditions underpin the issue of MPTFs as alternate authorisations assuring operations outside the strict requirements of the TCB and DASR M requirements and often at elevated levels of risk.

7.4.1.45 To make sure all reasonable knowledge is considered in the risk assessment supporting Flight Conditions and MPTF, the MTCH should be consulted to provide technical assessment inputs given access arrangements to type design data. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support/facilitate these assessments.

7.4.1.46 While not specifically identified, the reference to 'a design or engineering organisation suitably knowledgeable of the certified Type Design and with access to Type Design information' is usually read to mean the MTCH or OEM.

GM M.A.301(a)(2).2 Credible Data

7.4.1.47 Where operations are not at elevated levels of risk, but a defect remains preventing the release of the aircraft back to service, an operator may use 'credible data' for the deferral of defects in accordance with DASR M.A.301. Since the list of credible data includes type certification data, the MTCH would be a likely source of such information and be expected to provide it to operators as required. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support these assessments.

GM ORO.75 Use of Role Equipment

7.4.1.48 The MTCH is expected to support operators in the determination as to whether a piece of equipment is considered role equipment or a certified part.

7.4.1.49 Whilst the MAO has direct responsibility for integrating role equipment onto their aircraft, it is expected that they utilise technical assessments when appropriate. As the MTCH has access arrangements for assessments using type design data, the MTCH shall support the operator to ensure the part or equipment is integrated onto the type with appropriate consideration.

DASR AO.GEN.05(c) Management of Orders Instructions & Publications (OIP)

7.4.1.50 The MAO is required to have a documented agreement with the MTCH and seek MTCH support for control of air operational OIP and the use of Foreign Source Data (FSD).

7.4.1.51 This introduces an implicit requirement upon the MTCH to collaborate with the MAO via an agreement for review and appropriate approval of aviation operational OIP and FSD prior to use. This has particular relevance to the Aircraft Flight Manual (AFM). In the Defence context, the management of the AFM is complex with the one document having multiple uses and regulatory requirements. As

Superseded

a result, the MTCH shall be pivotal to ensure aviation operational OIP and FSD activities do not inadvertently alter content critical to compliance with the type certification basis.

7.4.1.52 Chapter 6.7 of the DASP Manual Volume 3 provides further guidance for OIP.

7.4.2 Continued Airworthiness Occurrence Reporting

Introduction

7.4.2.1 This section provides guidance to Occurrence reporting (OR) in the continued airworthiness domain (for design and production). This section is subordinate to the wider OR guidance provided as part of DASP Vol 3, chapter 6.3 which describes the wider OR framework.

7.4.2.2 Under DASR Part 21, organisations holding an approval have a requirement levied onto them to collect data on, conduct investigations of and provide analysis on any Failures, Malfunctions, Defects (FMD) or other occurrences, which creates or has the potential to create an unsafe condition. An unsafe condition is a state where an adverse effect on airworthiness exists being the result of a compromised or potentially compromised type design. Any occurrence that is assessed to have resulted in, or may result in, an unsafe condition[47],[48] must be reported to DASA and other organisations required by the implementing regulations.

7.4.2.3 Occurrence reporting by DASR 21 approval holder(s) is an essential continued airworthiness activity and enables risks and hazards associated with the type design to be identified and addressed in accordance with DASR 21.A.3A(a). All organisations that hold a DASR Part 21 approval including (but not limited to) the platform Military Type Certificate Holder (MTCH), Subpart J design organisations, Subpart F/G production organisations are obligated to have systems in place to achieve the regulatory intent of occurrence reporting.

Collecting FMD Data

7.4.2.4 The holder organisations operating under the DASR Part 21 regulations are expected to have arrangements in place that collects technical information from a spectrum of local and international sources/networks (civil and military) relevant to their platform. This has the primary purpose to access real time (critical) design related safety information for the product/part or appliance. The technical data may be directly applicable to types operated by the ADF or may require some applicability assessment before being considered for further consumption.

7.4.2.5 Collection of FMD data either directly from the ADF fleet or indirectly from other operators also has the purpose to provide the Holders with ongoing data that can be evaluated for patterns and/or reoccurrences. Such evaluation may identify failure issues that present as disparate, but may be linked. This level of analysis has the objective to identify latent design or manufacturing defects before they are realised during operation.

Occurrence Investigations in the DASR Part 21 Domain

7.4.2.6 In the Defence context, investigations involving FMD directly attributable to the type design and/or manufacturing are conducted by the platform MTCH under obligations in DASR 21.A.3A. Under this regulation, the MTCH must with all reasonable practicality initiate appropriate levels of investigation within their design support network to determine the root cause. This may take the form of reaching back into the OEM to evaluate the circumstances and determine the likely cause.

Superseded

Similarly, the production organisation or the part/component OEM may be consulted where a manufacturing issue needs analysis.

What constitutes a reportable Occurrence?

7.4.2.7 A FMD occurrence may originate from an issue identified on the ADF type or from a foreign fleet that is closely related to the ADF type. However, the immediate type design/airworthiness impacts from an FMD occurrence in the Part 21 domain are not always apparent and often requires detailed investigation to be completed. An occurrence may not be identifiable until investigation results are reported.

7.4.2.8 Similarly, there are instances where a failure, malfunction or defect, or analysis of failures, malfunctions or defects represents some level of shortfall to the type design but may not result in a reportable occurrence in accordance with DASR 21.A.3A(b) based on an assessment of the available information at that time. In these situations, the holder ought to make a judgement as to whether the shortfall constitutes a risk or not and what actions/advice is required to manage the risk (perceived or real). The Authority always encourages the community to be conservative in their judgements and provide an occurrence report - voluntary occurrence reports are an option.

7.4.2.9 In the Defence construct, the MTCH organisation is expected to receive relevant technical information (TI) from a range of sources including other operators (military or civilian, where relevant). In assessing the external TI, the MTCH must verify applicability to the ADF type and consider the ADF CRE. Once verified as applicable, a reportable occurrence is warranted satisfying any of the following conditions where the incoming technical information;

1. describes a design issue (real or potential) that leads to an unsafe condition; or
2. describes a safety concern that has a real or perceived airworthiness impact and requires some time compliance action; or
3. originates from the type OEM or Civil Aviation Authority (CAA) /Military Aviation Authority (MAA) regulator mandating an action with an accompanying risk assessment.

7.4.2.10 An occurrence on an ADF aircraft may require the outcome of an investigation before a determination can be made to report under DASR 21.A.3A. However, once the locally sourced TI is received, the same conditions of sub-paras 9a and 9b apply to determine if a reportable occurrence is warranted.

When and how to Report

7.4.2.11 Reporting occurrences to the Authority has the intent to make the Authority aware of an event that has caused or has potential to cause an unsafe condition in the current timeframe. This enables the Authority to begin their assurance function in real time and allow for intervention (where necessary) without undue delay. The reporting time period for the MTCH community is 72 hours for an occurrence once deemed reportable. It is acknowledged that the time between the actual occurrence and the MTCH being fully informed of an unsafe condition existing on their type can vary depending on many factors. Therefore, the 72 hour timeframe begins at the point where the MTCH organisation has enough information to make an informed determination of the airworthiness impact, based on the root cause (if known), type applicability, CRE considerations, etc.

7.4.2.12 The form and manner of which reportable occurrences are provided to the Authority from a MTCH organisation is via a DASR Form 44. The report shall contain (where practicable) all available information on the manufacturing or design deficiency, the results of any investigation to date, any

Superseded

actions they are taking or propose to take in order to correct the deficiency along with the submission of relevant data to support the actions.

MTCH Actions to address an unsafe condition resulting from FMD

7.4.2.13 The immediate actions that the MTCH organisation may take to eliminate and/or minimise the risks associated with the type design hazard will vary on a number of factors. However, the likelihood/consequence risk assessment will ultimately dictate the level of attention, timeliness, advice and resources that are attributed to the actions. Actions taken by the MTCH to address an unsafe condition should never rely on an Authority decision gate to implement.

7.4.2.14 The Authority will review the occurrence details and MTCH actions to gauge that the risk to aviation safety has been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) by the MTCH. This is not a one-off assessment; rather the unsafe condition determination by the MTCH organisation is an ongoing safety assurance activity conducted by DASA. It commences upon receipt of the occurrence and closes upon DASA's decision that the risk no longer warrants on-going monitoring by DASA.

7.4.2.15 Where the Authority does not have confidence that the design hazard has been eliminated or otherwise minimised SFARP, or if addressing the hazard requires development of a modification and subsequent fleetwide incorporation, then the DASA Airworthiness Directive (AD) process under DASR 21.A.3B may be invoked.

Structures and Propulsion Systems Guidance.

7.4.2.16 Structures and propulsion system specific considerations for the collection, investigation and analysis of failure, malfunctions, defects and other occurrences are addressed in AMC1 21.A.3A(a). Supporting guidance can be found in Chapter 6.6.3.

7.4.2.17 Specific guidance regarding risk analysis for propulsion systems (as could be used to develop the proposed corrective action(s) for a design- or manufacturing-related unsafe condition) is contained in Annex E to Chapter 7.2.

7.4.3 Airworthiness Directives (AD) in the DASP

Introduction

7.4.3.1 An Airworthiness Directive (AD) is *'a document issued (or adopted) by the Authority which mandates actions to be performed on an aircraft to restore an acceptable level of safety, when evidence shows that the safety level of this aircraft may otherwise be compromised'* [50]. Therefore, an AD is a key mechanism available to DASA to communicate mandatory action, in instances when an unsafe condition is determined to exist in an aircraft (and is likely to exist or develop in other aircraft) as a result of a deficiency in an aircraft's type design or conformance thereto.

7.4.3.2 This chapter sets out guidance for the use of ADs in the DASP. The guidance leverages civil practice, and expands on the regulatory criteria for the issue of an AD and key elements to execute the policy for the Defence aviation context.

Occurrence Reporting and Airworthiness Directives

Superseded

7.4.3.3 Whilst Defence-registered State aircraft are type-certified within the DASP (via the issue of a Military Type-Certificate (MTC)), and individual aircraft that conform to that type are awarded a Military Certificate of Airworthiness (MCoA), this is not a guarantee of enduring safety from a continued (and continuing) airworthiness perspective. This therefore necessitates that the potential for any unsafe condition (that may arise in-service) must be carefully monitored and managed.

7.4.3.4 Further to Chapter 7.4.2 (Continued Airworthiness Occurrence Reporting), respective Approval Holders[51] under the DASP have certain obligations[52] to DASA for the identification, communication and rectification of safety-related issues. DASA's role is to independently assure that the actions of the regulated community, in response to reportable/reported in-service occurrences affecting Defence-registered aircraft, are commensurate with the safety risk, and credible and defensible. This directly supports continued assessment of the validity of DASA-issued MTCs (/MSTCs) and/or MCoAs, and in certain instances, DASA's oversight of safety-related occurrences will need to consider if a DASA-issued AD is necessary to assure the safety of Defence aircraft (by explicitly approving and mandating the required corrective action to address an unsafe condition).

7.4.3.5 The nature of these occurrences, and the attendant severity and risk, vary considerably. In a practical sense, not every reported occurrence will (or should) result in an AD. In certain situations, it is entirely appropriate that lower-level safety-related issues reported to DASA by a sustainment enterprise (under DASR 21.A.3A) are just monitored (until defined closure criteria is met), if they do not actually constitute an unsafe condition *perse*.

Unsafe Condition Assessments (UCAs)

7.4.3.6 During the conduct of DASA's 'spectrum of assurance' for reported occurrences, the airworthiness impact to either the type, or individual aircraft of that type, must be considered. In every instance, what is unequivocally required is the determination of whether an unsafe condition exists (or not). Therefore, investigations and assessments conducted by Approval Holders within the regulated community must consider whether an unsafe condition exists; for this is not only DASA's function, but a shared responsibility. DASA's role is to be engaged with Approval Holders and determine/confirm[53] whether (or not) an unsafe condition exists (based on reports, investigations and assessments by, and engagement with, the regulated community[54]). DASA should generally not be conducting the UCA itself; for this is best-placed with respective Approval Holders[55] under DASRs (based upon type knowledge and understanding). That said, DASA always reserves the right to do so (if required).

Unsafe Conditions

7.4.3.7 Whilst DASR 21.A.3B(b) provides AMC and GM for what constitutes an unsafe condition, practical application is not always straight-forward in every instance, for discerning (and agreeing) which conditions are truly unsafe requires the exercise of professional judgement (by both Approval Holders and DASA). Moreover, the determination of what is truly an unsafe condition cannot be defined for every situation and scenario, for each platform (and DASA's assurance thereof). Generic aspects that will need to be considered are the:

1. nature of the deficiency/condition (and the associated consequence/likelihood of hazards)
2. elevated level of risk attributed to the deficiency (above that inherent in the type-certified design)
3. urgency for required mitigations, inspections and/or corrective action

Superseded

4. corresponding risk exposure period of (and any complexity within) required terminating action to resolve the deficiency.

7.4.3.8 It is important to understand that DASA (as the independent regulator) is not, and should never be, on the critical path to manage the day-to-day safety of aircraft. Under the DASRs (and the WHS Act 2011), regulated entities have obligations to ensure safety is not compromised and to alert DASA as the situations warrants. Therefore, regulated entities should not wait for DASA to provide a position before taking any appropriate action in response to an identified unsafe condition.

Criteria for issue of an AD

7.4.3.9 During the conduct of DASA's assurance of reported occurrences, and regardless of whether the actions of the Approval Holder are deemed to be credible and defensible, DASA will consider (on a case-by-case basis) the issue of an AD[56] when:

1. an unsafe condition has been determined by the Authority to exist in an aircraft, as a result of a deficiency in the aircraft, or an engine, propeller, part or appliance installed on this aircraft.

2. that condition is likely to exist or develop in other aircraft, including engine, propeller, part or appliance installed on those aircraft that may be affected by this unsafe condition.

7.4.3.10 In these instances, the 'safety benchmark' for the type or individual aircraft has (or potentially has) been compromised, and the continued validity of an aircraft's MCoA (and/or MTC) may be brought into question (via the presence of an unsafe condition). Therefore, DASA-approved inspection and/or remediation is necessary to restore an acceptable level of safety, via the issue of an AD.

7.4.3.11 Given an AD may be applicable to either all aircraft of a certified Defence type, or only certain individual aircraft of that type, ADs are by definition either type- or tail-related, issued to address identified in-service deficiencies pertaining to continued or continuing airworthiness (and potentially a hybrid thereof).

Purpose of an AD

7.4.3.12 The fundamental purpose of an AD is to:

1. approve corrective action and/or required inspections (proposed by the relevant Approval Holder under the DASRs)

2. communicate the presence of an unsafe condition affecting a Defence type and/or individual aircraft (that endangers flight safety) to the MAO/CAMO

3. mandate required action by the MAO/CAMO[57].

7.4.3.13 Regulated community compliance with DASA-issued ADs (to restore an acceptable level of safety) is mandatory within the DASP[58], which invokes the implementation of required action from a continuing airworthiness perspective under DASR Parts M and 145 (including military aircraft airworthiness review activities under DASR M Subpart I)[59].

Defence aviation context and considerations

Superseded

7.4.3.14 Since (EMAR-based) DASRs have a civil lineage – albeit adapted for the military context – fundamental aspects underpinning the intended application of DASR 21.A.3A and .3B are derived from ICAO-based concepts and civil regulations. That said, whilst DASA's assurance functions for reported unsafe conditions and the corresponding use of ADs within the DASP are *prima facie* the same, the combination of a number of inter-related features of the Defence aviation context requires additional policy considerations. In particular, how to pragmatically deal with the reality of:

1. sovereign government MTC Holder arrangements, that typically only coordinate the execution of holder obligations[60] and almost entirely leverage and recognise a much-broader (initial/) continued and continuing airworthiness management framework in place for a foreign type the same as, or similar to, the Defence type.
2. the general lack of centrality of the OEMs (as the original 'Approval Holders' for design and production that are not directly regulated under DASRs).
3. the nature of DASA as a relatively-small 'validating' Authority when issuing sovereign MTCs for Defence-registered aircraft (and most major changes to type-certificate (TC) thereafter).

7.4.3.15 Therefore, there is a strong reliance on the sustainment support arrangements established by CASG SPOs for the ongoing execution of sovereign MTC Holder functions required by DASR 21.A.3A and .3B [61], either with the actual OEM(s) and/or by leveraging the framework and actions of a foreign Civil/Military Aviation Authority (C/MAA), to support the identification and management of unsafe conditions applicable to Defence aircraft.

Sovereign MTC Holder support arrangements

7.4.3.16 The various in-service sustainment support arrangements implemented by CASG SPOs to support respective MTC Holder obligations, have differing degrees of OEM and/or foreign C/MAA involvement. Therefore, the extent to which sovereign MTC Holders leverage the initial, continued and continuing airworthiness management framework of a DASA-recognised foreign C/MAA, in direct support to the management of Defence types, will strongly influence the extent of sovereign decision-making required by MTC Holders (in the determination of required sovereign action to address an unsafe condition). In particular, those support arrangements that include a foreign C/MAA that acted as the primary certifying authority for an aircraft type similar to, or the same as, that operated by Defence.

7.4.3.17 Moreover, given the much-larger global fleets being oversighted and assured by respective foreign C/MAAs, the reality is that the vast majority of FMD/occurrences, assessments of any associated unsafe conditions, and the corresponding mandatory actions (to restore the safety benchmark) will be determined overseas (generally without sovereign MTC Holder and DASA involvement). However, FMD/occurrences for Defence aircraft do still arise, which may not be addressed by foreign type management arrangements. In particular, any design or part production deficiency that may be attributable to a military design or production organisation (MDO/MPO) approved by DASA under the DASP[62]. In these instances, the full intent of DASR 21.A.3A and .3B is required by respective Approval Holders and DASA.

7.4.3.18 Therefore, the degree of 'type management sovereignty' for Defence-registered aircraft – and therefore the extent to which sovereign decisions are required – will commensurately govern DASA's assurance of unsafe conditions affecting Defence-registered types (and the oversight of corresponding actions). That is, when more airworthiness-related 'type management' activity and

Superseded

decision-making is conducted in Australia, the greater DASA's involvement will be in the application of DASR 21.A.3A and .3B.

Sovereign Approval Holders propose required action to support the issue of an AD

7.4.3.19 When DASA decides that an AD needs to be issued within the DASP[63], the MTC Holder organisation (and/or other relevant Approval Holders under DASRs) should propose[64] appropriate corrective action and/or required inspections to DASA. Given sovereign MTC Holder organisations are primarily a coordinating (and not a design) organisation, OEM input should be considered mandatory, as well as C/MAA oversight and involvement (as appropriate)[65]. This therefore connects the original 'applicant' and the 'holder' of the design, as well as the primary certifying authority (that established the safety benchmark with the original 'OEM applicant' within their airworthiness management framework), which therefore executes the actual intent of DASR 21.A.3A and .3B.

7.4.3.20 Upon receipt, DASA's independent safety assurance function is to approve the holder's proposal, including required inspection(s) and/or rectification interval(s), and the associated risk exposure. DASA will engage with the Approval Holder and amend the proposal, if and as required. When satisfied that the AD's content (as proposed by the holder) provides appropriate terminating action to eliminate the unsafe condition (and to restore the 'safety benchmark'), and the associated risk during the exposure period will be otherwise minimised SFARP, DASA will issue an AD accordingly[66]. In doing so, DASA is explicitly approving the corrective action to address the unsafe condition and the corresponding exposure period.

Foreign ADs (or equivalent)

7.4.3.21 When sovereign MTC Holders receive relevant foreign ADs (or equivalent[67]) for assessment, and report this to DASA[68], the DASP is the beneficiary of relevant C/MAA assurance of the same/similar type to that operated by Defence. This broadly meets the intent of DASR 21.A.3A and .3B; for the 'problem' and the 'solution' is provided, that usually leverages the inputs of the actual OEM and recognises what the relevant C/MAA deemed mandatory. Therefore, a sovereign MTC Holder will need to consider the following:

1. the applicability of a foreign AD (or equivalent) to a Defence-registered type.
2. the availability and suitability of controls and corrective actions provided by a relevant foreign C/MAA that can be 'adopted' (including whether full (or partial) compliance and implementation is intended).
3. the extent to which a Defence type's Configuration, Role and Environment (CRE) considerations require necessary/appropriate variations to adapt the content of a foreign AD (or equivalent); and in particular, necessary/appropriate variations to risk controls, terminating action(s) and/or implementation timeframes/risk exposure periods.
4. the need to amplify other foreign-source safety advice for required actions and timeframes to rectify an unsafe condition[69].

7.4.3.22 Given the 'sovereignty' of DASA-issued MTCs (/MSTCs) and MCoAs for Defence-registered aircraft, the assessment of unsafe (or potentially unsafe) conditions identified for foreign aircraft that may affect Defence aircraft is fundamental to support the ongoing validity of these DASA-issued authorisations. However, it is important to note that these foreign ADs (or equivalent) are not automatically applicable and mandatory under the DASP, and despite the AD definition cited within

Superseded

DASR 21.A.3B(a), there is no regulatory mechanism within DASR 21 to 'adopt' foreign ADs (or equivalent)[70]. Therefore, whilst the regulated community may indeed decide to implement the required actions of a foreign AD (or equivalent) as a 'credible and defensible' means to address an unsafe condition for a Defence-registered aircraft, DASA nonetheless requires that applicable critical foreign safety-related information (and in particular, that issued by the primary certifying authority) is formally 'brought into the DASP' and actioned accordingly. The only way for this to occuris for DASA to issue an AD in the DASP[71], to mandate the same/similar action for Defence-registered aircraft.

Foreign ADs (or equivalent) issued by the primary certifying authority are mandatory when applicable to Defence-registered aircraft

7.4.3.23 DASA functions largely and almost exclusively as a 'validating authority', when issuing a sovereign MTC to establish the initial airworthiness of Defence types (and approving most major changes to TC thereafter), based upon recognition and leverage of the previous type-certification efforts of foreign C/MAAs. Similarly, the DASP should also recognise and leverage the type knowledge and understanding of the relevant C/MAA's management of continued and continuing airworthiness, for aircraft the same as/similar to Defence types.

7.4.3.24 Therefore, DASA's default policy position is that compliance with the technical content of foreign ADs (or equivalent) – issued by the primary certifying authority that DASA leveraged to underpin the award of a DASA MTC – is mandatory (when applicable to Defence-registered aircraft). If the primary certifying authority deemed a condition unsafe, then in near-all instances, their required mandatory action to address compromised airworthiness should be equally-applicable to Defence aircraft (notwithstanding any unique CRE considerations in certain situations).

7.4.3.25 The act of 'validating' the applicability and corresponding mandatory action within a foreign AD (or equivalent) for a Defence type is pragmatic and efficient. DASA issue of an AD when 'validating' a foreign AD (or equivalent) will in most instances be as simple as placing a DASA AD cover page on the foreign artefact(s) (if no changes are required), which may also include any minor adaption (that does not change the intent[72]), and promulgating this to the relevant MAO/CAMO for implementation.

7.4.3.26 Whilst this policy consideration would likely cater for many foreign ADs (or equivalent), DASA acknowledges there may be exceptions and complexities in certain situations, that require professional judgement. In particular, there may be compelling reasons why applicable foreign ADs are not intended for compliance (or only partial compliance), or there are substantial required and/or proposed variations on account of Defence CRE considerations (or otherwise) that will alter the intent and/or attendant risk. This will therefore require a much-greater degree of engagement between the relevant Approval Holder and DASA, to agree the content of the DASA AD (if issued).

Traceability with required mandatory action issued by the primary certifying authority

7.4.3.27 DASA's expectation is that sovereign MTC Holder arrangements implemented for each Defence type will monitor safety-related information from respective OEMs and C/MAAs (including other operators), to support required obligations under DASR 21.A.3A and .3B) (and DASR 21.A.44). In particular, this should include the documented methods and means to record the traceability of all actions mandated by the primary certifying authority[73], and the alignment with that implemented within the DASP.

7.4.3.28 For civil-derivative military aircraft, certified by a foreign MAA yet underpinned substantially by a foreign CAA's certification of the 'green aircraft', the applicability of foreign civil ADs would ideally be assessed and actioned by the relevant foreign MAA (that oversights the overseas

Superseded

fleet the same as/similar to a Defence type), but this may not always occur as expected. Therefore, due consideration should also be given to record the traceability (or otherwise) to Emergency or Alert Service Bulletins (issued by civil OEMs) and ADs (issued by the relevant CAA) that may not be mandated by the relevant MAA.

Platform DoSAs may issue ADs (for validated foreign ADs (or equivalent))

7.4.3.29 When a DASA AD needs to be issued within the DASP, and in instances where the relevant Platform Delegate of the Safety Authority (DoSA) is not developing the technical content therein – but rather only validating that a foreign AD (or equivalent) is applicable to, and should be mandatory for, Defence-registered aircraft – the Platform DoSA is the most-appropriate release authority (for, and on behalf of, DASA[74]). This is pragmatic and efficient, and is the most-responsive and agile arrangement (particularly for exigent circumstances), which is also aligned with a Platform DoSA's safety-related role and functions.

7.4.3.30 Moreover, this also fully aligns with the distributed model established for each Defence type to monitor, review and assess foreign safety-related data that may impact Defence aircraft, and should be invoked to the greatest extent possible[75]. The only caveat is that if the risk exposure is DHRM MEDIUM (or higher) until terminating action is accomplished, this should default to DASA (yet supported and staffed by the Platform DoSA).

AD issue in the absence of a foreign AD (or equivalent)

7.4.3.31 For the Defence aviation context, and in addition to the aforementioned, DASA will also consider (on a case-by-case basis) the issue of an AD in the DASP, in advance of a primary certifying authority's release of a foreign AD (or equivalent). DASA's expectation is that whenever continued operations are intended with protracted exposure to a (post-mitigation) residual risk to airworthiness – on account of an unsafe condition associated with catastrophic and hazardous consequences that cannot be eliminated or fully-controlled immediately by design – an AD in the DASP should be issued. This will usually manifest in situations where foreign MAAs have conducted a risk assessment and recommended initial treatment/controls for continued operations (due to the presence of an unsafe condition), yet the design solution and the attendant foreign AD (or equivalent) does not (and will not) exist for a significant period of time (to detail required terminating action and compliance timeframe to restore an acceptable level of safety).

7.4.3.32 This therefore sets a default position for compromised airworthiness associated with long-standing exposure to an elevated level of residual risk (whilst design solutions are being devised). In this instance, a DASA-issued AD therefore provides a means to formally communicate instances of elevated levels of risk within the DASP (bounded by a date for terminating action and compliance to be implemented), which will also provide improved Command awareness, visibility and traceability of required actions.

DASA-issued ADs associated with elevated risk should be underpinned by 7-Step Risk Management

7.4.3.33 By definition, continued (post-mitigation) operations with an unsafe condition that cannot be eliminated immediately constitutes an elevated level of risk to airworthiness during the exposure period, until terminating action detailed within an AD restores an acceptable level of safety.

7.4.3.34 Therefore, consistent with a MAO's DASR and WHS obligations, the elevated level of risk attributed to a deficiency (above that inherent in the certified design) and the corresponding residual risk exposure period should be underpinned by a MAO's Risk-Decision Brief (RDB). In particular, for instances that:

Superseded

1. deviate significantly from compliance requirements with 'validated and adopted' foreign ADs (or equivalent).

2. where there is markedly-elevated risk being retained, and the corresponding design solution required to address the deficiency will not be available for an extended period of time[76].

7.4.3.35 This policy position will primarily affect military aircraft (and likely not affect Defence-registered aircraft that are ostensibly civil). The need for an RDB for lower-level risks should be considered on a case-by-case basis (aligned with a MAO's Safety Management System (SMS)), and may not be required at all – particularly for instances where DASA leverages and 'adopts' foreign CAA ADs with no variations to risk controls and exposure periods.

7.4.3.36 MAO RDBs (that underpin DASA-issued ADs) will need to consider and disposition all available and suitable technical and operational risk controls, to support appropriate operating conditions and/or limitations. This therefore ensures and requires that MAO Hazard Tracking Authorities (HTAs) and Risk Management Authorities (RMAs) are suitably-engaged for airworthiness issues, and the corresponding DASA AD is a mechanism to communicate and document DASA's independent safety assurance for an agreed risk management strategy.

7.4.4 Other Design Approval Holders

7.4.4.1 This section addresses other design approval holders under the DASR framework. This primarily covers any Australian Military Technical Standard Order Authorisations (AUSMTSO) under DASR 21 Subpart O. AUSMTSO Authorisations are not expected to be widely used in the Defence regulatory framework and will only be issued by exception. The Authorisation is common in the civil domain under the term Technical Standard Order (TSO) and TSO Authorisations and encourages competition across the industry through novel design which does readily translate across into the military domain.

7.4.4.2 An AUSMTSO under DASR is considered equal in concept to the civil use where a TSO is defined as a minimum performance standard for specified materials, parts, and appliances used on civil aircraft. An AUSMTSO Authorisation enables the holder to manufacture a material, part, or appliances to a TSO standard. Receiving an AUSMTSO Authorisation is both a design and production approval, but importantly does not extend to installing and using the article in the aircraft.

7.4.4.3 In the civil domain, a TSO Authorisation enables the manufacture of articles that may be installed on an aircraft only after showing that the article meets the specific airworthiness requirements (certification basis) of a particular aircraft model. Receiving a TSO Authorisation verifies that an article meets a minimum performance requirement independent of the article's intended installation on an aircraft. Under the DASR, using the AUSMTSO Authorisation will be more nuanced and will not be issued on a competitive basis.

7.4.4.4 Common articles on modern day aircraft including Military aircraft that have their genesis through the civil TSO provisions include Embedded GPS and INS Units (EGIs), Auxiliary Power Units, Tires, seat belts, crew oxygen masks, seat assemblies, brake assemblies, antennae, various instrumentation, cargo containers along with many more. Under the DASR framework, the use of AUSMTSO has been very limited.

Superseded

7.4.4.5 Under DASR 21, Subpart O, the holder of an AUSMTSO has obligations to ensure that the article continually conforms to its design and is manufactured accordingly per regulations detailed under production (Subpart G). The holder is also subject to a number of other initial airworthiness regulations such as occurrence reporting and part marking with respect to their article. Although the Defence MTC construct results in a nuanced use, the AUSMTSO holder is required to engage with the aircraft Type certificate holder to integrate their article into the aircraft type or where design changes impact the integration.

7.5.1 Introduction

7.5.1.1 A Military Permit to Fly (MPTF) is a 'product authorisation' issued by DASA to aircraft that do not meet, or have not been shown to meet, the requirements of the Type-Certification Basis (TCB) and/or Military Air Operator Certificate (MAOC), but are nonetheless capable of safe flight under defined conditions and for specified purposes. An MPTF is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application.

7.5.1.2 An MPTF is a risk-based authorisation, within the suite of Defence aviation flexibility provisions provided under DASR GR.80, to facilitate military flexibility in support of a capability imperative, which is valid for a defined period of time, underpinned by a seven-step risk assessment with both technical and operational input.

7.5.1.3 Further to the overview of the Flight Conditions and MPTF authorisations provided at Chapter 5.3 Annex N, this chapter details DASR implementation of applications for, and approval of, Flight Conditions and MPTF (and the associated risk management aspects).

Audience

7.5.1.4 This chapter applies to DASR-regulated entities exercising roles or responsibilities when applying for an MPTF under DASR 21 Subpart P Military Permit To Fly. Whilst this will primarily be Military Air Operators (MAOs) – including Continuing Airworthiness Management Organisations (CAMOs) and service providers – it also extends to any organisation engaged to assist with the preparation of the application, such as: Military Type-Certificate (MTC) holders; design organisations (DASR Military Design Organisations (MDOs) and equivalents) and organisations involved in managing the configuration of Defence aircraft (CASG Systems Program Offices (SPOs) and Through-Life Support (TLS) contractors).

7.5.1.5 While cognisant of the above, the application for (and holding of) an MPTF within the DASR environment will almost exclusively be a MAO requirement for the subject aircraft defined within the MAOC Operations Specification (OpSpec)[77]. The MAO should therefore establish in-service procedures to implement attendant MPTF regulation and Acceptable Means of Compliance (AMC) that reflects the central role of the MAO Accountable Manager (AM) and authorised staff within the MPTF process.

Purpose

7.5.1.6 This chapter provides guidance in relation to Initial Airworthiness requirements under DASR 21 Subpart P, for developing MPTF applications, inclusive of: collating substantiation documentation; gaining operational endorsement; signing the declaration of safety; engaging with the Authority

Superseded

(inclusive of the Delegate of the Safety Authority (DoSA)) for approval and issue of the MPTF; and meeting MPTF holder obligations. Moreover, this chapter explains how applications for approval of flight conditions and an MPTF should follow the seven-step risk management process detailed in DASA AC 003-2018—Risk Management in the Defence Aviation Safety Program, and describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the Work Health and Safety Act 2011 (WHS Act).

Background

7.5.1.7 Within civilian aviation regulations, a permit to fly is predominately used to support development, certification, production and delivery of new aircraft and major modifications, and to support in-service operation outside the bounds of the Certificate of Airworthiness (CoA); such as ferry flights to a suitable maintenance venue for defect rectification or the conduct of an overdue scheduled servicing.

7.5.1.8 The use of MPTFs within the DASR context is subtly different. Design, certification and production of a new aircraft solely within a DASR MDO/MPO has not yet occurred, and flight test for development of major modifications will likely occur for Defence-registered aircraft operated by a MAO (rather than a DASR MDO/MPO at this stage). Furthermore, as recognised and afforded by DASR GR.80 Flexibility Provisions, Defence aviation requires flexibility to support capability imperatives for certain operational circumstances that would not be allowed within the civilian aviation domain.

7.5.1.9 Under normal circumstances, all Defence-registered aircraft should only be operated with a valid Military CoA (MCoA) issued by DASA. An MCoA is issued when the aircraft was shown, at the time of issue, to conform to its MTC awarded post-certification. Whilst in-service, the validity of the aircraft's MCoA is maintained by meeting the continuing airworthiness requirements of DASR M[78]. A valid MCoA represents a baseline level of airworthiness, aligning to both civil and military global conventions. Importantly, in the Defence context, an MPTF authorisation supplements, rather than replaces, the MCoA.

7.5.1.10 However, as stated, military aviation requires flexibility for Commanders to operate aircraft in certain circumstances without having met all the prescribed initial, continued or continuing airworthiness or aviation safety requirements, but are nonetheless capable of safe flight under defined conditions. In these circumstances, and without the necessary flexibility provisions in DASRs, the MAO would be unable to operate under the regulations. To accommodate Defence aviation flexibility, DASRs include provisions for issue of either of the following, to facilitate operation when the prescribed airworthiness or aviation safety requirements are not met:

1. MPTF under DASR 21 Subpart P Military Permit To Fly, which is augmented with AUS-unique AMC and Guidance Material (GM), which stipulate specific application requirements and include additional expectations for the holders of an MPTF, or
2. Command Clearance (CC) under DASR Specific Purpose Approval – SPA.10 *Command Clearance* [79].

7.5.2 Difference between MPTF and CC

7.5.2.1 The DASR SPA.10 CC provides for a similar outcome to that of an MPTF, in so far as the CC may also be used to authorise flight(s) where the MCoA's Instructions for Continuing Airworthiness (ICA) conditions are unable to be met. However, the key difference between the MPTF and CC is that the MPTF is an initial airworthiness authorisation subject to DASA approval and issue, whereas a CC is

Superseded

an operational authorisation via the command chain. In ideal circumstances, conditions that require an MPTF would be managed via an MPTF; however, in the event of compelling time-critical capability imperatives or emergencies, and where there is insufficient time to process an MPTF application, a DASR SPA.10 CC may be exercised.

7.5.2.2 Regardless of whether MPTF or CC provisions are used, the operating organisation remains responsible for meeting WHS obligations to eliminate or otherwise minimise risk to aviation safety, so far as reasonably practicable (SFARP). Therefore, both the MPTF application process and issue of a CC require the MAO to exercise the seven-step risk management process detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. However, an MPTF provides the MAO with independent assurance over the discharge of their obligations and should be sought whenever reasonably practicable. Should the requirement for operation of an aircraft under DASR SPA.10 be for an extended period, an MPTF or other appropriate authorisation must replace the CC.

7.5.3 Defence use of MPTFs

7.5.3.1 Whilst DASR 21.A.701(a) provides a non-exhaustive list of examples illustrating situations when an MPTF should be used, the majority of those examples are EASA/EMAR-based, and focused more on development of aircraft design, production, delivery and initial training within an OEM organisation (operating under privilege), as opposed to in-service scenarios that are typical for Defence aviation. For the Defence context, and as outlined within GM to DASR GR.80(c), aircraft operation in the following circumstances potentially entails flight at an elevated level of risk that may require an MPTF:

1. **Prior to initial issue of an MTC and MCoA.** DASR 21 precludes the issue of an MCoA if an MTC has not yet been issued. This will typically be due to the requirement to operate new aircraft prior to completion of the type-certification programme.

2. **Aircraft operation while continuing airworthiness requirements are not satisfied.** The aircraft has been issued an MCoA and is required for operational tasking; however, any of the following continuing airworthiness requirements have not been met:

   i. a defect that cannot be deferred as it has been assessed to endanger flight safety

   ii. scheduled maintenance in the Aircraft Maintenance Programme (AMP) has not been carried out

   iii. an Airworthiness Limitation (AwL) or Certification Maintenance Requirement (CMR) has been reached

   iv. an Airworthiness Directive (AD) has not been incorporated.

3. **Aircraft not conforming to an approved design configuration for the purpose of flight test.** Installation of a yet-to-be-approved modification for flight test, in order to gather compliance demonstration evidence to support approval of a change to type-certificate (or subsequent flights prior to the design change approval being issued).

4. **Aircraft operation outside approved limitations.** The aircraft has been issued an MCoA but is intended to be flown beyond the approved operating limitations in the Aircraft Flight Manual (AFM), or outside the approved role and/or environment detailed within the MAOC OpSpec. These circumstances can arise from either

Superseded

operational tasking or for the purpose of flight test (to support role expansion activities).

7.5.4 Overview of Organisational Responsibilities

7.5.4.1 The following organisations have specific responsibilities with respect to the application for, and issue of, MPTFs:

1. MAOs. MAOs are responsible for applying to DASA for the approval of flight conditions and the issue of an MPTF. They must fulfil the responsibilities of the applicant, including the conduct of a risk assessment that fully integrates all technical and operational considerations. MAOs should engage relevant external organisations in the course of preparing the application in order to effectively conduct an integrated risk assessment. These organisations may include the product's MTC holder, design organisations, CAMOs (and service providers), flight test organisations, and/or relevant maintenance organisations. All MPTFs are issued to MAOs who are then responsible for discharging the obligations of the holder of a MPTF.

2. DASA. Upon receipt of an application(s), DASA will provide independent assurance that there is evidence that the MAO met their obligations and has eliminated or otherwise minimised all risks SFARP. DASA assurance will focus on credible and defensible risk management, which provides advice to Commanders if the capability imperative has been sufficiently described and would support a decision-to-proceed with the identified Elevated Level of Risk (ELOR); however the decision-to-proceed always remains with the applicant.

7.5.5 Overview of MPTF Process and DASR Forms

7.5.5.1 The application process to obtain an MPTF is relatively straightforward, but does require clear identification of the participants and an understanding of the associated responsibilities. Whilst two separate applications are required, DASRs do not prohibit both being submitted to DASA concurrently. Relevant DASR Forms are as follows:

1. DASR Form 18b. Application for, and approval of, flight conditions that enable the aircraft to operate safely. This form is raised and submitted by an applicant to DASA. DASA approves the application and returns the approved form to the applicant.

2. DASR Form 21. Application for issue of an MPTF. Raised by the applicant and submitted to DASA. This may reference pre-existing and approved flight conditions within DASR Form 18b.

3. DASR Form 20a. Issue of an MPTF in response to a DASR Form 21 application. Raised by DASA and issued to the applicant; that is, the organisation responsible for conducting the associated flight(s) and ensuring the flight conditions are adhered to.

7.5.5.2 Further to GM to DASR 21 Subpart P, Annex A provides a 'swim-lane' flowchart illustrating the application process within organisational responsibilities. Reiterating, the approval of flight conditions is separate from the issue of an MPTF to give the applicant flexibility. Reasons include:

1. One set of flight conditions may underpin a number of MPTFs.

Superseded

2. The approval of flight conditions and the issue of an MPTF may be separated in time.

3. The issue of an MPTF by a local DoSA, in instances where DASA has previously approved flight conditions that are beyond the DoSA's delegation, may improve flexibility and timeliness.

4. The approval of flight conditions and issue of an MPTF represent different steps in the seven-step risk management process, and therefore address different WHS Act requirements.

7.5.6 Summary of the Seven-Step Risk Management Process

7.5.6.1 GM to DASR SMS.A.25(b)(2)(2.2) outlines Defence's seven-step risk management process (depicted in Figure 5), with further aviation-specific guidance detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. AC 003/2018 describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the WHS Act.

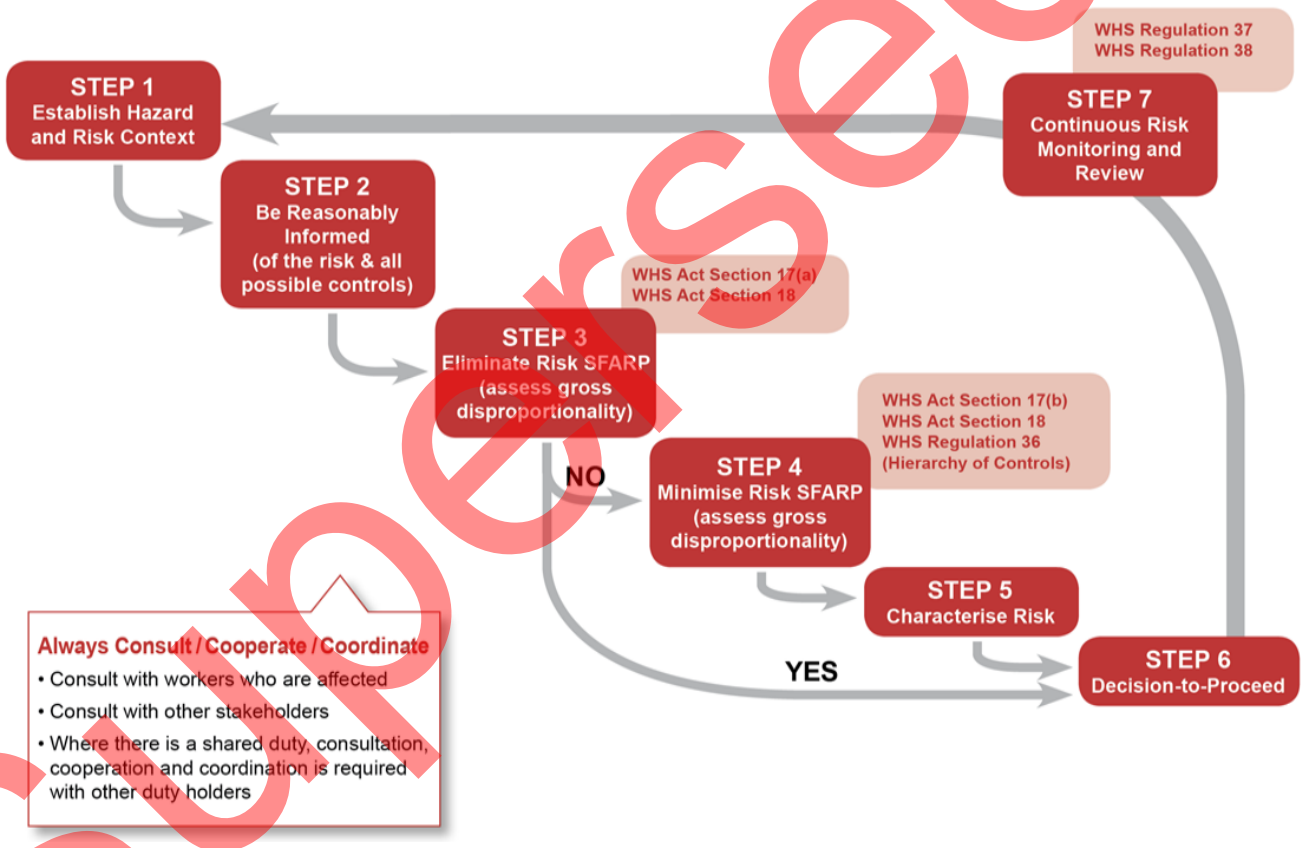

Figure 5: Safety Risk Management Process

7.5.6.1.2 DASR application forms for the approval of flight conditions and the issue of an MPTF collectively cover all of the required steps in the safety risk management process. DASR Forms 18b and 21 should summarise key information arising from the seven-step risk management process. Additional detail may be included in separate documents.

Superseded

7.5.7 Application for Approval of Flight Conditions

7.5.7.1 An approved set of flight conditions underpins every MPTF, which are the risk controls required to eliminate or otherwise minimise the risk SFARP. In applying for the approval of flight conditions, the applicant should execute and document Steps 1–5 of the seven-step risk management process. A single set of approved flight conditions may be applied to several MPTFs.

7.5.7.2 The specific application of these steps in applying for the approval of flight conditions are as follows:

1. **Step 1 – Establishing the risk context.** The applicant must define the task objective(s) including a clear strategic, operational or tactical imperative for the task and why it is necessary to fly with an ELOR. In defining task objective(s), the applicant should consider whether the task is new or existing, the discretionary/non-discretionary nature of the task and its urgency. The applicant should also identify and engage relevant stakeholders to ensure the risk assessment fully integrates all technical and operational factors. The risk context establishes the depth of risk assessment required and informs all reasonably practicable judgements. Establishing the context, also includes the duration of the activity. Retention of ELOR must be for the minimum possible duration to remain defensible within the WHS obligations and DASRs. As such, long-term MPTFs are unlikely to be defensible[80].

2. **Step 2.a – Being reasonably informed of the risks.** The applicant must proactively take steps to gain reasonable knowledge of the exact nature of all hazards and risks (both technical and operational). This may include use of existing OIP, the AFM, ICA or the provision of specialist advice from appropriate support organisations. This could include design organisations, technology or operational specialists, flight test specialists or the aircraft's OEM. There is no fixed list of who must be consulted for each application; instead, the applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context.

3. **Step 2.b – Being reasonably informed of all possible controls.** The applicant must take steps to gain reasonable knowledge of all possible controls (both technical and operational) in order to identify which ones are available and potentially suitable. Per Step 2.a, the applicant must seek relevant specialist advice where appropriate. Again, there is no fixed list of who must be consulted for each application. The applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context. The applicant must not discard any controls at this stage, as all identified controls should be used as inputs to Steps 3 and 4 in the risk management process.

4. **Steps 3 and 4 – Eliminate or otherwise minimise risk SFARP.** There is an explicit requirement to eliminate risk SFARP in the first instance and only if not reasonably practicable to do so (informed by the risk context established at Step 1), implement risk controls to minimise the risk SFARP. The applicant should systematically work through every control identified in Step 2 to determine if they are reasonably practicable to implement. The applicant must also address any additional hazards introduced by the risk controls. The integrated set of technical and operational risk controls that are reasonably practicable to implement, form the proposed flight conditions that will underpin the MPTF.

Superseded

5. **Step 5 – Characterising and communicating residual risk.** The applicant must characterise the residual risk using their safety risk management system (Note: DASA anticipates the residual risk will be characterised using the Defence Harmonised Risk Matrix (DHRM) in the Defence Aviation Safety Manual (DASM), but does not mandate its use). This step must include a declaration from the applicant that the flight conditions are a set of risk controls, integrated from a technical and operational perspective, which eliminates or otherwise minimises the risk SFARP.

7.5.7.3 Specific detail of the information and supporting documentation required to complete DASR Form 18b- *Application for Approval of Flight Conditions* is provided in the instruction sheets covering the form. See also DASR 21.A.708 and 21.A.709.

7.5.7.4 Flight Test. When an MPTF relates to flight test activity, DASRs require that flight conditions and operational endorsement must be provided by a competent MAO staff member, as determined by a DoSA-Flight Test (DoSA-FT)[81]. MAOs may apply to a DoSA-FT for a determination of competence for nominated MAO staff.

7.5.8 Approval of Flight Conditions

7.5.8.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can approve flight conditions. DASA will approve flight conditions if it has sufficient confidence that:

1. The applicant has given due consideration to the risk context, including the objectives and significance of the flying activity.
2. Elimination of the risk by restoring the aircraft to an airworthy condition IAW existing approved data, or deferring a defect, is not reasonably practicable.
3. Proposed flight conditions represent a set of risk controls that provide a credible and defensible level of safety for the flights/duration requested.
4. The applicant has appropriately characterised and communicated the residual risk.
5. The applicant has made an explicit declaration that the flight conditions, when implemented effectively, will eliminate or otherwise minimise the risk SFARP. The risk context of the application must support the depth of risk assessment undertaken and reasonably practicable judgements made by the applicant.

7.5.8.2 In assessing the application, DASA reviews the information supplied by the applicant and independently assures that it demonstrates the risk has been eliminated or minimised SFARP, and has been characterised accurately. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

Superseded

7.5.9 Application for an MPTF

7.5.9.1 Applications to DASA for the issue of an MPTF are made for specific aircraft and tasking using DASR Form 21 - *Application for a Military Permit to Fly*. All applications must reference an approved set of flight conditions, or an accompanying application for their approval. DASR Form 21 supports and records the applicant's 'decision-to-proceed' at Step 6 in the seven-step risk management process.

7.5.9.2 Note, in submitting an application for an MPTF and making the decision-to-proceed, the applicant also revisits Step 1 – Establishing the Risk Context, for that application. The test of SFARP is contextual and temporal; so this return to the risk context for the MPTF application is necessary to ensure that the applicant has made the decision-to-proceed based on the characterisation of risk in the flight conditions and in the context defined by the MPTF application, at the time of that application.

7.5.9.3 For example, the risk context of the flight conditions may be broad and enduring, covering activities such as 'deployed or directed operations'. However, the context of an application for an MPTF referencing those flight conditions must justify proceeding with the risk characterised in those flight conditions in its own right. As a result, an MPTF for a flight which itself is discretionary with little or no military capability imperative, relying upon flight conditions with a broad context such as 'deployed operations', may not be credible or defensible with the risk characterised in the referenced flight conditions, despite occurring while 'deployed'.

7.5.9.4 The key information required to support this step in the risk management process is the applicant's justification that:

1. The purpose of flight for this application is within the risk context of the referenced flight conditions and the specific task in this application warrants proceeding with the residual risk at the time of application.
2. The specific aircraft to be tasked meet(s) the configuration required by the approved flight conditions.
3. The conditions and restrictions (risk controls) in the approved flight conditions will be implemented on the subject aircraft for the subject flight(s).

7.5.9.5 The applicant must identify a suitable delegate within their organisation who has capacity to make the decision-to-proceed with the flight(s) (i.e. retain the risk). In making the decision-to-proceed, the applicant must act within their safety risk management system. Specific details of the information and supporting documentation required to complete DASR Form 21 - *Application for a Military Permit to Fly* is provided in the instruction sheets covering the form. See also DASR 21.A.707.

7.5.9.6 Flight Test. Within specialist Service Flight Test Organisations (FTOs), procedures exist to streamline MPTF applications and approvals for a range of flight test activities, such as:

1. Flight test activities on any Defence aircraft type to be conducted by, or under the direct supervision of, a Defence Aviation Authority (DAA)-approved FTO (all CAT 1 and 2 flight test and some CAT 4 tests)
2. Where Flight Test Instrumentation (FTI) or modifications are to be used, or
3. Where flight test operational substantiation and/or endorsement is required.

Superseded

7.5.9.7 MAOs considering flight test activities are encouraged to engage their respective Service FTO or a DoSA-FT, who will advise on the process to use. See also DASR FT–Flight Test.

7.5.10 Issue of a MPTF

7.5.10.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can issue an MPTF. DASA will issue an MPTF (via DASR Form 20a) if it has sufficient confidence that:

1. The decision-to-proceed has been made by an appropriate person within the applicant's organisation, given the characterisation of the residual risk (Note: DASA does not prescribe what this level is, nor what organisational authorisations they must hold).

2. The assignment of the responsibilities to implement and monitor risk controls (i.e. adherence to the approved flight conditions) is clear.

3. If applicable, there has been consideration that the flight conditions are compatible with any other MPTFs currently in effect for that aircraft (Note: The applicant is responsible for managing the implementation of multiple or concurrent MPTFs).

4. The risk context of the MPTF application is within that of the referenced flight conditions and supports the decision-to-proceed with the risk characterised by those flight conditions.

7.5.10.2 In assessing the application for an MPTF, DASA reviews the information supplied by the applicant and independently assures that it supports flying with an aircraft that does not meet the prescribed airworthiness or aviation safety requirements and may be operating at an ELOR. This will include whether the period of risk retention (the context) is defensible. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

7.5.10.3 Flight Test. When the MPTF relates to a flight test activity categorised IAW DASR.FT.05, flight conditions must be endorsed by competent staff of a MAO (as per para 22), and for a CAT 1 or 2 activity, Authority approval of flight conditions and issuing of the MPTF must be conducted by a DoSA-FT.

7.5.11 Obligations of the holder of an MPTF

7.5.11.1 As the holder of an MPTF, the MAO is responsible for ensuring the flight conditions are implemented and remain effective for the duration of the MPTF. This satisfies Step 7 of the seven-step risk management process and includes ensuring the risk context supporting the approved flight conditions remains applicable for the duration of the MPTF. See also DASR 21.A.727 and DASR 21.A.708.

7.5.11.2 Configuration management. An MPTF may introduce specific aircraft configuration management requirements, especially if an MPTF covers a yet-to-be-approved modification for operational use or flight test activity. MPTF conditions may include information such as: incorporation and maintenance instructions for new modifications; periodic inspections for non-standard damage;

Superseded

or increased usage data recording requirements. The CAMO must be aware of MPTFs that are applicable to a given aircraft to ensure overlapping continuing airworthiness requirements are resolved or coordinated, to ensure no loss of configuration management and the appropriate aircraft technical log and maintenance documentation remains accurate.

7.5.11.3 Operation by another MAO. The holder of an MPTF is responsible for ensuring the DASR 21.A.708 flight conditions are met. However, in instances where aircraft may be transferred between MAOs, this situation requires the holder to establish suitable arrangements for the transfer of holder obligations for an aircraft (that is subject to one or more MPTFs) when operated by another MAO.

7.5.12 MPTF Examples within DASR Context

7.5.12.1 Annex B provides a non-exhaustive list of examples intended to illustrate the conduct of the MPTF process within the DASR environment. Where uncertainty exists, contact a DASA Desk Officer (DIA-TC or DAVENG), the platform DoSA, or a DoSA-FT (for MPTFs related to flight test). In addition, Annex C provides a comprehensive guide to good practice and common issues pertaining to applications for flight conditions and MPTFs.

7.6.1 Military Design Organisations

Aim

7.6.1.1 This chapter details the approval and ongoing oversight of a Military Design Organisation (MDO). A MDO is approved under DASR Part21J and can only undertake design work related to the privileges granted under that approval and within the scope of that approval. Often the scope restricts what platforms a design can be applied to and can impose further limitations to aspects of their design work if required.

Introduction

7.6.1.2 Design organisation means an organisation responsible for the design of aircraft, aircraft engines, propellers, auxiliary power units, or related parts and appliances, and holding, or applying for, type-certificates, supplemental type-certificates, changes or repair design approvals. These design organisations that design aircraft, make changes to aircraft or design repairs of aircraft, and parts and appliances, need to fulfil the requirements as defined in DASR Part 21. Such organisations need to demonstrate that they have the right organisation, procedures, competencies and resources to effectively produce the design.

Obligations

7.6.1.3 DASA impose regulatory obligations on Design Organisations as part of the approval to ensure the airworthiness of aircraft and aviation products being designed within Defence. These obligations are intended to maintain high standards of design, engineering, and manufacturing processes throughout the defence aviation industry.

7.6.4 By placing obligations on design organisations, DASA aims to assure that the design, modification, and production of aircraft, components, and systems meet appropriate airworthiness standards.

Privileges

7.6.1.5 Under the DASR construct, the authority is the controlling signatory for all product released related to the type certificate. To reduce the burden on DASA, approved organisations are typically awarded privileges that allow work to be approved on behalf of the authority. For example, a design organisation may be privileged to approve minor changes to type design as well as minor and major repairs.

7.6.1.6 Granted privileges are documented on a Form 83. The Form 83 outlines the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

Superseded

7.6.1.7 An organisation attains a DASR 21 MDO Approval by submitting a Form 80 Application for Military Design Organisation Approval (MDOA) for DASA consideration, or a Form 82 Application for Significant Changes to Design Organisation Approval where a MDOA is already held but scope change is needed. Along with the application, the organisation must furnish a handbook (formerly an exposition) whereby all the processes utilised under the established Design Assurance System (DAS) are detailed. The Design Organisation Handbook Requirements are outlined in Appendix 1 of Chapter 5.3 of DASP Manual Volume 3.

DASA Design organisation assurance

7.6.1.8 Once a design organisation has gained an approval to conduct design activity, DASA will schedule oversight activities in order to assure that the MDO has maintained / is maintaining their approval to the standard as governed by the DASR Pt21 regulations. For organisations maintaining a Part21 approval, DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, and Resources as detailed in the approved Design organisation handbook, as well as consideration of the quality of design products.

7.6.1.9 The DAS is effectively the Quality Management System (QMS) specific to the output of designs against the scope issued under the Form 83. The DAS can utilise elements of the organisation QMS to satisfy requirements of the DAS. The DAS and the QMS are not the same and oversight of the DAS will be conducted specifically to design products produced.

Further information

1. DASP Manual Vol 3 Chapter 5.3 Annex E
2. DASR 21 Subpart J – Military Design Organisation Approval

7.6.2 Military Production Organisations

Aim

7.6.2.1 This chapter details the approval and ongoing oversight of a Military Production Organisation (MPO). A MPO is approved under DASR Part21 G and can only undertake production work related to the privileges granted under that approval. This includes what release documentation is acceptable under DASRs.

Introduction

7.6.2.2 Production for Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured. Acceptable release documentation is outlined at Chapter 7.3.2.

Obligations

7.6.2.3 With a Production Organisation Approval, DASA impose a set of obligations as part of the approval and as part of its regulatory framework to ensure the safety and airworthiness of aircraft and aviation products being utilised within Defence. By placing obligations on production organisations, DASA aims to assure that the production of aircraft, components, and systems meet rigorous safety and airworthiness standards.

Superseded

Privileges

7.6.2.4 Under the DASR construct, an approved MPO will be granted privileges to conduct design work to support changes to the type certificate for which the MTCH manages. Granted privileges are documented on a Form 55. The Form 55 is the certificate outlining the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

7.6.2.5 An organisation attains a DASR 21 MPO Approval by submitting a Form 55 Application for Military Production Organisation Approval (MDOA) for DASA consideration, or a Form 51 Application for Significant Changes to Production Organisation Approval where an MPOA is already held but scope change is needed. Along with the application, the organisation must furnish an exposition, whereby all the processes utilised to produce the category items under the ToA are documented.

7.6.2.6 Currently, DASA will not accept applications for production without a Military Production Organisation Approval as the authority is not resourced adequately to oversight this type of approval.

DASA production organisation assurance

7.6.2.7 Once a production organisation has gained an approval to produce category items, DASA will schedule oversight activities in order to assure the MPO has maintained/is maintaining their approval to the standard as governed by the DASR 21 regulations. DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, Resources which is detailed in the approved Production Organisation Exposition.

7.6.5 Guidance for Organisations Developing and Producing Aviation Software

Introduction

Superseded

7.6.5.1 This section provides guidance for the design and production of aviation software under DASR 21. This guidance does not apply to software designed or produced under recognition as defined in DASP Vol 3 Chapter 7.3.1 Production

7.6.5.2 Aviation software is classified as a 'part or appliance' and subject to the same rules applicable to all 'tangible' parts and appliances.

7.6.5.3 Aviation software refers only to software installed in an aircraft used for operating and controlling the aircraft and does not include mission system software, condition monitoring software, aeronautical information or ground-based aircraft diagnostic systems.

7.6.5.4 For the context of aviation software, the following definitions apply:

1. **Manufacturing** – is the development of aviation software, including compiling of source code into executable object code.
2. **Production** – is the process of preparing aviation software for distribution, including packaging the executable object code and associated engineering and technical data on distribution media.
3. **Replication** – is the process of copying aviation software (executable object code) that has been authorised through a production process.

Certification of Aviation Software

7.6.5.5 Organisations manufacturing software for installation on Defence registered aircraft must hold a Military Design Organisation Approval (MDOA) under DASR 21 Subpart J. The development of new (or the modification of existing) aviation software is a change to a product's type design and must be approved under DASR 21 Subpart D or E. For changes to aviation software classified as minor, a minor change approval can be issued by an organisation holding an MDOA in accordance with its Terms of Approval. For changes to aviation software classified as major, the approval must be issued by DASA as either an amended Military Type Certificate (MTC) or a Military Supplemental Type Certificate (MSTC).

Production of Aviation Software

7.6.5.6 The production of software is the responsibility of an organisation holding an appropriate Military Production Organisation Approval (MPOA) and the release of aviation software for installation on a Defence registered aircraft is via a DASR Form 1. The software's 'part' number (version) should be marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

7.6.5.7 DASR 21 does not allow the production of aviation software under an organisation's MDOA Terms of Approval. Organisations producing aviation software for installation in Defence registered aircraft must meet the requirements of DASR 21 Subpart G—Military Production Organisation Approval in order to obtain privileges to release the software for installation.

Replication of Aviation Software

7.6.5.8 Software authorised for installation on a Defence registered aircraft via a DASR Form 1 and provided to the Continuing Airworthiness Maintenance Organisation (CAMO) may be replicated by an Approved Maintenance Organisation (AMO) in accordance with OEM or DASR 21 MDO approved procedures. It is the responsibility of the CAMO or AMO to ensure that their quality systems have processes in place to manage and verify the integrity of the replicated software. This is typically done

Superseded

using a checksum value that is generated during production of software and provided to the CAMO or AMO alongside the produced software.

7.6.5.9 Any software replication process should also include a step to ensure the software's 'part' number (version) is marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

Organisation Approval Requirements

7.6.5.10 Development and production of software are often done by the same organisation. In this case, the organisation must hold both a MDOA under DASR 21 Subpart J and a MPOA under DASR 21 Subpart G in order to obtain the necessary privileges to approve the development and production of aviation software. Typically, there are no organisations with an MPOA with software scope without a corresponding MDOA with software scope.

7.6.5.11 Underpinning these organisation approvals and privileges are a Design Assurance System documented in a Handbook (Design Organisation Exposition/DOE), and a Production Quality System documented in a Production Organisation Exposition (POE). For a software development and production organisation, it is not necessary to have discrete and dedicated stand-alone procedures manuals entitled 'DOE' or 'POE' to meet both sets of organisation approval requirements. A single manual, document (irrespective of its title) or set of procedures that covers the development and production of software may simultaneously meet the requirements of both a DOE and POE.

7.6.5.12 The regulatory requirements of a DOE (DASR 21.A.243) and a POE (DASR 21.A.143) are the minimum required of such a manual or document to be awarded the relevant organisation approval and privileges. Any manual or document(s) identified as a DOE/POE (or both simultaneously) should be a working level document(s) published for use by personnel working in the organisation. The DOE/POE should not be written purely to satisfy regulatory requirements, although this aspect will be assessed by DASA when reviewing the working level documentation and the organisation's staff's understanding of it.

7.6.6 GUIDANCE ON CONSIDERING EXPLOSIVES IN AVIATION DESIGNS

Introduction

7.6.6.1 This DASPMAN section explains what Military Design Organisations (MDO) and Military Type Certification Holders (MTCH) must consider when performing design activities on aircraft systems containing explosives and integrating air-launched stores containing explosives onto aircraft[82]. Such design activities include physical design changes to systems and equipment containing explosives, assessments that unrelated design changes do not adversely impact explosive safety, changes to Airworthiness Limitations (AwL), changes to explosives-related Instructions for Continuing Airworthiness (ICA), monitoring for new explosive-related hazards within safety management systems (SMS), and aircraft stores compatibility engineering activities.

Superseded

What is an explosive?

7.6.6.2 An explosive is '… a substance manufactured with a view to producing an explosion or pyrotechnic effect[83].'Many Defence aircraft contain explosives, either forming part of an aircraft system (such as ejection seats) and within air-launched stores such as bombs, missiles and gun ammunition[84].

Explosives requirements within Type Certification Basis

7.6.6.3 In deciding what type of explosive requirements should be included in an aircraft's Type Certification Basis (TCB) the key document is the *European Military Airworthiness Certification Criteria* (EMACC) published by the European Defence Agency. The EMACC indicates that all explosives forming part of an aircraft system should be considered when developing TCB requirements. Accordingly, the TCB should include explosive-related requirements during initial certification and when MDOs develop major or minor changes to the type design.

7.6.6.4 For aircraft stores containing explosives the EMACC implies that the TCB should only consider requirements relevant to the installation, integration and interface of the aircraft and stores. That is, the TCB should only include explosive-related design requirements to the extent they affect the store's installation, integration and interface. Any subsequent major or minor changes to the type design should also only consider the installation, integration and interface of the store.

Legislative requirements

7.6.6.5 The legislation relevant to the safe design, maintenance and operation of Defence aircraft containing explosives is the Work Health and Safety Act (Cth) 2011 (the WHS Act), the Explosives Act (Cth) 1961, and their subordinate regulations.

Explosive Safety Regulatory Framework

7.6.6.6 To comply with their explosive-related obligations under all this legislation, MDOs and MTCHs must understand Defence's *Explosive Safety Regulatory Framework* (ESRF), which amplifies this legislation for the explosives context. The ESRF purpose is to provide a Defence-wide explosive safety risk management framework which ensures explosives safety risks are effectively managed. Explosives safety aims to '… prevent premature, unintentional, or unauthorised initiation of explosives and devices containing explosives; and with minimising the effects of explosions, combustion, toxicity, and any other deleterious effects'[85].Within the ESRF, Director General Explosive Ordnance (DGEO) is the Explosive Ordnance Safety Regulator (EOSR), supported by the Director of Ordnance Safety (DOS).

7.6.6.7 Under the ESRF, the safe conduct of activities involving explosives (including design) requires adherence to the following three fundamental concepts:

1. Explosives must be designed and manufactured to design requirements so as to eliminate or minimise explosives safety hazards so far as is reasonably practicable. This concept is referred to as 'safety and suitability for service' (S3).

2. Activities involving explosives must be conducted at locations where the consequence of an explosives safety mishap is understood, and risks are minimised (referred to as a 'safe location').

Superseded

3. Activities involving explosives must be conducted through safe work practices, conducted by trained and competent personnel, which will minimise both the likelihood and consequences of an explosives safety mishap (referred to as 'safe work practices').

7.6.6.8 In applying these three concepts, the ESRF provides requirements (12 principles and 28 regulations) and guidance relevant to the design, production, operation, maintenance, handling, storage and transport of explosives throughout its lifecycle.

7.6.6.9 The ESRF is documented within the following Defence Explosive Ordnance Publications (DEOP):

1. DEOP 100 comprises three volumes of which only Volume 2 Defence Explosives Safety Regulatory Framework has been issued. Volume 2 describes the 12 mandatory principles of the ESRF, not all of which are relevant to aviation design activities. For each principle, information is provided on its rationale, the expected outcome, the constraints, obligations, external requirements and controls. DEOP 100 Volume 2 also describes the ESRF risk management and assurance processes. The ESRF relies on organisational compliance with its mandatory requirements but does not provide organisational certifications.

2. DEOP 101 provides the 28 ESRF regulations with not all applying to aviation design activities. The regulations are not in a standard format, but most comprise a general overview, the requirements, responsibilities and any accompanying procedures. Each of the 28 regulations contain some mandatory requirements.

3. DEOP 102 provides information relevant to assessing the 'Safety and Suitability for Service of Defence Explosive Ordnance'. The publication mentions the 12 principles and the 28 regulations, while providing no further requirements relevant to aviation design activities. This DEOP also discusses several explosive-related hazards[86].

7.6.6.10 Within the ESRF, the EOSR releases Defence Explosives Safety Advisory Circulars (ESAC) to promulgate important safety information. ESACs do not mandate any actions, but provide informed, well-considered safety advice and guidance. ESACs can be accessed at: drnet/JCG/JLC/ExplosiveOrdnance/DOS/Pages/ESRF.aspx (Available on DPN Only)

Relationship between the DASF and ESRF

7.6.6.11 The ESRF is specifically intended to integrate with and support other Defence regulatory frameworks that aim to achieve safety outcomes, including aviation safety. Comparison of the DASF and ESRF demonstrates that regulated organisations within the DASF can comply with both the Defence Aviation Safety Regulations (DASR) and relevant ESRF requirements, with no inconsistencies between the two safety frameworks. Importantly, both safety frameworks are subject to the WHS Act's concept of shared duty holders (s16), who must consult, co-operate and co-ordinate their activities (s46) to ensure explosive-related risks are eliminated or otherwise minimised so far as is reasonably practicable (s17).

7.6.6.12 DASA regulates the design of aircraft systems and the integration of all air-launched stores onto a type. Complementing these regulations, DGEO provides mandatory explosive-related requirements (both principles and regulations) for the design of aircraft systems containing explosives and air-launched stores containing explosives.

Superseded

7.6.6.13 The S3 construct within the ESRF requires consideration of the hazards posed to explosives safety by carriage environments. Accordingly, the ESRF requires designers to consider whether the failure or partial performance of the non-explosive components of aircraft stores adversely affects the safety of the explosives within the store. Forms of component failure or partial performance that do not affect explosive safety are outside the ESRF scope, but are considered by Guided Weapons and Explosive Ordnance Group (GWEO) as part of its broader safety responsibilities.

ESRF applicability to DASR 21 scope

7.6.6.14 Several ESRF principles and regulations fall within the scope of DASR 21. Specifically:

1. ten of the 12 ESRF principles (Principles 1-10) impose obligations on aircraft designers within MDOs and MTCH organisations
2. all of these ten principles fall within the scope of DASR 21
3. compliance with DASR 21 provides total compliance with one principle (Principle 1), partial compliance with eight principles (Principles 2, 3, 5, 6, 7, 8, 9 and 10) and no compliance with one principle (Principle 4)
4. only four of the 28 ESRF regulations (1.1, 1.2, 1.5 and 2.5) within DEOP 101 impose obligations on aviation designers within MDOs and MTCH organisations
5. of these four regulations, three fall within the scope of DASR 21 (1.1, 1.5 and 2.5)
6. compliance with DASR 21 provides only partial compliance with these three regulations.

7.6.6.15 These principles and regulations within the scope of DASR 21 provide no limits or constraints on which individuals or organisations within Defence may perform design activities for aircraft systems and aircraft stores containing explosives.

Satisfying applicable ESRF requirements

7.6.6.16 Compliance with DASR 21 provides total or partial compliance with several mandatory ESRF principles and regulations. To achieve full compliance, MDOs and MTCHs must:

1. obtain explosives safety hazard and risk management advice from personnel and organisations competent in explosives safety management (refer paragraph 7.6.6.18)
2. when complying with DASR SMS, ensure that consideration is given to explosive-specific hazards and risks
3. ensure that explosives safety hazards and residual risks of explosives are identified and communicated to affected Services, Groups and others (including non-Defence entities)
4. aim to reduce the consequences of on-aircraft explosive hazards through careful design of where explosives are located in the aircraft and the quantity of explosives used
5. ensure that personnel performing design activities on aircraft systems and air-launched stores containing explosives receive explosive-related training compliant with ESRF Regulation 1.1 (eDEOP 101)[87]

Superseded

6. when creating Instructions for Continuing Airworthiness (ICA) for aircraft systems and air-launched stores containing explosives, be aware of the inspection requirements in ESRF Regulation 1.5 (eDEOP 101)

7. when engaged in the process for the initial certification of explosives installed in aircraft systems and amendments to their life limits, comply with the process described in Annex B.

7.6.6.17 While outside the scope of DASR 21, where MDOs handle explosives as part of the design process, they should ensure their sites, platforms and facilities have the necessary facility certifications, and that the minimum number of people are exposed and are aware of the risks.

Explosives safety hazard and risk management advice

7.6.6.18 MDOs and MTCHs can obtain explosives safety hazard and risk management advice from the following organisations competent in explosives safety management:

1. the Directorate of Ordnance Safety within Joint Logistics Command

2. Joint Proof and Experimental Unit within Joint Logistics Command

3. Aerospace Explosive Ordnance Systems Program Office within GWEO

4. Directorate of Engineering and Technical within GWEO's Systems Division.

7.6.6.19 MDOs and MTCHs should have confidence in the explosives safety hazard and risk management advice provided by these organisations because they:

1. have roles (either regulatory or in-practice) that require them to comprehensively understand explosive safety hazards and risks

2. are subject to the requirements of the well-established ESRF and will provide advice compliant with all relevant ESRF principles and regulations

3. have an extensive demonstrated history of providing safe explosives advice across Defence, including to the aviation community

4. work within well-developed engineering frameworks that have evolved over several years.

7.6.6.20 MDOs and MTCHs can consume explosives safety hazard and risk management advice from these specified organisations, without the need to invoke DASR 21.A.239. That is, they do not need to consider these organisations as a '… partner or subcontractor' and are not obliged to specify the manner in which the MDO/MTCH design assurance system accounts for the acceptability of the advice provided by these external organisations or specialist personnel within them.

7.6.6.21 Some forms of advice may not need be obtained case-by-case but could be obtained as a 'standing' advice relevant to a particular type of design change whenever it occurred (for example a proposed change to a component throwaway life or maintenance interval). The relevance of specific 'standing' advice to a new circumstance would depend on the aircraft type, the form of explosives, the aircraft's operating environment and its specific sustainment arrangements.

7.6.6.22 The relationships that MDOs establish with specialist explosives organisations should be documented in the Handbook (Design Organisation Exposition), required by DASR 21.A.243. Similarly,

Superseded

MTCHs should documents their relationships in the Type Continued Airworthiness Exposition required by GM 21.A.14(c) and discussed at DASPMAN Chapter 5.3 Annex J Appendix 1.

Other guidance

7.6.6.23 A variety of other Defence stakeholders can contribute to the safe design of aircraft systems containing explosives and the safe integration of air-launched stores containing explosives. Such organisations include:

1. **Maintenance organisations** - to understand the maintenance implications of design decisions and the utility of proposed ICA relating to explosives
2. **CAMOs** - to understand the continuing airworthiness implications of explosive-related design decisions, such as the potential need for pre-flight inspections and the effect of explosive-related component lives on the aircraft maintenance program
3. **MAOs** - to understand the operational implications of explosives-related design decisions, such as preferred aircrew actions for stores release
4. **DASA** - to understand the scope of the ability to approve minor explosives-related design changes
5. **Organisations who transport and store explosives.** Organisations within various Defence Groups and Services, whose primary roles is transporting and storing explosives, would not usually be a source of explosives design safety advice. Nevertheless, there may be occasions when MDOs should seek information from them that provides necessary context for design activities.

Design activities for aircraft systems containing explosives

7.6.6.24 An aircraft system may contain explosives, usually to separate an air-launched store from the aircraft, but sometimes to separate parts of the aircraft such as ejection seats and cockpit canopies. Specific guidance on the design activities for aircraft systems containing explosives is provided in Annex A.

Design activities for ALSE/role equipment containing explosives but not part of the aircraft's type design

7.6.6.25 ALSE/Role equipment containing explosives, but not part of the aircraft type design, are outside the scope of this chapter. Nevertheless, the ESRF requirements at 7.6.6.16 a/c/d/e still apply to organisations performing relevant design activities.

Design activities for air-launched stores containing explosives

7.6.6.26 An air-launched store is an aircraft store that is intended to be separated from an aircraft in flight. Some air-launched stores contain explosives:

1. to separate the store from the aircraft (such as some chaff, some flares, some sonobuoys and gun ammunition)[88]
2. to create an explosive effect post separation (such as bombs, missiles and flares)
3. for both purposes.

Superseded

7.6.6.27 Design activities on the explosives within air-launched stores are outside an MDO's scope, performed within the scope of GWEO organisations.

7.6.6.28 Specific guidance on the integration of air-launched stores containing explosives, which is within the MDO/MTCH scopes, is provided in Annex B.

7.4. Continued Airworthiness

7.1 Introduction

7.1.1 Background

7.1.1.1 While there is no internationally-accepted definition for Initial Airworthiness, common definitions for 'initial' (happening at the beginning) and 'airworthiness' (the fact of an aircraft being safe to fly) are helpful. After all, Initial Airworthiness does indeed focus extensively on whether a new aircraft is initially safe to fly - that is, whether it has been suitably designed and manufactured.

7.1.1.2 However, by convention, Initial Airworthiness also encompasses any design changes subsequently made to the new aircraft (including the certification of those changes) and the design of repairs. Furthermore, it includes the activities needed to ensure the design remains safe throughout its lifecycle, although this activity is often termed 'continued' airworthiness (not to be confused with 'continuing' airworthiness, per chapter 8).

7.1.1.3 This chapter presents an overview of the DASR approach to aircraft design, production and certification, which are the activities commonly associated with initial and continued airworthiness. The subsequent chapters will then explore several of these concepts in more detail.

7.1.1.4 Note this chapter is relevant only to Defence Registered aircraft; for non-Defence Registered aircraft, all initial and continued airworthiness functions are conducted per the requirements of the relevant Civil or military Aviation Authority (normally CASA).

7.1.2 DASR 21 – Aircraft Design, Production and Certification

7.1.2.1 From an Initial and Continued Airworthiness (INCA) perspective, an aircraft's lifecycle might follow a progression something like this:

a. To start, an engineering organisation demonstrates its professional ability to produce an aircraft design ('design organisation approval').

b. Next, the organisation produces a new aircraft design, and an Aviation Authority certifies that the design is suitably safe ('aircraft design and certification').

c. Individual aircraft are then produced, and an Aviation Authority certifies each as conforming to the certified design ('aircraft production and certification').

d. Over the following decades of fleet operation, numerous Minor and Major design changes and repairs will be made to the aircraft ('aircraft design changes and repairs').

e. Occasionally, there may be a need for limited flying of a possibly unairworthy aircraft, either to demonstrate a new capability or to avoid grounding an important asset ('permit to fly').

Superseded

f. Critically, throughout this complex lifecycle, an engineering organisation will need to monitor for defects in the design, facilitate risk management of the design, and so on ('type certificate holder').

g. Finally, an Aviation Authority might occasionally mandate certain remediation actions in the interests of fleet safety ('airworthiness directives').

7.1.2.2 Each of these seven functions, and several others, is regulated under DASR Pt 21– *Aircraft Design, Production and Certification.* The remainder of this chapter provides a brief summary of these functions.

7.1.2.3 **Design organisation approval.** Deficiencies in an aircraft's design can range from those with immediate catastrophic consequences (eg inadequate structural strength), to an erosion of safety margins (eg misleading navigation information), to an annoyance (eg a Minor human-machine interface flaw). Designing an aircraft where risks have been eliminated or otherwise minimised so far as is reasonably practicable (SFARP) is a particularly complex endeavour.

7.1.2.4 Consequently, the initial design of Defence aircraft should only be undertaken by skilled individuals within professional aircraft design organisations. DASRs make provision for DASA to issue Military Design Organisation Approval (MDOA) status to organisations who have demonstrated that they are able to maintain a design assurance system for the control and supervision of the design, and of design changes, of aircraft products, parts and appliances.

7.1.2.5 DASA's default expectation is that a new Defence aircraft will be designed by a MDOA of suitable scope. As a matter of pragmatism, however, DASR also make provision for Defence to accept designs that have been certified by a DASA-recognised civil or military Aviation Authority (CAA/MAA), without the need for the design organisation to be a DASA-approved MDOA, within certain bounds. This approach, often called 'prior acceptance' is explored in Chapter 7.2, *Product Certification*. These same provisions apply for design changes to an extant aircraft.

7.1.2.6 MDOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.7 **Initial aircraft design and certification.** Defence periodically acquires aircraft to meet a capability need. In practice, Defence usually acquires its new aircraft as off-the-shelf designs, and then incorporates design changes to cater for Defence's unique roles and operating environment. The entire design will meet a set of airworthiness requirements - commonly called a Type Certification Basis (TCB) - and the designer(s) will produce extensive evidence (via analysis, test and other means) to demonstrate that their design meets the TCB.

7.1.2.8 As noted in paragraph 7.1.2.5, these designs will be produced by a DASA-approved MDOA, or a design organisation whose design is certified by a DASA-recognised CAA/MAA, or sometimes both. Regardless, the final design will always be certified by DASA, signified by the issue of a Military Type Certificate (MTC)[1] for the aircraft.

7.1.2.9 In the absence of a pertinent CAA/MAA certification, DASA's certification for a new aircraft would be an immense undertaking for both DASA and the Defence acquisition organisation. More commonly, however, there will be a pertinent CAA/MAA certification, and leveraging off this certification can substantially reduce the impost on both organisations. In that case, much of the effort focuses on whether the certified design is compatible with Defence's intended Configuration, Role and Environment (CRE). Chapter 7.2, Product Certification, explores the certification process in detail.

Superseded

7.1.2.10 **Aircraft production and certification.** An expertly designed and certified aircraft provides the basis for safe aircraft operation. However, just as importantly, that design must be accurately implemented on the Defence aircraft.

7.1.2.11 DASR make provision for DASA to issue a Military Production Organisation Approval (MPOA) to an organisation when assured they have the ability to manufacture aircraft parts and appliances in conformity with approved data. DASR also make provision for Defence to accept an aircraft produced under the systems of a DASA-recognised CAA/MAA. This latter approach is used for most new Defence aircraft.

7.1.2.112 Following production of an individual aircraft, DASA must certify that the aircraft is in a state of airworthiness per the inherent level of safety specified on the MTC. This certification is signified by the DASA issue of a Military Certificate of Airworthiness (MCoA)[2] for each individual Defence aircraft.

7.1.2.13 Aircraft production and MCoAs are explored in Chapter 7.3, Production. MPOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.14 **Aircraft design changes and repairs.** Defence aircraft will usually be in service for several decades. During this time, numerous design changes will inevitably be implemented, either to enhance military capability or to address design or obsolescence problems. These design changes are classified under DASR as either Minor of Major, differentiated by the degree of airworthiness effect of the design change.

7.1.2.15 The DASR approach for Minor and Major design changes is very similar. They will both be performed by a DASA-approved MDOA or another design organisation whose design is certified by a recognised CAA/MAA, and both should preserve the level of airworthiness of the aircraft. For Major design changes, however, DASA will usually provide a proportionate level of independent assurance, and DASA itself will usually certify the design as safe. This certification is usually via an amendment to the MTC, although occasionally a Military Supplemental Type Certificate (MSTC) may be issued. Chapter 7.2, Product Certification, explores the certification process in detail.

7.1.2.16 Throughout an aircraft's life, degradation (damage) of the systems/structures integrity supporting safe flight may be compromised through direct (accidental impact and battle damage) overload, or insidious (fatigue, corrosion, moisture ingress, dis-bond, ultraviolet light etc) environmental sources. Repairs are those actions developed and implemented to restore damaged products to a suitably airworthy state. Similar to aircraft design changes, aircraft repairs are classified under DASR as Minor or Major, must be designed by a MDOA or other organisation agreed by DASA, and may be subjected to a proportionate level of DASA independent assurance.

7.1.2.17 **Permit to fly.** A Military Permit to Fly (MPTF) may be issued by DASA for an aircraft that does not meet, or has not been shown to meet, the requirements of its TCB, but is nonetheless capable of safe flight under defined conditions and for specified purposes. MPTFs are most commonly used for flight test (for aircraft development or role expansion activities), for flights where the design has not yet been certified, or for flights where the aircraft temporarily does not conform to the Type Design (eg due to unrepaired damaged, overdue maintenance, etc).

7.1.2.18 An MPTF may or may not entail an elevated level of risk, and is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application. Chapter 7.5, Flight Conditions and Military Permits to Fly, explores this in more detail.

Superseded

7.1.2.19 **Type certificate holder.** As noted earlier in this chapter, DASA issues an MTC for Defence Registered aircraft types. This MTC is issued to a suitable Commonwealth government organisation (usually the relevant Defence Systems Program Office), who are then charged with 'holding' the MTC.

7.1.2.20 Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed, and the level of safety inherent in the TCB is maintained. This includes, for a particular aircraft type, collecting aviation safety information (both locally and from external sources), ensuring operators are aware of extant hazards, ensuring that essential risk controls remain effective, leading local efforts to eliminate or further minimise known risks, and many other important roles.

7.1.2.21 These expansive holding responsibilities are often beyond the capacity and capability of the government organisation holding the MTC. Consequently, responsibility for the conduct of MTCH obligations is often vested with various support organisations, for example contractors, foreign project offices and other military operators. The government organisation remains accountable for all activities undertaken by those organisations.

7.1.2.22 Chapter 7.4, Continued Airworthiness, explores the MTCH role in more detail.

7.1.2.23 **Airworthiness directives.** In the Australian Defence context, the WHS Act and DASR place responsibility and obligation solely on the regulated community for managing the day-to-day safety of their aircraft, and for ensuring risks are eliminated or otherwise minimised so far as is reasonably practicable. DASR do, however, still make provision for DASA to mandate actions and/or impose conditions on aircraft operation in certain circumstances. This is achieved through the issue of an Airworthiness Directive (AD).

7.1.2.24 Like its civil counterpart, ADs under DASR provide a means to mandate an action in order to restore an aircraft to an acceptable level of safety, where that safety level may be otherwise compromised. However, due to Defence's unique context, DASA issues ADs infrequently, particularly in comparison to civil aviation.

7.1.2.25 Chapter 7.4, Continued Airworthiness, explores DASR ADs in more detail.

7.1.2.26 **Other.** In addition to the seven common INCA functions mentioned above, DASR 21 also makes provision for a number of niche functions. Since this chapter aims to provide an overview of INCA that is consumable to a wide audience, these niche functions will not be explored here. They include: Australian Military Technical Standard Order (AUSMTSO) authorisations, restricted type certificates, restricted certificates of airworthiness, approval of parts and appliances, and the identification of parts and appliances.

Structure of these chapters

7.1.2.27 This chapter has provided a brief overview of the functions encompassed within Initial and Continued Airworthiness. The subsequent chapters explore several of these functions in greater detail, as follows:

a. Chapter 7.2: Product certification

b. Chapter 7.3: Production and military certificates of airworthiness

c. Chapter 7.4: Continued airworthiness (including military type certificate holders, occurrence reporting, airworthiness directives and other organisational approvals)

d. Chapter 7.5: Flight conditions and military permits to fly

Superseded

e. Chapter 7.6: Design and production organisations.

7.2.1 – Introduction

7.2.1.1. Product certification authorisations represent DASA's assurance that an individual product complies with the applicable airworthiness[3] requirements. These are issued following review of compliance evidence presented by the applicant seeking product certification. Product certification authorisations covered under this chapter are MTCs, Changes to MTCs, MSTCs, and Repair Designs.

7.2.1.2. Product certification authorisations are built around four pillars of safety assurance; Organisational Capability, Compliance demonstration, Compliance Verification, and Obligations of the holder

7.2.1.3. **Organisational Capability.** Before an organisation can apply for a product certification, they need to be eligible. Eligibility is based on an assessment of whether the organisation is equipped/ resourced to achieve a successful authorisation.

7.2.1.4. **Compliance Demonstration.** The applicant for a product certification authorisation must show that their product complies with the applicable airworthiness requirements.

7.2.1.5. **Compliance Verification.** The authority must independently verify that compliance has been achieved to the applicable airworthiness requirements. As compliance demonstration and compliance verification are intrinsically linked, a certification programme is put in place to document the means by which the applicant will demonstrate compliance and the authority will verify compliance.

7.2.1.6. **Obligations of the Holder.** Following issue of a certification approval, the certificate holder must continue to carry out obligations outlined under the DASRs to ensure the product certification remains safe.

7.2.1.7. The following sections expand upon these safety assurance areas for each product certification authorisation.

7.2.2 – Type Certification – Military Type Certificates (DASR 21 Subpart B)

Overview

7.2.2.1 **Scope of Section.** Section 7.2.2 describes the DASR type certification process for obtaining a Military Type Certificate (MTC). Military Restricted Type Certificates (MRTCs) are not yet employed by DASA, and are not addressed herein.

7.2.2.2 **Military Type Certificate.** An MTC is issued by DASA to certify that a product's type design complies with the applicable Type Certification Basis (TCB) when operated within specified conditions and limitations. Further description of the MTC authorisation can be found in Section 5.3 Annex K.

Eligibility

Superseded

7.2.2.3 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the MTC.

7.2.2.4 DASR 21.A.13 (Eligibility), and by extension DASR 21.A.14 (Demonstration of Capability), define which organisations can apply for an MTC under DASR 21. As per DASR 21.A.14, applicants for an MTC can be:

1. A DASR 21 Subpart J approved Military Design Organisation (MDO) (21.A.14(a)). Holding a DASR 21J approval provides an organisation with the eligibility to apply directly to DASA for an MTC. However, given the scope of the Australian aviation industry, development and certification of a new aircraft wholly under a DASR 21J MDO will be a rare occurrence.

2. An organisation demonstrating its capability through alternative procedures (21.A.14(b)). An applicant may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to comply with this DASR. This eligibility provision is ostensibly aimed at products with simple or limited scope of design, or organisations starting toward a MDO approval or limited duration of design activities. Use of this provision to demonstrate capability to apply for an MTC would only be considered by DASA by exception.

3. A government organisation who has an agreement in place with a design organisation that has access to the type design data (21.A.14(c)). Any government organisation applying for an MTC may demonstrate its capability by having an agreement in place, accepted by DASA, with a design organisation that has access to the necessary type design data. This is the normal provision through which DASA expects government organisations (usually the relevant CASG System Program Office (SPO)) to demonstrate their capability to apply for an MTC. The agreement with the relevant design organisation shall include detailed statements how the actions and obligations are delegated to enable the government organisation, in cooperation with the contracted organisation, to comply with the requirements of Subpart J and DASR 21.A.44 (holder obligations). AMC and GM to 21.A.14(c) provide further information on demonstration of capability under this provision.

7.2.2.5 **MTC Applications by CASG SPOs (Project Offices).** To be issued an MTC by DASA, a CASG project office develops a Type Continued-Airworthiness Exposition (TCAE) for DASA review. The TCAE details the CASG arrangements with the design organisation(s) that has access to the type-design data and through which the provision of holder obligation functions occur. Further guidance on holder obligations and arrangements can be found in Section 7.4.1.

7.2.2.6 CASG project offices seeking issue of an MTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended acquisition program.

7.2.2.7 The eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J. Since a CASG project office scope of responsibility is usually limited to a single application, and does not include the through-life holder responsibilities, the CASG project office eligibility information is not required to be delivered as a single document and can instead be contained within

Superseded

Project or Acquisition documentation. The documentation requires review by DASA prior to the project office becoming eligible to act as an applicant. However, the CASG project office must include a transition plan to manage delivery of the Type Design to the MTC holder, and where the MTC holder organisation is being created, include plans for assessment of eligibility of the MTC holder, by DASA.

7.2.2.8 Additional guidance with respect to MTC applicant eligibility when CASG project offices wish to leverage recognition provisions is as follows:

1. Application will be exclusively based upon an aircraft type-design that has been certified by a recognised CAA/MAA. In this situation, the project office, in conjunction with any associated design organisation(s), can gain eligibility by demonstrating its ability to conduct the required certification programme activities (develop CPP, conduct applicability assessment against Defence context, develop the Defence TCB, and provide a declaration of compliance), rather than demonstrate full adherence to the DASR 21 Subpart J requirements.

2. Application will be based on a design that has not been certified, but was developed using a design system (organisation, people, processes, data, and tools) external to the DASR, and where that system is used to produce designs for certification by a recognised CAA/MAA. In this situation, the DASA recognition framework[4] must be leveraged by the project office to assist in demonstrating to DASA that the arrangements with the external DO provides an acceptable equivalence to the DASR 21 Subpart J requirements. Activities to meet the eligibility requirements should be completed prior to initial engagement with DASA and throughout certification programme activities. The project office is to address the following expectations in their respective eligibility submission:

   i. Confirm that the external design organisation is normally oversighted by a CAA/MAA recognised by DASA[5].

   ii. Confirm that the external design organisation has appropriate technical scope and expertise for the intended design(s).

   iii. Confirm that the systems, processes and personnel used in developing other designs for certification by the parent CAA/MAA will be used in the design development or holder activities associated with the ADF design.

   iv. Confirm that the design organisation is able to provide an attestation of compliance against the Defence TCB for any provided design product.

   Note: In some circumstances, the PO or MTC holder may wish to allow the external design organisation to engage directly with DASA for Defence TCB agreement, development and conduct of the CCP, and provision of a declaration of compliance to the Defence TCB. In this case, the eligibility documentation shall demonstrate that the external design organisation systems and process are sufficiently similar to the DASR 21J requirements to support such delegation.

   v. Confirm any expected oversight by the DO's parent CAA/MAA is appropriate.

   vi. Confirm where applicable, arrangements for DASA oversight are in place.

Superseded

vii. Articulate how the recognition arrangements as per paragraphs 7.2.2.8.(b)(iii), (iv) and (v) will be monitored and ensured during the design development and submission process[6].

Certification Programme

7.2.2.9 **Overview.** Under DASR 21, a certification programme is required for all applications for an MTC, and the certification programme requires formal acceptance by DASA.

7.2.2.10 The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a Certification Program Plan (CPP).

7.2.2.11 Two CPP templates are published on the DASA Website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the MTC CPP template.

7.2.2.12 The organisation(s) involved in the development and submission of a certification program for an MTC application will vary depending upon the acquisition arrangements. GM1 21.A.15(b) provides further guidance based on some common acquisition scenarios.

7.2.2.13 **Contents of a Certification Programme.** DASR 21.A.15(b) outlines the requirements for content of a certification programme for an MTC. Certification programmes must be tailored to meet the requirements of the certification activity.

7.2.2.14 The certification programme should be presented as a CPP containing the information required by DASR 21.A.15(b) and the supporting AMC. The MTC CPP template published by DASA will assist in meeting the required outcomes.

7.2.2.15 Two key outcomes are achieved through the development and DASA acceptance of the certification programme:

1. Applicant development and DASA agreement of the Defence TCB for the MTC[7].
2. Formalising and agreement on the approach to be taken for demonstrating compliance against the Defence TCB, and the DASA Level of Involvement (LoI) in compliance demonstration activities.

7.2.2.16 **Proposed Compliance Demonstration Items (CDIs)**. DASR 21.A.15(b)(5) requires that the CPP proposes a breakdown of the certification programme into meaningful groups of compliance demonstration activities and data, and a proposal for the means of compliance and related compliance documents.

7.2.2.17 A CDI is a meaningful group of compliance demonstration activities and data that can be considered, in isolation, for the purpose of performing the risk assessment that allows DASA to determine its LoI.

7.2.2.18 Applicants should follow AMC 21.A.15(b)(5) when proposing the CDIs, and the DASA MTC CPP template contains further guidance and tabular templates for presenting proposed CDIs.

7.2.2.19 **Proposed DASA LoI.** As outlined in AMC 21.A.15(b)(6), the Authority's LoI is a list of activities and data, in which the Authority retains the verification of compliance demonstration (e.g. review and acceptance of compliance data, witnessing of tests, etc.), as well as the depth of the verification. The depth of the verification for individual compliance reports, data, test witnessing, etc., may range

Superseded

from spot checks to extensive reviews. DASA will respond to those retained compliance demonstration activities and data with corresponding comments or a 'statement of no objection'. DASR 21.A.15(b)(6) requires that the CPP proposes the DASA LoI associated with compliance demonstration activities, noting that LoI should normally be proposed at the CDI level. As per DASR 21.A.15(b)(6), the DASA LoI must address the likelihood of an unidentified non-compliance with the TCB requirements and the potential impact of that non-compliance on safety (ie a risk-based determination). In practice, this is achieved through taking into consideration:

1. any novel or unusual features of the certification project, including operational, organisational and knowledge management aspects
2. the complexity of the design and/or demonstration of compliance
3. the criticality of the design or technology and the related safety risks, including those identified on similar designs
4. the performance and experience of the design organisation of the applicant in the domain concerned.

7.2.2.20 AMC 21.A.15(b)(6) contains a step-by-step process and extensive information that applicants should follow when determining the proposed DASA LoI. The DASA MTC CPP template also includes complementary guidance and tables. The three main steps that culminate in determining the DASA LoI are:

1. Step 1: Identification of the likelihood of an unidentified non-compliance. This includes taking into consideration novelty, complexity and the performance of the design organisation. Refer to Section 3.2 of AMC 21.A.15(b)(6) for details.
2. Step 2: Identification of the 'risk class'. This includes determining whether the potential impact of the non-compliance within a compliance demonstration activity (ie CDI) is critical or non-critical. This is then combined with the likelihood of an unidentified non-compliance (step 1) to determine the risk class. Refer to Sections 3.3-3.4 of AMC 21.A.15(b)(6) for details.
3. Step 3: Determination of the DASA LoI. Based on the qualitative risk class identified for each compliance demonstration activity (ie CDI), the applicant should propose a DASA LoI. Refer to Section 3.5 of AMC 21.A.15(b)(6) for details.

7.2.2.21 DASA will determine the depth and extent of its inspections for each CDI, based on the information provided in the certification programme and the applicant's proposal. DASA determination of LoI will be confirmed as part of DASA's acceptance of the CPP. Note that the depth and extent of DASA LoI may change throughout the project in order to account for changes that affect the basis of the initial LoI determination.

7.2.2.22 **Certification Programme Acceptance.** DASA acceptance of the certification programme is required for all MTC applications. Early engagement with DASA, and agreement on the key certification programme content, will reduce schedule and resource risks for the project. Delaying presentation of certification programmes to DASA until after compliance demonstration has commenced may result in delays, additional work, or additional resources, due to DASA:

1. determining that the proposed airworthiness requirements or means of compliance are unsuitable for the certification activity

Superseded

2. identifying a need for a LoI in compliance demonstration activities that have already been completed, therefore resulting in a need to repeat the compliance demonstration

3. identifying LoI that requires travel (eg for compliance demonstration being completed overseas) and insufficient time is available to organise funding and travel prior to the planned activity, resulting in a need to delay the activity

4. identifying a need for data access that was not accounted for prior to contracting or establishing government to government agreements for the activity, resulting in a need for contract changes or alternate workarounds.

7.2.2.23 DASA acceptance of a certification programme can be achieved incrementally, if some aspects are unknown at the beginning of the project or are expected to change throughout the project. A caveated acceptance may be possible to achieve agreement with DASA on specific aspects of the programme prior to full details being known. For an initial or caveated acceptance, the following is required:

1. identification of the applicant and any design organisations involved

2. broad detail on the design and aircraft intended use

3. an initial proposal for the TCB, including identification of the Primary Certification Code and identification of whether any TCB tailoring (including Military Certification Review Items (MCRIs)) will be required. Note: the TCB does not have to be fully defined at this point.

4. broad detail on the certification approach (i.e. whether there will be reliance on prior certification, or whether compliance demonstration evidence with be developed specifically for the DASA certification).

7.2.2.24 Where an incremental approach is taken to developing and achieving acceptance of the certification programme, the scope of acceptance intended by each version must be clearly understood and documented. A point at which the next update is required must be identified, this may be date based or linked to a specific project stage or milestone.

7.2.2.25 DASA acceptance of the certification programme will be agreed by formal communication, which will include confirmation of the DASA LoI for the activity, and any caveats on DASA acceptance.

7.2.2.26 **Certification Programme Updates.** In accordance with DASR 21.A.15(c), the certification programme is to be updated when there are changes to any of the content required under DASR 21.A.15(b). Key aspects that require the certification programme to be re-accepted by DASA are:

1. any changes that may impact on DASA LoI, such as:

   i. change to the design or intended use

   ii. change to compliance demonstration approach (including the means of compliance)

   iii. change to the CRE Assessment (CREA) or its outcomes for a program that is leveraging prior certification

   iv. change to design organisation resources or approvals

Superseded

2. any changes to the proposed TCB (except those achieving separate agreement via an MCRI)

3. significant changes to schedule that may impact on DASA LoI activities

7.2.2.27 Changes to the certification programme can be presented as an update to the original CPP, or via a supplement, depending on the scope of the changes.

7.2.2.28 Applicants should engage early with DASA (nominally DIA) staff and remain closely engaged with CPP development and subsequent amendment, heeding advice to prevent nugatory drafting and rewriting. The DASR Form 31 can be used to notify DASA of an upcoming certification project, to initiate discussions. A face-to-face session, before any CPP drafting occurs, is strongly recommended for for complex programs.

Type Certification Basis

7.2.2.29 **Contents of a TCB.** The TCB is an agreed set of airworthiness requirements that a product must be compliant with in order to obtain an MTC. The following DASR and concepts apply to the contents of a TCB:

1. DASR 21.A.16A (Airworthiness Codes). This regulation requires that DASA shall approve the use of Airworthiness Codes[8] and other detailed specifications that may be used to demonstrate compliance of products, parts and appliances. As noted in GM 21.A.16A, rather than define a Defence-unique Airworthiness Code, DASA has elected to recognise the Airworthiness Codes prescribed by several other CAAs and MAAs that have been demonstrated to achieve safe flight, and then prescribe supplementation as required. The Defence Aviation Safety Design Requirements Manual (DASDRM) identifies the Airworthiness Codes recognised by DASA.

2. DASR 21.A.16B (Special Conditions). This regulation requires that DASA shall approve any special detailed technical specification ('special conditions') if the related Airworthiness Code or specifications do not contain adequate or appropriate safety standards. As per 21.A.16B, the need for special conditions may arise due to:

   i. novel or unusual design features (relative to the design practices on which the applicable Airworthiness Code is based)

   ii. intended use of the product is unconventional

   iii. experience from other similar products in service or products having similar design features or newly identified hazards have shown that unsafe conditions may develop

   iv. applicable airworthiness codes do not exist for the concerned product class or do not address the requested kind of operations.

   In the Defence context, special conditions are required when the primary Airworthiness Code selected may contain deficiencies against contemporary airworthiness requirements and / or may not account for Defence's unique CRE. DASA uses the Defence Aviation Safety Design Requirements Manual (DASDRM) to define those 'essential' design requirements and standards that must be applied as special conditions to supplement Airworthiness Codes due to deficiencies in the Codes or to account for the Defence CRE. The DASDRM also defines a number of 'recommended'

Superseded

design requirements and standards for which compliance is not prescribed, but which should be applied where reasonably practicable.

3. DASR 21.A.17A (Type Certification Basis). This regulation defines the scope of the Defence TCB. The airworthiness requirements specified in the TCB include:

   i. the applicable requirements from the DASA recognised Airworthiness Code selected as a basis for the Defence aircraft certification (the Primary Certification Code (PCC))

   ii. the applicable 'essential' requirements prescribed in the Defence Aviation Safety Design Requirements Manual (DASDRM)

   iii. any supplementation or tailoring agreed to by DASA.

7.2.2.30 **Development of a Defence TCB.** Development of a Defence TCB is a joint activity between the applicant and DASA and is guided by the DASR listed above and the Defence Aviation Safety Design Requirements Manual (DASDRM). TCB agreement is obtained through acceptance of the certification programme in accordance with DASR 21.A.15(b).

7.2.2.31 The TCB for a new Defence aircraft type should be developed and agreed as early as practicable in the aircraft acquisition life-cycle. While a DASA-agreed TCB should be pursued prior to entering into an acquisition contract, this will not always be possible. In those cases, the acquisition project office may elect to present a draft TCB for DASA assessment as a cost and schedule risk reduction measure.

7.2.2.32 In most cases, DASR and the DASDRM allow the Defence TCB to be based on the recognised design standards used by the parent CAA/MAA under which the aircraft was initially designed and certified.

7.2.2.33 The TCB for a Defence aircraft must be consistent with Defence's intended role and operating environment for the aircraft. In the aircraft Type Certification domain, CRE is a pivotal concept. Where an ab-initio Type Certification programme is proposed for a Defence aircraft, defining the CRE is essential to ensure that the basis of certification is consistent with the intended Defence use of the aircraft.

7.2.2.34 Where the Defence Type Certification programme intends to leverage prior certification from a recognised CAA/MAA to any extent, a CRE Assessment (CREA) is required to confirm the applicability of that prior certification to the intended Defence use. Areas where the prior certification is not entirely applicable to the Defence CRE must be addressed through further compliance demonstration evidence, inclusion of additional requirements in the TCB, or tailoring of requirements for the TCB. Further guidance on leveraging prior certification is contained in Annex B to Section 7.2, and further guidance on the conduct of a CREA is contained in Annex C to Section 7.2.

7.2.2.35 **Tailoring the PCC.** During a certification program, there may be a need to tailor the PCC when seeking an MTC. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

7.2.2.36 Tailoring of the PCC may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.2.37 Tailoring of the PCC can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a Military Certification Review Item (MCRI).

Superseded

7.2.2.38 Annex A to Section 7.2 provides further guidance on tailoring the PCC, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support PCC tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Compliance Demonstration

7.2.2.39 **Overview.** Compliance demonstration evidence comprises of reports, engineering tool outputs, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the applicable TCB is demonstrated. The applicant shall demonstrate compliance with the type-certification basis either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.2.40 The agreed certification programme will include details of how compliance demonstration is being achieved for each project. Where difficulty arises in meeting the agreed certification programme activities or outcomes, engagement with DASA as early as practicable is recommended. This phase may identify issues in compliance demonstration evidence against the agreed Defence TCB that require equivalent safety finding arguments, processing of exceptions underpinned by an Airworthiness Issue Paper (AwIP) or equivalent, or introducing new interpretations or means of compliance. In these cases an MCRI, and an AwIP as required, should be raised and submitted by the applicant for DASA consideration.

7.2.2.41 **Leveraging Prior Certification.** Defence is rarely the prime customer for new aircraft, so most acquisitions will be based on an aircraft design that has or will be certified by another CAA/ MAA. DASR 21.A.20 enables an applicant for an MTC to leverage prior certification from a recognised CAA/MAA[9] to gain relief from developing compliance demonstration evidence.

7.2.2.42 The fundamental principle of leveraging prior certification is that any requisite Authority review of evidence; testing, or witnessing of testing; or inspections (refer DASR 21.A.33(b)) have already been performed by a competent Authority (ie a CAA/MAA recognised by DASA). Therefore, duplicate effort in terms of DASA also conducting inspections / analyses / tests is unnecessary. However, as per DASR AMC 21.A.20, in order to leverage the prior certification, the applicant for the MTC must ensure:

1. the certification is within the scope, conditions and caveats specific to DASA Recognition of the certifying CAA/MAA
2. the CAA/MAA is sufficiently experienced in certification of the particular design activity
3. the certification requirements employed by the CAA/MAA are understood and any deltas from the Defence TCB have been addressed
4. the CRE applied to the prior certification is understood and any deltas from the intended Defence CRE have been addressed
5. any safety risks associated with the CAA / MAA certification have been identified, and have been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) for the Defence CRE.

Superseded

7.2.2.43 Annex B to Section 7.2 provides additional guidance on the AMC 21.A.20 requirements for leveraging prior certification, and discusses common issues encountered with leveraging prior certification. Annex C to Section 7.2 provides further guidance on the conduct of a CREA to support relief from presenting CDE when leveraging prior recognition.

7.2.2.44 **Structures and Propulsion System Specific Guidance.** Guidance on the conduct of structures and propulsion system CREAs when leveraging prior certification can be found in GM1 21.A.20 and Chapter 6.6.2. Guidance to support AMC 21.A.41 (Structural and Propulsion System Critical Parts and Airworthiness Limitations (AUS)) can be found in Chapter 6.6.2.

MTC Application, Issuance and Type Certificate Data Sheet (TCDS)

7.2.2.45 **Application.** Upon completion of all activities identified within the CPP, including development of compliance demonstration evidence and completion of DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for issuance of an MTC. The exact format of the application for an MTC will differ depending upon each project, and should be agreed within the CPP.

7.2.2.46 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will issue the MTC.

7.2.2.47 For acquisitions of new aircraft types, the Defence Aviation Authority (Defence AA) will generally elect to convene an Airworthiness Board (AwB). Aircraft acquisition AwBs, including applicant and DASA submission of documents to support the AwB, are separate to the DASR type certification process outlined within this section. AwBs are discussed further in Section 6.1.2 and Section 13.

7.2.2.48 **Type Certificate Data Sheet (TCDS).** A TCDS will accompany each MTC. The TCDS contains all information (or reference thereto) about the type certification of the product including the TCB, the type design, operating limitations, the Aircraft Flight Manual (AFM), Instructions for Continuing Airworthiness (ICA), Airworthiness Limitations (AwLs), Certification Maintenance Requirements (CMRs), critical parts list (if applicable) and any other data necessary for the continued safe operation of the product.

7.2.2.49 DASA will develop and issue the TCDS concurrently with the MTC.

DASA Assurance

7.2.2.50 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining an MTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).
2. DASA agreement of the TCB, including tailoring (refer 'Type Certification Basis' section above).
3. DASA LoI in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme'

Superseded

section above). In all cases, DASA LoI activities should be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer below for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, and issue of the MTC and TCDS.

7.2.2.51 **DASA Assurance when Leveraging Prior Certification.** Where the certification programme indicates that an applicant is proposing to leverage prior certification from a recognised CAA/MAA, then DASA assurance activities will focus on the criteria outlined in AMC 21.A.20. The guidance outlined in Annex B to Section 7.2 provides an indication of the considerations that DASA will examine as part its assurance activities.

7.2.2.52 For certain aspects, the CPP will only be providing a proposal for how the applicant intends to address the criteria for leveraging prior certification outlined in AMC 21.A.20. For example, the applicant may need to conduct further activities to confirm that the CAA/MAA is sufficiently experienced in certification of the particular design activity, conduct further analysis to show that the design is compliant for the Defence CRE, and conduct sovereign assessments for safety risk decisions or risk retention made by an MAA. Therefore, DASA will typically request the applicant provide relevant documentation prior to, or as part of, the final application.

7.2.2.53 Note that while leveraging prior certification may provide relief from the need to develop new compliance demonstration evidence, it does not provide relief from the need to present compliance demonstration evidence to DASA. As such, DASA may request to review evidence that supported the prior certification where it is deemed necessary. Where it is not possible for the applicant to provide this evidence to DASA, for example due to limitations on access to OEM data, this will be negotiated between the applicant and DASA on a case-by-case basis.

MTC Holder Obligations

7.2.2.54 MTC holder obligations are outlined in DASR 21.A.44. Refer to Section 7.4.1 for detailed guidance on MTC holder obligations.

7.2.3 – Changes to Type Certificates and Military Supplemental Type Certificates (DASR 21 Subpart D and E)

Overview

7.2.3.1 **Scope of Section.** Section 7.2.3 primarily describes the DASR type certification process for major changes to the type certificate and obtaining a Military Supplemental Type Certificates (MSTC). Minor changes to the type certificate are only briefly addressed herein.

7.2.3.2 **Change to a Type Certificate.** As defined by DASR 21.A.41, the type certificate includes:

1. The Type Design, which includes[10]:

Superseded

i. The drawings and specifications, and a listing of those drawings and specifications, necessary to define the configuration and the design features of the product shown to comply with the applicable TCB;

ii. Information on materials and processes and on methods of manufacture and assembly of the product necessary to ensure the conformity of the product;

iii. An approved Airworthiness Limitations Section (ALS) of the ICA as defined by the applicable airworthiness codes; and

iv. Any other data allowing by comparison the determination of the airworthiness of later products of the same type.

2. Operating Limitations

3. The TCDS

4. The applicable TCB

5. Any other conditions or limitations prescribed for the product in the applicable airworthiness requirements.

7.2.3.3 A change to any aspect of the items listed above is considered a change to the type certificate, and must be undertaken in accordance with DASR 21 Subpart D or E.

7.2.3.4 Note that DASR M.A.304(d) allows for the Operator to directly consume data for minor changes that has been approved within the framework of Authorities recognised by DASA. Under this pathway, the requirements of DASR 21 are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate. Data for major changes cannot be directly consumed via recognition, and must be processed in accordance with DASR 21 Subpart D or E. Refer to Section 8.2 for further information on the direct consumption of data via recognition. Consumption of data for minor changes via recognition is not discussed any further within this section.

Classification

7.2.3.5 In accordance with DASR 21.A.91, all changes to the type certificate must be classified as minor or major.

7.2.3.6 A minor change is defined as a change that has no appreciable effect on the mass, balance, structural strength, reliability, operational characteristics, or other characteristics affecting the airworthiness of the product. All other changes are defined as major. Guidance on classification of changes to type certificates, including examples of changes that should be classified as major, can be found in DASR GM 21.A.91.

7.2.3.7 DASR 21J MDO approval holders will typically have the privilege to classify changes that are within the scope (e.g. technology or platform types) of their terms of approval. As noted in DASR GM 21.A.91, DASA should be consulted for clarification wherever there is doubt as to the classification of a change. Furthermore, when the strict application of the DASR GM 21.A.91 paragraph 3.4 criteria results in a major classification, the applicant may request reclassification, if justified, and DASA can take the responsibility in reclassifying the change.

Processing of Minor Changes

Superseded

7.2.3.8 Minor changes to the type certificate must be undertaken in accordance with DASR 21 Subpart D, and can be approved by DASA or a DASR 21J MDO approval holder with the necessary privilege and scope. DASA expects that in the Defence context, minor changes to type certificates undertaken in accordance with DASR 21 Subpart D will be developed and approved by a DASR 21J MDO[11].

Processing of Major Changes

7.2.3.9 Changes that are classified as major can be processed and approved as a:

1. major change to the existing MTC under DASR 21 Subpart D, or
2. a MSTC under DASR 21 Subpart E.

7.2.3.10 The decision to apply for a major change (DASR 21 Subpart D) versus a MSTC (DASR 21 Subpart E) will depend upon the specific context. Under the DASR construct, both these authorisations will be issued to the government MTC holder. The default approach is usually issue a major change to the existing MTC, however, as discussed in the following sub-section, there may be cases where an MSTC is more appropriate.

Use of Military Supplemental Type Certificates (MSTCs)

7.2.3.11 The reasons for using an MSTC are different in the Defence context from in the civilian context. This sub-section provides guidance on when an MSTC should be used under the DASR.

7.2.3.12 **Civil use of Supplemental Type Certificates (STCs).** In the civil context, STCs are generally used for commercial purposes. They are used where a designer (either the OEM or another designer) alters the aircraft to provide a new capability that they can sell separately to the original Type Certificate. Of note, designers who are not the holder of the original Type Certificate can only ever apply for STCs for design changes that are classified as major, as it is not possible to apply for a major change to a certificate you do not hold.

7.2.3.13 Major changes to the Type Certificate are limited to changes done by the Type Certificate Holder, and are mostly (though not always) mandatory Service Bulletins and Airworthiness Directives to address safety issues identified in service as part of the holder obligations (eg DASR 21.A.3A).

7.2.3.14 **Use of MSTCs Under DASR.** Under the DASR the reasons for using an MSTC are different to the civil context. The following are the reasons that an MSTC (as opposed to a major change to the MTC) would be used under the DASR:

1. Sub-fleet: An MSTC may be used to manage a sub-fleet. This would be where there is one or more aircraft in the fleet that are intended to be configured or operated in a significantly different manner to the remainder of the fleet. Note, sub-fleets can also be managed via major changes to the MTC, so an MSTC may be used but is not the only option for management of sub-fleets.
2. Significant Change to the TCB: An MSTC may be used to manage a change that involves a distinct change to the TCB. Generally this will be the result of reliance on prior certification which has adopted a different PCC than that used for the original MTC. While the change to the PCC may be able to be managed via MCRI(s), it may reduce the complexity of ongoing management of the authorisations by covering the change under an MSTC.

Superseded

3. Large and Complex Changes: An MSTC may be used for large and complex changes. While the process for review and approval of a major change or an MSTC is the same, use of an MSTC provides greater visibility, and as a result greater clarity, of the precise nature and scope of the change. MSTCs are often understood by Defence Operators as being a change of more significance, which warrants greater operational consideration.

4. Management Reasons: An MSTC may be used for ease of management from the perspective of the MTC holder. This may be required to provide alignment between the DASR authorisations and authorisations being leveraged via recognition. It may be simpler for an MTC holder to manage their obligations if the Defence authorisations are aligned with the OEM authorisations.

7.2.3.15 Note that when changes are applied to the MTC for a platform that also has MSTC(s), the compatibility of the change with the existing MSTC(s) must be explicitly addressed. Under the civil system, a change to the Type Certificate does not need to explicitly consider compatibility with potential STCs. It is the Operator's responsibility to consider the impact of change to the Type Certificate against any STCs applied to their aircraft, and to engage the STC holder as required. However, in the DASR context, the MTC and MSTCs are frequently more integrated and less able to be clearly separated from each other. In addition, the MTC and MSTCs are all held by the same organisation so separating consideration of the MTC and MSTCs is unnecessary and adds confusion for no benefit. As such, it is not appropriate to progress a major change to the MTC without considering the impact on existing MSTCs.

Eligibility

7.2.3.16 Applicant eligibility requirements exist to control how designs and applications are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance evidence and how the declaration of compliance is made, and has confidence in the applicant's ability to fulfil the obligations associated with holding the relevant authorisation.

7.2.3.17 **Major Change to the MTC.** In accordance with DASR 21.A.92, only the MTC holder can apply for a major change to the MTC. However, as noted by DASR GM 21.A.92(a), this includes any organisation acting on behalf of the MTC holder. DASA considers it appropriate for a design organisation to act as the applicant for a major change (on behalf of the MTC holder) where:

1. the agreement between the MTC holder and design organisation required by DASR 21.A.14(c) permits,

2. the TCAE reflects the agreement and arrangements under which such applications may occur, and

3. the proposed design change is within the scope of the design organisation's approval.

7.2.3.18 In all cases, the MTC holder must sign the final application for the major change (ie Form 31A) to confirm that they have been consulted on, and have no objection to, the major change, and will carry out holder responsibilities.

7.2.3.19 During sustainment, additional design organisations may be engaged by the MTC holder to support new modifications or reflect expanding design support agreements. In these cases, the MTC holder should inform DASA of the proposed support arrangements and define additional oversight requirements to support specific applications.

Superseded

7.2.3.20 **MSTC.** In accordance with DASR 21.A.112A, any organisation that has demonstrated, or is in the process of demonstrating, its capability under DASR 21.A.112B shall be eligible as an applicant for an MSTC. The DASR 21.A.112B demonstration of capability requirements are essentially the same as those of DASR 21.A.14 (refer to the 'Eligibility' guidance in Section 7.2.2, and relevant AMC and GM for further information).

7.2.3.21 However, as noted by DASR GM 21.A.115, DASA will issue all MSTCs to the relevant government MTC holder organisation. This means that, in effect, all applications for MSTC are being made on behalf of the MTC holder who will be the eventual holder of the MSTC. Applicants for MSTCs must be able to demonstrate that they are acting on behalf of the MTC holder.

7.2.3.22 **Major Change or MSTC Applications by CASG Project Offices.** In some cases, the CASG project office may act as the applicant for a major change or MSTC for larger or more complex modifications to an existing aircraft, such as for a mid-life upgrade program or significant capability upgrades.

7.2.3.23 Since only the MTC holder can apply for major changes to the existing MTC, the CASG project office would be considered to be applying for the approval on behalf of the MTC holder. For MSTC applications, the CASG project office could be considered the applicant under the DASR 21.A.112B(c) exception clause. In either case, the eligibility assessment will focus on the arrangement between CASG and supporting design organisation(s), and address how the arrangements comply with the requirements of DASR 21 Subpart J.

7.2.3.24 Also refer to the 'MTC Applications by CASG SPOs (Project Offices)' guidance in Section 7.2.2 for further information, including guidance on applicant eligibility when CASG project offices wish to leverage recognition provisions.

7.2.3.25 CASG project offices seeking to apply for a major change or MSTC are strongly encouraged to initiate early contact with DASA during the appropriate stage of the Capability Life Cycle (such as preceding, or early in, the Acquisition phase) to discuss how the DASR eligibility provisions will be met for the intended program.

Certification Programme

7.2.3.26 **Overview.** Under DASR 21, a certification programme is required for all changes to type certificates and MSTCs. The certification programme provides the details necessary to understand the design activity and how certification will be achieved for that activity. A stand-alone document that presents the certification programme for formal DASA acceptance is termed a CPP.

7.2.3.27 For MSTC and 'complex'[12] major change programs, the certification programme must be presented to DASA for formal acceptance prior to the final application and declaration of compliance, and it is recommended that it be presented as a CPP. For other certification activities, the certification programme may be documented through the design pack or final application, and does not require formal DASA acceptance. Table 7.1 summarises the certification programme requirements for different design activities.

Certification Activity	DASR Reference	Formal DASA Acceptance Required?	Comments
Application for an MSTC	21.A.113(b)	Yes	Certification programme should be presented as a

Superseded

	21.A.93(b)		CPP containing the information required by 21.A.93(b) and the supporting AMC. The DASA major change/MSTC CPP template will assist in meeting the required outcomes.
Application for a 'complex' major change	21.A.93(b)	Yes	
Application for a 'simple' major change	21.A.93(b)	Yes	Certification programme can be provided with the final application for approval of the change.
Minor change to type-certificate	21.A.93(b)[13]	No	

Table 1: Certification Programme Requirements for Design Change Activities

7.2.3.28 Two CPP templates are published on the DASA website (one for MTCs and one for major changes/MSTCs), which provide detailed guidance on the structure and content of a certification programme. This section should be read in conjunction with the major change/MSTC CPP template.

7.2.3.29 The organisation(s) involved in the development and submission of a certification program for a major change or an MSTC application will vary depending upon the platform support arrangements. As noted above, the design organisation that supports the MTC holder functions may act as the applicant on behalf of the MTC holder in certain circumstances. In these cases, the design organisation will usually develop the CPP and engage with DASA for formal acceptance when required.

7.2.3.30 **Simple Major Changes.** For 'simple'[14] major changes, the certification programme may be presented with the final application (ie with the Form 31a pack). This approach introduces a risk that if DASA identifies issues with the certification programme, or with the decision to treat the change as simple, there may be a requirement for rework of compliance demonstration activities, resulting in a delay to the program. As such, this approach should only be followed where the change is straightforward; for example, OEM Service Bulletins that have received CAA/MAA certification. If there is doubt as to whether a change would meet the definition of 'simple', DASA Type Certification section should be contacted for advice.

7.2.3.31 **Contents of a Certification Programme.** DASR 21.A.93(b) outlines the requirements for content of a certification programme for a major change or an MSTC.

7.2.3.32 Certification programmes must be tailored to meet the requirements of the certification activity. If a change has been assessed as 'simple', then there is no need to do a full breakdown of the programme into CDIs or to provide a detailed LoI proposal, as the LoI must be assessed as nil to meet the definition of a simple change. For changes that rely on prior certification, the breakdown of the programme into CDIs is only required for areas that are not able to fully leverage prior certification (ie where additional compliance demonstration evidence is being developed).

7.2.3.33 For 'complex' major changes and MSTC, the certification programme should be presented as a CPP containing the information required by DASR 21.A.93(b) and the supporting AMC and GM. The major change/MSTC CPP template published by DASA will assist in meeting the required outcomes.

Superseded

7.2.3.34 **Further Guidance.** Refer to the certification programme information in Section 7.2.2 for further guidance on proposal of CDIs and DASA LoI, as well as certification programme acceptance and updates.

Certification Basis

7.2.3.35 For all changes to a product, the design organisation must identify the areas affected by the change and the corresponding certification basis (airworthiness requirements) for those areas. The applicable airworthiness requirements will depend upon the nature of the change, and can be generalised as follows:

1. **Substantial changes.** Some changes are so extensive that a new type certificate is required (refer DASR 21.A.19), and therefore would require an entirely new TCB to be established. Substantial changes for an existing aircraft type are unlikely within the Defence context.

2. **Significant (major) changes.** For major changes that are categorised as significant[15] under DASR 21.A.101, then the latest amendment level of the airworthiness requirements referenced in the TCB should be used for the change.

3. **Non-significant (major) changes.** For major changes that are not categorised as significant, then the DASR 21.A.101(b) exception clause allows the existing airworthiness requirements in the TCB to be used for the change. DASR 21.A.101(b) also allows the existing airworthiness requirements to be used for a significant change in cases where use of the latest amendment of the airworthiness requirements referenced in the TCB would not contribute materially to the level of safety, or is impractical.

4. **Minor changes.** Minor changes, by definition, do not affect the airworthiness of the product. This means that it is appropriate to use the existing airworthiness requirements in the TCB for the change (refer DASR 21.A.95(b)(1) and DASR AMC 21.A.95).

7.2.3.36 As stated above, using the existing airworthiness requirements in the TCB is usually considered adequate for minor changes and non-significant major changes. However, as noted in DASR GM 21.A.93(b)(2), Australia's WHS Act levies additional obligations on designers, namely to exercise 'reasonable knowledge' when determining that any risk inherent in designs has been minimised SFARP. Updates (later amendments) to applicable standards may provide insight into hazards and potential controls that are not identified in the existing TCB. The requirements prescribed in the DASDRM also provide a source of requirements and standards that can assist engineers to satisfy their obligation to exercise reasonable knowledge of hazards and associated controls in aircraft design.

7.2.3.37 The certification programme for the change should identify the proposed certification basis (ie existing or latest amendment level, with justification as required) and any 'reinvestigations' required[16].

7.2.3.38 **Changed Product Rule.** DASR 21.A.101 is commonly referred to as the 'changed product rule' and is used by applicants and DASA to establish the certification basis for major changes and MSTCs. The primary decision under the changed product rule is whether the latest amendment of the airworthiness requirements referenced in the TCB must be used (ie significant major change), or whether the nature of the major change allows the existing airworthiness requirements to be used (ie non-significant major change). If an applicant elects to comply with the latest amendment for a major

Superseded

change that could otherwise be categorised as non-significant, then the change will be compliant with DASR 21.A.101(a) and no further justification would be required.

7.2.3.39 DASR GM 21.A.101 contains extensive guidance and a step-by-step process for applicants to follow in order to establish the proposed certification basis for the major change. A summary of the changed product rule criteria and outcomes is shown below in Table 7.2. Table 7.2 is taken from Appendix B to GM 21.A.101, and only provides a brief summary of the extensive guidance and step-by-step process contained in DASR GM 21.A.101. A number of the Appendices to GM 21.A.101 refer to the EASA GM 21.A.101, including Appendix A of EASA GM 21.A.101 which provides examples of changes that EASA, the FAA and other Authorities considered to be 'substantial', 'significant' and 'non-significant'.

<table>

</table>

Table 2: Establishing Certification Basis for Changed Products

7.2.3.40 Significant major changes shall also comply with the relevant 'essential' design requirements defined in the DASDRM (refer DASR AMC 21.A.101).

7.2.3.41 Note that for major changes, DASR 21.A.101(e) is a further exception clause that allows applicants to propose an alternative to the airworthiness requirements in the TCB. DASA may agree to the use of an alternative set of airworthiness requirements provided the alternative provides at least an equivalent level of safety to the existing TCB.

7.2.3.42 The process and justification used to comply with DASR 21.A.101 should be included within the certification programme, and the DASA major change/MSTC CPP template contains specific headings to include this information.

7.2.3.43 When applicants believe that the major change under consideration may be significant, or have questions about application of DASR 21.A.101, then engagement with DASA as early as practicable is recommended.

7.2.3.44 **Tailoring the TCB.** During a certification program, there may be a need to tailor the TCB when seeking a major change approval. This tailoring may be required to supplement the PCC for a specific technology area, to specify later amendments of requirements or to otherwise account for the Defence CRE.

Superseded

7.2.3.45 Tailoring of the TCB may be required to address a range of situations, such as CRE differences, special conditions, new means of compliance or any other certification issues that require clarification or interpretation.

7.2.3.46 Tailoring of the TCB can be achieved by directly including additional requirements or standards in the Defence TCB, or through use of a MCRI.

7.2.3.47 Annex A to Section 7.2 provides further guidance on tailoring the TCB, including when an MCRI is required and the MCRI categories adopted and employed by DASA, when Operator agreement is required to support TCB tailoring and how that agreement should be achieved, and illustration of the process involved in obtaining DASA agreement for tailoring.

Reclassification of Changes Requiring TCB Tailoring

7.2.3.48 Occasionally, changes to type certificates that would otherwise be classified as minor, are required to be classified as major only because of the need to tailor the TCB. This section outlines an approach to enable these changes to be reclassified to minor, once the TCB tailoring has been agreed. This approach will allow greater use of DASR 21J MDO privileges, and reduce DASA assurance in areas where there is not a clear safety benefit.

7.2.3.49 **Reclassification Justification.** DASR GM 21.A.91 states that any changes that require an adjustment of the TCB, other than electing to comply with a later amendment of a requirement, must be classified as major. However, it also states that when the strict application of the classification criteria for a design change results in a major classification, the applicant may request re-classification, if justified, and DASA can take the responsibility in re-classifying the change.

7.2.3.50 DASA has identified that, for changes that are classified as major solely due to a need to tailor the TCB, continuing to process these as major changes once the tailoring of the TCB has been agreed imposes additional administrative burden without commensurate safety benefit, and can result in a delay to the introduction of safety improvements or capability upgrades. As such, DASA considers it appropriate for these changes to be re-classified to minor, as allowed by DASR GM 21.A.91, and either directly consumed (if subject to prior certification) or approved by a DASR 21J approved organisation holding appropriate privileges.

7.2.3.51 **Reclassification Process** (Figure1). Reclassification is only possible once the tailoring of the TCB has been agreed. An applicant may submit the requests for TCB tailoring and reclassification concurrently, allowing a single DASA response, or the reclassification request may be submitted after the tailoring has been agreed. Requests for reclassification are to be submitted via Letter or Minute to DASA via the DIA Type Certification mailbox (dasa.typecert@defence.gov.au). Requests must be submitted by an organisation that meets the eligibility requirements to apply for a major change under DASR 21 Subpart D (ie the MTC holder or a design organisation that provides MTC holder functions as part of establishing holder capability).[17]

7.2.3.52 The applicant must provide confirmation that the design would meet the requirements to be classified as minor if not for the tailoring of the TCB. This may be provided as an assessment from a DASR 21J approved organisation that has privileges to classify changes, or by providing evidence of approval as a minor change under the system of a recognised CAA/MAA with an equivalent classification system.

Superseded

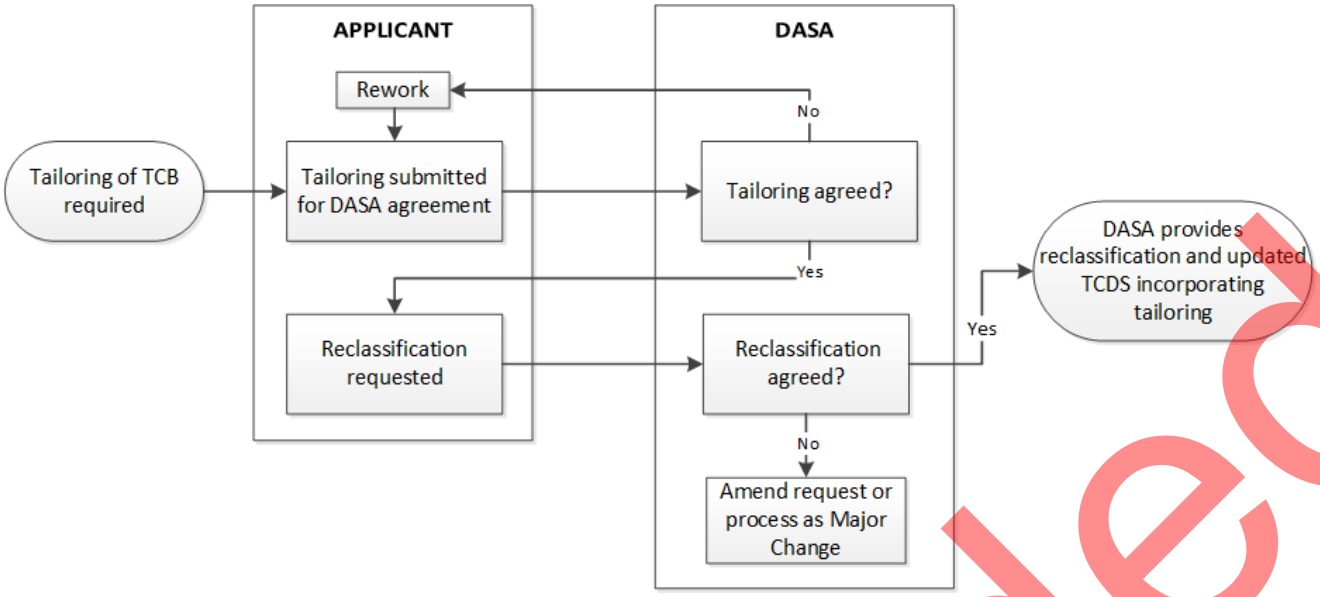

Figure 1: Process for reclassification when TCB tailoring is required

Compliance Demonstration

7.2.3.53 Compliance demonstration evidence comprises of reports, drawings, specifications, calculations, analysis etc. and provides a record of the means by which compliance with the TCB requirements applicable to the change / MSTC is demonstrated. The applicant shall demonstrate compliance with the applicable TCB requirements either:

1. through compliance demonstration evidence developed by a MDOA holder (or alternative as agreed by DASA); or
2. through appropriate evidence of prior certification provided by another CAA / MAA.

7.2.3.54 Refer to the 'Compliance Demonstration' evidence guidance in Section 7.2.2 for further information.

Application, Approval / Issue and TCDS Update

7.2.3.55 **Application.** Upon completion of all activities identified within the certification programme, including development of compliance demonstration evidence and DASA LoI, the applicant provides the required declaration of compliance (refer DASR 21.A.20(d)) and formally applies to DASA for approval of a major change, or issuance of an MSTC, using the DASR Form 31A.

7.2.3.56 **Issuance.** Upon receipt of the application, DASA assures itself that agreed certification programme activities have been completed, and will approve the major change or issue the MSTC.

7.2.3.57 **TCDS.** As required, DASA will develop and issue the TCDS update concurrently with the major change approval or MSTC issuance.

DASA Assurance

7.2.3.58 DASA independent safety assurance activities occur throughout the type certification process, and will vary in nature, scope and depth based on each individual project. Key DASA assurance activities for obtaining a major change or MSTC include:

1. DASA acceptance of the certification programme (refer 'Certification Programme' section above).

Superseded

2. DASA agreement of the TCB, including tailoring (refer 'Certification Basis' section above).

3. DASA Level of Involvement (LoI) in compliance demonstration activities. The term LoI describes DASA's involvement in the verification of compliance demonstration. DASA LoI can include review of compliance data and information; testing, or witnessing of compliance testing; or inspections (refer DASR 21.A.33(b)). Depending upon the design, DASA LoI may occur over an extended duration and include on-site witness activities. DASA LoI will have been defined in the certification program (refer 'Certification Programme' section above). In all cases, DASA LoI activities must be successfully completed prior to the applicant's declaration of compliance.

4. DASA assurance activities related to leveraging prior certification. These activities can be broadly described as DASA review of the evidence and artefacts that support the applicant's claims that prior CAA/MAA certification can be leveraged (refer to the 'DASA Assurance' guidance in Section 7.2.2 for more detailed information).

5. DASA assurance activities related to the final application. These activities typically include review / evaluation of compliance artefacts submitted as part of the final application, approval of the major change or issue of the MTC, and update of the TCDS as required.

Holder Obligations

7.2.3.59 Given the DASR only allows the MTC holder to be the applicant for a major change to an existing MTC, there are no separate DASR holder obligations for major changes, and the MTC holder must undertake the obligations laid out in DASR 21.A.44 for the MTC, including and all major changes thereto.

7.2.3.60 Obligations for holders of an MSTC are laid out in DASR 21.A.118A . However, given DASA's policy of issuing all MSTCs to the government MTC holder organisation, and the fact that the DASR 21.A.118A obligations are essentially the same as those ofDASR 21.A.44, the MTC holder simply needs to continue to undertake all obligation laid out in DASR 21.A.44 for the MTC and all MSTCs they hold.

7.2.3.61 Refer to Section 7.4.1 for detailed guidance on the DASR 21.A.44 MTC holder obligations.

7.2.4 – Repair Designs (DASR 21 Subpart M)

Overview

7.2.4.1 Data that is used to accomplish repairs needs to be approved by a suitable and competent organisation. Data may be approved through a repair design approval process where DASA is the certifying authority, or through a process where recognition is used. These two broad pathways are covered by DASR M.A.304, which provides the requirements for data that is used to carry out repairs and modifications:

1. DASR M.A.304(a) and (b) allow data to be used that has been approved by DASA, and by a Design Organisation approved under DASR 21, respectively. In both cases DASA is the certifying authority and the requirements of DASR 21 Subpart M (Repairs) are applicable.

Superseded

2. DASR M.A.304(d) allows for the consumption of data that has been approved within the framework of Authorities recognised by DASA. In this instance the repair approval requirements of DASR 21 Subpart M (Repairs) are not applicable. Direct consumption of data is subject to a suitability assessment (see AMC and GM to DASR M.A.304(d)) in accordance with the scope, conditions and caveats of the relevant recognition certificate.

7.2.4.2 This section is relevant to data for repairs conforming to DASR M.A.304(a) and (b) and provides:

1. an overview of the repair approval process in accordance with DASR 21 Subpart M (Repairs)
2. guidance for design organisations and MTC holders regarding DASA's expectations for repair design development and approval
3. more detailed guidance in the form of a number of common repair scenarios.

7.2.4.3 Guidance regarding use of repair data in accordance with DASR M.A.304, including consumption of data using recognition provisions, is provided in the Section 8.2.

7.2.4.4 Note that additional general information about Repair Design authorisations is contained in Section 5.3 Annex R.

DASR 21 Repair Design Privileges

7.2.4.5 DASR 21 Subpart J privileges related to repair designs include the privilege to:

1. classify repairs (DASR 21.A.263(c)(1)),
2. approve minor repairs (DASR 21.A.263(c)(2)), and
3. approve certain[18] major repairs (DASR 21.A.263(c)(5)).

7.2.4.6 These privileges require the design organisation to have procedures agreed to by DASA, usually by issue of a Military Design Organisation Approval (MDOA). These procedures would normally be documented in a Design Organisation Handbook[19].

Repair Process

7.2.4.7 The overall process for development, approval and embodiment of repairs where DASA is the certifying authority is outlined in Table 7.3. Further guidance, in the form of specific scenarios are outlined in Annex D to Section 7.2 Repair Design Approval Scenarios. Note that the scenarios in Annex D are defined as an aid for explanation, rather than as a series of strict processes.

Stage	Description	Responsibility
Identify and Assess Damage	Damage identified for which there is no existing pre-approved solution.	CAMO
Develop Repair Design	Repair design data is developed.	Design organisation

Superseded

Repair Classification	Repair classified in accordance with the requirements of DASR 21.A.435a.	DASA or an appropriately approved design organisation under a procedure agreed with DASA
Repair Certification	Establish Certification Basis (CB). Demonstrate compliance with required CB elements, Compliance Verification, Declare Compliance. Submit application for approval if required.	Applicant that meets the eligibility criteria[20]
Repair Approval	Approval of Repair. The assignment of obligations to the repair approval holder (dependent on classification).	DASA or an appropriately approved design organisation under a procedure agreed with DASA.
Repair Configuration Management	Manage the accomplishment of repairs and maintain a record of aircraft configuration, which includes repairs.	CAMO
Production of Repair Parts	Produce repair parts.	Appropriately approved production organisation, under DASR 21 Subpart G or Subpart F, or an appropriately approved maintenance organisation under DASR 145
Repair Embodiment	Embody repair.	Appropriately approved maintenance organisation under DASR 145 or appropriately approved production organisation under DASR 21 Subpart G
Ongoing Holder Obligations		Repair design approval holder

Table 3: Repair Process where DASA is the Certifying Authority

Repair Design Classification

7.2.4.8 As per DASR 21.A.435a – Classification and approval of Repairs – a repair must be classified as either minor or major in accordance with the criteria laid out in DASR 21.A.435a. Classification of repairs guides DASA to apply appropriate assurance oversight and allows for the obligations of the holder of a repair design approval to be identified. Classification does not affect the certification basis, demonstration of compliance, independent checking or declaration of compliance and, as such, whether a repair is classified as major or minor does not affect the engineering rigour applied to the repair. Repair classification may be made by either DASA or by an appropriately privileged design organisation under a procedure agreed to with DASA[21].

7.2.4.9 DASR GM 21.A.435a states that a new repair – a repair that has not previously been approved for the application being considered on the individual aircraft in question – is classified as major if it has an appreciable effect on structural performance, weight, balance, systems, operational characteristics or other characteristics affecting airworthiness. This is elaborated on to highlight that repairs needing extensive static, fatigue or damage tolerance justification or testing, or requiring

Superseded

methods, techniques or practices that are unusual, are to be classified as major. This GM identifies repairs that require permanent changes to Airworthiness Limitations (AwLs) to be classified as major.

7.2.4.10 The paragraphs below give examples of what may need to be considered in developing a repair classification procedure. Each organisation must develop its own procedure which meets the requirements of DASR 21.A.435a, 21.A.239, 21.A.263 and 21.A.243 and is tailored to the organisations scope of work. However, the considerations below, based on the guidance provided in the GM 21.A.435a and GM 21.A.91, are provided to further clarify DASA's expectations of such a procedure.

7.2.4.11 For clarity, classification may consider the following three characteristics of the repair design:

1. Severity – the effect of the repair on airworthiness.
2. Complexity – the complexity of the design and the certification requirements.
3. Novelty – whether the design has been developed in accordance with established methods and practices for the repair application in question.

7.2.4.12 Generally repairs may be classified as major except when all of the following criteria are met:

1. Severity is low. Examples of the types of details that would be expected from repairs of low severity include:
    i. Structural performance, in terms of static strength, fatigue performance, damage tolerance performance, flutter and stiffness characteristics, is unaffected by the repair.
    ii. Load paths and load sharing in the vicinity of the repair are unaffected by the repair.
    iii. Weight and balance change is not greater than that allowed in the weight and balance manual or Original Equipment Manufacturer (OEM) repair guidance for weight and balance. This includes changes in centre of gravity and load distribution. Weight and balance of control surfaces can be particularly affected by even small changes.
    iv. Changes do not affect the operation or redundancy of a system, or an adjacent system.
    v. Changes do not affect operational characteristics.
    vi. Other characteristics related to airworthiness, or to environmental characteristics of the platform (such as noise, fuel venting and exhaust characteristics), are not affected including, but not limited to, fire protection, propulsion systems integrity and crashworthiness.
2. The repair design and the certification requirements are not complex. Examples of the types of details that would be expected from repairs of low complexity include:
    i. Repair requires no or minimal re-assessment or re-evaluation of original certification substantiation data
    ii. Repair design elements are straightforward.

Superseded

iii. Original type certification data is available, or if not available appropriate data can be established without complex engineering, and no assumptions are required in the definition of the certification requirements.

3. There are no new or novel features to the repair. Examples of the types of details that would be expected from a repair that does not have new or novel features include:

   i. Techniques, methods and practices are those employed in the regular management of the platform and type of defect.

   ii. Techniques, methods and practices are those accounted for in the platform Type Design.

7.2.4.13 It is recognised that in some cases not all data will be available at the time of initial repair classification, and so, judgement must be exercised. In the case where later data indicates that the initial classification is no longer valid, a repair may be reclassified. In this case, consultation with DASA and, where necessary, reconsideration of the Certification Programme (CP), is expected.

7.2.4.14 These classification considerations are outlined in Figure 2.

Superseded

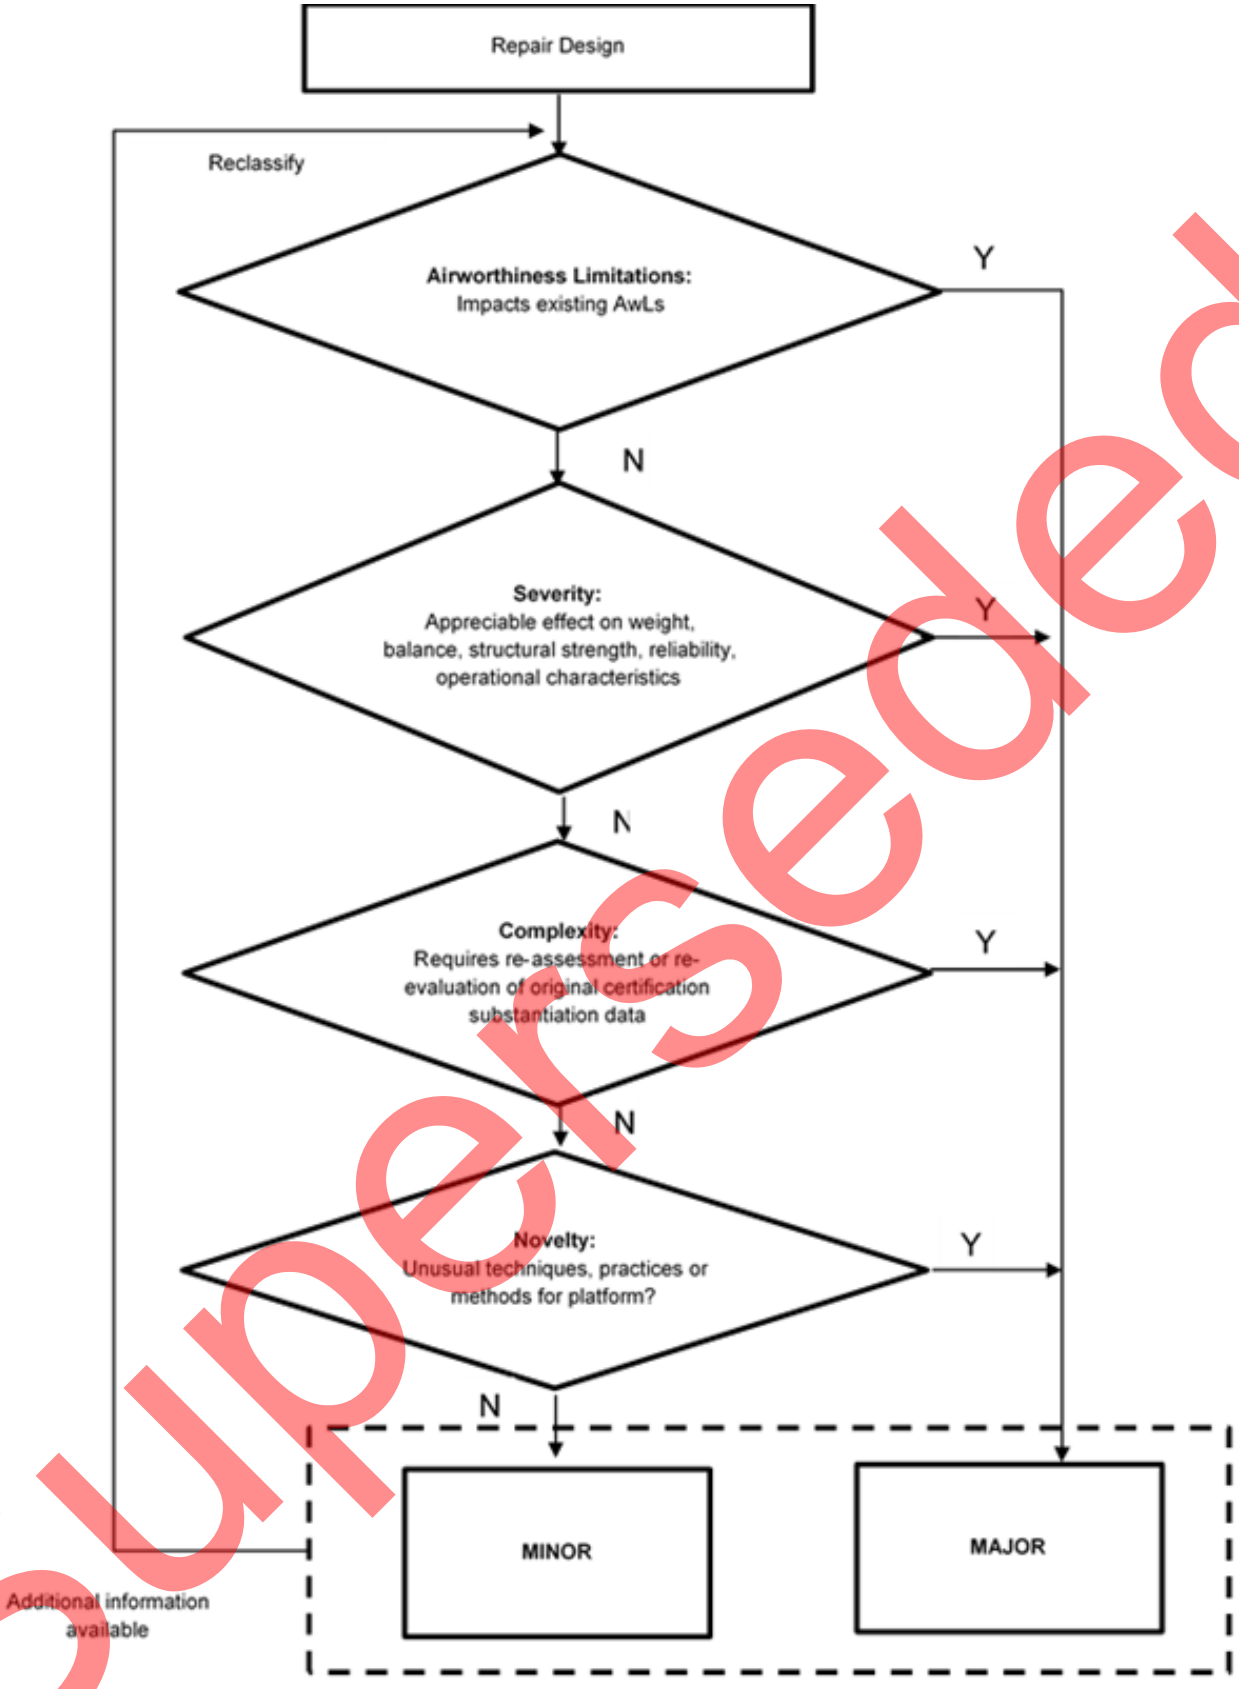

Figure 2 : Repair Classification Principles

Eligibility

7.2.4.15 Applicant eligibility requirements exist to control how designs are developed and presented to DASA for review and inspection. These ensure that DASA has visibility of the applicant's organisation, understands and has confidence in the generation of compliance documents, artefacts

Superseded

and how the declaration of compliance is made. This provides DASA with confidence in the applicant's ability to fulfil the obligations of the repair approval holder where applicable. As such applicants for repairs must meet eligibility criteria as defined in DASR 21.A.432A.

7.2.4.16 To be eligible as an applicant for a major repair design approval, the applicant is to either hold an approval under DASR 21 Subpart J, or may seek DASA agreement for the use of procedures setting out the specific design practices, resources and sequence of activities necessary to demonstrate capability, or may be a government organisation which has agreements in place with a design organisation with access to the type design data.

7.2.4.17 Any organisation is eligible to apply for approval of a minor repair design. It is recommended that an organisation considering applying for DASA approval of a minor repair design seeks approval through an organisation holding a minor repair approval privilege under DASR 21 Subpart J, as DASA priorities will likely lead to delays in the approval of minor repairs.

Approval

7.2.4.18 Repair design approvals may be issued by DASA or an appropriately privileged design organisation, in accordance with DASR 21.A.435b.

7.2.4.19 In the case where DASA is issuing a major repair design approval, DASA receipt of a DASR Form 31B should signify the completion of a period of engagement between the applicant and DASA during which the certification activities agreed within the CP have been undertaken[22], including satisfactory DASA inspection of compliance documents. Upon receipt of the application, DASA assures itself that agreed CP activities have been completed, and if assured, DASA issues to the designated major repair design approval holder a signed DASR Form 31B for major repairs under DASR 21 Subpart M.

7.2.4.20 Design organisations approved under DASR 21 Subpart J can approve designs for minor repairs and certain major repairs, subject to the scope and privileges recorded in their terms of approval, and subject to their internal procedures agreed to by DASA. Further guidance based on repair classification is as follows:

1. **Minor Repairs.** Most MDOA holders approved by DASA will have the privilege to approve minor repairs that are within the scope of their terms of approval (privilege DASR 21.A.263(c)(2)).

2. **Major Repairs.** Some MDOA holders approved by DASA may also have the privilege to approve certain major repair designs that are within the scope of their terms of approval (privilege DASR AMC1 21.A.263(c)(5). The definition of 'certain major repairs' is provided in DASR AMC1 21.A.263(c)(5), (8) and (9), and depends upon whether or not the MDOA holder holds the relevant MTC, MSTC or Australian Military Technical Standard Order Authorisation (AUSMTSOA). In all cases, the ability to exercise the major repair approval privilege is subject to additional criteria and limits based on the characteristics of each individual repair design. For MDOA holders who do not hold the MTC, MSTC or AUSMTSOA, each new major repair design should be assessed against the 'List associated with the privilege' and the relevant 'Justification document' to determine whether the privilege can be exercised. Refer to AMC1 and AMC2 to DASR 21.A.263(c)(5), (8) and (9) for further information on award of, and exercising, the privilege to approve certain major changes.

Holder Obligations

Superseded

7.2.4.20 Following approval of the repair design, the obligations for the repair are assigned to the holder of the repair design approval in accordance with DASR 21.A.451. For both minor and major repairs these obligations include:

1. DASR 21.A.4 – Coordination between Design and Production.
2. DASR 21.A.447 – Record Keeping.
3. DASR 21.A.449 – Instructions for Continuing Airworthiness.
4. DASR 21.A.451(a)2 – Specify the markings in accordance within accordance with DASR 21.A.804(a).

7.2.4.21 For major repairs additional obligations of the holder of the repair design approval include:

1. DASR 21.A.3A – Failures, Malfunctions and Defects.
2. DASR 21.A.3B – Airworthiness Directives.
3. DASR 21.A.439 – Production of Repair Parts.
4. DASR 21.A.441 – Repair Embodiment.
5. DASR 21.A.443 – Limitations.
6. DASR 21.A.433(b) – Substantiation Data.

Superseded

7.2.5 – Instructions for Continuing Airworthiness (ICA)

Basic Principles of ICA

7.2.5.1 **ICA and maintenance data.** ICA is only a subset of all maintenance data that must be complied with in the conduct of maintenance[23]. Other sources of maintenance data include Airworthiness Directives (or other applicable requirements or operational directives issued by DASA), modification and repair implementation instructions and applicable maintenance standard practices. ICA should not be used as a collective term for all maintenance data as other sources of maintenance data are derived from different sources and subject to different regulation. This section deals only with ICA, not all forms of maintenance data.

7.2.5.2 **Airworthiness requirement.** The applicant for an MTC must develop ICA as required by the Type Certification Basis (TCB). Civil primary certification codes used for military products contain clauses (e.g. FAR/CS 23/25/27/29.1529 (aircraft), FAR 33.4 and CS-E 25 (engines), and FAR 35.4 and CS-P 40 (propellers)) that prescribe the content and format of ICA. Products with a military-derived TCB (e.g. from MIL-HDBK-516) have equivalent requirements for the development of maintenance instructions that achieve a similar intent to the civil airworthiness requirements above.

7.2.5.3 **Content and scope of ICA.** To meet the ICA requirements of a civil airworthiness code (or equivalent requirements of a military-derived TCB), the applicant for an MTC must provide:

1. Scheduling information for all recommended maintenance tasks. This information is normally contained in a Maintenance Review Board Report (MRBR) (or equivalent document).

2. Maintenance instructions including those required for servicing, troubleshooting, the methods of removing and replacing items, system testing, ground running, symmetry checks, weighing, towing, jacking, storage limitations etc. This will typically be provided in the form of an Aircraft Maintenance Manual(s), Structural Repair Manual, Fault Isolation Manual, Illustrated Parts Catalogue etc. This information can be amended by the MTC holder (broad scope to amend the master copy) or maintenance organisations approved under DASR 145 (very narrow scope to modify).

3. Mandatory maintenance requirements in a segregated and clearly distinguishable section of the ICA, typically called the Airworthiness Limitation Section (ALS). The ALS contains the mandatory maintenance tasks and intervals, identified in the type certification process. Specific terminology and requirements for the ALS content will vary depending upon the PCC, however, the ALS will generally include mandatory requirements such as:

   i. Airworthiness Limitations (AwLs). AwLs encompass mandatory retirement / replacement intervals and mandatory inspection requirements (including inspection interval(s) and the inspection method). The term AwLs is most often associated with structural life limits and structural inspections that result from FAR/CS 2x.571 or the equivalent fatigue/damage tolerance requirements in military certification standards. However, the term AwL may also be used for other aircraft systems, such as mandatory replacement times for Electrical Wiring and Interconnect System (EWIS) components. As noted within AMC 21.A.41, the definition of an AwL 'interval' includes the interval metric (e.g. flight hours, landings, Equivalent Flight Hours (EFH), Fatigue Index (FI) / Fatigue Life Expended Index (FLEI), engine cycles, etc), and any algorithm, equation, factor(s) or other engineering data which must be used to calculate life accrual against the interval.

   ii. Critical Design Configuration Control Limitations (CDCCLs). CDCCLs identify the critical design features such as proper wire separation, proper installation of a panel gasket, minimum bonding jumper resistance levels, etc., that must be maintained in exactly the same manner throughout the life of the aircraft in order to comply with the type certificate and maintain airworthiness. The purpose of CDCCLs is to provide instructions to ensure these critical features are present throughout the life of the aircraft and are inspected and verified when alterations, repairs, or maintenance actions occur in the area. Design features that are CDCCLs are defined and controlled by FAA Special Federal Aviation Regulation (SFAR) 88 and preserves critical features of the aircraft needed for the Flammability Reduction Means to perform their intended function and prevent the occurrence of an unsafe condition.

   iii. Certification Maintenance Requirements (CMRs)[24]. CMRs are required inspections or maintenance tasks, and associated intervals, developed to achieve compliance with safety analysis requirements (e.g. FAR/CS 25.1309/29.1309, other discrete safety analyses requirements such as FAR/CS 25.671, 25.783, 25.901, and 25.933, and FAR/CS 29 equivalents). A CMR is intended to detect safety-significant latent failures (failures not known to the flight or ground crew) that would, in combination with one or more other

Superseded

specific failures or events, result in a hazardous or catastrophic failure condition. A CMR can also be used to establish a required task to detect an impending wear-out of an item whose failure is associated with a hazardous or catastrophic failure condition.

7.2.5.4 **ICA and the MTC.** Even though a complete set of ICA is required to obtain an MTC, only the ALS of the ICA (or equivalent terminology including CDCCLs and CMRs) forms part of the type design[25] however, they do form part of the Type Certificate. Stand-alone amendments to ICA, other than the ALS, are allowed to be changed by the MTC holder using a procedure agreed with DASA. Note: when completing a stand-alone change to ICA other than the ALS, the MTC holder is not exercising a privilege, but is instead fulfilling their obligation to keep the ICA current[26]. Changes to the ALS of the ICA must be processed as a change to the MTC, and should be classified as a major change[27].

7.2.5.5 **Identification of ICA.** The complete set of ICA for any product should be identified on the TCDS. Other information or instructions required for continuing airworthiness or safe operation of the aircraft, e.g. the approved Aircraft Maintenance Programme (AMP) or a Minimum Equipment List (MEL), is not ICA and is not subject to regulation applicable to ICA.

7.2.5.6 **ICA supplements.** Some major changes to an MTC, MSTCs, minor changes or minor/major repair designs may require variations to the product's ICA[28]. Variations to ICA arising from these design changes or repairs stand-alone from the product's master ICA and are published as an ICA supplement[29]. This gives the aircraft operating organisation the flexibility in managing the ICA applicable to their aircraft, depending on which approved changes and repairs they have chosen to embody. The approval of ICA supplements (including any changed or additional mandatory maintenance requirements) are encapsulated in the approval of the design change or repair. ICA supplements should be identified on the Supplemental Type Certificate Data Sheet, or on the minor change or repair design approval.

7.2.5.7 **ICA and the AMP.** The approved AMP in and of itself is not ICA for the simple reason the ICA requirements of the TCB do not mandate an AMP to be developed by the applicant for an MTC. The recommended maintenance tasks and intervals in the MRBR and the mandatory maintenance requirements identified in the ALS, combined with other requirements unique to each operator's role and usage (including data from a reliability programme) forms the basis for approval of each operator's AMP.

7.2.5.8 The maintenance instructions provided by the MTC holder (or ICA supplements provided by other design approval holders) will provide detail on how to carry out the tasks and inspections in the AMP and should only be amended by the MTC holder (or other relevant design/repair approval holder for ICA supplements) – see paragraph 7.2.5.4 above. Mandatory maintenance requirements must be clearly identified as mandatory in the AMP and cannot be extended without a corresponding approval of a major change to the MTC, or issue of an MSTC. Other ICA must be changed by the MTC holder using DASA agreed procedures. Changes to other recommended task and inspection intervals in the AMP can be approved by a CAMO using a procedure agreed with DASA, without requiring approval of a change to the MTC[30].

Responsibilities for ICA

7.2.5.9 **MTC holders**. The MTC holder is Defence's custodian of the product's ICA regardless of its original author. The MTC holder is responsible for the ICA's content, amendment and distribution to all organisations that operate the aircraft. The MTC holder can amend the ICA (in accordance with

Superseded

approval processes) and must distribute amendments to those organisations affected. If a change to a mandatory maintenance requirement is required, the change must be approved by DASA before distribution of the amendment. The MTC holder's processes for discharging its responsibilities for ICA (even if exercised through external organisations) must be included in the MTC holder's Type Continued Airworthiness Exposition (TCAE). Regardless of a product's TCB, the MTC holder should be able to identify all ICA and have that documented in the TCDS.

7.2.5.10 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their ICA supplements as the MTC holder has for the product's master ICA.

7.2.5.11 **Aircraft operating organisations.** Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to ICA (and ICA supplements) to the extent necessary for the scope of maintenance services being provided.

7.2.5.12 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable ICA and relevant ICA supplements. Maintenance organisations may locally modify ICA or ICA supplements using an approved procedure specified in their Maintenance Organisation Exposition (MOE) only for the purposes of efficiency, achieving the intent of the ICA when the instructions are deficient, or for the use of alternative tools/equipment[31]. A maintenance organisation must notify the MTC holder (or relevant design approval holder in the case of ICA supplements) when it has locally modified ICA, so consideration can be given to amending the master copy for wider distribution. A maintenance organisation modifying ICA for the purposes stated above does not constitute approving an amendment to the ICA (i.e. the source document) held by the MTC holder (or ICA supplement held by another design approval holder). Only the MTC holder or holder of the ICA supplement can approve amendments to ICA, noting the need to also seek approval of a major change to the type certificate if the amendment alters any mandatory maintenance requirements.

Non-Destructive Testing (NDT) ICA

7.2.5.13 NDT ICA are applied to ensure the airworthiness of aircraft through the inspection of aircraft structure and components. NDT ICA is often used as part of damage tolerance inspection regimes to ensure structural integrity. Consequently, it is critical to ensure that NDT ICA is developed by competent staff and provides sufficient information to enable NDT staff to perform inspections effectively.

7.2.5.14 NDT ICA provided to a DASR 145 Maintenance Organisation should include the following minimum information:

1. the inspection procedure to be used
2. the inspection area
3. the material type of the inspection area
4. the type of discontinuities to be detected.

7.2.5.15 Those organisations responsible for developing NDT ICA (DASR 21J Design Organisations, MTC holder) should consider using NDT Level 3 staff (as defined in EN4179) to verify that inspections are achievable, repeatable and meet the expected detection requirements of the design or repair. This is especially important where NDT ICA is used to support an AwL.

Superseded

7.2.5.16 The procedure for approving or modifying NDT ICA should be documented in the relevant organisation exposition. DASA recommends that personnel certified to NDT Level 3 in the relevant method be employed to approve and/or modify existing NDT ICA for application in specific circumstances. This accords with the requirements of European Standard EN4179.

Master Minimum Equipment List (MMEL)

7.2.5.17 An MMEL is a document created specifically to permit the continued operation of an aircraft type with unserviceable equipment. It is a list of items of equipment that may be temporarily unserviceable / inoperative under certain conditions and limitations, while still maintaining the level of safety intended in the design standards. The MMEL cannot, in itself, be regarded as providing operational permission. It, however, can be the basis for the development of an individual Operator's Minimum Equipment List (MEL).

7.2.5.18 An MMEL forms part of the MTC. Approval of new MMEL or an MMEL amendment should be undertaken in accordance with the relevant DASR 21 Subpart[32]. Further guidance on MMEL development and approval in contained in Chapter 8.2.2, including information on:

1. typical characteristics and contents of an MMEL
2. options for developing an MMEL
3. suitable certification specifications for an MMEL
4. classification (major/minor) for changes to an MMEL
5. the DASA MMEL approval process.

7.2.5.19 Note that DASA is currently evaluating EMAR 21 version 2.0 changes that introduce the Operational Suitability Data (OSD) concept and requirements. MMELs are considered a category of OSD, and therefore, this section will be updated in the future once the relevant DASR 21 updates have been incorporated.

7.2.6 – Manuals

Basic Principles for Manuals

7.2.6.1 T**ypes of Manuals.** As per DASR 21.A.57, the holder of a type-certificate shall produce, maintain and update master copies of all manuals required by the applicable TCB.

7.2.6.2 Manuals (for the purpose of DASR 21.A.57) will fall into one of two broad categories:

1. **Aircraft Flight Manual (AFM).** The AFM is an authoritative source of information necessary for the safe operation of an aircraft. It contains the aircraft's operating limitations, operating procedures, performance information and other information and instructions necessary to operate the aircraft safely. Note that this information may be contained in several documents that contain limitations, information and instructions to ensure safe aircraft operation. Examples of other documents/ publications (in addition to the AFM) may include a Flight Crew Operating Manual, Mission Crew Operating Manuals and Pilot Handling Notes.

Superseded

2. **Manuals Containing ICA.** Certification codes require that the ICA must be published in the form of a manual or manuals[33]. The relevant certification code requirements will dictate the specific ICA content that must be published. Due to the broad and varied type of information that must be published, ICA for a particular aircraft type will usually be distributed through a variety of manuals, such as Aircraft / Engine / Propeller Maintenance Manual, Structural Repair Manual, Engine / Propeller Installation Manual. As noted above at paragraph 7.2.5.5, the MTC holder should be able to identify the publications and manuals that meet the intent of ICA requirements.

7.2.6.3 **AFM Guidance.** DASA AC 008/2020 contains detailed information on AFM content and approval, amending AFM content and use of AFM supplements. Further information specific to changes to type certificates which affect AFMs include:

1. DASR GM 21.A.91 which contains guidance for the classification of changes to AFMs
2. DASR AMC3 21.A.263(c)(2) which contains information on approval of minor changes to the type certificate which affect the AFM.

7.2.6.4 **Approval of Manuals.** Even though particular manuals are required by the TCB and therefore required to obtain an MTC, only certain contents of manuals will form part of the enduring MTC and / or require DASA approval. Contents of manuals that requires DASA approval includes:

1. The ALS of the ICA[34] (i.e. as published within a maintenance manual). Refer Section 7.2.5 for further guidance.
2. Mandatory AFM content (Operating Limitations, Operating Procedures and Performance Information). Refer DASA AC 008/2020 for further guidance.

7.2.6.5 Consequently, amendments to other manual contents is not a change to the MTC and can be undertaken by the MTC holder using a procedure agreed with DASA. Furthermore, as noted by AMC1 21.A.57, the process to update a manual may be separate from the process to approve or authorise the content of the manual[35].

7.2.6.5 **Manuals in the Context of Defence Aviation Orders, Instructions and Procedures (OIP) Management.** Manuals (for the purpose DASR 21.A.57) are part of the Defence Aviation OIP for the platform type. Lifecycle management of Defence Aviation OIP is discussed further in Section 6.7. A key message of Section 6.7 is that in addition to accuracy and completeness of OIP (a well-established principle in DASR 21), the usability / readability of OIP can cause or contribute to aviation safety hazards. Therefore, aviation safety hazards related to Defence Aviation OIP should be managed through an organisation's SMS. Note that this principle is consistent with DASR GM1 21.A.239(a) paragraph 3.1.5 which states that design organisations should "establish a system to collect in-service experience to be used for the improvement of the [maintenance and operating] instructions".

Responsibilities for Manuals

7.2.6.6 **MTC Holder.** In order to meet their obligation under DASR 21.A.57, the MTC holder should establish a system to produce, maintain and update manuals. As per DASR AMC 21.A.57, this system should ensure:

1. manuals are complete, current, and uniquely identified;
2. manuals contain their authority for use, document name, date of issue, and document/amendment status details;

Superseded

3. manuals are provided in a medium compatible with user requirements;

4. new issues, re-issues and/or amendments are approved and/or endorsed by appropriate appointments prior to their release, noting that the process to update a manual may be separate from the process to approve or authorise the content of the manual, eg approve AwL in ICA;

5. manual management records are accurately maintained, controlled, traceable and are accessible; and

6. manuals can be reproduced to any previous amendment status.

7.2.6.7 **Other design/repair approval holders.** Holders of an MSTC, minor change approval or repair design approval have the same responsibilities for their manuals or manual supplements as the MTC holder has for the product's master set of manuals.

7.2.6.8 **Aircraft operating organisations.** The operating organisations must manage and distribute the AFM and all other relevant manuals as part of their OIP Management System[36]. Continuing Airworthiness Management Organisations (CAMOs) are required to ensure all their maintenance service providers have access to all relevant manuals to the extent necessary for the scope of maintenance services being provided. The operating organisation should manage any aviation OIP related hazards through their SMS, and coordinate with the MTC holder, or applicable design organisation, as required to effect any necessary updates or improvements to manuals.

7.2.6.9 **Maintenance organisations.** Maintenance organisations conducting aircraft, engine, propeller or component maintenance are required to comply with all applicable manuals. Maintenance organisations shall establish procedures to ensure that if found, any inaccurate, incomplete or ambiguous procedure, practice, information or maintenance instruction contained in the maintenance data used by maintenance personnel is recorded and notified to the author of the maintenance data[37].

7.3 Production and Military Certificates of Airworthiness

7.3.1 Production Assurance in the Defence Aviation Safety Program

Aim

7.3.1.1 This chapter details how the production of aircraft components is assured in the Defence Aviation Safety Program (DASP). This includes what release documentation is acceptable under DASRs, and the means through which that documentation is obtained. This chapter only covers aircraft components and does not include whole aircraft. For whole aircraft see MCoA - Chapter 5.3 Annex O and MPO – Chapter 7.6.

Introduction

7.3.1.2 Production of Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured.

Superseded

Acceptable release documentation

7.3.1.3 The purpose of release documentation is to provide evidence that the manufactured component conforms to approved design data. Aircraft components to be installed on Defence registered aircraft must be accompanied by one of the following release documents:

a. DASR Form 1—Authorised Release Certificate.

b. A native or alternate component Certificate of Release to Service (CRS) issued within a recognised airworthiness framework (refer to Chapter 6.5 —Recognition of other Aviation Authorities for identification of a native and alternate component CRS).

c. For standard parts or items designated as specific equipment under DASR 21.A.303, a Certificate of Conformity from the item's manufacturer (refer AMC to DASR 145.A.42(a)(4)).

d. For components fabricated under DASR 145.A.42(c), certificates of conformity produced by the fabricating maintenance organisation that are acceptable to DASA.

7.3.1.4 Release documentation under (a), (b) or (c) above enables that component to cross organisational (and possibly national) boundaries between its manufacture and installation. Manufactured components that do not need to cross organisational boundaries can be installed with locally produced certificates of conformity that contain all of the technical information found on a DASR Form 1 per item (d) above.

DASA production assurance

7.3.1.5 DASA assures production of all Defence aircraft components using one of three mechanisms depending on the release documents required by continuing airworthiness regulations. This is depicted below in Figure 3.

Assurance through Recognition Frameworks

7.3.1.6 The majority of aircraft and aircraft component manufacture for Defence occurs outside Australia and is assured through DASA's recognition framework. To be installed on a Defence registered aircraft, these components must be accompanied by a recognised native (Form 1 equivalent) or alternate release certificate. Each DASA Recognition Certificate provides details on the unique conditions and caveats to be applied to validate the native or alternate release certificates. Production of components assured through recognition do not require a DASR Form 1 as it provides no additional safety assurance above what is inherent under the recognition framework.

Assurance through DASR 21 – production by Military Production Organisation Approval (MPOA) or letter of agreement holder

7.3.1.7 Components manufactured outside of a recognised airworthiness framework (other than standard parts, specific equipment or components fabricated under DASR 145.A.42(c)) require a DASR Form 1 for installation. To issue a DASR Form 1 an organisation must hold a Military Production Organisation Approval (MPOA) under DASR 21 Subpart G, or a letter of agreement to manufacture under DASR 21 Subpart F . In this instance, the award and oversight of MPOA is DASA's assurance mechanism for the production of such components.

7.3.1.8 The only organisations that DASA will consider for award of MPOA are those that do not hold a recognised approval that enables release of the manufactured components under a native or alternate artefact (see Chapter 6.5 —Recognition of other Aviation Authorities). That is, the

Superseded

requirements of DASR 21 Subparts G will be imposed on an organisation for the sole purpose of issuing a DASR Form 1 for the manufactured components.

Assurance through DASR 145 – fabrication by maintenance organisations

7.3.1.9 DASR Form 1 must not be used for components fabricated by maintenance organisations under their DASR 145 approval. A locally produced certificate of conformity must be used instead. DASA's assurance of this production is via the issue and oversight of the organisation's DASR 145 approval. A DASR 145 MO will only have this activity included in the scope of their DASR 145 approval if they can sufficiently demonstrate their capability to perform such fabrication. Note that unless otherwise approved by DASA, only the DASR 145 MO who fabricated the component can install this component.

Figure 3: Production Assurance and Release Documentation under DASP

Manufacture and release of test articles

Superseded

7.3.1.10 If a test article is manufactured to gather certification evidence, the responsibility to control the manufacture of that article and ensure it accurately reflects the proposed design data rests entirely with the organisation seeking certification of the design. For test article manufacture required to achieve certification of a major change, the Certification Programme should describe the production control processes that will be used by the applicant in producing the test articles. If DASR Form 1 is used to release a test article for trial installation in an aircraft, Block 12 of the DASR Form 1 must clearly state that the article is in conformity with non-approved design data. The manufacture of test articles for certification does not require MPOA under DASR 21 Subparts G or a letter of agreement under DASR 21 Subpart F. These principles also apply for minor changes being approved under MDOA privilege.

Manufacture of modification kits

7.3.1.11 Maintenance organisations approved under DASR 145 may fabricate modification kits and issue certificates of conformity provided (a) the scope of their DASR 145 approval allows it, and (b) the completed modification kit will be installed by the same maintenance organisation (and under the same DASR 145 approval) issuing the certificate of conformity. Modification kits meeting both criteria above must not be released using DASR Form 1, but must still be manufactured to the approved design data and have locally produced certificates of conformity attesting to that fact. Fabrication of modification kits for onward supply cannot be performed under a DASR 145 approval and constitutes series production that must be assured by either recognition or through DASR 21. Modification kits manufactured external to the installing maintenance organisation must be accompanied by a DASR Form 1, or release documentation acceptable to DASA through recognition.

7.3.1.16 DASR 21 Subpart G – Military Production Organisation Approval

7.3.2 Military Certificate of Airworthiness (MCoA)

Introduction

7.3.2.1 This section supplements the DASP policy and provides guidance in support of DASR 21, Subpart H relating to MCoAs, their purpose, and their issue. The guidance included in this section discusses the MCoA concept and application from both an Australian Defence context, and where appropriate for the purposes of description, a civil aviation context.

7.3.2.2 Restricted MCoAs are also discussed where appropriate; however, such MCoAs are of limited utility in the Australian Defence context, and unlikely to be issued.

Purpose

7.3.2.3 A MCoA is an aircraft operating authorisation issued against an airframe tail that has the purpose to validate that the airframe conforms to the type design as specified on the Military Type

Superseded

Certificate (MTC). It serves as the final assurance artefact that the airframe is in a state of airworthiness per the inherent level of safety afforded by the type design and the underlying MTC basis. It is enabled by an organisation or operator, who has registered the airframe on the Australian Defence register, and has ensured conformity through meeting various requirements.

7.3.2.4 A restricted MCoA will follow the same rules albeit that the airframe shall conform to a restricted MTC and to specific airworthiness requirements ensuring adequate safety.

Application

7.3.2.5 MCoAs in the Australian Defence context can only be issued by the DASA or a Delegate of the Safety Authority (DoSA). The release document is via a DASR Form 25 Military Certificate Of Airworthiness and applies only to aircraft that are registered on the Defence register in Australia.

7.3.2.6 An application for a MCoA shall be made by an eligible organisation via DASR Form 25a - Application for Certificate Of Airworthiness. In the Australian Defence context, the MAO and/or their CAMO are eligible to be applicants for a MCoA as holders of a MAOC. Aircraft that are Non-Defence Registered (NDR) are not subject to Airworthiness DASRs, and are subject to a separate airworthiness requirements, typically under the applicable airworthiness Civil Aviation Safety Regulations. See further DASP Vol 3 guidance on NDR at Chapter 6.1.3.

7.3.2.7 A MCoA application shall be made in a form and manner established by the Authority (DASA in Australia) of the State of Registry[38], per DASR.21.A.174(a). When considering a MCoA application, the Authority will consider all documentation in support of the state of the airframe at application. This has particular significance for used aircraft, where records of usage, maintenance, modifications and repairs may not be to the standard normally required by Defence.

7.3.2.8 The MCoA application presents documentation that the aircraft conforms to the type design approved under the relevant MTC. The required documentation, artefacts, reports and historical evidence (if applicable) to support the application shall be in accordance with DASR.21.A.174(b). Any deviations from the certified type design must be approved by an appropriately authorised design organisation.

7.3.2.9 For used aircraft, DASA will require a Military Airworthiness Review Certificate (MARC) conducted in accordance with DASR Part M regulations before issuing an MCoA. The MARC review is a physical survey of the aircraft and supports issue of the MCoA to satisfy DASA that the submitted documentation is reflective of the physical aircraft. The MARC process is further discussed as part of paragraphs 7.3.2.15 and 7.3.2.16 of this section.

Issue of a MCoA

7.3.2.10 A MCoA can only be approved and issued if all modifications, repairs and/or production deviations implemented on the airframe are approved under DASR 21, or under a recognised national civil or military airworthiness framework.

7.3.2.11 For new civil or commercial derivative aircraft (CDA) delivered to Defence, the acquisition project should seek a civil export CoA from the Civil Aviation Authority (CAA), via the prime aircraft OEM, where a civil Type Certificate (TC) is in place. This export CoA needs to be obtained prior to transfer to the Defence register, and forms the foundation for the issue of an Australian MCoA. Failure to obtain an export CoA for a civil or CDA may limit DASA's ability to issue an evidence based MCoA.

7.3.2.12 For instances where a civil Type Certificate (TC) is not in force or Defence is leasing an aircraft that has been in civilian use, the requirement for a CAA CoA can be demonstrated if a CAA

Superseded

authorised delegate provides a document that attests the aircraft would be eligible for issue of a Standard or Export CoA, if the aircraft was to be registered by a Civil Aviation Authority. Defence will accept only a Standard CoA under DASR 21.A.172, DASR 21.A.173 and DASR 21.A.174. DASA-DIA staff should be consulted for specific advice.

Validity and Amendment

7.3.2.13 The MCoA Holder (typically the MAO) is responsible for the continuing validity of an MCoA. A MCoA may be amended or modified only by the Authority (DASA in Australia) of the State of registry[39]. A MCoA may be issued for an unlimited duration, and remains valid subject to the conditions described in DASR.21.A.181.

7.3.2.14 Additionally, the ongoing validity of a MCoA requires that damage be assessed, and all applicable modifications and repairs carried out, using as appropriate the data requirements of DASR.M.A.304.

7.3.2.15 The validity of a MCoA is periodically renewed via the MARC process, as per DASR.M.A.901. This involves an airworthiness review of the aircraft and its continuing airworthiness records. The initial airworthiness review is due within 12 months of the issue date of the aircraft's initial MCoA. The validity of MARCs issued by a CAMO may be extended twice for a period of one year each time if the aircraft has been in a controlled environment.

7.3.2.16 The MAO is accountable for the continuing airworthiness of an aircraft and shall ensure that no flight takes place unless the MCoA and the MARC remain valid, as per DASR.M.A.201. If a MCoA becomes invalid, the MAO must return the aircraft to an airworthy condition before operating the aircraft or seek an alternate flying authorisation. A new MCoA is only required if the aircraft is being returned to the Defence register after removal, or the certificate is revoked by the Authority (DASA in Australia) of the State of registry[40]

7.4.1 Military Type Certificate Holders

Introduction

7.4.1.1 A Military Type Certificate Holder within the DASR framework provides Defence a suitable entity to 'hold' the Type Certificate. Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed and that the inherent safety that the platform type certification basis affords is maintained.

7.4.1.2 Unlike civil TC obligations, Defence MTC obligations are not enforceable via national legislation, meaning there is no enduring obligation under law for foreign organisations to manage

Superseded

the basis of certification through the product's life cycle. Therefore, in the application of DASRs, the Defence MTCH is a government organisation, most likely the organisation that acquired the product under contract.

Application of DASR provisions for the MTCH

7.4.1.3 The following principles guide the application of the above regulatory provisions:

a. **Principle 1.** DASA issues an MTC for Defence registered aircraft types. Unlike the civil context, a separate TC for the aircraft power plant and/or propeller has not been issued thus far and is nominally included as part of the platform TC.

b. **Principle 2.** DASA shall only issue MTCs to suitable Commonwealth government organisations (the holding organisation) to hold the MTC. The holder is responsible for ensuring that holder functions/obligations are executed. In the Defence context, the MTCH is able to achieve the regulatory intent via a direct or indirect arrangement with the aircraft/engine OEM.

c. **Principle 3.** Military Supplemental Type Certificates (MSTCs) will also be held by the MTCH or holding organisation, with the MTCH responsible for carrying out all MSTC functions/obligations. An MSTC in the Defence context can supplement the MTC for managing sub-fleets, significant changes to the TCB, large and complex changes. They are not used to achieve a commercial outcome such as in the civil design domain.

MTCH Safety Objectives

7.4.1.4 The MTCH has two aviation safety objectives:

a. To support the safe operation of the aircraft type by command units. Achieving Defence strategic objectives requires continuous capability enhancement, and at times, the conduct of operations at markedly elevated levels of risk. In addition, operators of aircraft will require explanatory information, advice and data to operate the type safely. The MTCH must have access to type design data, or support arrangements with the aircraft/engine OEM for the provision of designs and advice to support safe operation of the type.

b. To continuously monitor the type in service and ensure the ongoing validity of the Type Certificate, by investigating issues and providing corrective actions where required. The initial certification of a type establishes the known and understood level of safety inherent in the standards against which it was certified. Through the life of the type, latent hazards within the certified design, not identified during initial certification, may emerge requiring some action to address. Similarly, the use of the aircraft may vary and new designs be incorporated. Regardless, the MTCH has the high level objective to maintain the level of safety intended during initial certification.

Australian Context

7.4.1.5 The MTCH must account for the unique Defence context where the MTCH is not the OEM of the type and noting that the DASR are an amplification of the broader Work Health and Safety[41] obligations for the Defence aviation environment. In this context, the MTCH is the steward of the Defence type in service. To fulfil this role:

1. The MTCH should be broadly aware of all historic and emerging hazards relevant to their type[42]. This awareness requires:

Superseded

i. The collection of relevant aviation safety information (occurrences etc.) from within the Defence aviation system;

ii. The collection of relevant aviation safety information (occurrences, service bulletins, airworthiness directives etc.) from operators and authorities of similar types; and

iii. Consideration and conduct of additional verification activities(such as test programs) to generate further data independently and as necessary.

2. The MTCH is to lead the risk management of the type for the life of type, from initial certification to withdrawal from service. This leadership includes:

i. Ensuring operators are made, and remain, aware of the hazards extant in their type;

ii. Ensuring that essential risk controls (both technical and operational) pertaining to the safety of the type are, and remain, effective;

iii. Leading local efforts to eliminate or further minimise known hazards;

iv. Influencing external organisations (such as OEMs, joint user groups, co-operative partnerships etc.) to eliminate or further minimise known hazards.

MTCH Structure

7.4.1.6 To support these safety objectives, the MTCH organisation is broadly structured around two key systems, as detailed in Figure 4. These systems are responsible for the interactions regulated by DASA and are required elements of the MTCH supporting organisation.[43] They are:

a. The Safety Management System (SMS). This system ensures that the MTCH will collect operational data, analyse that data, investigate potential safety concerns and provide corrective actions.

b. The Design Assurance System (DAS). This system provides products (for example Service Bulletins correcting deficiencies, publication updates etc.) to operators of the Type.

Superseded

Figure 4: Safety Structure pyramid

7.4.1.7 Note that the safety management and design assurance systems are generic and are broadly applicable to all MTCH structures and implementations noting their varying constructs. It is likely that in implementing the systems, each MTCH through their partner organisation will employ business processes specific to their context. For example, the MTCH may rely upon long standing Defence engineering processes such as Technical Information Review, System Safety Working Groups and Configuration Control Boards to achieve the SMS intent. Similarly, the DAS of a foreign design organisation may not be entirely aligned with the requirements described in DASR 21.A.239 invoking the need to utilise Authority recognition arrangements.

7.4.1.8 Each organisation that holds a Type Certificate will be different and the model outlined in Figure 4 will not be a one-size fits all construct. It is appropriate that each organisation will implement these functions with different size, scale, or complexity, dependent on their need. For example, a CDA

Superseded

may rely on a large portion of sub-contractor products from civil aircraft OEMs operating under legislated civil safety constructs, and thus will not require a large compliance verification element.

MTCH Responsibilities

7.4.1.9 In the Australian Defence context, the government organisation holding the MTC is usually relatively small and is supported by one or more other organisations (contractors, foreign Defence organisation, OEMs etc.). As a result, responsibility for the conduct of MTCH obligations is often vested with these support organisations. This has led to confusion regarding accountabilities. To clarify:

a. Regardless of the organisational construct, the government organisation is the MTCH, and is accountable for all activities undertaken by its partners with respect to the obligations of the MTCH.

b. As such, it is unlikely that a passive compliance assurance relationship between the government organisation and its partners will suffice. DASA needs to be assured that the MTCH is able to meet its obligations – this may require the government organisation to lead key MTCH activities and be active in resourcing, prioritising, and implementing MTCH activities to ensure continued airworthiness and supporting safe operation of the type by the operator.

Eligibility to hold an MTC

7.4.1.10 A government organisation can be eligible to hold an *MTCH* under one of three regulatory provisions when applying for an MTC:

a. DASR 21.A.14(a). This provision is applicable where the government organisation has demonstrated its capability by holding a Military Design Organisation Approval (MDOA), and thus meets the requirements of DASR Subpart J and is capable of performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources.

b. DASR 21.A.14(b). This provision is an exception to subpart (a) where the organisation has no demonstrated capability, but may be able to obtain an MDOA in the future, and thus alternative procedures can be used in the starting phase as an organisation moves toward an MDOA or where there are limited duration design activities that may be required (such as initial certification of a platform).

c. DASR 21.A.14(c). This provision is an exception to subparts (a) and (b) where the government organisation is not capable of meeting the requirements of Subpart J and/or performing design activities (including the finding and declaration of compliance) across the key design disciplines relevant to their platform using internal or organic resources. In this instance, the government organisation is entirely reliant upon partners to meet the requirements of Subpart J.

Initial Assessment of MTCH capability

7.4.1.11 In the Defence context, assessment of the capability of the MTCH occurs in parallel to certification of the aircraft type, but must be completed before a Type Certificate can be awarded to the MTCH. DASA assessment of MTCH capability will include:

Superseded

a. An initial assessment of the organisation's personnel, processes, resources and support arrangements to establish that the MTCH will be able to perform/carry out the MTCH obligations outlined in DASR 21 and that the processes are present and suitable.

b. Supplementary on-site activities such as observing System Safety Working Groups, or reviewing Failure, Malfunction, and Defect data collected, in order to establish that the organisation is operating and effective.

c. An assessment of the MTCH Type Continued Airworthiness Exposition (TCAE). The TCAE describes all MTCH arrangements in order to execute the holder obligations and maintain the integrity of the type certificate. The broad content of the TCAE shall include, but is not limited to the description of the MTCH framework, design support arrangements, processes, procedures, governance, resources, and MAO/CAMO interfaces in place to meet the regulatory intent for the platform. In addition, the TCAE should include a detailed compliance matrix explicitly describing their arrangements in place to execute each MTCH obligation. The TCAE is the appropriate document where nuances particular to the platform and/or MTCH arrangements shall be described for Authority awareness and/or proposed alternative means of compliance.

MTCH Oversight & Enforcement

7.4.1.12 Oversight and Enforcement on the MTCH will be conducted by DASA as assurance activities in either a routine or a targeted format. The activities will have the objective to assess a MTCH organisation in their execution of MTCH obligations and functions. The scope of the assessment may involve any of the explicit and/or implicit obligations and may be a result of feedback received to warrant an assurance activity. Findings will be issued for non-compliances; however, the DASA team carrying out the assessment also looks to provide outcomes aiming to improve the overall effectiveness of the MTCH organisation. Oversight and enforcement on the MTCH arrangement will be based on the MTCH executing their obligations in accordance with the regulatory intent and their TCAE.

7.4.1.13 Further guidance on the DASA oversight and enforcement framework is provided in DASP Vol 3, section 4-1-5

MTCH Obligations

7.4.1.14 Within the DASRs the MTCH have the following obligations.

DASR 21.A.3A – Failures Malfunctions and Defects

7.4.1.15 This has three aspects which must be undertaken:

1. DASR 21.A.3A(a). Have a system for the collection, investigation and analysis of data relating to failures, malfunctions, defects or other occurrences, which cause or might cause adverse effects on the airworthiness of the product.

b. DASR 21.A.3A(b). Report to DASA occurrences, which may result in an unsafe condition.

c. DASR 21.A.3A(c). Investigate the root cause of occurrences and implement actions to eliminate or otherwise minimize any resulting hazards and their associated risks

Superseded

SFARP. If DASA finds action is required to correct the deficiency, the MTCH shall submit the relevant data to DASA.

7.4.1.16 **Reporting to DASA.** Where the MTCH assesses that an occurrence of a failure, malfunction or defect "may result in an unsafe condition[44]" that occurrence must be reported to DASA. Note this is a more limited and very specific subset of all occurrences that must be collected and considered by the MTCH. For these 'reportable occurrences' the MTCH must also report the results of MTCH investigations and any proposed action by the MTCH to DASA.

7.4.1.17 **Investigate and implement actions.** In the event that an unsafe condition may exist, the MTCH is obliged to take appropriate actions and be pro-active to eliminate and/or minimise the associated risks so far as reasonably practical. DASR 21.A.3A does not require the MTCH to consult DASA for review or approval prior to initiating any analysis, investigation and/or remediation actions. DASA provides additional, external and independent assurance of the actions of the MTCH but does not lead the MTCH in satisfying DASR 21.A.3A.

7.4.1.18 Further guidance on Occurrence reporting is provided in DASP Vol 3, section 7-4-2 and section 6-3

DASR 21.A.3B Airworthiness Directives

7.4.1.19 Where DASA determines an Airworthiness Directive (AD) is required for mandating actions for remediating an unsafe condition the MTCH must:

1. propose appropriate corrective actions and/or inspections

b. provide operators of the type all data required to comply with the AD

c. provide solutions/data to DASA to correct the deficiency and restore aircraft safety. This may include additional data to that provided under DASR 21.A.3A, specifically to support the release of an AD.

7.4.1.20 DASA's decision to release an AD may occur immediately following an occurrence or many weeks, months, or even years later. Per paragraph 7.4.1.17, the MTCH is to proceed with actions to eliminate the hazard or minimise the risks independently of DASA. This provision exists to support DASA mandating action proposed by the MTCH, not to direct the MTCH in the execution of their role.

7.4.1.21 Further guidance on Airworthiness Directives in the ADF context is provided in DASP Vol 3, section 7-4-3

DASR 21.A.4 Coordination between Design and production.

7.4.1.22 The MTCH shall coordinate between design and production organisations, to provide production data, as well as receive failure/malfunction/defect data from production organisations.

7.4.1.23 Where whole aircraft, parts and/or modification kits etc. are being produced, the MTCH arrangements are to ensure that the design and produced article align. For example, if the design is changing (materials/dimensions/finishing etc.) then that information will be provided to the organisation producing the item. Similarly, there cannot be changes to the item being produced without the knowledge of the MTCH and/or the responsible design organisation supporting the platform. Finally, this agreement must ensure the communication of occurrences, especially from the production organisation to the MTCH and/or their design organisation.

DASR 21.A.42 Integration

Superseded

7.4.1.24 The MTCH shall be responsible for the integration of Products, Weapons and other Systems onto the aircraft type.

7.4.1.25 This requirement places the obligation on the MTCH to consider the impact to airworthiness on integrating products, weapons or other systems, onto the aircraft. As the MTCH is also the only organisation eligible to apply for a major change to the type, the DAS of the MTCH (in cooperation with their partner organisations) must be sufficient to enable this. This obligation is not limited to aircraft components, but as expanded upon in Paragraph 7.4.1.49 for role equipment as well.

DASR 21.A.55 Record Keeping

7.4.1.26 The MTCH shall hold all relevant design information necessary to ensure the continued airworthiness of the type and make this available to DASA as required.

7.4.1.27 In the Defence context, the MTCH will not be the OEM, and the regulations cannot assume the MTCH created the type design data. Thus, this regulation ensures that the MTCH can access all data necessary to support the type design and ensure that major changes to the type continue to meet the appropriate airworthiness requirements.

DASR 21.A.57 Manuals

7.4.1.28 The MTCH shall produce, maintain and update master copies of all manuals required by the TCB and provide copies, on request, to DASA.

7.4.1.29 A manual under this regulation is part of the type design considered during type certification. It follows that any manual assessed during certification is therefore required by the TCB under this regulation. Such manuals contain content critical to keep the type airworthy or to operate the type safely within its designed limits. An example of a manual is the Aircraft flight manual, an engine manual[45] or a propeller manual[46].

7.4.1.30 For the purpose of initial certification, the MTCH is to provide manuals applicable to the ADF type. Thus, manuals produced for aircraft/products certified under other airworthiness authorities must be evaluated prior to releasing under the DASR. For the purpose of maintaining initial airworthiness in line with OEM issued updates, the MTCH must maintain and update master copies by enabling changes to be evaluated. Prior to promulgation, such change proposals will;

a. consider applicability to any unique ADF aspects or environment.

b. classify the content being considered.

7.4.1.31 The regulation implies that the MTCH will execute the obligation in a timely manner commensurate to the (safety) criticality of the update and any OEM advice.

7.4.1.32 Further guidance on the Aircraft Flight manual in the ADF context can be found in AC 008/2020

DASR 21.A.61 Instructions for Continuing Airworthiness

7.4.1.33 The MTCH shall provide the Instructions for Continuing Airworthiness (ICA) required by the TCB to operators. Changes to that ICA will also be provided to all operators.

7.4.1.34 ICA detail the methods, inspections, processes, and procedures necessary to maintain the aircraft and/or products in an airworthy condition and within the usage parameters of the aircraft

Superseded

design. ICA are an airworthiness requirement of the TCB and are prepared at initial certification by the appropriate manufacturer for each product, part or appliance. The regulation requires the MTCH to furnish the complete set of ICA to the Operator and to maintain the currency of the ICA for the ADF Type.

7.4.1.35 In the Defence context, this has particular relevance for the MTCH as often type design data will be produced under other regulatory systems and ICA will not be clearly identified. Part of the responsibility of the MTCH under this regulation is to identify and manage the ICA for a type where the OEM documentation has not explicitly referenced which instructions are ICA. This is usually where the aircraft is largely of military design, and in these cases, the MTCH will require an established relationship with the OEMs to enable clarification of maintenance documentation, when it cannot be determined from inspection what maintenance data is ICA.

DASR 21.A.44(b) - Identification of Products, parts and Appliances (DASR 21 Subpart Q)

7.4.1.36 Identification of products, parts and appliances. The MTCH shall:

a. specify how parts are to be identified.

b. specify how identification data (plates/etchings etc.) are to be handled.

c. identify critical parts.

7.4.1.37 In the context of EMAR, this obligation leverages a responsibility onto the MTCH to specify part marking schemes to their production organisations, who in the European context could be located in multiple countries. However in the Defence context the MTCH will in most cases rely on existing design organisation/production organisation arrangements in foreign countries with part identification already in place. To achieve the intent, the MTCH will appropriately leverage the OEMs part identification systems/schemes and only if applicable, specify the manner in which locally produced products, parts and appliances are identified.

7.4.1.38 Further guidance on Production in the ADF context is provided in DASP Vol 3, section 7-3-1.

DASR 21.A.44(c) - Continued Integrity of the Aircraft Structure and Propulsion System

7.4.1.39 DASR 21.A.44(c) requires that the MTCH shall ensure the continued integrity of the aircraft structure and propulsion system through ongoing monitoring and periodic assessment. Acceptable means of compliance for this regulation is provided in AMC 21.A.44(c). Chapter 6.6.3 provides extensive guidance to support application of AMC 21.A.44(c).

MTCH Obligations– Implicit Obligations

What is an implicit obligation?

7.4.1.40 In addition to the eligibility criteria listed at DASR 21.A.14(c) and the obligations listed at DASR 21.A.44(c), the regulations also include implicit obligations and expectations for the MTCH. That is, while an obligation has not been expressed, as “the MTCH must….” the operation of a regulation (or the AMC to that regulation) clearly depends upon the MTCH performing a function to ensure the continued airworthiness of the type or the safe operation of that type.

DASR 21.A.113 and 115

7.4.1.41 An applicant for a Supplemental Type Certificate (STC) shall prepare data to support the application independently or as part of an arrangement with the MTCH. In the defence context, the MTCH will hold all STCs and is therefore pivotal to enable an STC application through a ‘no technical

Superseded

objection' assessment and to provide the necessary design data. The advice provided by the MTCH shall enable for the safe integration by multiple design organisations of STCs onto the platform.

DASR 21.A.445 Subpart M Repairs

7.4.1.42 The MTCH is to support organisations performing major and minor repairs including unrepaired damage assessments by providing adequate information to enable their evaluation.

7.4.1.43 The MTCH may commission/initiate the activities through their supporting design organisation with appropriate approvals in place to design structural repairs. The MTCH will enable the provision of sufficient technical data where necessary.

AMC 21.A.709(b)(3) Approval of Flight Conditions

7.4.1.44 Flight Conditions underpin the issue of MPTFs as alternate authorisations assuring operations outside the strict requirements of the TCB and DASR M requirements and often at elevated levels of risk.

7.4.1.45 To make sure all reasonable knowledge is considered in the risk assessment supporting Flight Conditions and MPTF, the MTCH should be consulted to provide technical assessment inputs given access arrangements to type design data. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support/facilitate these assessments.

7.4.1.46 While not specifically identified, the reference to 'a design or engineering organisation suitably knowledgeable of the certified Type Design and with access to Type Design information' is usually read to mean the MTCH or OEM.

GM M.A.301(a)(2).2 Credible Data

7.4.1.47 Where operations are not at elevated levels of risk, but a defect remains preventing the release of the aircraft back to service, an operator may use 'credible data' for the deferral of defects in accordance with DASR M.A.301. Since the list of credible data includes type certification data, the MTCH would be a likely source of such information and be expected to provide it to operators as required. In the Defence environment and noting other regulatory guidance, the MTCH organisation shall support these assessments.

GM ORO.75 Use of Role Equipment

7.4.1.48 The MTCH is expected to support operators in the determination as to whether a piece of equipment is considered role equipment or a certified part.

7.4.1.49 Whilst the MAO has direct responsibility for integrating role equipment onto their aircraft, it is expected that they utilise technical assessments when appropriate. As the MTCH has access arrangements for assessments using type design data, the MTCH shall support the operator to ensure the part or equipment is integrated onto the type with appropriate consideration.

DASR AO.GEN.05(c) Management of Orders Instructions & Publications (OIP)

7.4.1.50 The MAO is required to have a documented agreement with the MTCH and seek MTCH support for control of air operational OIP and the use of Foreign Source Data (FSD).

7.4.1.51 This introduces an implicit requirement upon the MTCH to collaborate with the MAO via an agreement for review and appropriate approval of aviation operational OIP and FSD prior to use. This has particular relevance to the Aircraft Flight Manual (AFM). In the Defence context, the management of the AFM is complex with the one document having multiple uses and regulatory requirements. As

Superseded

a result, the MTCH shall be pivotal to ensure aviation operational OIP and FSD activities do not inadvertently alter content critical to compliance with the type certification basis.

7.4.1.52 Chapter 6.7 of the DASP Manual Volume 3 provides further guidance for OIP.

7.4.2 Continued Airworthiness Occurrence Reporting

Introduction

7.4.2.1 This section provides guidance to Occurrence reporting (OR) in the continued airworthiness domain (for design and production). This section is subordinate to the wider OR guidance provided as part of DASP Vol 3, chapter 6.3 which describes the wider OR framework.

7.4.2.2 Under DASR Part 21, organisations holding an approval have a requirement levied onto them to collect data on, conduct investigations of and provide analysis on any Failures, Malfunctions, Defects (FMD) or other occurrences, which creates or has the potential to create an unsafe condition. An unsafe condition is a state where an adverse effect on airworthiness exists being the result of a compromised or potentially compromised type design. Any occurrence that is assessed to have resulted in, or may result in, an unsafe condition[47],[48] must be reported to DASA and other organisations required by the implementing regulations.

7.4.2.3 Occurrence reporting by DASR 21 approval holder(s) is an essential continued airworthiness activity and enables risks and hazards associated with the type design to be identified and addressed in accordance with DASR 21.A.3A(a). All organisations that hold a DASR Part 21 approval including (but not limited to) the platform Military Type Certificate Holder (MTCH), Subpart J design organisations, Subpart F/G production organisations are obligated to have systems in place to achieve the regulatory intent of occurrence reporting.

Collecting FMD Data

7.4.2.4 The holder organisations operating under the DASR Part 21 regulations are expected to have arrangements in place that collects technical information from a spectrum of local and international sources/networks (civil and military) relevant to their platform. This has the primary purpose to access real time (critical) design related safety information for the product/part or appliance. The technical data may be directly applicable to types operated by the ADF or may require some applicability assessment before being considered for further consumption.

7.4.2.5 Collection of FMD data either directly from the ADF fleet or indirectly from other operators also has the purpose to provide the Holders with ongoing data that can be evaluated for patterns and/or reoccurrences. Such evaluation may identify failure issues that present as disparate, but may be linked. This level of analysis has the objective to identify latent design or manufacturing defects before they are realised during operation.

Occurrence Investigations in the DASR Part 21 Domain

7.4.2.6 In the Defence context, investigations involving FMD directly attributable to the type design and/or manufacturing are conducted by the platform MTCH under obligations in DASR 21.A.3A. Under this regulation, the MTCH must with all reasonable practicality initiate appropriate levels of investigation within their design support network to determine the root cause. This may take the form of reaching back into the OEM to evaluate the circumstances and determine the likely cause.

Superseded

Similarly, the production organisation or the part/component OEM may be consulted where a manufacturing issue needs analysis.

What constitutes a reportable Occurrence?

7.4.2.7 A FMD occurrence may originate from an issue identified on the ADF type or from a foreign fleet that is closely related to the ADF type. However, the immediate type design/airworthiness impacts from an FMD occurrence in the Part 21 domain are not always apparent and often requires detailed investigation to be completed. An occurrence may not be identifiable until investigation results are reported.

7.4.2.8 Similarly, there are instances where a failure, malfunction or defect, or analysis of failures, malfunctions or defects represents some level of shortfall to the type design but may not result in a reportable occurrence in accordance with DASR 21.A.3A(b) based on an assessment of the available information at that time. In these situations, the holder ought to make a judgement as to whether the shortfall constitutes a risk or not and what actions/advice is required to manage the risk (perceived or real). The Authority always encourages the community to be conservative in their judgements and provide an occurrence report - voluntary occurrence reports are an option.

7.4.2.9 In the Defence construct, the MTCH organisation is expected to receive relevant technical information (TI) from a range of sources including other operators (military or civilian, where relevant). In assessing the external TI, the MTCH must verify applicability to the ADF type and consider the ADF CRE. Once verified as applicable, a reportable occurrence is warranted satisfying any of the following conditions where the incoming technical information;

1. describes a design issue (real or potential) that leads to an unsafe condition; or
2. describes a safety concern that has a real or perceived airworthiness impact and requires some time compliance action; or
3. originates from the type OEM or Civil Aviation Authority (CAA) /Military Aviation Authority (MAA) regulator mandating an action with an accompanying risk assessment.

7.4.2.10 An occurrence on an ADF aircraft may require the outcome of an investigation before a determination can be made to report under DASR 21.A.3A. However, once the locally sourced TI is received, the same conditions of sub-paras 9a and 9b apply to determine if a reportable occurrence is warranted.

When and how to Report

7.4.2.11 Reporting occurrences to the Authority has the intent to make the Authority aware of an event that has caused or has potential to cause an unsafe condition in the current timeframe. This enables the Authority to begin their assurance function in real time and allow for intervention (where necessary) without undue delay. The reporting time period for the MTCH community is 72 hours for an occurrence once deemed reportable. It is acknowledged that the time between the actual occurrence and the MTCH being fully informed of an unsafe condition existing on their type can vary depending on many factors. Therefore, the 72 hour timeframe begins at the point where the MTCH organisation has enough information to make an informed determination of the airworthiness impact, based on the root cause (if known), type applicability, CRE considerations, etc.

7.4.2.12 The form and manner of which reportable occurrences are provided to the Authority from a MTCH organisation is via a DASR Form 44. The report shall contain (where practicable) all available information on the manufacturing or design deficiency, the results of any investigation to date, any

Superseded

actions they are taking or propose to take in order to correct the deficiency along with the submission of relevant data to support the actions.

MTCH Actions to address an unsafe condition resulting from FMD

7.4.2.13 The immediate actions that the MTCH organisation may take to eliminate and/or minimise the risks associated with the type design hazard will vary on a number of factors. However, the likelihood/consequence risk assessment will ultimately dictate the level of attention, timeliness, advice and resources that are attributed to the actions. Actions taken by the MTCH to address an unsafe condition should never rely on an Authority decision gate to implement.

7.4.2.14 The Authority will review the occurrence details and MTCH actions to gauge that the risk to aviation safety has been eliminated or otherwise minimised So Far As is Reasonably Practicable (SFARP) by the MTCH. This is not a one-off assessment; rather the unsafe condition determination by the MTCH organisation is an ongoing safety assurance activity conducted by DASA. It commences upon receipt of the occurrence and closes upon DASA's decision that the risk no longer warrants on-going monitoring by DASA.

7.4.2.15 Where the Authority does not have confidence that the design hazard has been eliminated or otherwise minimised SFARP, or if addressing the hazard requires development of a modification and subsequent fleetwide incorporation, then the DASA Airworthiness Directive (AD) process under DASR 21.A.3B may be invoked.

Structures and Propulsion Systems Guidance.

7.4.2.16 Structures and propulsion system specific considerations for the collection, investigation and analysis of failure, malfunctions, defects and other occurrences are addressed in AMC1 21.A.3A(a). Supporting guidance can be found in Chapter 6.6.3.

7.4.2.17 Specific guidance regarding risk analysis for propulsion systems (as could be used to develop the proposed corrective action(s) for a design- or manufacturing-related unsafe condition) is contained in Annex E to Chapter 7.2.

7.4.3 Airworthiness Directives (AD) in the DASP

Introduction

7.4.3.1 An Airworthiness Directive (AD) is *'a document issued (or adopted) by the Authority which mandates actions to be performed on an aircraft to restore an acceptable level of safety, when evidence shows that the safety level of this aircraft may otherwise be compromised'* [50]. Therefore, an AD is a key mechanism available to DASA to communicate mandatory action, in instances when an unsafe condition is determined to exist in an aircraft (and is likely to exist or develop in other aircraft) as a result of a deficiency in an aircraft's type design or conformance thereto.

7.4.3.2 This chapter sets out guidance for the use of ADs in the DASP. The guidance leverages civil practice, and expands on the regulatory criteria for the issue of an AD and key elements to execute the policy for the Defence aviation context.

Occurrence Reporting and Airworthiness Directives

Superseded

7.4.3.3 Whilst Defence-registered State aircraft are type-certified within the DASP (via the issue of a Military Type-Certificate (MTC)), and individual aircraft that conform to that type are awarded a Military Certificate of Airworthiness (MCoA), this is not a guarantee of enduring safety from a continued (and continuing) airworthiness perspective. This therefore necessitates that the potential for any unsafe condition (that may arise in-service) must be carefully monitored and managed.

7.4.3.4 Further to Chapter 7.4.2 (Continued Airworthiness Occurrence Reporting), respective Approval Holders[51] under the DASP have certain obligations[52] to DASA for the identification, communication and rectification of safety-related issues. DASA's role is to independently assure that the actions of the regulated community, in response to reportable/reported in-service occurrences affecting Defence-registered aircraft, are commensurate with the safety risk, and credible and defensible. This directly supports continued assessment of the validity of DASA-issued MTCs (/MSTCs) and/or MCoAs, and in certain instances, DASA's oversight of safety-related occurrences will need to consider if a DASA-issued AD is necessary to assure the safety of Defence aircraft (by explicitly approving and mandating the required corrective action to address an unsafe condition).

7.4.3.5 The nature of these occurrences, and the attendant severity and risk, vary considerably. In a practical sense, not every reported occurrence will (or should) result in an AD. In certain situations, it is entirely appropriate that lower-level safety-related issues reported to DASA by a sustainment enterprise (under DASR 21.A.3A) are just monitored (until defined closure criteria is met), if they do not actually constitute an unsafe condition *perse*.

Unsafe Condition Assessments (UCAs)

7.4.3.6 During the conduct of DASA's 'spectrum of assurance' for reported occurrences, the airworthiness impact to either the type, or individual aircraft of that type, must be considered. In every instance, what is unequivocally required is the determination of whether an unsafe condition exists (or not). Therefore, investigations and assessments conducted by Approval Holders within the regulated community must consider whether an unsafe condition exists; for this is not only DASA's function, but a shared responsibility. DASA's role is to be engaged with Approval Holders and determine/confirm[53] whether (or not) an unsafe condition exists (based on reports, investigations and assessments by, and engagement with, the regulated community[54]). DASA should generally not be conducting the UCA itself; for this is best-placed with respective Approval Holders[55] under DASRs (based upon type knowledge and understanding). That said, DASA always reserves the right to do so (if required).

Unsafe Conditions

7.4.3.7 Whilst DASR 21.A.3B(b) provides AMC and GM for what constitutes an unsafe condition, practical application is not always straight-forward in every instance, for discerning (and agreeing) which conditions are truly unsafe requires the exercise of professional judgement (by both Approval Holders and DASA). Moreover, the determination of what is truly an unsafe condition cannot be defined for every situation and scenario, for each platform (and DASA's assurance thereof). Generic aspects that will need to be considered are the:

1. nature of the deficiency/condition (and the associated consequence/likelihood of hazards)
2. elevated level of risk attributed to the deficiency (above that inherent in the type-certified design)
3. urgency for required mitigations, inspections and/or corrective action

Superseded

4. corresponding risk exposure period of (and any complexity within) required terminating action to resolve the deficiency.

7.4.3.8 It is important to understand that DASA (as the independent regulator) is not, and should never be, on the critical path to manage the day-to-day safety of aircraft. Under the DASRs (and the WHS Act 2011), regulated entities have obligations to ensure safety is not compromised and to alert DASA as the situations warrants. Therefore, regulated entities should not wait for DASA to provide a position before taking any appropriate action in response to an identified unsafe condition.

Criteria for issue of an AD

7.4.3.9 During the conduct of DASA's assurance of reported occurrences, and regardless of whether the actions of the Approval Holder are deemed to be credible and defensible, DASA will consider (on a case-by-case basis) the issue of an AD[56] when:

1. an unsafe condition has been determined by the Authority to exist in an aircraft, as a result of a deficiency in the aircraft, or an engine, propeller, part or appliance installed on this aircraft.

2. that condition is likely to exist or develop in other aircraft, including engine, propeller, part or appliance installed on those aircraft that may be affected by this unsafe condition.

7.4.3.10 In these instances, the 'safety benchmark' for the type or individual aircraft has (or potentially has) been compromised, and the continued validity of an aircraft's MCoA (and/or MTC) may be brought into question (via the presence of an unsafe condition). Therefore, DASA-approved inspection and/or remediation is necessary to restore an acceptable level of safety, via the issue of an AD.

7.4.3.11 Given an AD may be applicable to either all aircraft of a certified Defence type, or only certain individual aircraft of that type, ADs are by definition either type- or tail-related, issued to address identified in-service deficiencies pertaining to continued or continuing airworthiness (and potentially a hybrid thereof).

Purpose of an AD

7.4.3.12 The fundamental purpose of an AD is to:

1. approve corrective action and/or required inspections (proposed by the relevant Approval Holder under the DASRs)

2. communicate the presence of an unsafe condition affecting a Defence type and/or individual aircraft (that endangers flight safety) to the MAO/CAMO

3. mandate required action by the MAO/CAMO[57].

7.4.3.13 Regulated community compliance with DASA-issued ADs (to restore an acceptable level of safety) is mandatory within the DASP[58], which invokes the implementation of required action from a continuing airworthiness perspective under DASR Parts M and 145 (including military aircraft airworthiness review activities under DASR M Subpart I)[59].

Defence aviation context and considerations

Superseded

7.4.3.14 Since (EMAR-based) DASRs have a civil lineage – albeit adapted for the military context – fundamental aspects underpinning the intended application of DASR 21.A.3A and .3B are derived from ICAO-based concepts and civil regulations. That said, whilst DASA's assurance functions for reported unsafe conditions and the corresponding use of ADs within the DASP are *prima facie* the same, the combination of a number of inter-related features of the Defence aviation context requires additional policy considerations. In particular, how to pragmatically deal with the reality of:

1. sovereign government MTC Holder arrangements, that typically only coordinate the execution of holder obligations[60] and almost entirely leverage and recognise a much-broader (initial/) continued and continuing airworthiness management framework in place for a foreign type the same as, or similar to, the Defence type.
2. the general lack of centrality of the OEMs (as the original 'Approval Holders' for design and production that are not directly regulated under DASRs).
3. the nature of DASA as a relatively-small 'validating' Authority when issuing sovereign MTCs for Defence-registered aircraft (and most major changes to type-certificate (TC) thereafter).

7.4.3.15 Therefore, there is a strong reliance on the sustainment support arrangements established by CASG SPOs for the ongoing execution of sovereign MTC Holder functions required by DASR 21.A.3A and .3B [61], either with the actual OEM(s) and/or by leveraging the framework and actions of a foreign Civil/Military Aviation Authority (C/MAA), to support the identification and management of unsafe conditions applicable to Defence aircraft.

Sovereign MTC Holder support arrangements

7.4.3.16 The various in-service sustainment support arrangements implemented by CASG SPOs to support respective MTC Holder obligations, have differing degrees of OEM and/or foreign C/MAA involvement. Therefore, the extent to which sovereign MTC Holders leverage the initial, continued and continuing airworthiness management framework of a DASA-recognised foreign C/MAA, in direct support to the management of Defence types, will strongly influence the extent of sovereign decision-making required by MTC Holders (in the determination of required sovereign action to address an unsafe condition). In particular, those support arrangements that include a foreign C/MAA that acted as the primary certifying authority for an aircraft type similar to, or the same as, that operated by Defence.

7.4.3.17 Moreover, given the much-larger global fleets being oversighted and assured by respective foreign C/MAAs, the reality is that the vast majority of FMD/occurrences, assessments of any associated unsafe conditions, and the corresponding mandatory actions (to restore the safety benchmark) will be determined overseas (generally without sovereign MTC Holder and DASA involvement). However, FMD/occurrences for Defence aircraft do still arise, which may not be addressed by foreign type management arrangements. In particular, any design or part production deficiency that may be attributable to a military design or production organisation (MDO/MPO) approved by DASA under the DASP[62]. In these instances, the full intent of DASR 21.A.3A and .3B is required by respective Approval Holders and DASA.

7.4.3.18 Therefore, the degree of 'type management sovereignty' for Defence-registered aircraft – and therefore the extent to which sovereign decisions are required – will commensurately govern DASA's assurance of unsafe conditions affecting Defence-registered types (and the oversight of corresponding actions). That is, when more airworthiness-related 'type management' activity and

Superseded

decision-making is conducted in Australia, the greater DASA's involvement will be in the application of DASR 21.A.3A and .3B.

Sovereign Approval Holders propose required action to support the issue of an AD

7.4.3.19 When DASA decides that an AD needs to be issued within the DASP[63], the MTC Holder organisation (and/or other relevant Approval Holders under DASRs) should propose[64] appropriate corrective action and/or required inspections to DASA. Given sovereign MTC Holder organisations are primarily a coordinating (and not a design) organisation, OEM input should be considered mandatory, as well as C/MAA oversight and involvement (as appropriate)[65]. This therefore connects the original 'applicant' and the 'holder' of the design, as well as the primary certifying authority (that established the safety benchmark with the original 'OEM applicant' within their airworthiness management framework), which therefore executes the actual intent of DASR 21.A.3A and .3B.

7.4.3.20 Upon receipt, DASA's independent safety assurance function is to approve the holder's proposal, including required inspection(s) and/or rectification interval(s), and the associated risk exposure. DASA will engage with the Approval Holder and amend the proposal, if and as required. When satisfied that the AD's content (as proposed by the holder) provides appropriate terminating action to eliminate the unsafe condition (and to restore the 'safety benchmark'), and the associated risk during the exposure period will be otherwise minimised SFARP, DASA will issue an AD accordingly[66]. In doing so, DASA is explicitly approving the corrective action to address the unsafe condition and the corresponding exposure period.

Foreign ADs (or equivalent)

7.4.3.21 When sovereign MTC Holders receive relevant foreign ADs (or equivalent[67]) for assessment, and report this to DASA[68], the DASP is the beneficiary of relevant C/MAA assurance of the same/similar type to that operated by Defence. This broadly meets the intent of DASR 21.A.3A and .3B; for the 'problem' and the 'solution' is provided, that usually leverages the inputs of the actual OEM and recognises what the relevant C/MAA deemed mandatory. Therefore, a sovereign MTC Holder will need to consider the following:

1. the applicability of a foreign AD (or equivalent) to a Defence-registered type.
2. the availability and suitability of controls and corrective actions provided by a relevant foreign C/MAA that can be 'adopted' (including whether full (or partial) compliance and implementation is intended).
3. the extent to which a Defence type's Configuration, Role and Environment (CRE) considerations require necessary/appropriate variations to adapt the content of a foreign AD (or equivalent); and in particular, necessary/appropriate variations to risk controls, terminating action(s) and/or implementation timeframes/risk exposure periods.
4. the need to amplify other foreign-source safety advice for required actions and timeframes to rectify an unsafe condition[69].

7.4.3.22 Given the 'sovereignty' of DASA-issued MTCs (/MSTCs) and MCoAs for Defence-registered aircraft, the assessment of unsafe (or potentially unsafe) conditions identified for foreign aircraft that may affect Defence aircraft is fundamental to support the ongoing validity of these DASA-issued authorisations. However, it is important to note that these foreign ADs (or equivalent) are not automatically applicable and mandatory under the DASP, and despite the AD definition cited within

Superseded

DASR 21.A.3B(a), there is no regulatory mechanism within DASR 21 to 'adopt' foreign ADs (or equivalent)[70]. Therefore, whilst the regulated community may indeed decide to implement the required actions of a foreign AD (or equivalent) as a 'credible and defensible' means to address an unsafe condition for a Defence-registered aircraft, DASA nonetheless requires that applicable critical foreign safety-related information (and in particular, that issued by the primary certifying authority) is formally 'brought into the DASP' and actioned accordingly. The only way for this to occuris for DASA to issue an AD in the DASP[71], to mandate the same/similar action for Defence-registered aircraft.

Foreign ADs (or equivalent) issued by the primary certifying authority are mandatory when applicable to Defence-registered aircraft

7.4.3.23 DASA functions largely and almost exclusively as a 'validating authority', when issuing a sovereign MTC to establish the initial airworthiness of Defence types (and approving most major changes to TC thereafter), based upon recognition and leverage of the previous type-certification efforts of foreign C/MAAs. Similarly, the DASP should also recognise and leverage the type knowledge and understanding of the relevant C/MAA's management of continued and continuing airworthiness, for aircraft the same as/similar to Defence types.

7.4.3.24 Therefore, DASA's default policy position is that compliance with the technical content of foreign ADs (or equivalent) – issued by the primary certifying authority that DASA leveraged to underpin the award of a DASA MTC – is mandatory (when applicable to Defence-registered aircraft). If the primary certifying authority deemed a condition unsafe, then in near-all instances, their required mandatory action to address compromised airworthiness should be equally-applicable to Defence aircraft (notwithstanding any unique CRE considerations in certain situations).

7.4.3.25 The act of 'validating' the applicability and corresponding mandatory action within a foreign AD (or equivalent) for a Defence type is pragmatic and efficient. DASA issue of an AD when 'validating' a foreign AD (or equivalent) will in most instances be as simple as placing a DASA AD cover page on the foreign artefact(s) (if no changes are required), which may also include any minor adaption (that does not change the intent[72]), and promulgating this to the relevant MAO/CAMO for implementation.

7.4.3.26 Whilst this policy consideration would likely cater for many foreign ADs (or equivalent), DASA acknowledges there may be exceptions and complexities in certain situations, that require professional judgement. In particular, there may be compelling reasons why applicable foreign ADs are not intended for compliance (or only partial compliance), or there are substantial required and/or proposed variations on account of Defence CRE considerations (or otherwise) that will alter the intent and/or attendant risk. This will therefore require a much-greater degree of engagement between the relevant Approval Holder and DASA, to agree the content of the DASA AD (if issued).

Traceability with required mandatory action issued by the primary certifying authority

7.4.3.27 DASA's expectation is that sovereign MTC Holder arrangements implemented for each Defence type will monitor safety-related information from respective OEMs and C/MAAs (including other operators), to support required obligations under DASR 21.A.3A and .3B) (and DASR 21.A.44). In particular, this should include the documented methods and means to record the traceability of all actions mandated by the primary certifying authority[73], and the alignment with that implemented within the DASP.

7.4.3.28 For civil-derivative military aircraft, certified by a foreign MAA yet underpinned substantially by a foreign CAA's certification of the 'green aircraft', the applicability of foreign civil ADs would ideally be assessed and actioned by the relevant foreign MAA (that oversights the overseas

Superseded

fleet the same as/similar to a Defence type), but this may not always occur as expected. Therefore, due consideration should also be given to record the traceability (or otherwise) to Emergency or Alert Service Bulletins (issued by civil OEMs) and ADs (issued by the relevant CAA) that may not be mandated by the relevant MAA.

Platform DoSAs may issue ADs (for validated foreign ADs (or equivalent))

7.4.3.29 When a DASA AD needs to be issued within the DASP, and in instances where the relevant Platform Delegate of the Safety Authority (DoSA) is not developing the technical content therein – but rather only validating that a foreign AD (or equivalent) is applicable to, and should be mandatory for, Defence-registered aircraft – the Platform DoSA is the most-appropriate release authority (for, and on behalf of, DASA[74]). This is pragmatic and efficient, and is the most-responsive and agile arrangement (particularly for exigent circumstances), which is also aligned with a Platform DoSA's safety-related role and functions.

7.4.3.30 Moreover, this also fully aligns with the distributed model established for each Defence type to monitor, review and assess foreign safety-related data that may impact Defence aircraft, and should be invoked to the greatest extent possible[75]. The only caveat is that if the risk exposure is DHRM MEDIUM (or higher) until terminating action is accomplished, this should default to DASA (yet supported and staffed by the Platform DoSA).

AD issue in the absence of a foreign AD (or equivalent)

7.4.3.31 For the Defence aviation context, and in addition to the aforementioned, DASA will also consider (on a case-by-case basis) the issue of an AD in the DASP, in advance of a primary certifying authority's release of a foreign AD (or equivalent). DASA's expectation is that whenever continued operations are intended with protracted exposure to a (post-mitigation) residual risk to airworthiness – on account of an unsafe condition associated with catastrophic and hazardous consequences that cannot be eliminated or fully-controlled immediately by design – an AD in the DASP should be issued. This will usually manifest in situations where foreign MAAs have conducted a risk assessment and recommended initial treatment/controls for continued operations (due to the presence of an unsafe condition), yet the design solution and the attendant foreign AD (or equivalent) does not (and will not) exist for a significant period of time (to detail required terminating action and compliance timeframe to restore an acceptable level of safety).

7.4.3.32 This therefore sets a default position for compromised airworthiness associated with long-standing exposure to an elevated level of residual risk (whilst design solutions are being devised). In this instance, a DASA-issued AD therefore provides a means to formally communicate instances of elevated levels of risk within the DASP (bounded by a date for terminating action and compliance to be implemented), which will also provide improved Command awareness, visibility and traceability of required actions.

DASA-issued ADs associated with elevated risk should be underpinned by 7-Step Risk Management

7.4.3.33 By definition, continued (post-mitigation) operations with an unsafe condition that cannot be eliminated immediately constitutes an elevated level of risk to airworthiness during the exposure period, until terminating action detailed within an AD restores an acceptable level of safety.

7.4.3.34 Therefore, consistent with a MAO's DASR and WHS obligations, the elevated level of risk attributed to a deficiency (above that inherent in the certified design) and the corresponding residual risk exposure period should be underpinned by a MAO's Risk-Decision Brief (RDB). In particular, for instances that:

Superseded

1. deviate significantly from compliance requirements with 'validated and adopted' foreign ADs (or equivalent).

2. where there is markedly-elevated risk being retained, and the corresponding design solution required to address the deficiency will not be available for an extended period of time[76].

7.4.3.35 This policy position will primarily affect military aircraft (and likely not affect Defence-registered aircraft that are ostensibly civil). The need for an RDB for lower-level risks should be considered on a case-by-case basis (aligned with a MAO's Safety Management System (SMS)), and may not be required at all – particularly for instances where DASA leverages and 'adopts' foreign CAA ADs with no variations to risk controls and exposure periods.

7.4.3.36 MAO RDBs (that underpin DASA-issued ADs) will need to consider and disposition all available and suitable technical and operational risk controls, to support appropriate operating conditions and/or limitations. This therefore ensures and requires that MAO Hazard Tracking Authorities (HTAs) and Risk Management Authorities (RMAs) are suitably-engaged for airworthiness issues, and the corresponding DASA AD is a mechanism to communicate and document DASA's independent safety assurance for an agreed risk management strategy.

7.4.4 Other Design Approval Holders

7.4.4.1 This section addresses other design approval holders under the DASR framework. This primarily covers any Australian Military Technical Standard Order Authorisations (AUSMTSO) under DASR 21 Subpart O. AUSMTSO Authorisations are not expected to be widely used in the Defence regulatory framework and will only be issued by exception. The Authorisation is common in the civil domain under the term Technical Standard Order (TSO) and TSO Authorisations and encourages competition across the industry through novel design which does readily translate across into the military domain.

7.4.4.2 An AUSMTSO under DASR is considered equal in concept to the civil use where a TSO is defined as a minimum performance standard for specified materials, parts, and appliances used on civil aircraft. An AUSMTSO Authorisation enables the holder to manufacture a material, part, or appliances to a TSO standard. Receiving an AUSMTSO Authorisation is both a design and production approval, but importantly does not extend to installing and using the article in the aircraft.

7.4.4.3 In the civil domain, a TSO Authorisation enables the manufacture of articles that may be installed on an aircraft only after showing that the article meets the specific airworthiness requirements (certification basis) of a particular aircraft model. Receiving a TSO Authorisation verifies that an article meets a minimum performance requirement independent of the article's intended installation on an aircraft. Under the DASR, using the AUSMTSO Authorisation will be more nuanced and will not be issued on a competitive basis.

7.4.4.4 Common articles on modern day aircraft including Military aircraft that have their genesis through the civil TSO provisions include Embedded GPS and INS Units (EGIs), Auxiliary Power Units, Tires, seat belts, crew oxygen masks, seat assemblies, brake assemblies, antennae, various instrumentation, cargo containers along with many more. Under the DASR framework, the use of AUSMTSO has been very limited.

Superseded

7.4.4.5 Under DASR 21, Subpart O, the holder of an AUSMTSO has obligations to ensure that the article continually conforms to its design and is manufactured accordingly per regulations detailed under production (Subpart G). The holder is also subject to a number of other initial airworthiness regulations such as occurrence reporting and part marking with respect to their article. Although the Defence MTC construct results in a nuanced use, the AUSMTSO holder is required to engage with the aircraft Type certificate holder to integrate their article into the aircraft type or where design changes impact the integration.

7.5.1 Introduction

7.5.1.1 A Military Permit to Fly (MPTF) is a 'product authorisation' issued by DASA to aircraft that do not meet, or have not been shown to meet, the requirements of the Type-Certification Basis (TCB) and/or Military Air Operator Certificate (MAOC), but are nonetheless capable of safe flight under defined conditions and for specified purposes. An MPTF is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application.

7.5.1.2 An MPTF is a risk-based authorisation, within the suite of Defence aviation flexibility provisions provided under DASR GR.80, to facilitate military flexibility in support of a capability imperative, which is valid for a defined period of time, underpinned by a seven-step risk assessment with both technical and operational input.

7.5.1.3 Further to the overview of the Flight Conditions and MPTF authorisations provided at Chapter 5.3 Annex N, this chapter details DASR implementation of applications for, and approval of, Flight Conditions and MPTF (and the associated risk management aspects).

Audience

7.5.1.4 This chapter applies to DASR-regulated entities exercising roles or responsibilities when applying for an MPTF under DASR 21 Subpart P Military Permit To Fly. Whilst this will primarily be Military Air Operators (MAOs) – including Continuing Airworthiness Management Organisations (CAMOs) and service providers – it also extends to any organisation engaged to assist with the preparation of the application, such as: Military Type-Certificate (MTC) holders; design organisations (DASR Military Design Organisations (MDOs) and equivalents) and organisations involved in managing the configuration of Defence aircraft (CASG Systems Program Offices (SPOs) and Through-Life Support (TLS) contractors).

7.5.1.5 While cognisant of the above, the application for (and holding of) an MPTF within the DASR environment will almost exclusively be a MAO requirement for the subject aircraft defined within the MAOC Operations Specification (OpSpec)[77]. The MAO should therefore establish in-service procedures to implement attendant MPTF regulation and Acceptable Means of Compliance (AMC) that reflects the central role of the MAO Accountable Manager (AM) and authorised staff within the MPTF process.

Purpose

7.5.1.6 This chapter provides guidance in relation to Initial Airworthiness requirements under DASR 21 Subpart P, for developing MPTF applications, inclusive of: collating substantiation documentation; gaining operational endorsement; signing the declaration of safety; engaging with the Authority

Superseded

(inclusive of the Delegate of the Safety Authority (DoSA)) for approval and issue of the MPTF; and meeting MPTF holder obligations. Moreover, this chapter explains how applications for approval of flight conditions and an MPTF should follow the seven-step risk management process detailed in DASA AC 003-2018—Risk Management in the Defence Aviation Safety Program, and describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the Work Health and Safety Act 2011 (WHS Act).

Background

7.5.1.7 Within civilian aviation regulations, a permit to fly is predominately used to support development, certification, production and delivery of new aircraft and major modifications, and to support in-service operation outside the bounds of the Certificate of Airworthiness (CoA); such as ferry flights to a suitable maintenance venue for defect rectification or the conduct of an overdue scheduled servicing.

7.5.1.8 The use of MPTFs within the DASR context is subtly different. Design, certification and production of a new aircraft solely within a DASR MDO/MPO has not yet occurred, and flight test for development of major modifications will likely occur for Defence-registered aircraft operated by a MAO (rather than a DASR MDO/MPO at this stage). Furthermore, as recognised and afforded by DASR GR.80 Flexibility Provisions, Defence aviation requires flexibility to support capability imperatives for certain operational circumstances that would not be allowed within the civilian aviation domain.

7.5.1.9 Under normal circumstances, all Defence-registered aircraft should only be operated with a valid Military CoA (MCoA) issued by DASA. An MCoA is issued when the aircraft was shown, at the time of issue, to conform to its MTC awarded post-certification. Whilst in-service, the validity of the aircraft's MCoA is maintained by meeting the continuing airworthiness requirements of DASR M[78]. A valid MCoA represents a baseline level of airworthiness, aligning to both civil and military global conventions. Importantly, in the Defence context, an MPTF authorisation supplements, rather than replaces, the MCoA.

7.5.1.10 However, as stated, military aviation requires flexibility for Commanders to operate aircraft in certain circumstances without having met all the prescribed initial, continued or continuing airworthiness or aviation safety requirements, but are nonetheless capable of safe flight under defined conditions. In these circumstances, and without the necessary flexibility provisions in DASRs, the MAO would be unable to operate under the regulations. To accommodate Defence aviation flexibility, DASRs include provisions for issue of either of the following, to facilitate operation when the prescribed airworthiness or aviation safety requirements are not met:

1. MPTF under DASR 21 Subpart P Military Permit To Fly, which is augmented with AUS-unique AMC and Guidance Material (GM), which stipulate specific application requirements and include additional expectations for the holders of an MPTF, or
2. Command Clearance (CC) under DASR Specific Purpose Approval – SPA.10 *Command Clearance* [79].

7.5.2 Difference between MPTF and CC

7.5.2.1 The DASR SPA.10 CC provides for a similar outcome to that of an MPTF, in so far as the CC may also be used to authorise flight(s) where the MCoA's Instructions for Continuing Airworthiness (ICA) conditions are unable to be met. However, the key difference between the MPTF and CC is that the MPTF is an initial airworthiness authorisation subject to DASA approval and issue, whereas a CC is

Superseded

an operational authorisation via the command chain. In ideal circumstances, conditions that require an MPTF would be managed via an MPTF; however, in the event of compelling time-critical capability imperatives or emergencies, and where there is insufficient time to process an MPTF application, a DASR SPA.10 CC may be exercised.

7.5.2.2 Regardless of whether MPTF or CC provisions are used, the operating organisation remains responsible for meeting WHS obligations to eliminate or otherwise minimise risk to aviation safety, so far as reasonably practicable (SFARP). Therefore, both the MPTF application process and issue of a CC require the MAO to exercise the seven-step risk management process detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. However, an MPTF provides the MAO with independent assurance over the discharge of their obligations and should be sought whenever reasonably practicable. Should the requirement for operation of an aircraft under DASR SPA.10 be for an extended period, an MPTF or other appropriate authorisation must replace the CC.

7.5.3 Defence use of MPTFs

7.5.3.1 Whilst DASR 21.A.701(a) provides a non-exhaustive list of examples illustrating situations when an MPTF should be used, the majority of those examples are EASA/EMAR-based, and focused more on development of aircraft design, production, delivery and initial training within an OEM organisation (operating under privilege), as opposed to in-service scenarios that are typical for Defence aviation. For the Defence context, and as outlined within GM to DASR GR.80(c), aircraft operation in the following circumstances potentially entails flight at an elevated level of risk that may require an MPTF:

1. **Prior to initial issue of an MTC and MCoA.** DASR 21 precludes the issue of an MCoA if an MTC has not yet been issued. This will typically be due to the requirement to operate new aircraft prior to completion of the type-certification programme.

2. **Aircraft operation while continuing airworthiness requirements are not satisfied.** The aircraft has been issued an MCoA and is required for operational tasking; however, any of the following continuing airworthiness requirements have not been met:

   i. a defect that cannot be deferred as it has been assessed to endanger flight safety

   ii. scheduled maintenance in the Aircraft Maintenance Programme (AMP) has not been carried out

   iii. an Airworthiness Limitation (AwL) or Certification Maintenance Requirement (CMR) has been reached

   iv. an Airworthiness Directive (AD) has not been incorporated.

3. **Aircraft not conforming to an approved design configuration for the purpose of flight test.** Installation of a yet-to-be-approved modification for flight test, in order to gather compliance demonstration evidence to support approval of a change to type-certificate (or subsequent flights prior to the design change approval being issued).

4. **Aircraft operation outside approved limitations.** The aircraft has been issued an MCoA but is intended to be flown beyond the approved operating limitations in the Aircraft Flight Manual (AFM), or outside the approved role and/or environment detailed within the MAOC OpSpec. These circumstances can arise from either

Superseded

operational tasking or for the purpose of flight test (to support role expansion activities).

7.5.4 Overview of Organisational Responsibilities

7.5.4.1 The following organisations have specific responsibilities with respect to the application for, and issue of, MPTFs:

1. MAOs. MAOs are responsible for applying to DASA for the approval of flight conditions and the issue of an MPTF. They must fulfil the responsibilities of the applicant, including the conduct of a risk assessment that fully integrates all technical and operational considerations. MAOs should engage relevant external organisations in the course of preparing the application in order to effectively conduct an integrated risk assessment. These organisations may include the product's MTC holder, design organisations, CAMOs (and service providers), flight test organisations, and/or relevant maintenance organisations. All MPTFs are issued to MAOs who are then responsible for discharging the obligations of the holder of a MPTF.

2. DASA. Upon receipt of an application(s), DASA will provide independent assurance that there is evidence that the MAO met their obligations and has eliminated or otherwise minimised all risks SFARP. DASA assurance will focus on credible and defensible risk management, which provides advice to Commanders if the capability imperative has been sufficiently described and would support a decision-to-proceed with the identified Elevated Level of Risk (ELOR); however the decision-to-proceed always remains with the applicant.

7.5.5 Overview of MPTF Process and DASR Forms

7.5.5.1 The application process to obtain an MPTF is relatively straightforward, but does require clear identification of the participants and an understanding of the associated responsibilities. Whilst two separate applications are required, DASRs do not prohibit both being submitted to DASA concurrently. Relevant DASR Forms are as follows:

1. DASR Form 18b. Application for, and approval of, flight conditions that enable the aircraft to operate safely. This form is raised and submitted by an applicant to DASA. DASA approves the application and returns the approved form to the applicant.

2. DASR Form 21. Application for issue of an MPTF. Raised by the applicant and submitted to DASA. This may reference pre-existing and approved flight conditions within DASR Form 18b.

3. DASR Form 20a. Issue of an MPTF in response to a DASR Form 21 application. Raised by DASA and issued to the applicant; that is, the organisation responsible for conducting the associated flight(s) and ensuring the flight conditions are adhered to.

7.5.5.2 Further to GM to DASR 21 Subpart P, Annex A provides a 'swim-lane' flowchart illustrating the application process within organisational responsibilities. Reiterating, the approval of flight conditions is separate from the issue of an MPTF to give the applicant flexibility. Reasons include:

1. One set of flight conditions may underpin a number of MPTFs.

Superseded

2. The approval of flight conditions and the issue of an MPTF may be separated in time.

3. The issue of an MPTF by a local DoSA, in instances where DASA has previously approved flight conditions that are beyond the DoSA's delegation, may improve flexibility and timeliness.

4. The approval of flight conditions and issue of an MPTF represent different steps in the seven-step risk management process, and therefore address different WHS Act requirements.

7.5.6 Summary of the Seven-Step Risk Management Process

7.5.6.1 GM to DASR SMS.A.25(b)(2)(2.2) outlines Defence's seven-step risk management process (depicted in Figure 5), with further aviation-specific guidance detailed in DASA AC 003/2018—Risk Management in the Defence Aviation Safety Program. AC 003/2018 describes the key elements of safety risk management that must be implemented by organisations to ensure compliance with the WHS Act.

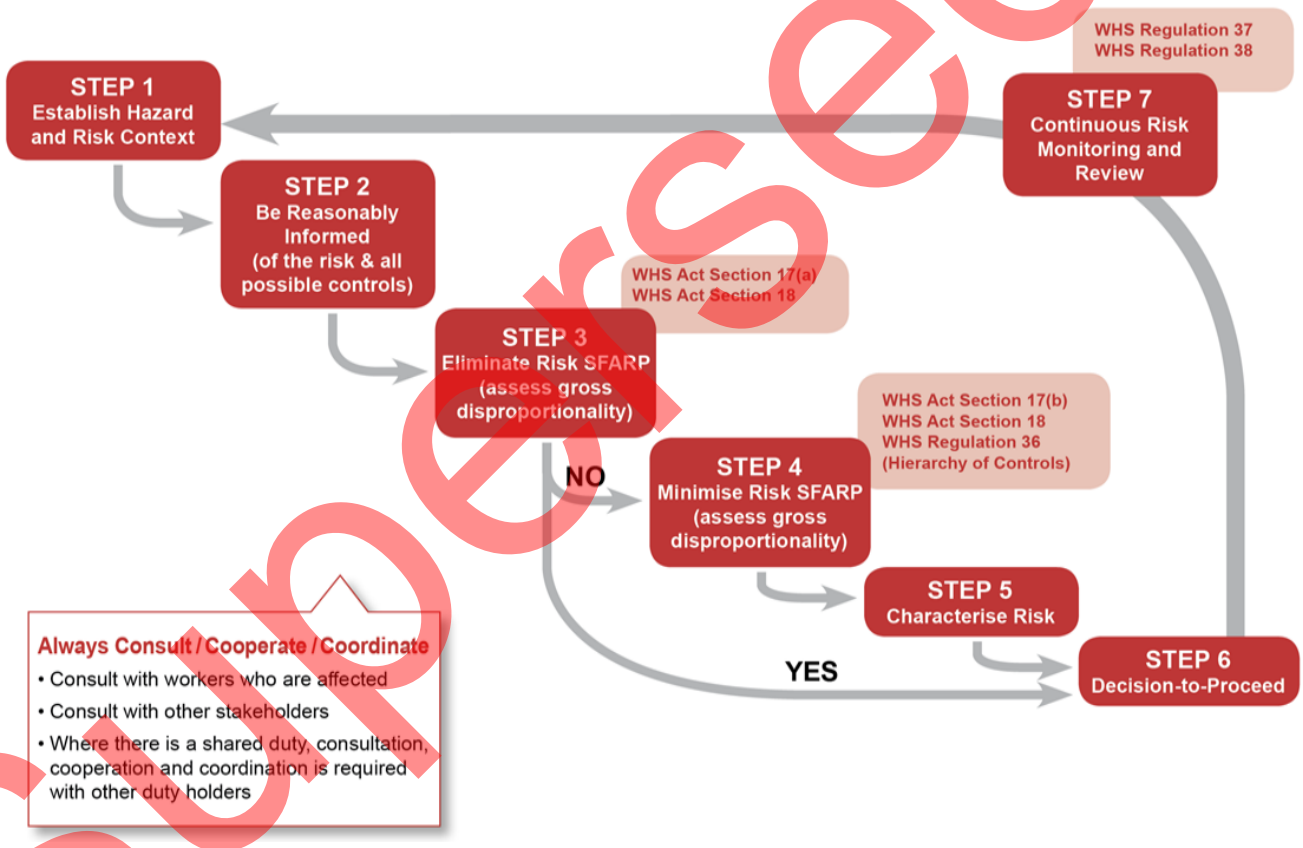

Figure 5: Safety Risk Management Process

7.5.6.1.2 DASR application forms for the approval of flight conditions and the issue of an MPTF collectively cover all of the required steps in the safety risk management process. DASR Forms 18b and 21 should summarise key information arising from the seven-step risk management process. Additional detail may be included in separate documents.

Superseded

7.5.7 Application for Approval of Flight Conditions

7.5.7.1 An approved set of flight conditions underpins every MPTF, which are the risk controls required to eliminate or otherwise minimise the risk SFARP. In applying for the approval of flight conditions, the applicant should execute and document Steps 1–5 of the seven-step risk management process. A single set of approved flight conditions may be applied to several MPTFs.

7.5.7.2 The specific application of these steps in applying for the approval of flight conditions are as follows:

1. **Step 1 – Establishing the risk context.** The applicant must define the task objective(s) including a clear strategic, operational or tactical imperative for the task and why it is necessary to fly with an ELOR. In defining task objective(s), the applicant should consider whether the task is new or existing, the discretionary/non-discretionary nature of the task and its urgency. The applicant should also identify and engage relevant stakeholders to ensure the risk assessment fully integrates all technical and operational factors. The risk context establishes the depth of risk assessment required and informs all reasonably practicable judgements. Establishing the context, also includes the duration of the activity. Retention of ELOR must be for the minimum possible duration to remain defensible within the WHS obligations and DASRs. As such, long-term MPTFs are unlikely to be defensible[80].

2. **Step 2.a – Being reasonably informed of the risks.** The applicant must proactively take steps to gain reasonable knowledge of the exact nature of all hazards and risks (both technical and operational). This may include use of existing OIP, the AFM, ICA or the provision of specialist advice from appropriate support organisations. This could include design organisations, technology or operational specialists, flight test specialists or the aircraft's OEM. There is no fixed list of who must be consulted for each application; instead, the applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context.

3. **Step 2.b – Being reasonably informed of all possible controls.** The applicant must take steps to gain reasonable knowledge of all possible controls (both technical and operational) in order to identify which ones are available and potentially suitable. Per Step 2.a, the applicant must seek relevant specialist advice where appropriate. Again, there is no fixed list of who must be consulted for each application. The applicant must always take those steps (including consultation with other organisations) that are reasonably practicable in their context. The applicant must not discard any controls at this stage, as all identified controls should be used as inputs to Steps 3 and 4 in the risk management process.

4. **Steps 3 and 4 – Eliminate or otherwise minimise risk SFARP.** There is an explicit requirement to eliminate risk SFARP in the first instance and only if not reasonably practicable to do so (informed by the risk context established at Step 1), implement risk controls to minimise the risk SFARP. The applicant should systematically work through every control identified in Step 2 to determine if they are reasonably practicable to implement. The applicant must also address any additional hazards introduced by the risk controls. The integrated set of technical and operational risk controls that are reasonably practicable to implement, form the proposed flight conditions that will underpin the MPTF.

Superseded

5. **Step 5 – Characterising and communicating residual risk.** The applicant must characterise the residual risk using their safety risk management system (Note: DASA anticipates the residual risk will be characterised using the Defence Harmonised Risk Matrix (DHRM) in the Defence Aviation Safety Manual (DASM), but does not mandate its use). This step must include a declaration from the applicant that the flight conditions are a set of risk controls, integrated from a technical and operational perspective, which eliminates or otherwise minimises the risk SFARP.

7.5.7.3 Specific detail of the information and supporting documentation required to complete DASR Form 18b- *Application for Approval of Flight Conditions* is provided in the instruction sheets covering the form. See also DASR 21.A.708 and 21.A.709.

7.5.7.4 Flight Test. When an MPTF relates to flight test activity, DASRs require that flight conditions and operational endorsement must be provided by a competent MAO staff member, as determined by a DoSA-Flight Test (DoSA-FT)[81]. MAOs may apply to a DoSA-FT for a determination of competence for nominated MAO staff.

7.5.8 Approval of Flight Conditions

7.5.8.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can approve flight conditions. DASA will approve flight conditions if it has sufficient confidence that:

1. The applicant has given due consideration to the risk context, including the objectives and significance of the flying activity.
2. Elimination of the risk by restoring the aircraft to an airworthy condition IAW existing approved data, or deferring a defect, is not reasonably practicable.
3. Proposed flight conditions represent a set of risk controls that provide a credible and defensible level of safety for the flights/duration requested.
4. The applicant has appropriately characterised and communicated the residual risk.
5. The applicant has made an explicit declaration that the flight conditions, when implemented effectively, will eliminate or otherwise minimise the risk SFARP. The risk context of the application must support the depth of risk assessment undertaken and reasonably practicable judgements made by the applicant.

7.5.8.2 In assessing the application, DASA reviews the information supplied by the applicant and independently assures that it demonstrates the risk has been eliminated or minimised SFARP, and has been characterised accurately. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

Superseded

7.5.9 Application for an MPTF

7.5.9.1 Applications to DASA for the issue of an MPTF are made for specific aircraft and tasking using DASR Form 21 - *Application for a Military Permit to Fly*. All applications must reference an approved set of flight conditions, or an accompanying application for their approval. DASR Form 21 supports and records the applicant's 'decision-to-proceed' at Step 6 in the seven-step risk management process.

7.5.9.2 Note, in submitting an application for an MPTF and making the decision-to-proceed, the applicant also revisits Step 1 – Establishing the Risk Context, for that application. The test of SFARP is contextual and temporal; so this return to the risk context for the MPTF application is necessary to ensure that the applicant has made the decision-to-proceed based on the characterisation of risk in the flight conditions and in the context defined by the MPTF application, at the time of that application.

7.5.9.3 For example, the risk context of the flight conditions may be broad and enduring, covering activities such as 'deployed or directed operations'. However, the context of an application for an MPTF referencing those flight conditions must justify proceeding with the risk characterised in those flight conditions in its own right. As a result, an MPTF for a flight which itself is discretionary with little or no military capability imperative, relying upon flight conditions with a broad context such as 'deployed operations', may not be credible or defensible with the risk characterised in the referenced flight conditions, despite occurring while 'deployed'.

7.5.9.4 The key information required to support this step in the risk management process is the applicant's justification that:

1. The purpose of flight for this application is within the risk context of the referenced flight conditions and the specific task in this application warrants proceeding with the residual risk at the time of application.
2. The specific aircraft to be tasked meet(s) the configuration required by the approved flight conditions.
3. The conditions and restrictions (risk controls) in the approved flight conditions will be implemented on the subject aircraft for the subject flight(s).

7.5.9.5 The applicant must identify a suitable delegate within their organisation who has capacity to make the decision-to-proceed with the flight(s) (i.e. retain the risk). In making the decision-to-proceed, the applicant must act within their safety risk management system. Specific details of the information and supporting documentation required to complete DASR Form 21 - *Application for a Military Permit to Fly* is provided in the instruction sheets covering the form. See also DASR 21.A.707.

7.5.9.6 Flight Test. Within specialist Service Flight Test Organisations (FTOs), procedures exist to streamline MPTF applications and approvals for a range of flight test activities, such as:

1. Flight test activities on any Defence aircraft type to be conducted by, or under the direct supervision of, a Defence Aviation Authority (DAA)-approved FTO (all CAT 1 and 2 flight test and some CAT 4 tests)
2. Where Flight Test Instrumentation (FTI) or modifications are to be used, or
3. Where flight test operational substantiation and/or endorsement is required.

Superseded

7.5.9.7 MAOs considering flight test activities are encouraged to engage their respective Service FTO or a DoSA-FT, who will advise on the process to use. See also DASR FT–Flight Test.

7.5.10 Issue of a MPTF

7.5.10.1 Only DASA (including DoSAs, within the scope of their delegation) or an organisation with the appropriate privilege can issue an MPTF. DASA will issue an MPTF (via DASR Form 20a) if it has sufficient confidence that:

1. The decision-to-proceed has been made by an appropriate person within the applicant's organisation, given the characterisation of the residual risk (Note: DASA does not prescribe what this level is, nor what organisational authorisations they must hold).

2. The assignment of the responsibilities to implement and monitor risk controls (i.e. adherence to the approved flight conditions) is clear.

3. If applicable, there has been consideration that the flight conditions are compatible with any other MPTFs currently in effect for that aircraft (Note: The applicant is responsible for managing the implementation of multiple or concurrent MPTFs).

4. The risk context of the MPTF application is within that of the referenced flight conditions and supports the decision-to-proceed with the risk characterised by those flight conditions.

7.5.10.2 In assessing the application for an MPTF, DASA reviews the information supplied by the applicant and independently assures that it supports flying with an aircraft that does not meet the prescribed airworthiness or aviation safety requirements and may be operating at an ELOR. This will include whether the period of risk retention (the context) is defensible. While DASA does not seek to interfere in the decision-making that properly belongs to the Command Chain, or substitute its judgment for that of the Commander, DASA supports the Commander via the independent assessment that those decisions are credible and defensible.

7.5.10.3 Flight Test. When the MPTF relates to a flight test activity categorised IAW DASR.FT.05, flight conditions must be endorsed by competent staff of a MAO (as per para 22), and for a CAT 1 or 2 activity, Authority approval of flight conditions and issuing of the MPTF must be conducted by a DoSA-FT.

7.5.11 Obligations of the holder of an MPTF

7.5.11.1 As the holder of an MPTF, the MAO is responsible for ensuring the flight conditions are implemented and remain effective for the duration of the MPTF. This satisfies Step 7 of the seven-step risk management process and includes ensuring the risk context supporting the approved flight conditions remains applicable for the duration of the MPTF. See also DASR 21.A.727 and DASR 21.A.708.

7.5.11.2 Configuration management. An MPTF may introduce specific aircraft configuration management requirements, especially if an MPTF covers a yet-to-be-approved modification for operational use or flight test activity. MPTF conditions may include information such as: incorporation and maintenance instructions for new modifications; periodic inspections for non-standard damage;

Superseded

or increased usage data recording requirements. The CAMO must be aware of MPTFs that are applicable to a given aircraft to ensure overlapping continuing airworthiness requirements are resolved or coordinated, to ensure no loss of configuration management and the appropriate aircraft technical log and maintenance documentation remains accurate.

7.5.11.3 Operation by another MAO. The holder of an MPTF is responsible for ensuring the DASR 21.A.708 flight conditions are met. However, in instances where aircraft may be transferred between MAOs, this situation requires the holder to establish suitable arrangements for the transfer of holder obligations for an aircraft (that is subject to one or more MPTFs) when operated by another MAO.

7.5.12 MPTF Examples within DASR Context

7.5.12.1 Annex B provides a non-exhaustive list of examples intended to illustrate the conduct of the MPTF process within the DASR environment. Where uncertainty exists, contact a DASA Desk Officer (DIA-TC or DAVENG), the platform DoSA, or a DoSA-FT (for MPTFs related to flight test). In addition, Annex C provides a comprehensive guide to good practice and common issues pertaining to applications for flight conditions and MPTFs.

7.6.1 Military Design Organisations

Aim

7.6.1.1 This chapter details the approval and ongoing oversight of a Military Design Organisation (MDO). A MDO is approved under DASR Part21J and can only undertake design work related to the privileges granted under that approval and within the scope of that approval. Often the scope restricts what platforms a design can be applied to and can impose further limitations to aspects of their design work if required.

Introduction

7.6.1.2 Design organisation means an organisation responsible for the design of aircraft, aircraft engines, propellers, auxiliary power units, or related parts and appliances, and holding, or applying for, type-certificates, supplemental type-certificates, changes or repair design approvals. These design organisations that design aircraft, make changes to aircraft or design repairs of aircraft, and parts and appliances, need to fulfil the requirements as defined in DASR Part 21. Such organisations need to demonstrate that they have the right organisation, procedures, competencies and resources to effectively produce the design.

Obligations

7.6.1.3 DASA impose regulatory obligations on Design Organisations as part of the approval to ensure the airworthiness of aircraft and aviation products being designed within Defence. These obligations are intended to maintain high standards of design, engineering, and manufacturing processes throughout the defence aviation industry.

7.6.4 By placing obligations on design organisations, DASA aims to assure that the design, modification, and production of aircraft, components, and systems meet appropriate airworthiness standards.

Privileges

7.6.1.5 Under the DASR construct, the authority is the controlling signatory for all product released related to the type certificate. To reduce the burden on DASA, approved organisations are typically awarded privileges that allow work to be approved on behalf of the authority. For example, a design organisation may be privileged to approve minor changes to type design as well as minor and major repairs.

7.6.1.6 Granted privileges are documented on a Form 83. The Form 83 outlines the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

Superseded

7.6.1.7 An organisation attains a DASR 21 MDO Approval by submitting a Form 80 Application for Military Design Organisation Approval (MDOA) for DASA consideration, or a Form 82 Application for Significant Changes to Design Organisation Approval where a MDOA is already held but scope change is needed. Along with the application, the organisation must furnish a handbook (formerly an exposition) whereby all the processes utilised under the established Design Assurance System (DAS) are detailed. The Design Organisation Handbook Requirements are outlined in Appendix 1 of Chapter 5.3 of DASP Manual Volume 3.

DASA Design organisation assurance

7.6.1.8 Once a design organisation has gained an approval to conduct design activity, DASA will schedule oversight activities in order to assure that the MDO has maintained / is maintaining their approval to the standard as governed by the DASR Pt21 regulations. For organisations maintaining a Part21 approval, DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, and Resources as detailed in the approved Design organisation handbook, as well as consideration of the quality of design products.

7.6.1.9 The DAS is effectively the Quality Management System (QMS) specific to the output of designs against the scope issued under the Form 83. The DAS can utilise elements of the organisation QMS to satisfy requirements of the DAS. The DAS and the QMS are not the same and oversight of the DAS will be conducted specifically to design products produced.

Further information

1. DASP Manual Vol 3 Chapter 5.3 Annex E
2. DASR 21 Subpart J – Military Design Organisation Approval

7.6.2 Military Production Organisations

Aim

7.6.2.1 This chapter details the approval and ongoing oversight of a Military Production Organisation (MPO). A MPO is approved under DASR Part21 G and can only undertake production work related to the privileges granted under that approval. This includes what release documentation is acceptable under DASRs.

Introduction

7.6.2.2 Production for Defence registered aircraft is assured by DASA through the issue of Certificates of Airworthiness. For Certificates of Airworthiness to remain valid through the life of the aircraft, only components accompanied by acceptable release documentation may be installed on the aircraft. Acceptable release documentation can take various forms, depending on the means through which production is assured. Acceptable release documentation is outlined at Chapter 7.3.2.

Obligations

7.6.2.3 With a Production Organisation Approval, DASA impose a set of obligations as part of the approval and as part of its regulatory framework to ensure the safety and airworthiness of aircraft and aviation products being utilised within Defence. By placing obligations on production organisations, DASA aims to assure that the production of aircraft, components, and systems meet rigorous safety and airworthiness standards.

Superseded

Privileges

7.6.2.4 Under the DASR construct, an approved MPO will be granted privileges to conduct design work to support changes to the type certificate for which the MTCH manages. Granted privileges are documented on a Form 55. The Form 55 is the certificate outlining the Terms of Approval for the organisation and lists the privileges for which the organisation can utilise the approval.

Approval documentation

7.6.2.5 An organisation attains a DASR 21 MPO Approval by submitting a Form 55 Application for Military Production Organisation Approval (MDOA) for DASA consideration, or a Form 51 Application for Significant Changes to Production Organisation Approval where an MPOA is already held but scope change is needed. Along with the application, the organisation must furnish an exposition, whereby all the processes utilised to produce the category items under the ToA are documented.

7.6.2.6 Currently, DASA will not accept applications for production without a Military Production Organisation Approval as the authority is not resourced adequately to oversight this type of approval.

DASA production organisation assurance

7.6.2.7 Once a production organisation has gained an approval to produce category items, DASA will schedule oversight activities in order to assure the MPO has maintained/is maintaining their approval to the standard as governed by the DASR 21 regulations. DASA will look at the Organisational Structure, Responsibilities Assigned, Procedures, Resources which is detailed in the approved Production Organisation Exposition.

7.6.5 Guidance for Organisations Developing and Producing Aviation Software

Introduction

Superseded

7.6.5.1 This section provides guidance for the design and production of aviation software under DASR 21. This guidance does not apply to software designed or produced under recognition as defined in DASP Vol 3 Chapter 7.3.1 Production

7.6.5.2 Aviation software is classified as a 'part or appliance' and subject to the same rules applicable to all 'tangible' parts and appliances.

7.6.5.3 Aviation software refers only to software installed in an aircraft used for operating and controlling the aircraft and does not include mission system software, condition monitoring software, aeronautical information or ground-based aircraft diagnostic systems.

7.6.5.4 For the context of aviation software, the following definitions apply:

1. **Manufacturing** – is the development of aviation software, including compiling of source code into executable object code.
2. **Production** – is the process of preparing aviation software for distribution, including packaging the executable object code and associated engineering and technical data on distribution media.
3. **Replication** – is the process of copying aviation software (executable object code) that has been authorised through a production process.

Certification of Aviation Software

7.6.5.5 Organisations manufacturing software for installation on Defence registered aircraft must hold a Military Design Organisation Approval (MDOA) under DASR 21 Subpart J. The development of new (or the modification of existing) aviation software is a change to a product's type design and must be approved under DASR 21 Subpart D or E. For changes to aviation software classified as minor, a minor change approval can be issued by an organisation holding an MDOA in accordance with its Terms of Approval. For changes to aviation software classified as major, the approval must be issued by DASA as either an amended Military Type Certificate (MTC) or a Military Supplemental Type Certificate (MSTC).

Production of Aviation Software

7.6.5.6 The production of software is the responsibility of an organisation holding an appropriate Military Production Organisation Approval (MPOA) and the release of aviation software for installation on a Defence registered aircraft is via a DASR Form 1. The software's 'part' number (version) should be marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

7.6.5.7 DASR 21 does not allow the production of aviation software under an organisation's MDOA Terms of Approval. Organisations producing aviation software for installation in Defence registered aircraft must meet the requirements of DASR 21 Subpart G—Military Production Organisation Approval in order to obtain privileges to release the software for installation.

Replication of Aviation Software

7.6.5.8 Software authorised for installation on a Defence registered aircraft via a DASR Form 1 and provided to the Continuing Airworthiness Maintenance Organisation (CAMO) may be replicated by an Approved Maintenance Organisation (AMO) in accordance with OEM or DASR 21 MDO approved procedures. It is the responsibility of the CAMO or AMO to ensure that their quality systems have processes in place to manage and verify the integrity of the replicated software. This is typically done

Superseded

using a checksum value that is generated during production of software and provided to the CAMO or AMO alongside the produced software.

7.6.5.9 Any software replication process should also include a step to ensure the software's 'part' number (version) is marked on the media hosting the software for installation, in accordance with the requirements of DASR 21 Subpart Q.

Organisation Approval Requirements

7.6.5.10 Development and production of software are often done by the same organisation. In this case, the organisation must hold both a MDOA under DASR 21 Subpart J and a MPOA under DASR 21 Subpart G in order to obtain the necessary privileges to approve the development and production of aviation software. Typically, there are no organisations with an MPOA with software scope without a corresponding MDOA with software scope.

7.6.5.11 Underpinning these organisation approvals and privileges are a Design Assurance System documented in a Handbook (Design Organisation Exposition/DOE), and a Production Quality System documented in a Production Organisation Exposition (POE). For a software development and production organisation, it is not necessary to have discrete and dedicated stand-alone procedures manuals entitled 'DOE' or 'POE' to meet both sets of organisation approval requirements. A single manual, document (irrespective of its title) or set of procedures that covers the development and production of software may simultaneously meet the requirements of both a DOE and POE.

7.6.5.12 The regulatory requirements of a DOE (DASR 21.A.243) and a POE (DASR 21.A.143) are the minimum required of such a manual or document to be awarded the relevant organisation approval and privileges. Any manual or document(s) identified as a DOE/POE (or both simultaneously) should be a working level document(s) published for use by personnel working in the organisation. The DOE/POE should not be written purely to satisfy regulatory requirements, although this aspect will be assessed by DASA when reviewing the working level documentation and the organisation's staff's understanding of it.

7.6.6 GUIDANCE ON CONSIDERING EXPLOSIVES IN AVIATION DESIGNS

Introduction

7.6.6.1 This DASPMAN section explains what Military Design Organisations (MDO) and Military Type Certification Holders (MTCH) must consider when performing design activities on aircraft systems containing explosives and integrating air-launched stores containing explosives onto aircraft[82]. Such design activities include physical design changes to systems and equipment containing explosives, assessments that unrelated design changes do not adversely impact explosive safety, changes to Airworthiness Limitations (AwL), changes to explosives-related Instructions for Continuing Airworthiness (ICA), monitoring for new explosive-related hazards within safety management systems (SMS), and aircraft stores compatibility engineering activities.

Superseded

What is an explosive?

7.6.6.2 An explosive is '… a substance manufactured with a view to producing an explosion or pyrotechnic effect[83].'Many Defence aircraft contain explosives, either forming part of an aircraft system (such as ejection seats) and within air-launched stores such as bombs, missiles and gun ammunition[84].

Explosives requirements within Type Certification Basis

7.6.6.3 In deciding what type of explosive requirements should be included in an aircraft's Type Certification Basis (TCB) the key document is the *European Military Airworthiness Certification Criteria* (EMACC) published by the European Defence Agency. The EMACC indicates that all explosives forming part of an aircraft system should be considered when developing TCB requirements. Accordingly, the TCB should include explosive-related requirements during initial certification and when MDOs develop major or minor changes to the type design.

7.6.6.4 For aircraft stores containing explosives the EMACC implies that the TCB should only consider requirements relevant to the installation, integration and interface of the aircraft and stores. That is, the TCB should only include explosive-related design requirements to the extent they affect the store's installation, integration and interface. Any subsequent major or minor changes to the type design should also only consider the installation, integration and interface of the store.

Legislative requirements

7.6.6.5 The legislation relevant to the safe design, maintenance and operation of Defence aircraft containing explosives is the Work Health and Safety Act (Cth) 2011 (the WHS Act), the Explosives Act (Cth) 1961, and their subordinate regulations.

Explosive Safety Regulatory Framework

7.6.6.6 To comply with their explosive-related obligations under all this legislation, MDOs and MTCHs must understand Defence's *Explosive Safety Regulatory Framework* (ESRF), which amplifies this legislation for the explosives context. The ESRF purpose is to provide a Defence-wide explosive safety risk management framework which ensures explosives safety risks are effectively managed. Explosives safety aims to '… prevent premature, unintentional, or unauthorised initiation of explosives and devices containing explosives; and with minimising the effects of explosions, combustion, toxicity, and any other deleterious effects'[85].Within the ESRF, Director General Explosive Ordnance (DGEO) is the Explosive Ordnance Safety Regulator (EOSR), supported by the Director of Ordnance Safety (DOS).

7.6.6.7 Under the ESRF, the safe conduct of activities involving explosives (including design) requires adherence to the following three fundamental concepts:

1. Explosives must be designed and manufactured to design requirements so as to eliminate or minimise explosives safety hazards so far as is reasonably practicable. This concept is referred to as 'safety and suitability for service' (S3).

2. Activities involving explosives must be conducted at locations where the consequence of an explosives safety mishap is understood, and risks are minimised (referred to as a 'safe location').

Superseded

3. Activities involving explosives must be conducted through safe work practices, conducted by trained and competent personnel, which will minimise both the likelihood and consequences of an explosives safety mishap (referred to as 'safe work practices').

7.6.6.8 In applying these three concepts, the ESRF provides requirements (12 principles and 28 regulations) and guidance relevant to the design, production, operation, maintenance, handling, storage and transport of explosives throughout its lifecycle.

7.6.6.9 The ESRF is documented within the following Defence Explosive Ordnance Publications (DEOP):

1. DEOP 100 comprises three volumes of which only Volume 2 Defence Explosives Safety Regulatory Framework has been issued. Volume 2 describes the 12 mandatory principles of the ESRF, not all of which are relevant to aviation design activities. For each principle, information is provided on its rationale, the expected outcome, the constraints, obligations, external requirements and controls. DEOP 100 Volume 2 also describes the ESRF risk management and assurance processes. The ESRF relies on organisational compliance with its mandatory requirements but does not provide organisational certifications.

2. DEOP 101 provides the 28 ESRF regulations with not all applying to aviation design activities. The regulations are not in a standard format, but most comprise a general overview, the requirements, responsibilities and any accompanying procedures. Each of the 28 regulations contain some mandatory requirements.

3. DEOP 102 provides information relevant to assessing the 'Safety and Suitability for Service of Defence Explosive Ordnance'. The publication mentions the 12 principles and the 28 regulations, while providing no further requirements relevant to aviation design activities. This DEOP also discusses several explosive-related hazards[86].

7.6.6.10 Within the ESRF, the EOSR releases Defence Explosives Safety Advisory Circulars (ESAC) to promulgate important safety information. ESACs do not mandate any actions, but provide informed, well-considered safety advice and guidance. ESACs can be accessed at: drnet/JCG/JLC/ExplosiveOrdnance/DOS/Pages/ESRF.aspx (Available on DPN Only)

Relationship between the DASF and ESRF

7.6.6.11 The ESRF is specifically intended to integrate with and support other Defence regulatory frameworks that aim to achieve safety outcomes, including aviation safety. Comparison of the DASF and ESRF demonstrates that regulated organisations within the DASF can comply with both the Defence Aviation Safety Regulations (DASR) and relevant ESRF requirements, with no inconsistencies between the two safety frameworks. Importantly, both safety frameworks are subject to the WHS Act's concept of shared duty holders (s16), who must consult, co-operate and co-ordinate their activities (s46) to ensure explosive-related risks are eliminated or otherwise minimised so far as is reasonably practicable (s17).

7.6.6.12 DASA regulates the design of aircraft systems and the integration of all air-launched stores onto a type. Complementing these regulations, DGEO provides mandatory explosive-related requirements (both principles and regulations) for the design of aircraft systems containing explosives and air-launched stores containing explosives.

Superseded

7.6.6.13 The S3 construct within the ESRF requires consideration of the hazards posed to explosives safety by carriage environments. Accordingly, the ESRF requires designers to consider whether the failure or partial performance of the non-explosive components of aircraft stores adversely affects the safety of the explosives within the store. Forms of component failure or partial performance that do not affect explosive safety are outside the ESRF scope, but are considered by Guided Weapons and Explosive Ordnance Group (GWEO) as part of its broader safety responsibilities.

ESRF applicability to DASR 21 scope

7.6.6.14 Several ESRF principles and regulations fall within the scope of DASR 21. Specifically:

1. ten of the 12 ESRF principles (Principles 1-10) impose obligations on aircraft designers within MDOs and MTCH organisations
2. all of these ten principles fall within the scope of DASR 21
3. compliance with DASR 21 provides total compliance with one principle (Principle 1), partial compliance with eight principles (Principles 2, 3, 5, 6, 7, 8, 9 and 10) and no compliance with one principle (Principle 4)
4. only four of the 28 ESRF regulations (1.1, 1.2, 1.5 and 2.5) within DEOP 101 impose obligations on aviation designers within MDOs and MTCH organisations
5. of these four regulations, three fall within the scope of DASR 21 (1.1, 1.5 and 2.5)
6. compliance with DASR 21 provides only partial compliance with these three regulations.

7.6.6.15 These principles and regulations within the scope of DASR 21 provide no limits or constraints on which individuals or organisations within Defence may perform design activities for aircraft systems and aircraft stores containing explosives.

Satisfying applicable ESRF requirements

7.6.6.16 Compliance with DASR 21 provides total or partial compliance with several mandatory ESRF principles and regulations. To achieve full compliance, MDOs and MTCHs must:

1. obtain explosives safety hazard and risk management advice from personnel and organisations competent in explosives safety management (refer paragraph 7.6.6.18)
2. when complying with DASR SMS, ensure that consideration is given to explosive-specific hazards and risks
3. ensure that explosives safety hazards and residual risks of explosives are identified and communicated to affected Services, Groups and others (including non-Defence entities)
4. aim to reduce the consequences of on-aircraft explosive hazards through careful design of where explosives are located in the aircraft and the quantity of explosives used
5. ensure that personnel performing design activities on aircraft systems and air-launched stores containing explosives receive explosive-related training compliant with ESRF Regulation 1.1 (eDEOP 101)[87]

Superseded

6. when creating Instructions for Continuing Airworthiness (ICA) for aircraft systems and air-launched stores containing explosives, be aware of the inspection requirements in ESRF Regulation 1.5 (eDEOP 101)

7. when engaged in the process for the initial certification of explosives installed in aircraft systems and amendments to their life limits, comply with the process described in Annex B.

7.6.6.17 While outside the scope of DASR 21, where MDOs handle explosives as part of the design process, they should ensure their sites, platforms and facilities have the necessary facility certifications, and that the minimum number of people are exposed and are aware of the risks.

Explosives safety hazard and risk management advice

7.6.6.18 MDOs and MTCHs can obtain explosives safety hazard and risk management advice from the following organisations competent in explosives safety management:

1. the Directorate of Ordnance Safety within Joint Logistics Command

2. Joint Proof and Experimental Unit within Joint Logistics Command

3. Aerospace Explosive Ordnance Systems Program Office within GWEO

4. Directorate of Engineering and Technical within GWEO's Systems Division.

7.6.6.19 MDOs and MTCHs should have confidence in the explosives safety hazard and risk management advice provided by these organisations because they:

1. have roles (either regulatory or in-practice) that require them to comprehensively understand explosive safety hazards and risks

2. are subject to the requirements of the well-established ESRF and will provide advice compliant with all relevant ESRF principles and regulations

3. have an extensive demonstrated history of providing safe explosives advice across Defence, including to the aviation community

4. work within well-developed engineering frameworks that have evolved over several years.

7.6.6.20 MDOs and MTCHs can consume explosives safety hazard and risk management advice from these specified organisations, without the need to invoke DASR 21.A.239. That is, they do not need to consider these organisations as a '… partner or subcontractor' and are not obliged to specify the manner in which the MDO/MTCH design assurance system accounts for the acceptability of the advice provided by these external organisations or specialist personnel within them.

7.6.6.21 Some forms of advice may not need be obtained case-by-case but could be obtained as a 'standing' advice relevant to a particular type of design change whenever it occurred (for example a proposed change to a component throwaway life or maintenance interval). The relevance of specific 'standing' advice to a new circumstance would depend on the aircraft type, the form of explosives, the aircraft's operating environment and its specific sustainment arrangements.

7.6.6.22 The relationships that MDOs establish with specialist explosives organisations should be documented in the Handbook (Design Organisation Exposition), required by DASR 21.A.243. Similarly,

Superseded

MTCHs should documents their relationships in the Type Continued Airworthiness Exposition required by GM 21.A.14(c) and discussed at DASPMAN Chapter 5.3 Annex J Appendix 1.

Other guidance

7.6.6.23 A variety of other Defence stakeholders can contribute to the safe design of aircraft systems containing explosives and the safe integration of air-launched stores containing explosives. Such organisations include:

1. **Maintenance organisations** - to understand the maintenance implications of design decisions and the utility of proposed ICA relating to explosives
2. **CAMOs** - to understand the continuing airworthiness implications of explosive-related design decisions, such as the potential need for pre-flight inspections and the effect of explosive-related component lives on the aircraft maintenance program
3. **MAOs** - to understand the operational implications of explosives-related design decisions, such as preferred aircrew actions for stores release
4. **DASA** - to understand the scope of the ability to approve minor explosives-related design changes
5. **Organisations who transport and store explosives.** Organisations within various Defence Groups and Services, whose primary roles is transporting and storing explosives, would not usually be a source of explosives design safety advice. Nevertheless, there may be occasions when MDOs should seek information from them that provides necessary context for design activities.

Design activities for aircraft systems containing explosives

7.6.6.24 An aircraft system may contain explosives, usually to separate an air-launched store from the aircraft, but sometimes to separate parts of the aircraft such as ejection seats and cockpit canopies. Specific guidance on the design activities for aircraft systems containing explosives is provided in Annex A.

Design activities for ALSE/role equipment containing explosives but not part of the aircraft's type design

7.6.6.25 ALSE/Role equipment containing explosives, but not part of the aircraft type design, are outside the scope of this chapter. Nevertheless, the ESRF requirements at 7.6.6.16 a/c/d/e still apply to organisations performing relevant design activities.

Design activities for air-launched stores containing explosives

7.6.6.26 An air-launched store is an aircraft store that is intended to be separated from an aircraft in flight. Some air-launched stores contain explosives:

1. to separate the store from the aircraft (such as some chaff, some flares, some sonobuoys and gun ammunition)[88]
2. to create an explosive effect post separation (such as bombs, missiles and flares)
3. for both purposes.

Superseded

7.6.6.27 Design activities on the explosives within air-launched stores are outside an MDO's scope, performed within the scope of GWEO organisations.

7.6.6.28 Specific guidance on the integration of air-launched stores containing explosives, which is within the MDO/MTCH scopes, is provided in Annex B.

Annexes

(a) Design activities for aircraft systems containing explosives

(b) Integration of air-launched stores containing explosives

Superseded

7.1 Introduction

7.1.1 Background

7.1.1.1 While there is no internationally-accepted definition for Initial Airworthiness, common definitions for 'initial' (happening at the beginning) and 'airworthiness' (the fact of an aircraft being safe to fly) are helpful. After all, Initial Airworthiness does indeed focus extensively on whether a new aircraft is initially safe to fly - that is, whether it has been suitably designed and manufactured.

7.1.1.2 However, by convention, Initial Airworthiness also encompasses any design changes subsequently made to the new aircraft (including the certification of those changes) and the design of repairs. Furthermore, it includes the activities needed to ensure the design remains safe throughout its lifecycle, although this activity is often termed 'continued' airworthiness (not to be confused with 'continuing' airworthiness, per chapter 8).

7.1.1.3 This chapter presents an overview of the DASR approach to aircraft design, production and certification, which are the activities commonly associated with initial and continued airworthiness. The subsequent chapters will then explore several of these concepts in more detail.

7.1.1.4 Note this chapter is relevant only to Defence Registered aircraft; for non-Defence Registered aircraft, all initial and continued airworthiness functions are conducted per the requirements of the relevant Civil or military Aviation Authority (normally CASA).

7.1.2 DASR 21 – Aircraft Design, Production and Certification

7.1.2.1 From an Initial and Continued Airworthiness (INCA) perspective, an aircraft's lifecycle might follow a progression something like this:

a. To start, an engineering organisation demonstrates its professional ability to produce an aircraft design ('design organisation approval').

b. Next, the organisation produces a new aircraft design, and an Aviation Authority certifies that the design is suitably safe ('aircraft design and certification').

c. Individual aircraft are then produced, and an Aviation Authority certifies each as conforming to the certified design ('aircraft production and certification').

d. Over the following decades of fleet operation, numerous Minor and Major design changes and repairs will be made to the aircraft ('aircraft design changes and repairs').

e. Occasionally, there may be a need for limited flying of a possibly unairworthy aircraft, either to demonstrate a new capability or to avoid grounding an important asset ('permit to fly').

Superseded

f. Critically, throughout this complex lifecycle, an engineering organisation will need to monitor for defects in the design, facilitate risk management of the design, and so on ('type certificate holder').

g. Finally, an Aviation Authority might occasionally mandate certain remediation actions in the interests of fleet safety ('airworthiness directives').

7.1.2.2 Each of these seven functions, and several others, is regulated under DASR Pt 21– *Aircraft Design, Production and Certification.* The remainder of this chapter provides a brief summary of these functions.

7.1.2.3 **Design organisation approval.** Deficiencies in an aircraft's design can range from those with immediate catastrophic consequences (eg inadequate structural strength), to an erosion of safety margins (eg misleading navigation information), to an annoyance (eg a Minor human-machine interface flaw). Designing an aircraft where risks have been eliminated or otherwise minimised so far as is reasonably practicable (SFARP) is a particularly complex endeavour.

7.1.2.4 Consequently, the initial design of Defence aircraft should only be undertaken by skilled individuals within professional aircraft design organisations. DASRs make provision for DASA to issue Military Design Organisation Approval (MDOA) status to organisations who have demonstrated that they are able to maintain a design assurance system for the control and supervision of the design, and of design changes, of aircraft products, parts and appliances.

7.1.2.5 DASA's default expectation is that a new Defence aircraft will be designed by a MDOA of suitable scope. As a matter of pragmatism, however, DASR also make provision for Defence to accept designs that have been certified by a DASA-recognised civil or military Aviation Authority (CAA/MAA), without the need for the design organisation to be a DASA-approved MDOA, within certain bounds. This approach, often called 'prior acceptance' is explored in Chapter 7.2, *Product Certification*. These same provisions apply for design changes to an extant aircraft.

7.1.2.6 MDOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.7 **Initial aircraft design and certification.** Defence periodically acquires aircraft to meet a capability need. In practice, Defence usually acquires its new aircraft as off-the-shelf designs, and then incorporates design changes to cater for Defence's unique roles and operating environment. The entire design will meet a set of airworthiness requirements - commonly called a Type Certification Basis (TCB) - and the designer(s) will produce extensive evidence (via analysis, test and other means) to demonstrate that their design meets the TCB.

7.1.2.8 As noted in paragraph 7.1.2.5, these designs will be produced by a DASA-approved MDOA, or a design organisation whose design is certified by a DASA-recognised CAA/MAA, or sometimes both. Regardless, the final design will always be certified by DASA, signified by the issue of a Military Type Certificate (MTC)[1] for the aircraft.

7.1.2.9 In the absence of a pertinent CAA/MAA certification, DASA's certification for a new aircraft would be an immense undertaking for both DASA and the Defence acquisition organisation. More commonly, however, there will be a pertinent CAA/MAA certification, and leveraging off this certification can substantially reduce the impost on both organisations. In that case, much of the effort focuses on whether the certified design is compatible with Defence's intended Configuration, Role and Environment (CRE). Chapter 7.2, Product Certification, explores the certification process in detail.

Superseded

7.1.2.10 **Aircraft production and certification.** An expertly designed and certified aircraft provides the basis for safe aircraft operation. However, just as importantly, that design must be accurately implemented on the Defence aircraft.

7.1.2.11 DASR make provision for DASA to issue a Military Production Organisation Approval (MPOA) to an organisation when assured they have the ability to manufacture aircraft parts and appliances in conformity with approved data. DASR also make provision for Defence to accept an aircraft produced under the systems of a DASA-recognised CAA/MAA. This latter approach is used for most new Defence aircraft.

7.1.2.112 Following production of an individual aircraft, DASA must certify that the aircraft is in a state of airworthiness per the inherent level of safety specified on the MTC. This certification is signified by the DASA issue of a Military Certificate of Airworthiness (MCoA)[2] for each individual Defence aircraft.

7.1.2.13 Aircraft production and MCoAs are explored in Chapter 7.3, Production. MPOAs are explored in Chapter 7.6, Design and Production Organisations.

7.1.2.14 **Aircraft design changes and repairs.** Defence aircraft will usually be in service for several decades. During this time, numerous design changes will inevitably be implemented, either to enhance military capability or to address design or obsolescence problems. These design changes are classified under DASR as either Minor of Major, differentiated by the degree of airworthiness effect of the design change.

7.1.2.15 The DASR approach for Minor and Major design changes is very similar. They will both be performed by a DASA-approved MDOA or another design organisation whose design is certified by a recognised CAA/MAA, and both should preserve the level of airworthiness of the aircraft. For Major design changes, however, DASA will usually provide a proportionate level of independent assurance, and DASA itself will usually certify the design as safe. This certification is usually via an amendment to the MTC, although occasionally a Military Supplemental Type Certificate (MSTC) may be issued. Chapter 7.2, Product Certification, explores the certification process in detail.

7.1.2.16 Throughout an aircraft's life, degradation (damage) of the systems/structures integrity supporting safe flight may be compromised through direct (accidental impact and battle damage) overload, or insidious (fatigue, corrosion, moisture ingress, dis-bond, ultraviolet light etc) environmental sources. Repairs are those actions developed and implemented to restore damaged products to a suitably airworthy state. Similar to aircraft design changes, aircraft repairs are classified under DASR as Minor or Major, must be designed by a MDOA or other organisation agreed by DASA, and may be subjected to a proportionate level of DASA independent assurance.

7.1.2.17 **Permit to fly.** A Military Permit to Fly (MPTF) may be issued by DASA for an aircraft that does not meet, or has not been shown to meet, the requirements of its TCB, but is nonetheless capable of safe flight under defined conditions and for specified purposes. MPTFs are most commonly used for flight test (for aircraft development or role expansion activities), for flights where the design has not yet been certified, or for flights where the aircraft temporarily does not conform to the Type Design (eg due to unrepaired damaged, overdue maintenance, etc).

7.1.2.18 An MPTF may or may not entail an elevated level of risk, and is always associated with a set of flight conditions that may be approved prior to, or in conjunction with, the MPTF application. Chapter 7.5, Flight Conditions and Military Permits to Fly, explores this in more detail.

Superseded

7.1.2.19 **Type certificate holder.** As noted earlier in this chapter, DASA issues an MTC for Defence Registered aircraft types. This MTC is issued to a suitable Commonwealth government organisation (usually the relevant Defence Systems Program Office), who are then charged with 'holding' the MTC.

7.1.2.20 Holding the type certificate involves undertaking certain obligations that ensure the type certificate is managed, and the level of safety inherent in the TCB is maintained. This includes, for a particular aircraft type, collecting aviation safety information (both locally and from external sources), ensuring operators are aware of extant hazards, ensuring that essential risk controls remain effective, leading local efforts to eliminate or further minimise known risks, and many other important roles.

7.1.2.21 These expansive holding responsibilities are often beyond the capacity and capability of the government organisation holding the MTC. Consequently, responsibility for the conduct of MTCH obligations is often vested with various support organisations, for example contractors, foreign project offices and other military operators. The government organisation remains accountable for all activities undertaken by those organisations.

7.1.2.22 Chapter 7.4, Continued Airworthiness, explores the MTCH role in more detail.

7.1.2.23 **Airworthiness directives.** In the Australian Defence context, the WHS Act and DASR place responsibility and obligation solely on the regulated community for managing the day-to-day safety of their aircraft, and for ensuring risks are eliminated or otherwise minimised so far as is reasonably practicable. DASR do, however, still make provision for DASA to mandate actions and/or impose conditions on aircraft operation in certain circumstances. This is achieved through the issue of an Airworthiness Directive (AD).
